Z86L79/L80

LOW-VOLTAGE MICROCONTROLLER

FEATURES

Part	ROM (KB)	RAM* (Bytes)	I/O	Voltage Range
Z86L79	4	237	24	2.0V to 3.9V
Z86L80	8	237	24	2.0V to 3.9V

Note: *General-Purpose

- Three Standby Modes (Typical)
  - STOP - 2 µA
  - HALT - 0.8 mA
  - Low Voltage Standby ($<V_{LV}$)
- Expanded Register File Control Registers
- Special Architecture to Automate Both Generation and Reception of Complex Pulses or Signals:
  - One Programmable 8-Bit Counter/Timer with Two Capture Registers
  - One Programmable 16-Bit Counter/Timer with One Capture Register
  - Programmable Input Glitch Filter for Pulse Reception
- Five Priority Interrupts
- Low Voltage Detection and Standby Mode
- Watch-Dog/Power-On Reset Circuits
- Two Independent Comparators with Programmable Interrupt Polarity
- On-Chip Oscillator that Accepts a Crystal, Ceramic Resonator, LC, RC, or External Clock Drive
- Mask Selectable 200 kOhm Pull-Ups on Ports 0, 2, 3
  - All Eight Port 2 Bits at One Time or Not
  - Pull-Ups Automatically Disabled Upon Selecting Individual Pins as Outputs.
- Maskable SingleTrip Point Inputs on P00 Through P03.
- Permanently Enabled WDT Option (Maskable)
- 28-Pin DIP and SOIC Packages

GENERAL DESCRIPTION

The Z86L79/L80 family of IR (InfraRed) Controllers are ROM-based members of the Z8® MCU single-chip microcontroller family with 237 bytes of general-purpose RAM. The only differentiating factor between these two versions is the availability of ROM. Zilog's CMOS microcontrollers offer fast execution, efficient use of memory, sophisticated interrupts, input/output bit manipulation capabilities, automated pulse generation/reception, and easy hardware/software system expansion along with cost-effective and low power consumption.

The Z86L7X architecture is based on Zilog's 8-bit microcontroller core with an Expanded Register File to allow access to register mapped peripherals, I/O circuits, and powerful counter/timer circuitry. The Z8® MCU offers a flexible I/O scheme, an efficient register and address space structure, and a number of ancillary features that are useful in many consumer, automotive, computer peripheral, and battery operated hand-held applications.

GENERAL DESCRIPTION (Continued)

Z8® applications demand powerful I/O capabilities. The Z86L79/80 fulfills this with two package options with 24 pins of dedicated input and output. These lines are grouped into three ports. Each port consists of eight lines and is configurable under software control to provide timing, status signals, and parallel I/O.

There are three basic address spaces available to support a wide range of configurations: Program Memory, Register File, and Expanded Register File. The Register File is composed of 256 bytes of RAM. It includes four I/O port registers, ten control and status registers, and the rest are general purpose registers. The Expanded Register File consists of three register groups.

To unburden the program from coping with such real-time problems as generating complex waveforms or receiving and demodulating complex waveform/pulses, the Z86L7X family offers a new intelligent counter/timer architecture with 8-bit and 16-bit counter/timers (Figure 1). Also included are a large number of user-selectable modes, and two on-board comparators to process analog signals with separate reference voltages (Figure 2).

Notes: All Signals with a preceding front slash, "/", are active Low, e.g., B//W (WORD is active Low); /B/W (BYTE is active Low, only).

Power connections follow conventional descriptions below:

Connection	Circuit	Device
Power	V_{CC}	V_{DD}
Ground	GND	V_{SS}

ABSOLUTE MAXIMUM RATINGS

Sym	Description	Min	Max	Units
V_{CC}	Supply Voltage (*)	–0.3	+7.0	V
T_{STG}	Storage Temp.	–65°	+150°	C
T_A	Oper. Ambient Temp.		†	C

Notes:
* Voltage on all pins with respect to GND.
† See Ordering Information.

Stresses greater than those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; operation of the device at any condition above those indicated in the operational sections of these specifications is not implied. Exposure to absolute maximum rating conditions for an extended period may affect device reliability.

STANDARD TEST CONDITIONS

The characteristics listed below apply for standard test conditions as noted. All voltages are referenced to GND. Positive current flows into the referenced pin (Figure 5).

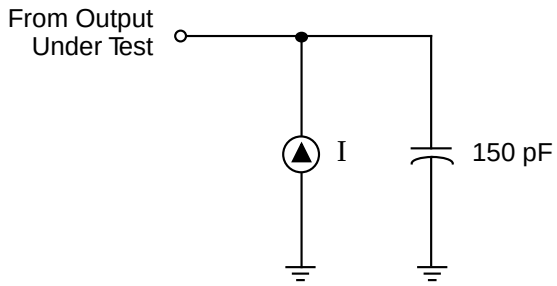

Figure 5. Test Load Diagram

PIN FUNCTIONS

XTAL1 Crystal 1 (time-based input). This pin connects a parallel-resonant crystal, ceramic resonator, LC, or RC network or an external single-phase clock to the on-chip oscillator input.

XTAL2 Crystal 2 (time-based output). This pin connects a parallel-resonant, crystal, ceramic resonant, LC, or RC network to the on-chip oscillator output.

Port 0 (P07-P00). Port 0 is an 8-bit, bidirectional, CMOS compatible port. These eight I/O lines are configured under software control as a nibble I/O port. The output drivers are push-pull in this configuration.

Using single trip point ROM mask option, Port 00-03 can be programmed to allow direct interface to applications that require single point comparison like mouse/trackball IR sensors. ROM mask option will enable the 0.4 V_{DD} trip Point Buffers on these inputs.

An optional 200 kOhms (port wide) pull-up is available as a mask option on all bits for the L79/L80 versions.

These pull-ups are disabled when configured (bit by bit) as an output.

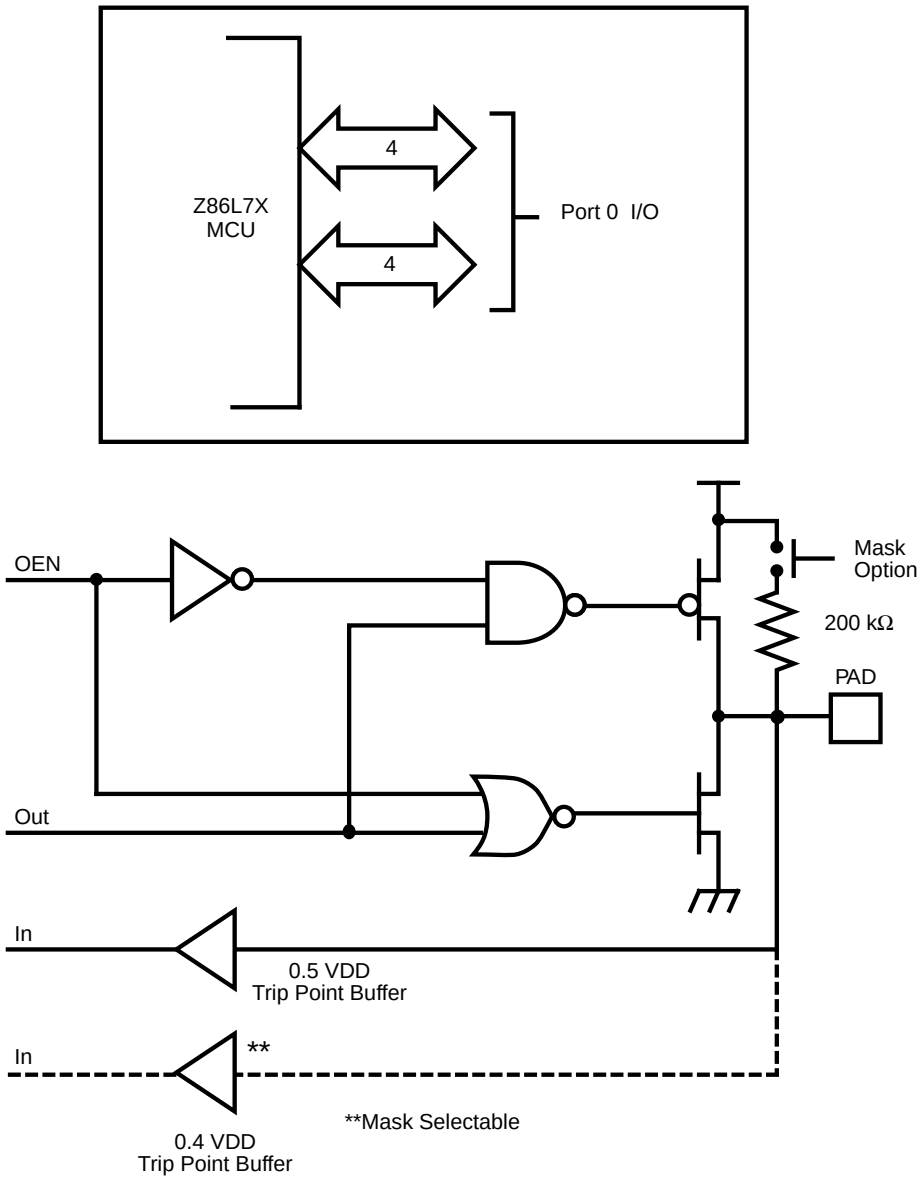

Figure 9. Port 0 Configuration

PIN FUNCTIONS (Continued)

Port 2 (P27-P20). Port 2 is an 8-bit, bidirectional, CMOS compatible I/O port. These eight I/O lines can be independently configured under software control as inputs or outputs. Port 2 is always available for I/O operation. A mask option is available to connect eight 200 kOhms (±50%) pull-up resistors on this port. Bits programmed as outputs are globally programmed as either push-pull or open-drain. Port 2 may be placed under handshake control. In this configuration, Port 3 lines, P31 and P36 are used as the handshake controls lines /DAV2 and RDY2. The handshake signal assignment for Port 3, lines P31 and P36 is dictated by the direction (input or output) assigned to Bit 7, Port 2 (Figure 6). The CCP wakes up with the eight bits of Port 2 configured as inputs with open-drain outputs.

Port 2 also has an 8-bit input NOR and an NAND gates which can be used to wake up the part from STOP mode (Figure 38). P20 can be programmed to access the edge selection circuitry (Figure 10).

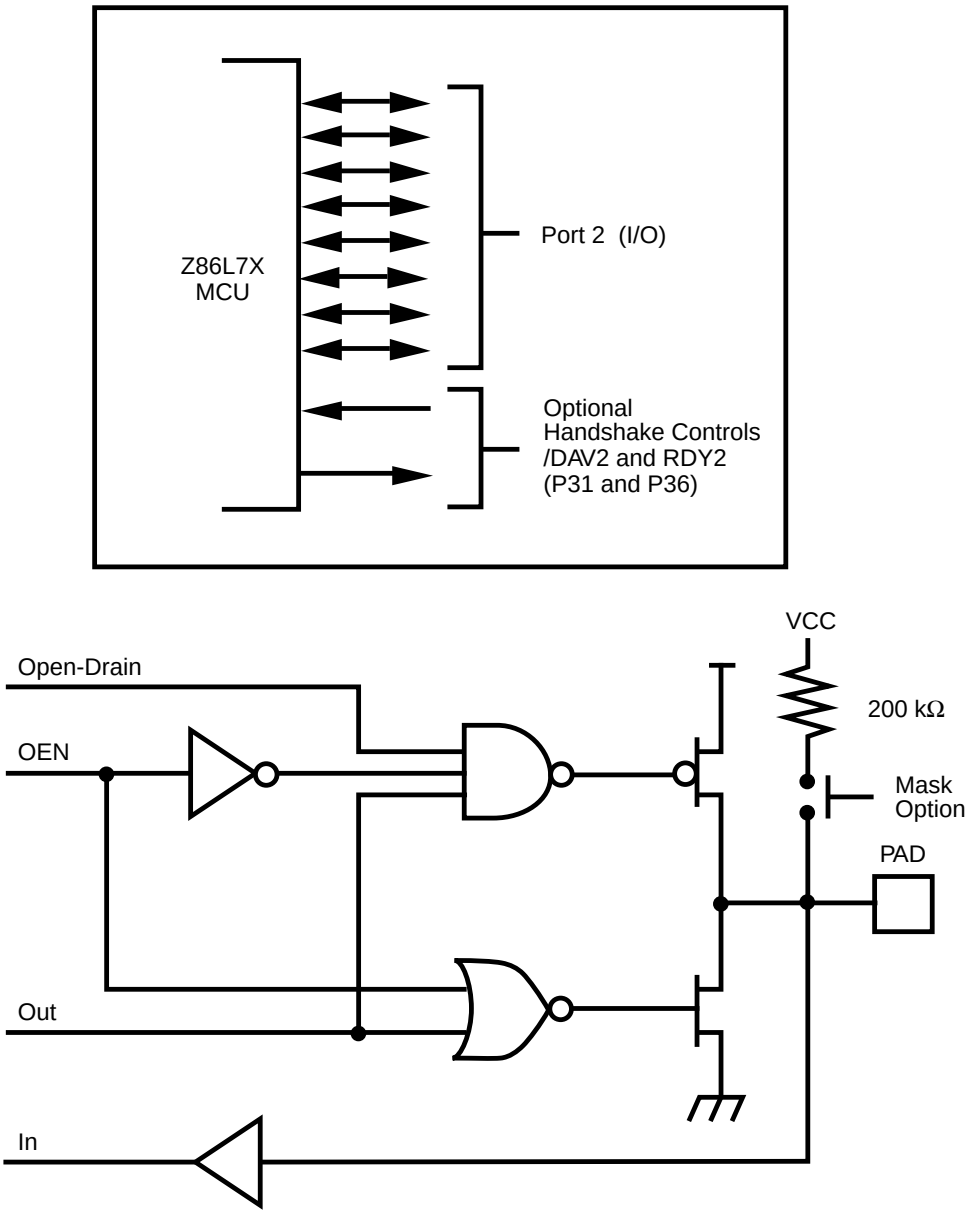

Figure 10. Port 2 Configuration

Port 3 (P37-P31). Port 3 is a 7-bit, CMOS compatible three fixed input and four fixed output port. Port 3 consists of three fixed input (P33-P31) and four fixed output (P37-P34), and can be configured under software control for Input/Output, Interrupt, Port handshake, Data Memory functions and output from the counter/timers. P31, P32, and P33 are standard CMOS inputs; outputs are push-pull, except for P34, 35 which are controlled by P3M, D0.

Two on-board comparators process analog signals on P31 and P32 with reference to the voltage on Pref1 and P33. The analog function is enabled by programming the Port 3 Mode Register (bit 1). P31 and P32 are programmable as rising, falling, or both edge triggered interrupts (IRQ register bits 6 and 7). Pref1 and P33 are the comparator reference voltage inputs. Access to the edge detection circuit is through P31 or P20. Handshake lines Ports 0, 1, and 2 are available on P31 through P36.

Port 3 provides the following control functions: handshake for Ports 0, and 2 (/DAV and RDY); four external interrupt request signals (IRQ3-IRQ0). (See Table 2).

Port 3 also provides output for each of the counter/timers and the AND/OR Logic. Control is performed by programming bits D5-D4 of CTRI, bit 0 of CTR0 and bit 0 of CTR2.

Table 2. Pin Assignments

Pin	I/O	C/T	Comp.	Int.	P0 HS	P2 HS
Pref1	IN		RF1			
P31	IN	ISP	AN1	IRQ2		D/R
P32	IN		AN2	IRQ0	D/R	
P33	IN		RF2	IRQ1		
P34	OUT	T8	A01			
P35	OUT	T16			R/D	
P36	OUT	T8/16				R/D
P37	OUT		A02			

Notes:
1. HS = Handshake Signals
2. D = /DAV
3. R = RDY

Comparator Inputs. Port 3, P31 and P32 all have a comparator front end. The comparator reference voltages are on P33 and Pref1. The internal P33 register and its corresponding IRQ1 is connected to the Stop-Mode Recovery source selected by the SMR. In this mode, any of the Stop-Mode Recovery sources can be used to toggle the P33 bit or generate IRQ1. In digital mode, P33 can be used as a Port 3 register input or IRQ1 for P33 (Figure 8).

Note: The comparators are disabled in STOP mode.

Comparator Outputs. These may be programmed to be outputted on P34 and P37 through the PCON register (Figure 11).

PIN FUNCTIONS (Continued)

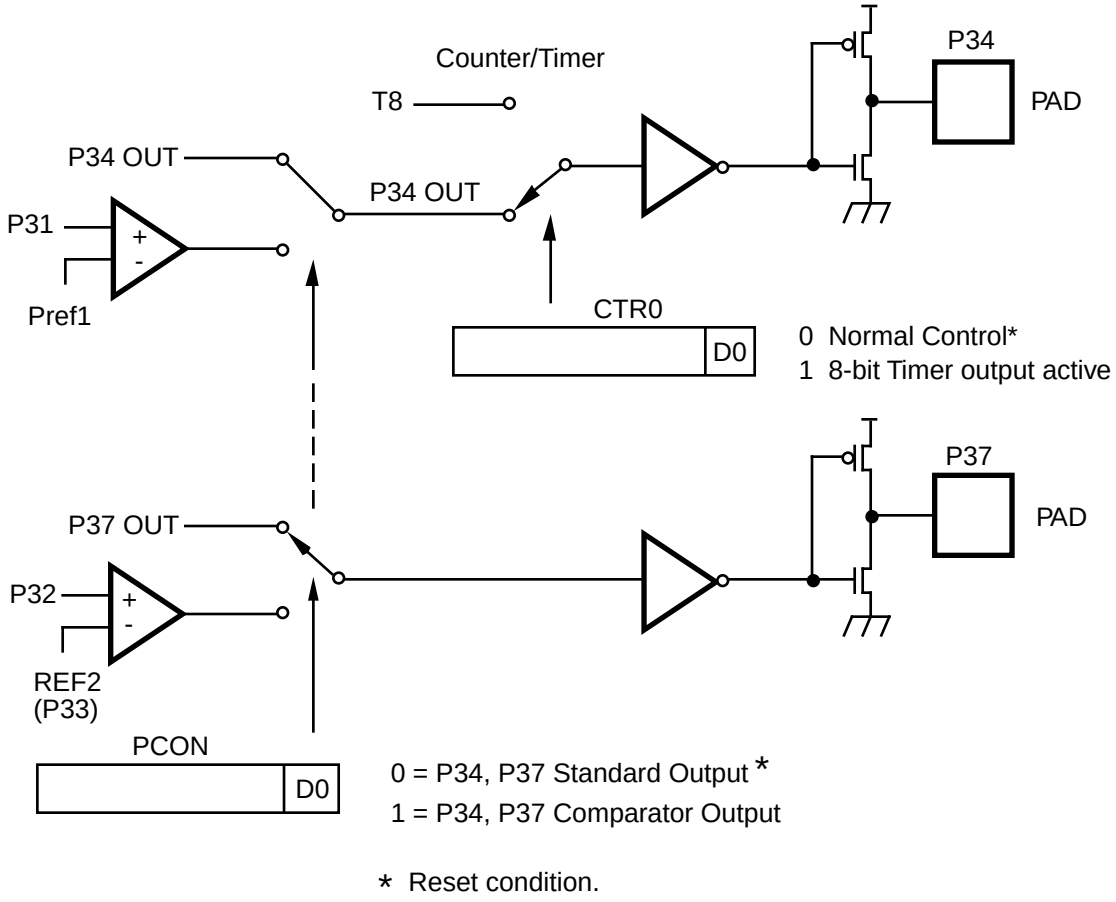

Figure 11. Port 3 Comparator Configuration

Reset. Program execution begins at location 000CH, 5-10 TpC cycles after the RST is released. For Power-On Reset, the typical reset output time is 5 ms. The Z86L7X does not reset WDTMR, SMR, P2M or P3M registers on a Stop-Mode Recovery operation either from WDT or the programmed STOP mode recovery source.

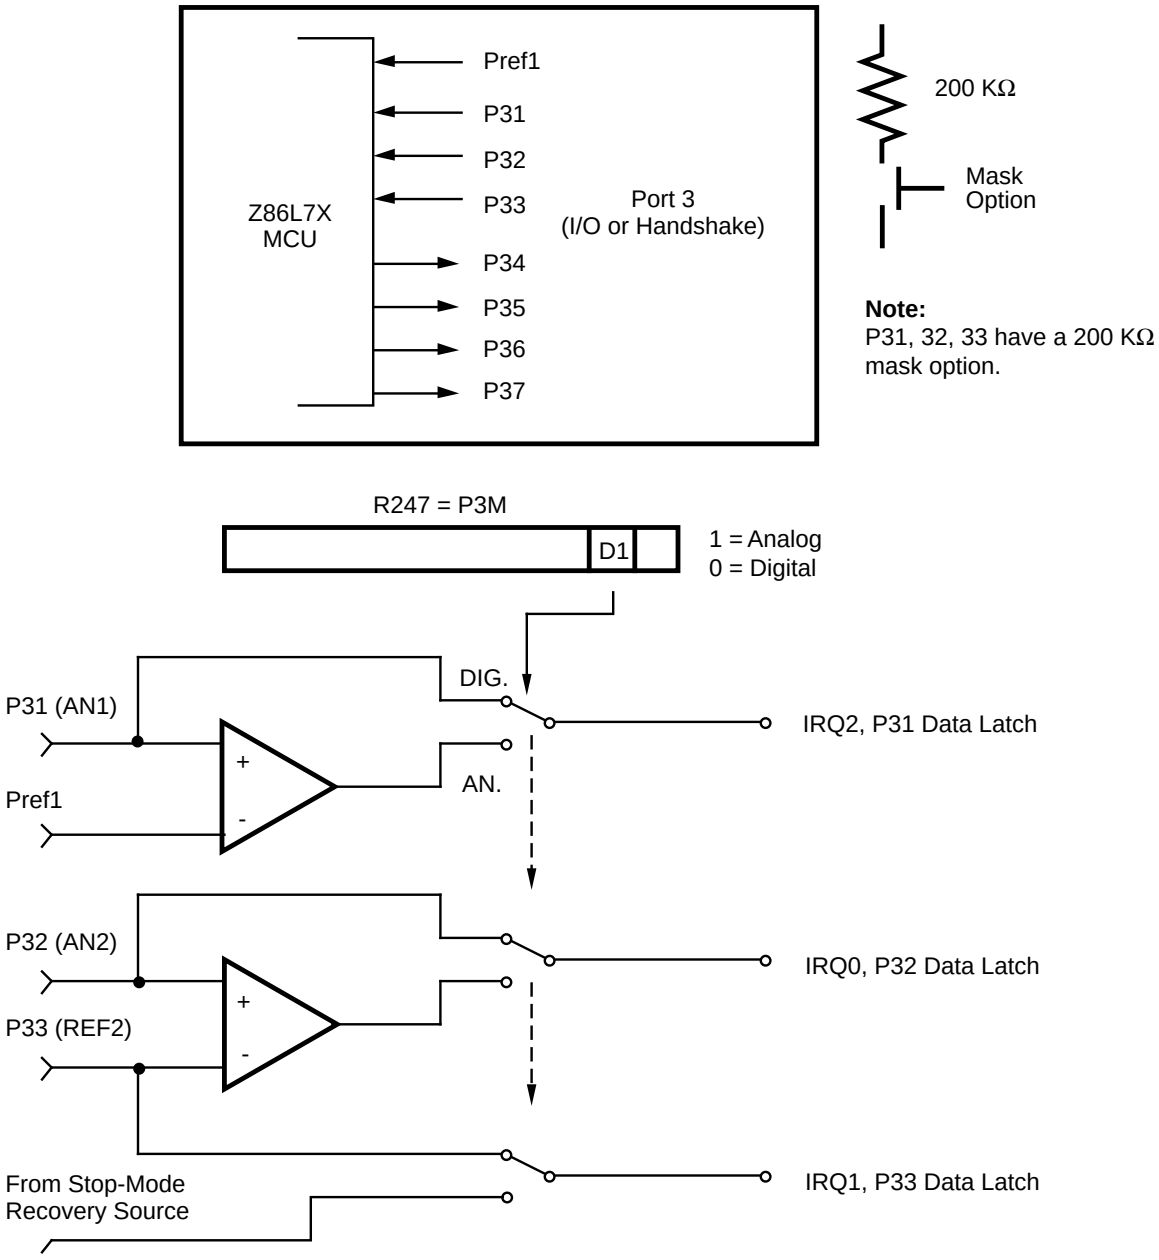

Figure 12. Port 3 Configuration

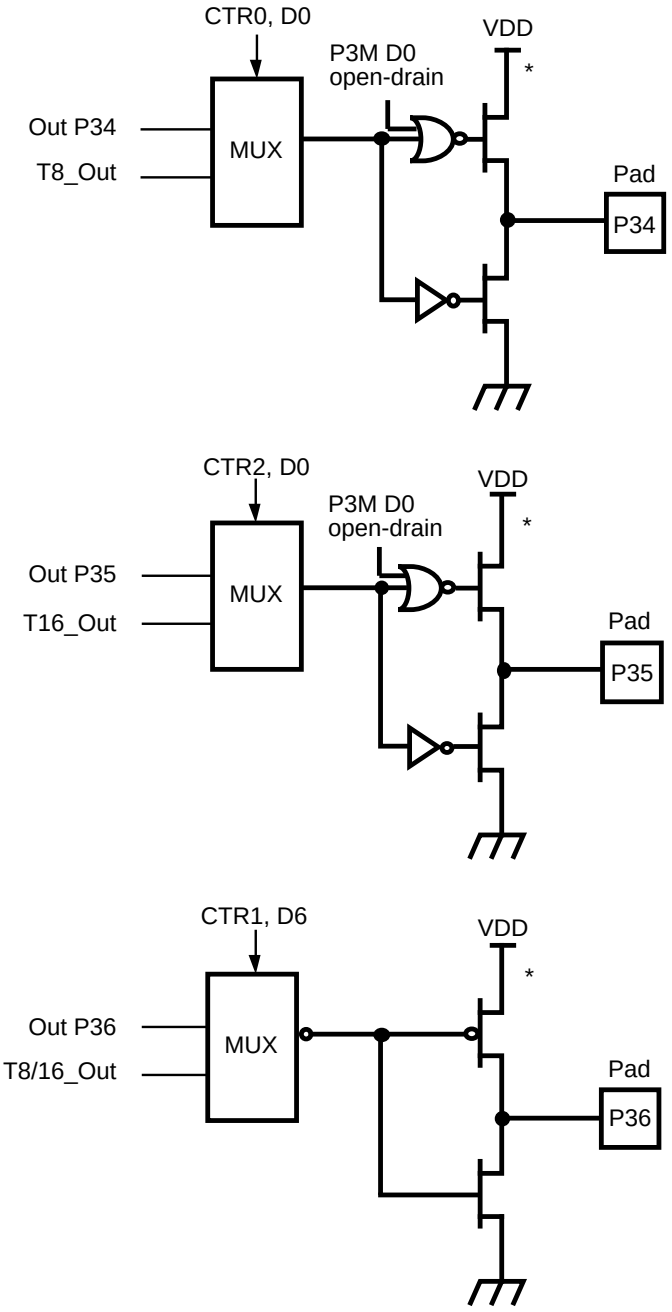
PIN FUNCTIONS (Continued)



* Default after reset output is push-pull.

Figure 13. Port 3 Configuration

FUNCTIONAL DESCRIPTION

The Z8 CCP™ incorporates special functions to enhance the Z8's functionality in consumer and battery operated applications.

Reset. The device is reset in one of the following conditions:

- Power-On Reset
- Watch-Dog Timer
- Stop-Mode Recovery Source
- Low Voltage Detection

Program Memory. The Z86L7X addresses up to 4K and 8 Kbytes of internal program memory. (Figure 10). The first 12 bytes of program memory are reserved for the interrupt vectors. These locations contain five 16-bit vectors that correspond to the five available interrupts. Addresses 12 to 4K, and 8K (dependent on version) consist of on-chip mask-programmed ROM.

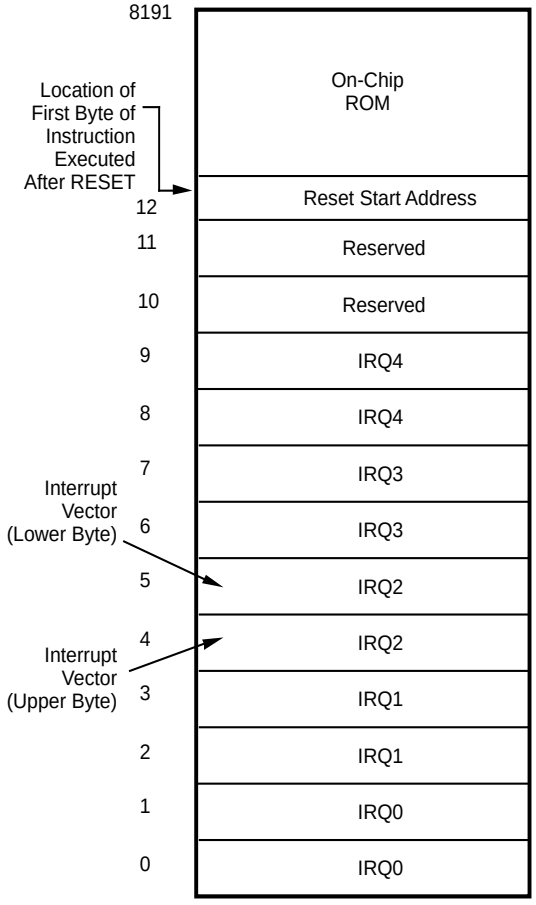


Figure 14. Program Memory Map

External Data Memory. Not accessible using the 28-pin Z86L79/80.

Expanded Register File. The register file has been expanded to allow for additional system control registers, and for mapping of additional peripheral devices along with I/O ports into the register address area. The Z8 register address space R0 through R15 has now been implemented as 16 groups of 16 registers per group. These register groups are known as the ERF (Expanded Register File). Bits 7-4 of register RP select the working register group. Bits 3-0 of register RP select the expanded register group (Figure 15).

The upper nibble of the register pointer (Figure 12) selects which group of 16 bytes in the register file, out of the full 256, will be accessed. The lower nibble selects the expanded register file bank and, in the case of the Z86L79/80 Banks F and D are implemented. A 0H in the lower nibble will allow the normal register file to be addressed, but any other value from 1H to FH will exchange the lower 16 registers in favor of an expanded register group of 16 registers.

For example:

Z86L79/80: (See Figure 15)

R253 RP = 00H
R0 = Port 0
R1 = Port 1
R2 = Port 2
R3 = Port 3

But if:

R253 RP = 0DH
R0 = CTRL0
R1 = CTRL1
R2 = CTRL2
R3 = Reserved

The counter/timers are mapped into ERF group D. Access is easily done using the following example:

LD RP, #0DH Select ERF D for access and register Bank 0 as the working register group

LDR0,#xx access CTRL0

LD1, #xx access CTRL1

LDRP, #7DH Select expanded register group(ERF) Bank D for access and register Group 7 as the working register Group.

LD R1, 2 CTRL2 → register 71H

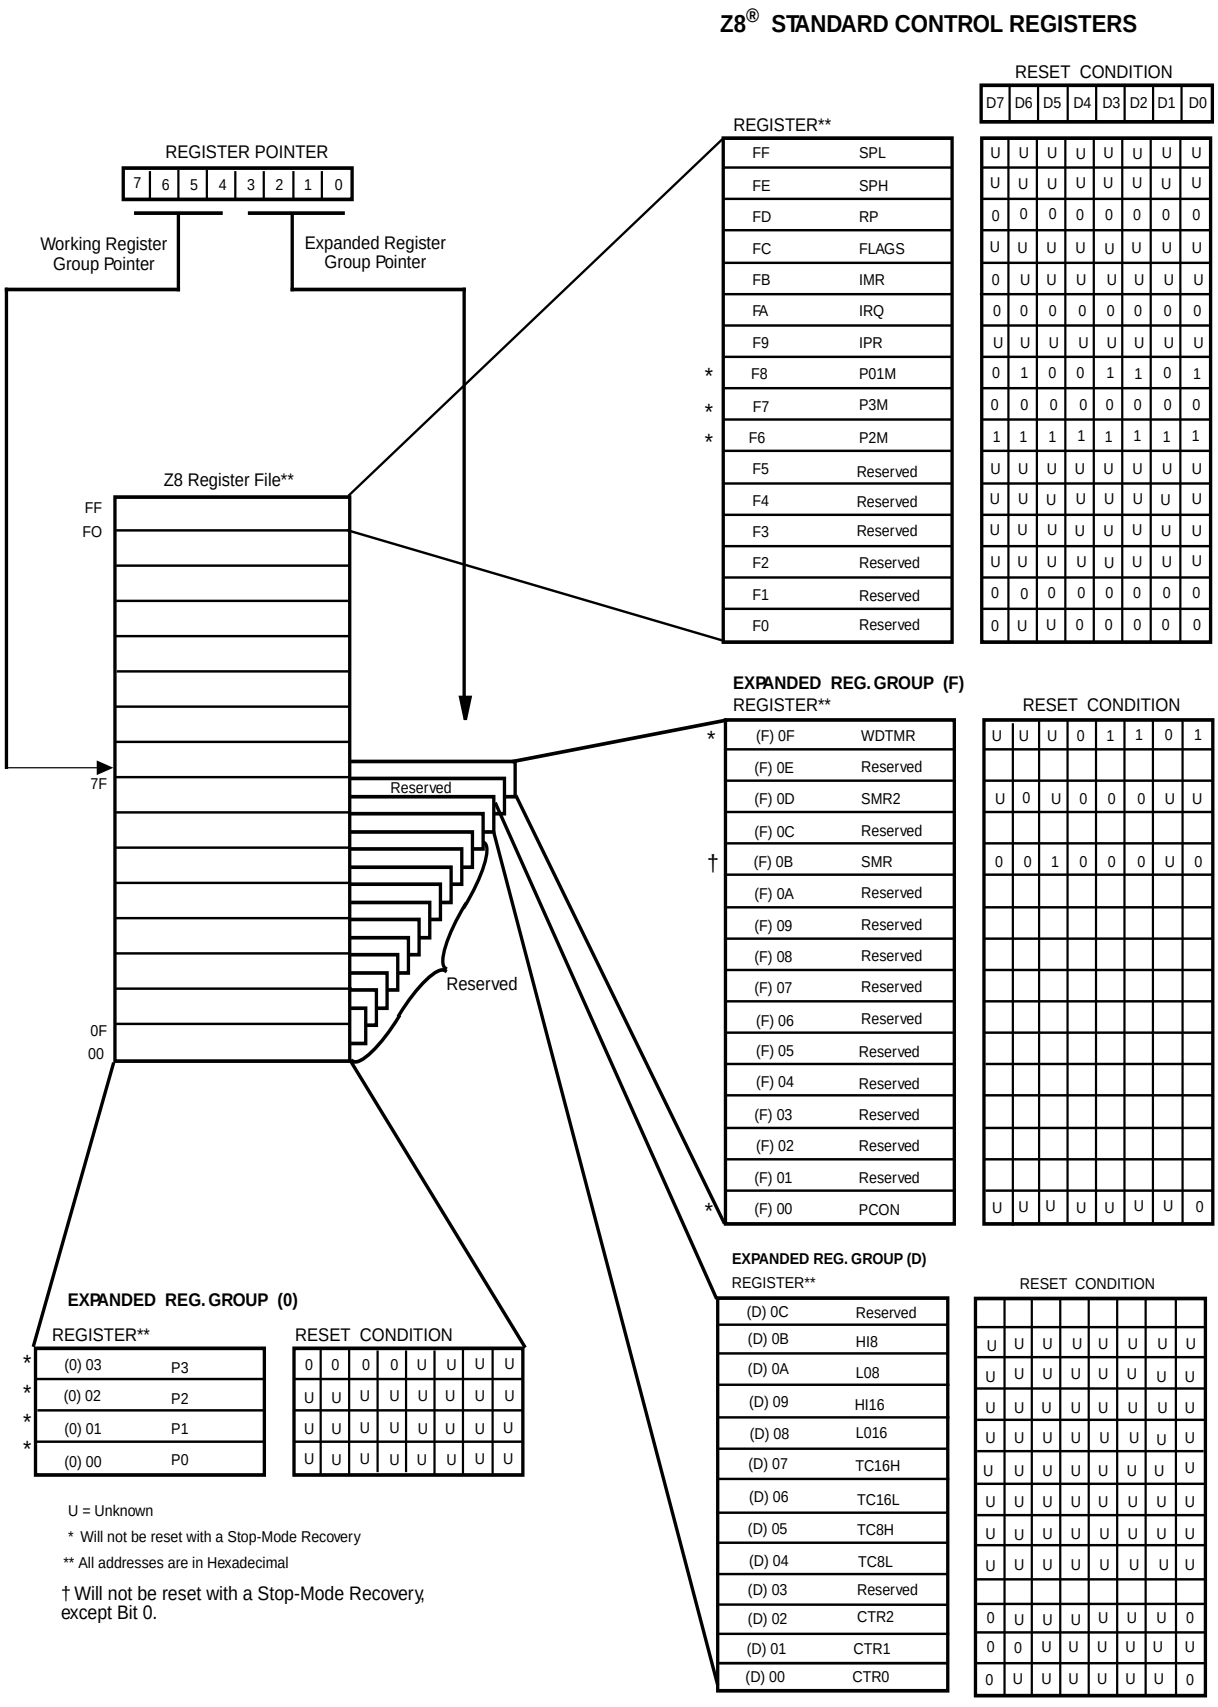

Figure 15. Expanded Register File Architecture

FUNCTIONAL DESCRIPTION (Continued)

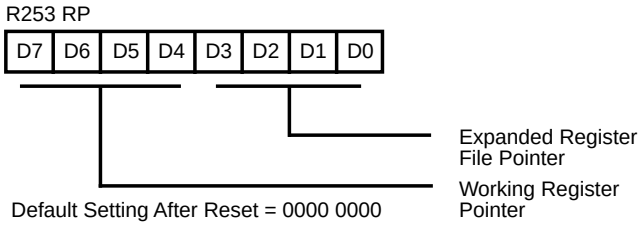

Figure 16. Register Pointer

Register File. The register file consists of four I/O port registers, 236 general-purpose registers with 10 control and status registers (R3-R0, R239-R4, and R255-R246, respectively), plus three Expanded Register Groups (0, D, and F) which reside in the expanded register group. Instructions can access registers directly or indirectly through an 8-bit address field. This allows a short, 4-bit register address using the Register Pointer (Figure 14). In the 4-bit mode, the register file is divided into 16 working register groups, each occupying 16 continuous locations. The Register Pointer addresses the starting location of the active working register group.

Note: Register Bank E0-EF is only accessed through working registers and indirect addressing modes. R240-R245 registers are reserved.

Stack. The Z86L7X external data memory or the internal register file is used for the stack. An 8-bit Stack Pointer (R255) is used for the internal stack that resides within the general-purpose registers (R4-R239). SPH is used as a general-purpose register only when using internal stacks.

Note: When SPH is used as a general-purpose register and Port 0 is in address mode, the contents of SPH will be loaded into Port 0 whenever the internal stack is accessed

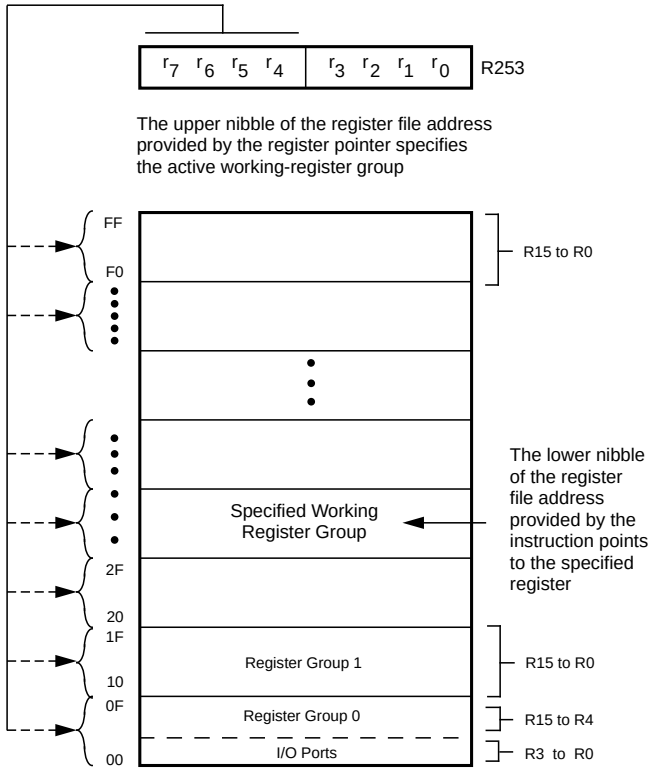

Figure 17. Register Pointer

Counter/Timer Register Description

·	Expanded Register Group D
(D)%0C	Reserved
(D)%0B	HI8
(D)%0A	LO8
(D)%09	HI16

CTR0: Counter/Timer8 Control Register Description

T8 Enable. This field enables T8 when set (written) to 1.

Single/Modulo-N. When set to 0 (modulo-n), the counter reloads the initial value when the terminal count is reached. When set to 1 (single pass), the counter stops when the terminal count is reached.

Time-Out. This bit is set when T8 times out (terminal count reached). To reset this bit, a 1 should be written to this location. **This is the only way to reset this status condition, therefore, care should be taken to reset this bit prior to using/enabling the counter/timers.**

Note: Care must be taken when utilizing the OR or AND commands to manipulate CTR0, bit 5 and CTR1, bits 0 and 1 (Demodulation Mode). These instructions use a Read-Modify-Write sequence in which the current status from the CTR0 and CTR1 registers will be ORed or ANDed with the designated value and then written back into the registers. Example: When the status of bit 5 is 1, a reset condition will occur.

T8 Clock. Defines the frequency of the input signal to T8.

Capture_INT_Mask. Set this bit to allow interrupt when data is captured into either LO8 or HI8 upon a positive or negative edge detection in demodulation mode.

Counter_INT_Mask. Set this bit to allow interrupt when T8 has a time out.

P34_Out. This bit defines whether P34 is used as a normal output pin or the T8 output.

CTR1(D)%01: Controls the functions in common with the T8 and T16.

CTR1 Register Description

Mode. If it is 0, the Counter/Timers are in the transmit mode, otherwise they are in the demodulation mode.

P36_Out/Demodulator_Input. In Transmit Mode, this bit defines whether P36 is used as a normal output pin or the combined output of T8 and T16.

In Demodulation Mode, this bit defines whether the input signal to the Counter/Timers is from P20 or P31.

T8/T16_Logic/Edge _Detect. In Transmit Mode, this field defines how the outputs of T8 and T16 are combined (AND, OR, NOR, NAND).

In Demodulation Mode, this field defines which edge should be detected by the edge detector.

Transmit_Submode/Glitch Filter. In Transmit Mode, this field defines whether T8 and T16 are in the "Ping-Pong" mode or in independent normal operation mode. Setting this field to "Normal Operation Mode" terminates the "Ping-Pong Mode" operation. When set to 10, T16_OUT is immediately set to A0. When set to 11, T16 is immediately forced to a 1.

In Demodulation Mode, this field defines the width of the glitch that should be filtered out.

Initial_T8_Out/Rising_Edge. In Transmit Mode, if 0, the output of T8 is set to 0 when it starts to count. If 1, the output of T8 is set to 1 when it starts to count. Note: When (CTR1, D1, D0) Bits are loaded, T8_OUT and T16_OUT will switch to the opposite state. This ensures a transition to the initial value once the counters are enabled. Therefore, it is not advisable to change (CTR1, D1, D0) Bits while the counters are running.

In Demodulation Mode, this bit is set to 1 when a rising edge is detected in the input signal. In order to reset it, a 1 should be written to this location.

Initial_T16 Out/Falling _Edge. In Transmit Mode, if it is 0, the output of T16 is set to 0 when it starts to count. If it is 1, the output of T16 is set to 1 when it starts to count. This bit is effective only in Normal or Ping-Pong Mode (CTR1, D3, D2).

In Demodulation Mode, this bit is set to 1 when a falling edge is detected in the input signal. In order to reset it, a 1 should be written to this location.

CTR2 (D)%02: Counter/Timer16 Control Register.

Field	Bit Position		Value	Description
T16_Enable	7-------	R	0*	Counter Disabled
			1	Counter Enabled

			1	T16 Output on P35

Note: *Indicates the value upon Power-On Reset.

CTR2 Description

T16_Enable. This field enables T16 when set to 1.

Single/Modulo-N. In Transmit Mode, when set to 0, the counter reloads the initial value when terminal count is reached. When set to 1, the counter stops when the terminal count is reached.

In Demodulation Mode, when set to 0 , T16 captures and reloads on detection of all the edges; when set to 1, T16 captures and detects on the first edge, but ignores the subsequent edges. For details, see the description of T16 Demodulation Mode.

Time_Out. This bit is set when T16 times out (terminal count reached). In order to reset it, a 1 should be written to this location.

T16_Clock. Defines the frequency of the input signal to Counter/Timer16.

Capture_INT_Mask. Set this bit to allow interrupt when data is captured into LO16 and HI16.

Counter_INT_Mask. Set this bit to allow interrupt when T16 times out.

P35_Out. This bit defines whether P35 is used as a normal output pin or T16 output.

SMR2(F)%0D: Stop-Mode Recovery Register 2.

Field	Bit Position		Value	Description
Reserved	7-------		0	Reserved (Must be 0)
Recovery Level	-6------	W	0*	Low
			1	High
Reserved	--5-----		0	Reserved (Must be 0)
Source	---432--	W	000*	A. POR Only
			001	B. NAND of P23-P20
			010	C. NAND or P27-P20
			011	D. NOR of P33-P31
			100	E. NAND of P33-P31
			101	F. NOR of P33-P31, P00,P07
			110	G. NAND of P33-P31,P00,P07
			111	H. NAND of P33-P31,P22-P20
Reserved	------10		00	Reserved (Must be 0)

Note: *Indicates the value upon Power-On Reset.

FUNCTIONAL DESCRIPTION (Continued)

Port pins configured as outputs are ignored as an SMR2 recover source. For example, if NAND of P23-P20 is selected as the recover source and P20 is configured as output, then P20 is ignored as a recover source. The effective recover source in this case is NAND of P23-P21.

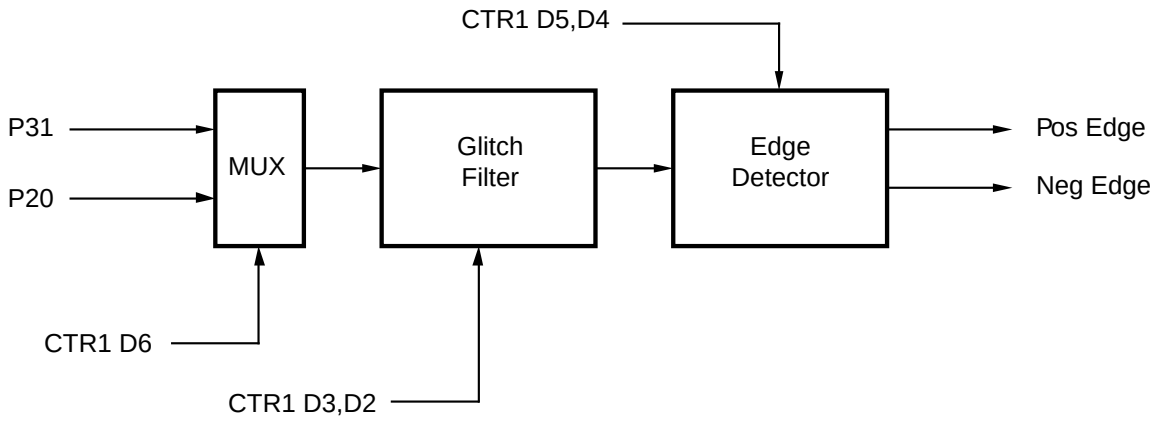

Figure 18. Glitch Filter Circuitry

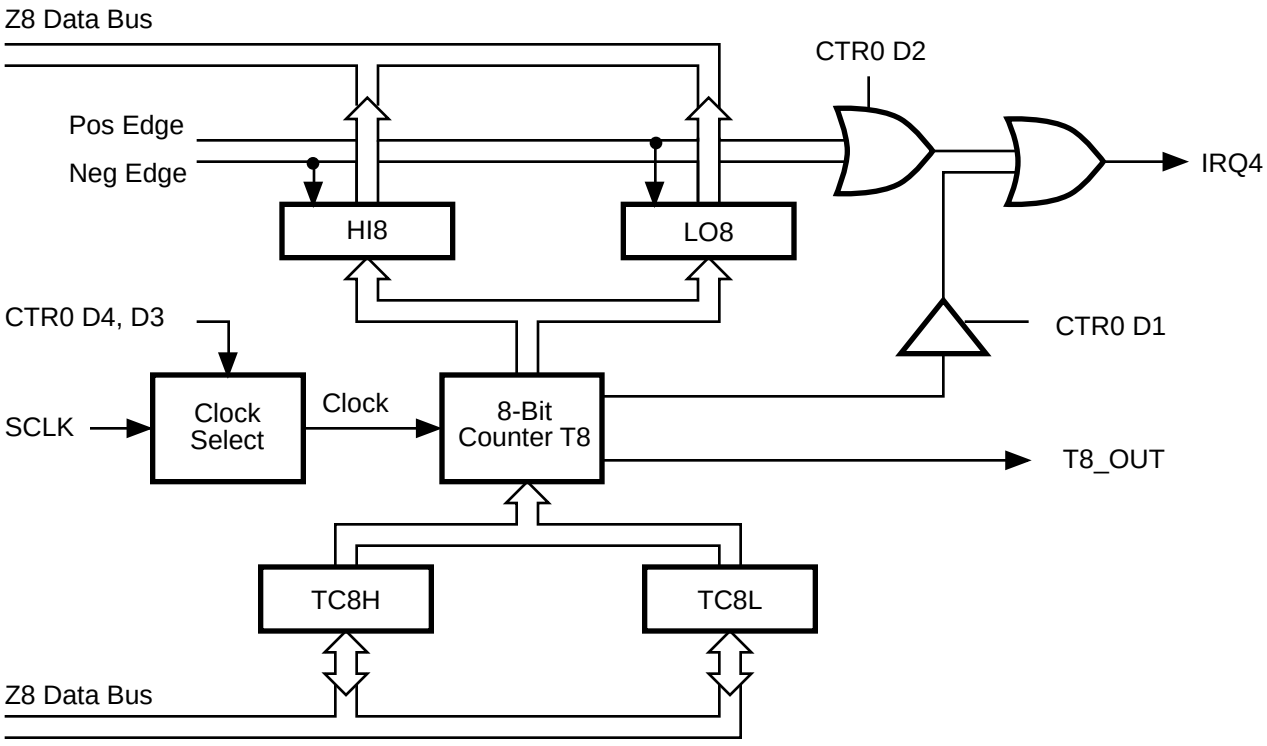

Figure 19. 8-Bit Counter/Timer Circuits

FUNCTIONAL DESCRIPTION (Continued)

Input Circuit
The edge detector monitors the input signal on P31 or P20. Based on CTR1 D5-D4, a pulse is generated at the Pos Edge or Neg Edge line when an edge is detected. Glitches in the input signal which have a width less than specified (CTR1 D3, D2) are filtered out.

T8 Transmit Mode
When T8 is enabled, the output of T8 depends on CTR1, D1. If it is 0, T8_OUT is 1. If it is 1, T8_OUT is 0.

When T8 is enabled, the output T8_OUT switches to the initial value (CTR1 D1). If the initial value (CTR1 D1) is 0, TC8L is loaded, otherwise TC8H is loaded into the counter. In Single-Pass Mode (CTR0 D6), T8 counts down to 0 and stops, T8_OUT toggles, the time-out status bit (CTR0 D5) is set, and a time-out interrupt can be generated if it is enabled (CTR0 D1) (Figure 22). In Modulo-N Mode, upon reaching terminal count, T8_OUT is toggled, but no interrupt is generated. Then T8 loads a new count (if the T8_OUT level now is 0), TC8L is loaded; if it is 1, TC8H is loaded. T8 counts down to 0, toggles T8_OUT, sets the time-out status bit (CTR0 D5) and generates an interrupt if enabled (CTR0 D1) (Figure 23). This completes one cycle. T8 then loads from TC8H or TC8L according to the T8_OUT level, and repeats the cycle.

The user can modify the values in TC8H or TC8L at any time. The new values take effect when they are loaded. Care must be taken not to write these registers at the time the values are to be loaded into the counter/timer, to ensure known operation. An initial count of 1 is not allowed (a non-function will occur). An initial count of 0 will cause TC8 to count from 0 to %FF to %FE (Note, % is used for hexadecimal values). Transition from 0 to %FF is not a time-out condition.

Note: Using the same instructions for stopping the counter/timers and setting the status bits is not recommended. Two successive commands, first stopping the counter/timers, then resetting the status bits is necessary. This is required because it takes one counter/timer clock interval for the initiated event to actually occur.

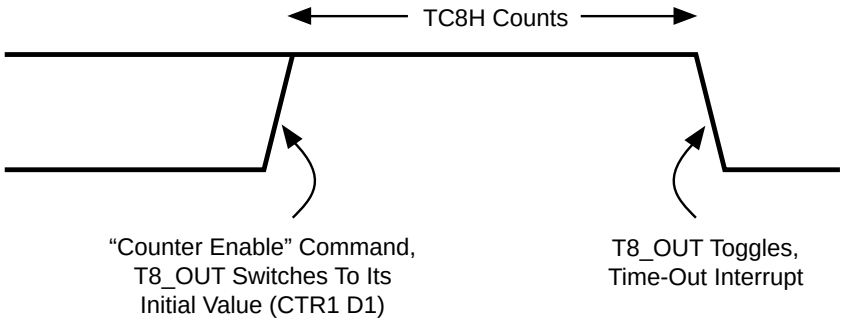

Figure 20. T8_OUT in Single-Pass Mode

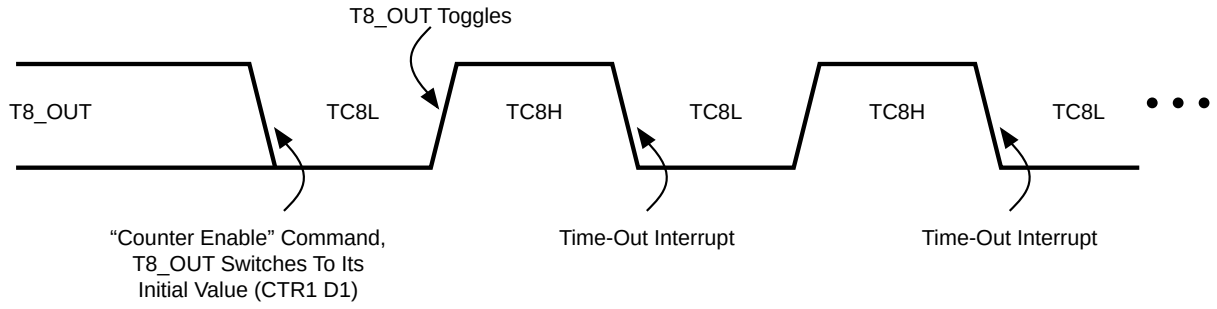

Figure 21. T8_OUT in Modulo-N Mode

T8 Demodulation Mode

The user should program TC8L and TC8H to %FF. After T8 is enabled, when the first edge (rising, falling, or both depending on CTR1 D5, D4) is detected, it starts to count down. When a subsequent edge (rising, falling, or both depending on CTR1 D5, D4) is detected during counting, the current value of T8 is one's complemented and put into one of the capture registers. If it is a positive edge, data is put into LO8, if negative edge, HI8. One of the edge detect status bits (CTR1 D1, D0) is set, and an interrupt can be generated if enabled (CTR0 D2). Meanwhile, T8 is loaded with %FF and starts counting again. Should T8 reach 0, the time-out status bit (CTR0 D5) is set, an interrupt can be generated if enabled (CTR0 D1), and T8 continues counting from %FF (Figure 22).

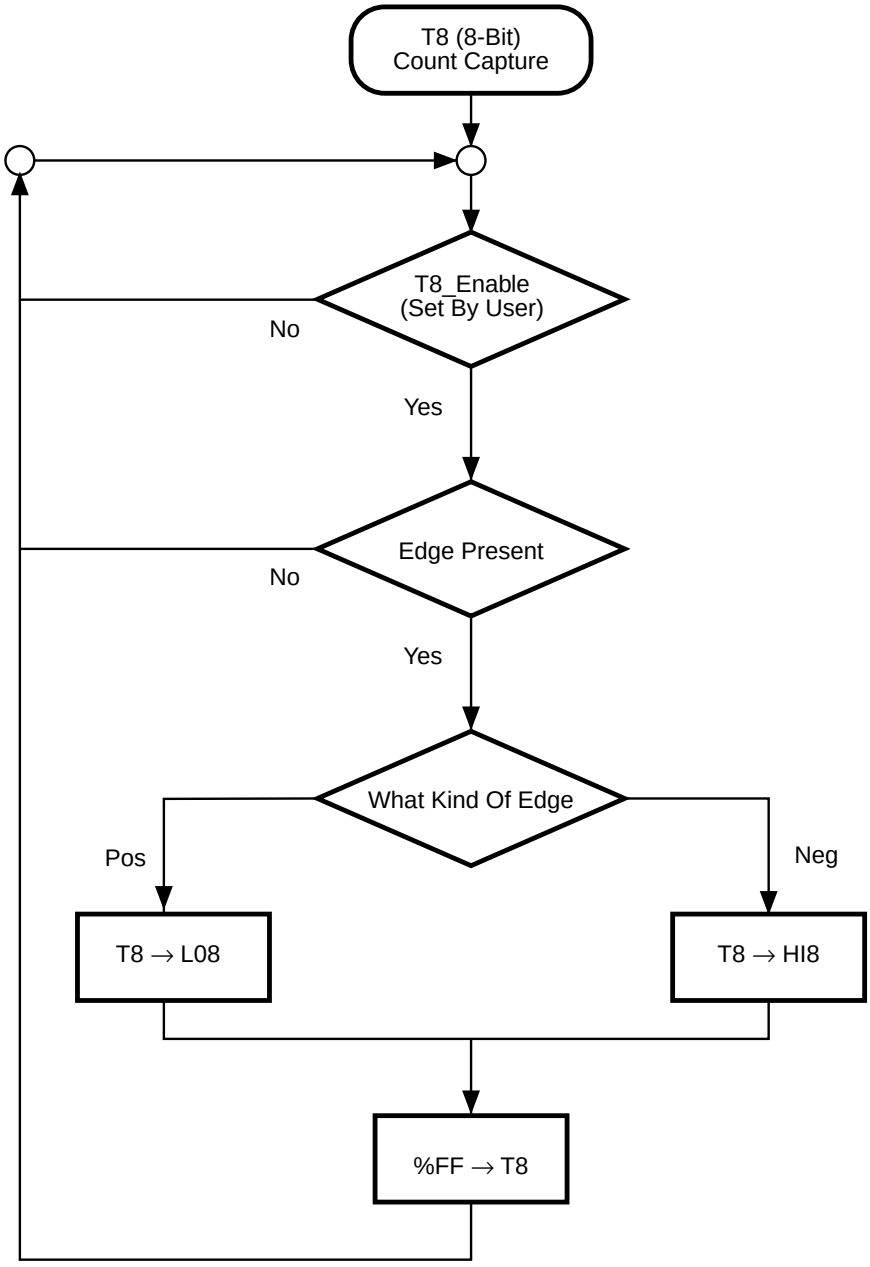

Figure 22. Demodulation Mode Count Capture Flowchart

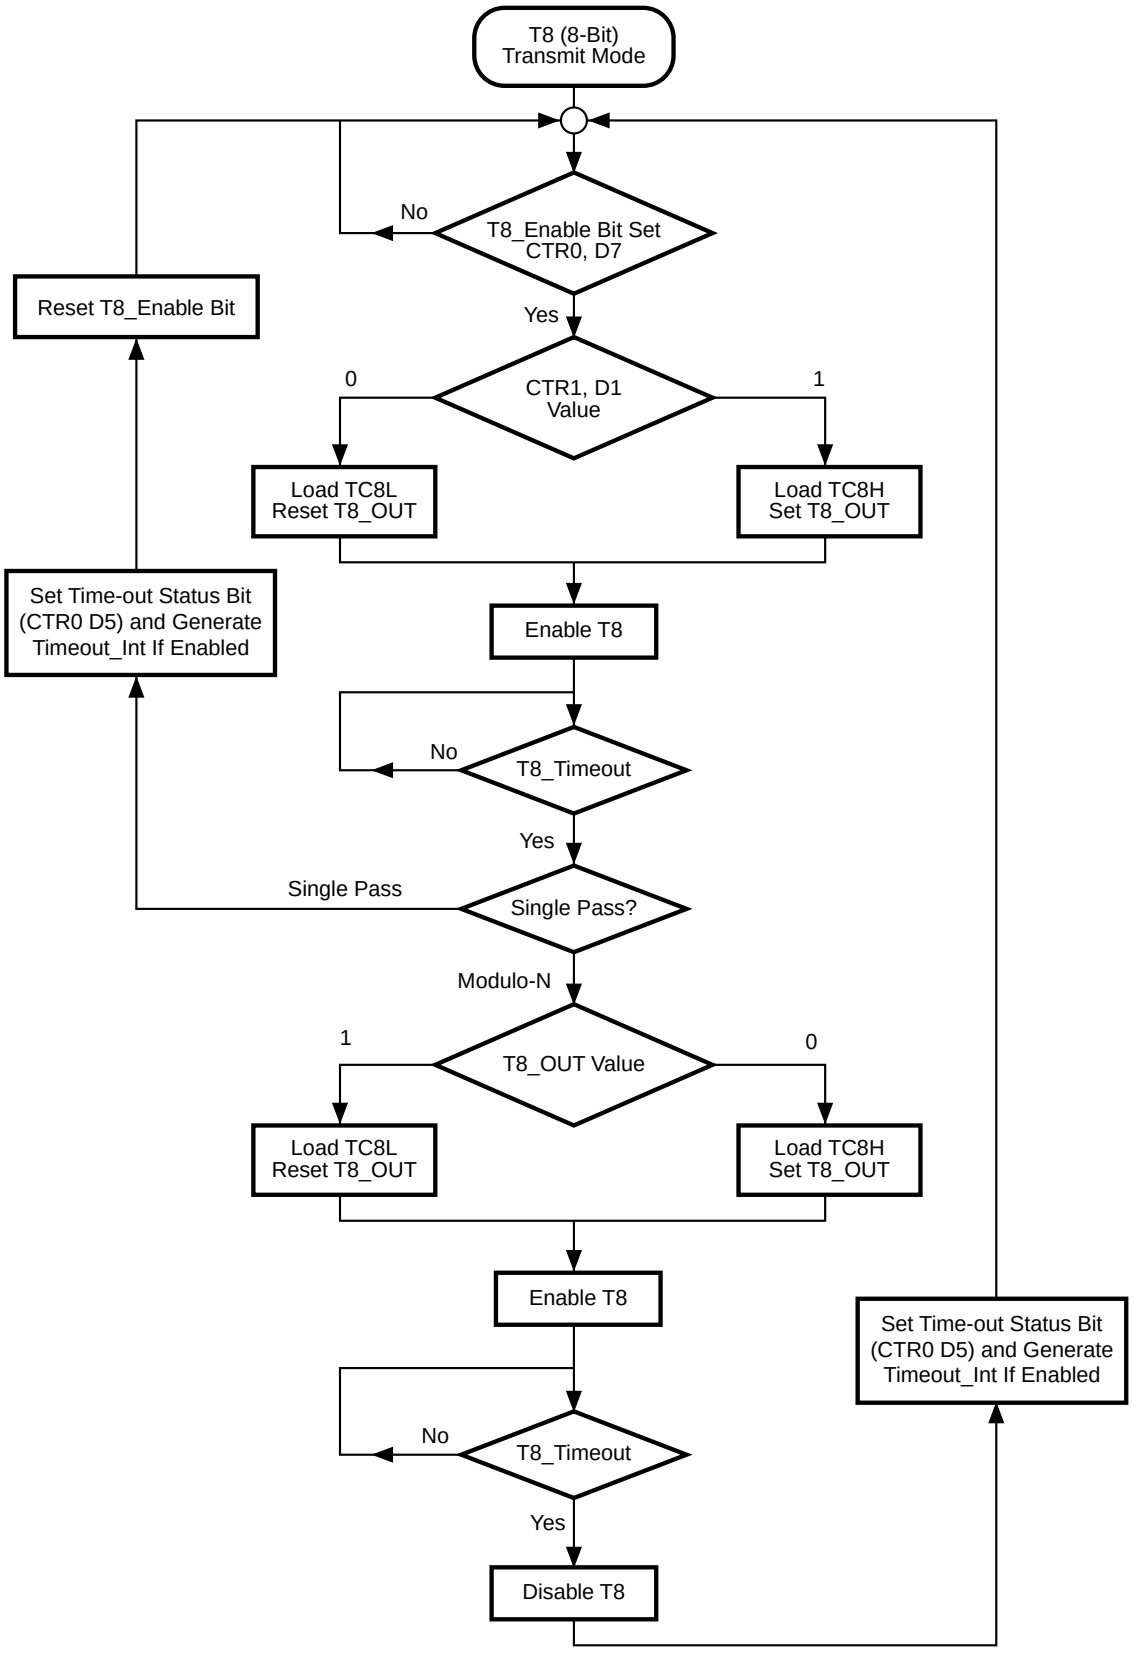

Figure 23. Transmit Mode Flowchart

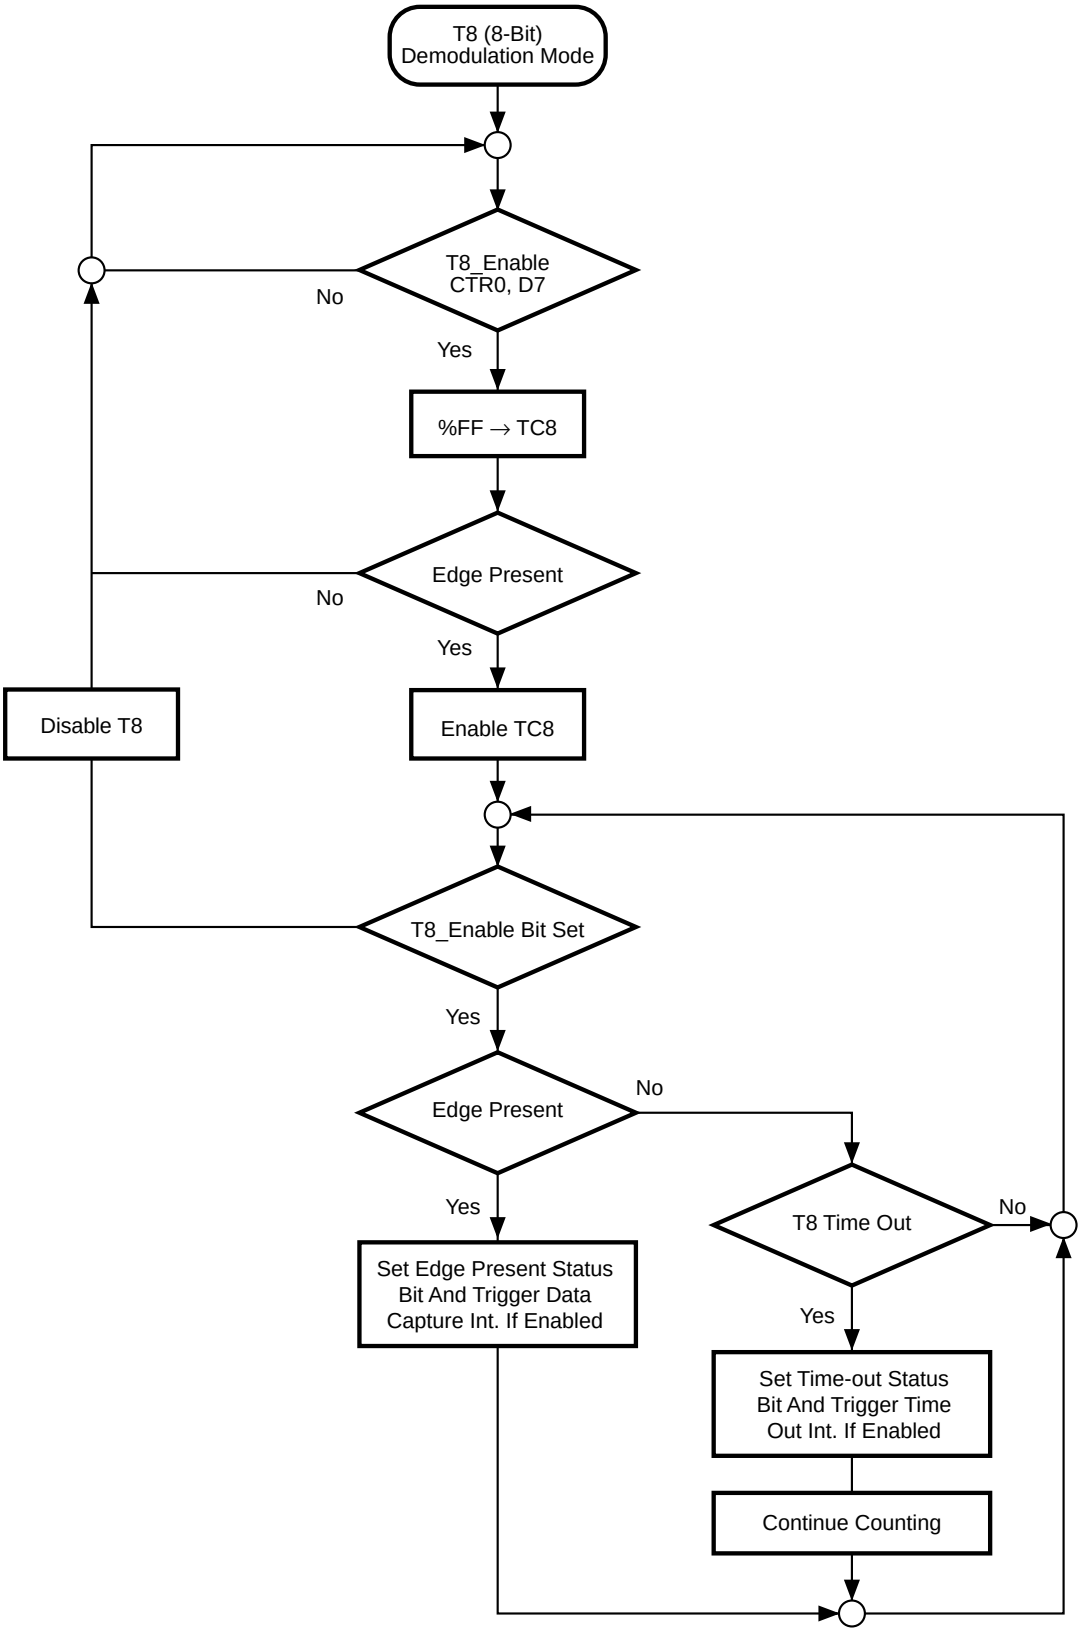

Figure 24. Demodulation Mode Flowchart

FUNCTIONAL DESCRIPTION (Continued)

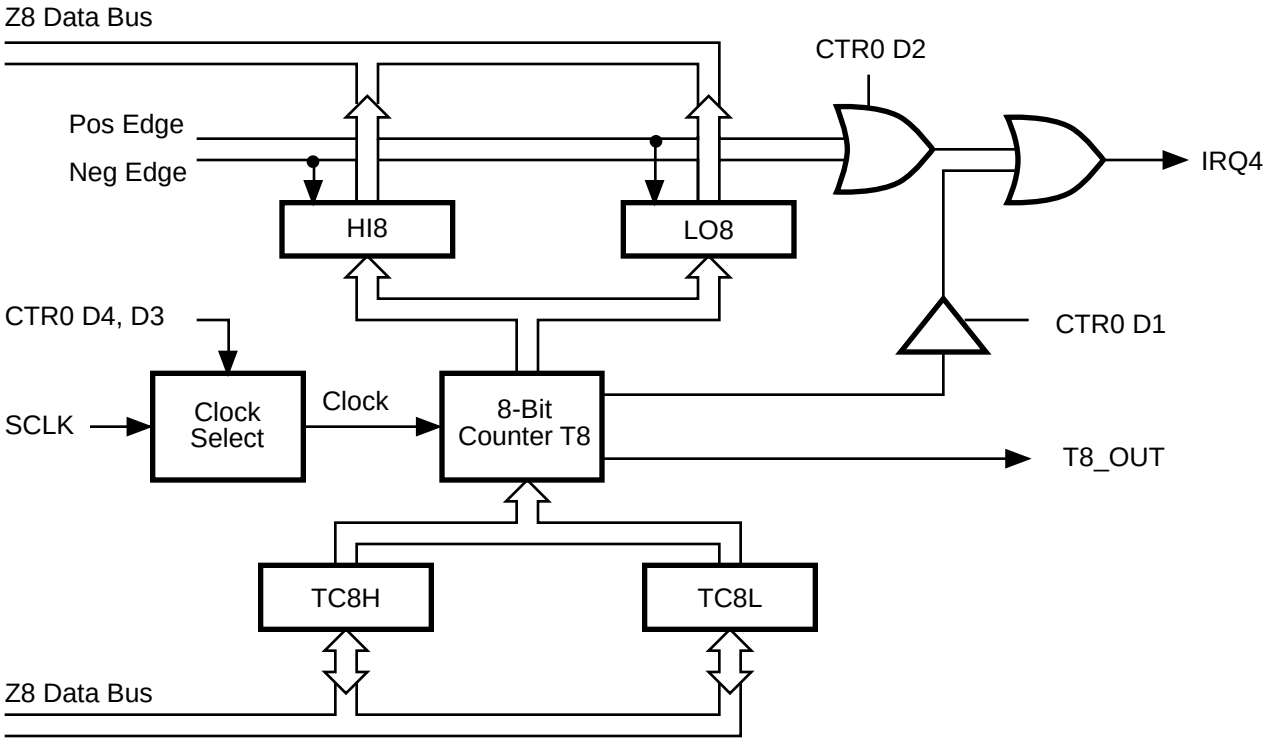

Figure 25. 16-Bit Counter/TImer Circuits

T16 Transmit Mode

In Normal or Ping-Pong Mode, the output of T16 when not enabled is dependent on CTR1, D0. If it is a 0, T16_OUT is a 1; if it is a 1, T16_OUT is 0. The user can force the output of T16 to either a 0 or 1 whether it is enabled or not by programming CTR1 D3, D2 to a 10 or 11.

When T16 is enabled, TC16H * 256 + TC16L is loaded, and T16_OUT is switched to its initial value (CTR1 D0). When T16 counts down to 0, T16_OUT is toggled (in Normal or Ping-Pong Mode), an interrupt is generated if enabled (CTR2 D1), and a status bit (CTR2 D5) is set. Note that global interrupts will override this function as described in the interrupts section. If T16 is in Single-Pass Mode, it is stopped at this point. If it is in Modulo-N Mode, it is loaded with TC16H * 256 + TC16L and the counting continues.

The user can modify the values in TC16H and TC16L at any time. The new values take effect when they are loaded. Care must be taken not to load these registers at the time the values are to be loaded into the counter/timer, to ensure known operation. An initial count of 1 is not allowed. An initial count of 0 will cause T16 to count from 0 to %FF FF to %FFFE. Transition from 0 to %FFFF is not a time-out condition.

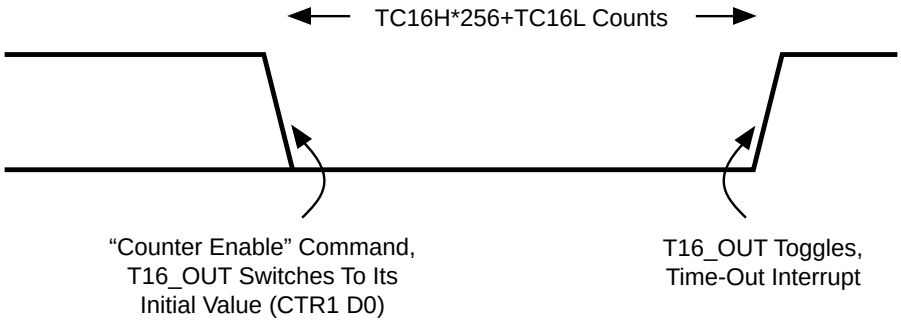

Figure 26. T16_OUT in Single-Pass Mode

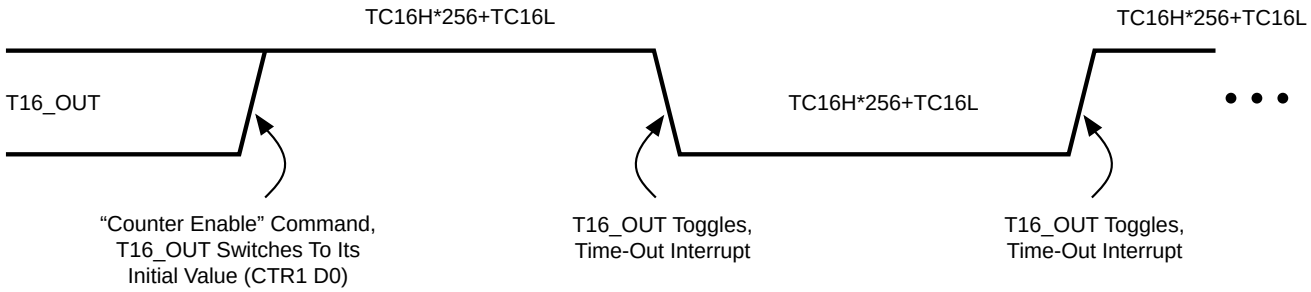

Figure 27. T16_OUT in Modulo-N Mode

T16 Demodulation Mode

The user should program TC16L and TC16H to %FF. After T16 is enabled, when the first edge (rising, falling, or both depending on CTR1 D5, D4) is detected, begins to count down.

If D6 of CTR2 is 0: When a subsequent edge (rising, falling, or both depending on CTR1 D5, D4) is detected during counting, the current count in T16 is one's complemented and put into HI16 and LO16. When data is captured, one of the edge detect status bits (CTR1 D1, D0) is set and an interrupt is generated if enabled (CTR2 D2). T16 is loaded with %FFFF and starts again.

If D6 of CTR2 is 1: T16 ignores the subsequent edges in the input signal and continues counting down. A time out of T8 will cause T16 to capture its current value and generate an interrupt if enabled (CTR2, D2). In this case, T16 does not reload and continues counting. If D6 bit of CTR2 is toggled (by writing a 0 then a 1 to it), T16 will capture and reload on the next edge (rising, falling, or both depending on CTR1 D5, D4) but continue to ignore subsequent edges.

Should T16 reach 0, it continues counting from %FFFF; meanwhile, a status bit (CTR2 D5) is set and an interrupt time-out can be generated if enabled (CTR2 D1).

FUNCTIONAL DESCRIPTION (Continued)

Ping-Pong Mode

This operation mode is only valid in Transmit Mode. T8 and T16 need to be programmed in Single-Pass Mode (CTR0 D6, CTR2 D6) and Ping-Pong Mode needs to be programmed in CTR1 D3, D2. The user can begin the operation by enabling either T8 or T16 (CTR0 D7 or CTR2 D7). For example, if T8 is enabled, T8_OUT is set to this initial value (CTR1 D1). According to T8_OUT's level, TC8H or TC8L is loaded into T8. After the terminal count is reached, T8 is disabled and T16 is enabled. T16_OUT switches to its initial value (CTR1 D0), data from TC16H and TC16L is loaded, and T16 starts to count. After T16 reaches the terminal count it stops, T8 is enabled again, and the whole cycle repeats. Interrupts can be allowed when T8 or T16 reaches terminal control (CTR0 D1, CTR2 D1). To stop the Ping-Pong operation, write 00 to bits D3 and D2 of CTR1.

Note:Enabling Ping-Pong operation while the counter/timers are running may cause intermittent counter/timer function. Disable the counter/timers, then reset the status flags prior to instituting this operation.

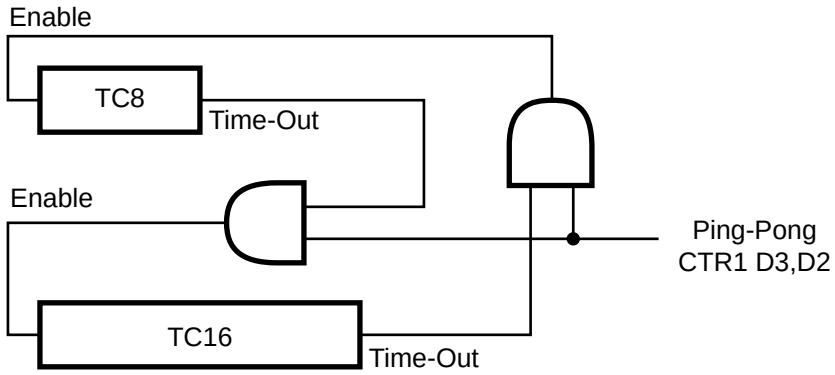

Figure 28. Ping-Pong Mode

To Initiate Ping-Pong Mode

First, make sure both counter/timers are not running. Then set T8 into Single-Pass Mode (CTR0 D6), set T16 into Single-Pass Mode (CTR2 D6), and set Ping-Pong Mode (CTR1 D2, D3). These instructions do not have to be in any particular order. Finally, start Ping-Pong Mode by enabling either T8 (CTR0 D7) or T16 (CTR2 D7).

During Ping-Pong Mode

The enable bits of T8 and T16 (CTR0 D7, CTR2 D7) will be cleared by hardware. The time-out bits (CTR0 D5, CTR2 D5) will be set every time the counter/timers reach the terminal count.

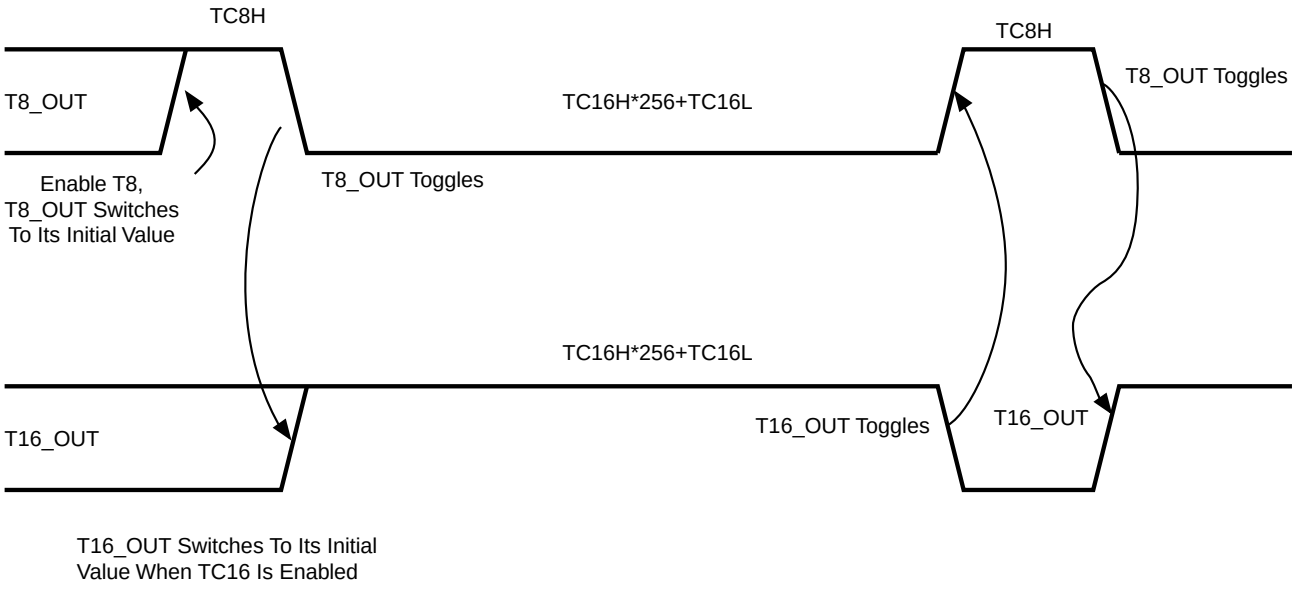

Figure 29. T8_OUT and T16_OUT in Ping-Pong Mode

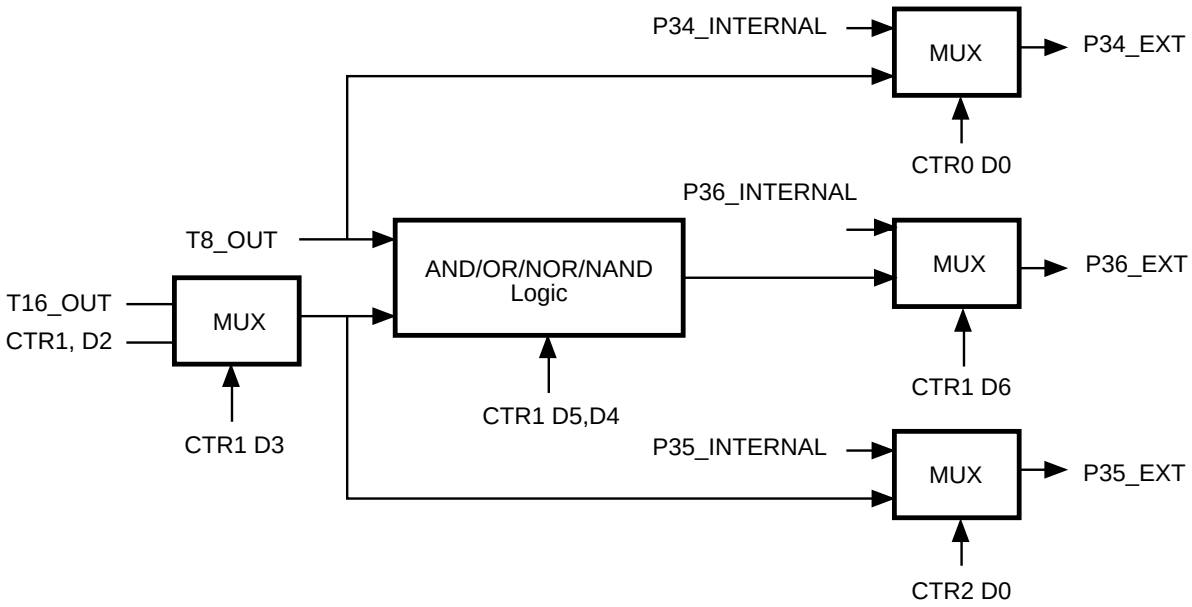

Figure 30. Output Circuit

FUNCTIONAL DESCRIPTION (Continued)

Interrupts. The Z86L7X has five different interrupts. The interrupts are maskable and prioritized (Figure 31). The five sources are divided as follows: three sources are claimed by Port 3 lines P33-P31, the remaining two by the counter/timers (Table 3). The Interrupt Mask Register globally or individually enables or disables the five interrupt requests.

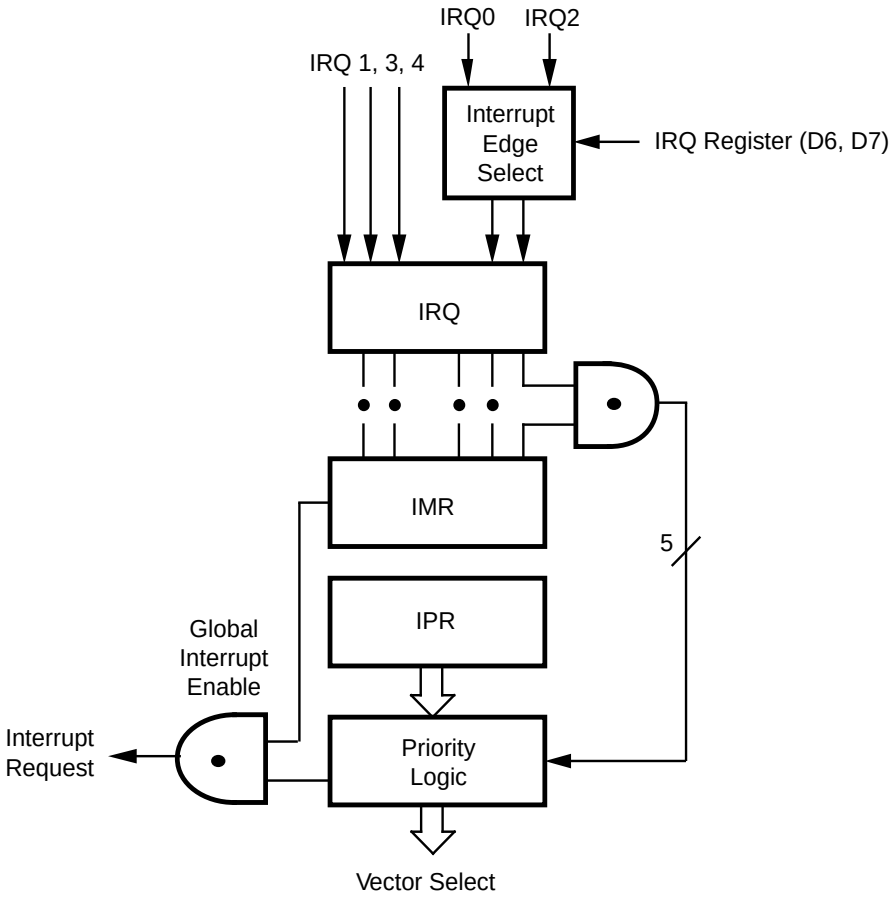

Figure 31. Interrupt Block Diagram

Table 3. Interrupt Types, Sources, and Vectors

Name	Source	Vector Location	Comments
IRQ0	/DAV0, IRQ0	0, 1	External (P32), Rising Falling Edge Triggered
IRQ1,	IRQ1	2, 3	External (P33), Falling Edge Triggered
IRQ2	/DAV2, IRQ2, T_{IN}	4, 5	External (P31), Rising Falling Edge Triggered
IRQ3	T16	6, 7	Internal
IRQ4	T8	8, 9	Internal
IRQ5		10,11	Software generated

When more than one interrupt is pending, priorities are resolved by a programmable priority encoder controlled by the Interrupt Priority register. An interrupt machine cycle is activated when an interrupt request is granted. This disables all subsequent interrupts, saves the Program Counter and Status Flags, and then branches to the program memory vector location reserved for that interrupt. All Z86L7X interrupts are vectored through locations in the program memory. This memory location and the next byte contain the 16-bit address of the interrupt service routine for that particular interrupt request. To accommodate polled interrupt systems, interrupt inputs are masked and the Interrupt Request register is polled to determine which of the interrupt requests need service.

An interrupt resulting from AN1 is mapped into IRQ2, and an interrupt from AN2 is mapped into IRQ0. Interrupts IRQ2 and IRQ0 may be rising, falling, or both edge triggered, and are programmable by the user. The software can poll to identify the state of the pin.

Programming bits for the Interrupt Edge Select are located in the IRQ Register (R250), bits D7 and D6. The configuration is shown in Table 4.

Table 4. IRQ Register

IRQ		Interrupt Edge	
D7	D6	IRQ2	IRQ0
0	0	F	F
0	1	F	R
1	0	R	F
1	1	R/F	R/F

Notes:
F = Falling Edge
R = Rising Edge
In analog mode, the Stop-Mode Recovery sources selected by the SMR register are connected to IRQ1 input. Any of the Stop-Mode Recovery sources for SMR (except P31, P32, and P33) can be used to generate IRQ1 (falling edge triggered).

Clock. The Z86L7X on-chip oscillator has a high-gain, parallel-resonant amplifier for connection to a crystal, LC, ceramic resonator, or any suitable external clock source (XTAL1 = Input, XTAL2 = Output). The crystal should be AT cut, 1 MHz to 8 MHz maximum, with a series resistance (RS) less than or equal to 100 Ohms. The Z86L7X on-chip oscillator may be driven with a cost-effective RC network or other suitable external clock source.

FUNCTIONAL DESCRIPTION (Continued)

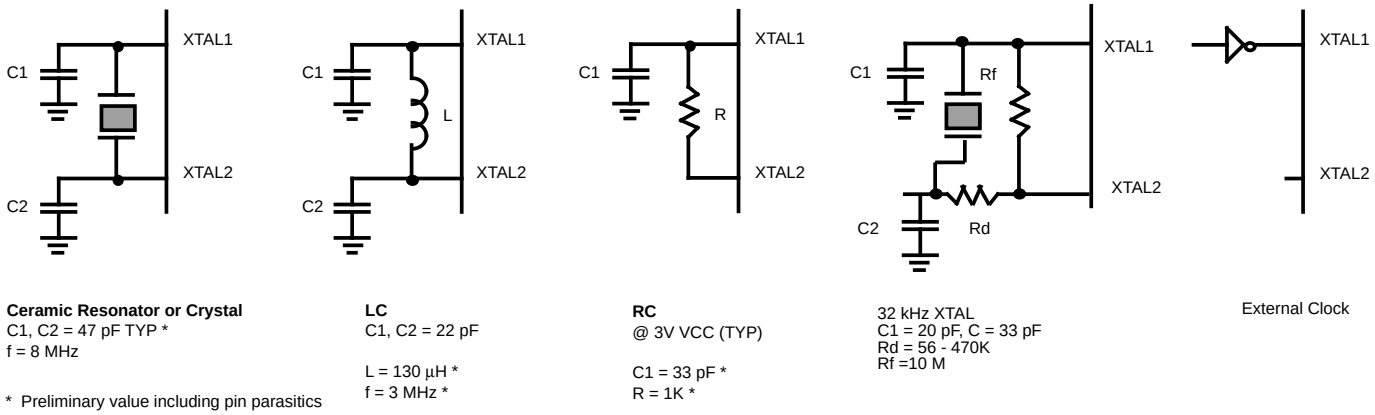
The crystal should be connected across XTAL1 and XTAL2 using the suppliers recommended capacitors from each pin to ground. The RC oscillator configuration is an external resistor connected from XTAL1 to XTAL2, with a frequency-setting capacitor from XTAL1 to ground (Figure 32).

Power-On Reset (POR). A timer circuit clocked by a dedicated on-board RC oscillator is used for the Power-On Reset (POR) timer function. The POR time allows V_{CC} and the oscillator circuit to stabilize before instruction execution begins.

The POR timer circuit is a one-shot timer triggered by one of three conditions:

1. Power Fail to Power OK status including waking up from Low Voltage standby mode.
2. Stop-Mode Recovery (if D5 of SMR = 1).
3. WDT Time-Out.

The POR time is a nominal 5 ms. Bit 7 of the Stop-Mode Register determines whether the POR timer is bypassed after Stop-Mode Recovery (typical for external clock, RC, LC oscillators).



Ceramic Resonator or Crystal
C1, C2 = 47 pF TYP *
f = 8 MHz

* Preliminary value including pin parasitics

LC
C1, C2 = 22 pF

L = 130 µH *
f = 3 MHz *

RC
@ 3V VCC (TYP)

C1 = 33 pF *
R = 1K *

32 kHz XTAL
C1 = 20 pF, C = 33 pF
Rd = 56 - 470K
Rf =10 M

External Clock

Figure 32. Oscillator Configuration

HALT. HALT turns off the internal CPU clock, but not the XTAL oscillation. The counter/timers and external interrupts IRQ0, IRQ1, IRQ2, IRQ3, and IRQ4 remain active. The devices are recovered by interrupts, either externally or internally generated. An interrupt request must be executed (enabled) to exit HALT mode. After the interrupt service routine, the program continues from the instruction after the HALT.

STOP. This instruction turns off the internal clock and external crystal oscillation and reduces the standby current to 10 µA (typical) or less. STOP mode is terminated only by a reset, such as WDT time-out, POR, SMR, or external reset. This causes the processor to restart the application program at address 000CH. In order to enter STOP (or HALT) mode, it is necessary to first flush the instruction pipeline to avoid suspending execution in mid-instruction. To do this, the user must execute a NOP (opcode = FFH) immediately before the appropriate sleep instruction, i.e.,

```
FF    NOP    ; clear the pipeline
6F    STOP   ; enter STOP mode
             or
FF    NOP    ; clear the pipeline
7F    HALT   ; enter HALT mode
```

Note: A WDT time-out during STOP mode will have the same effect like a recovery from any programmed STOP mode recovery source except the reset delay of TPOR will occur.

Note: The comparators are disabled in STOP mode.

Port Configuration Register (PCON). The PCON register configures the comparator output on Port 3. It is located in the expanded register file at Bank F, location 00 (Figure 33).

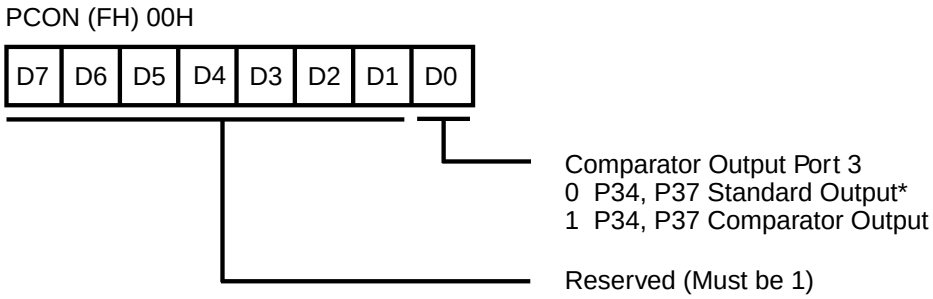


Figure 33. Port Configuration Register (PCON) (Write Only)

Comparator Output Port 3 (D0). Bit 0 controls the comparator used in Port 3. A 1 in this location brings the comparator outputs to P34 and P37, and a 0 releases the Port to its standard I/O configuration.

Stop-Mode Recovery Register (SMR). This register selects the clock divide value and determines the mode of Stop-Mode Recovery (Figure 34). All bits are write only except bit 7, which is read only. Bit 7 is a flag bit that is hardware set on the condition of STOP recovery and reset by a power-on cycle. Bit 6 controls whether a low level or a high level is required from the recovery source. Bit 5 controls the reset delay after recovery. Bits 2, 3, and 4, the SMR register, specify the source of the Stop-Mode Recovery signal. Bits 0 and 1 determine the frequency of SCLK/TCLK in relation to the OSC. The SMR is located in Bank F of the Expanded Register Group at address 0BH.

FUNCTIONAL DESCRIPTION (Continued)

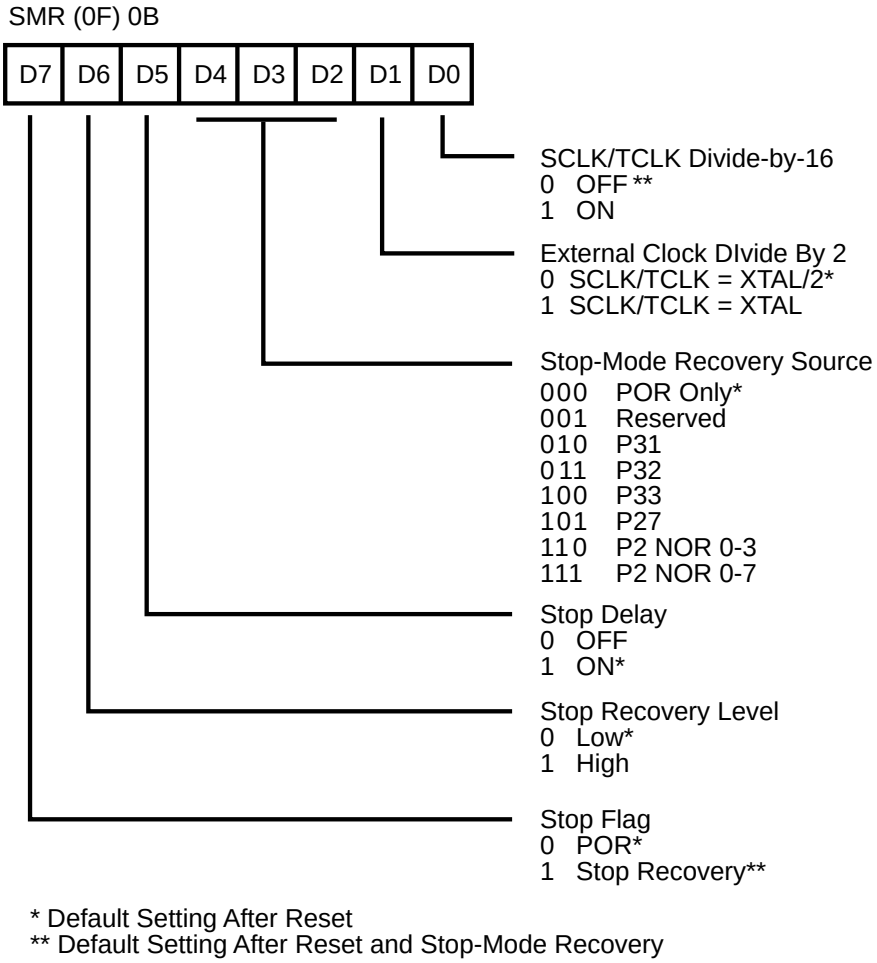

Figure 34. Stop-Mode Recovery Register

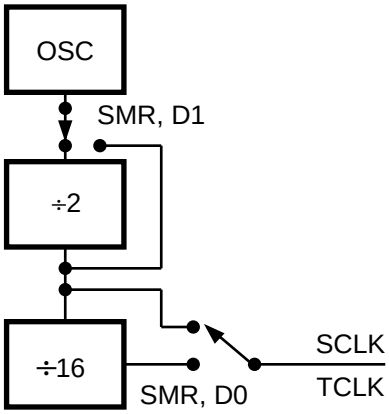

Figure 35. SCLK Circuit

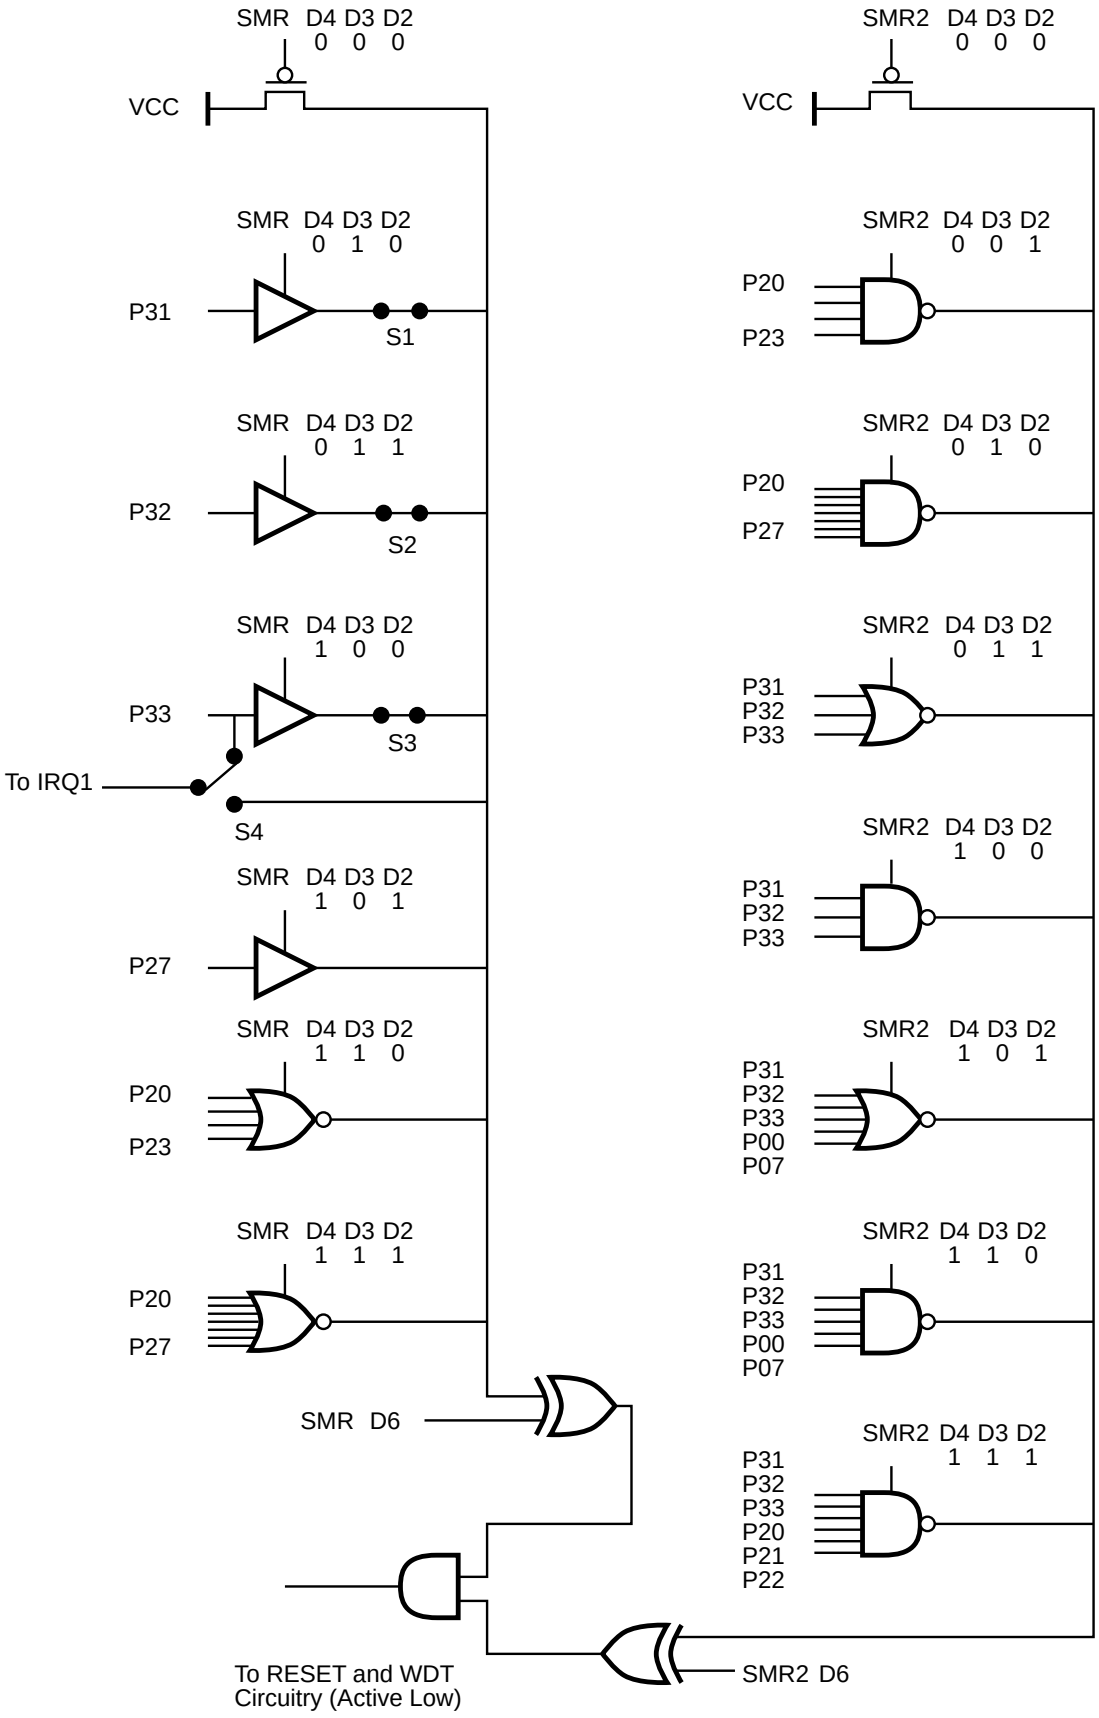

Figure 36. Stop-Mode Recovery Source

FUNCTIONAL DESCRIPTION (Continued)

SCLK/TCLK Divide-by-16 Select (D0)**.** D0 of the SMR controls a Divide-by-16 prescaler of SCLK/TCLK. The purpose of this control is to selectively reduce device power consumption during normal processor execution (SCLK control) and/or HALT mode (where TCLK sources interrupt logic). After Stop-Mode Recovery, this bit is set to a 0.

External Clock divide-by-two (D1)**.** This bit can eliminate the oscillator divide-by-two-circuitry. When this bit is 0, the System Clock (SCLK) and Timer Clock (TCLK) are equal to the external clock frequency divided-by-two. The SCLK/TCLK is equal to the external clock frequency when this bit is set (D1=1). Using this bit together with D7 of PCON further helps lower EMI (i.e., D7 (PCON)=0, D1 (SMR) = 1). The default setting is zero. Maximum external clock frequency is 4 MHz when SMR Bit D1=1 where SCLK/TCLK=XTAL.

Note: When changing the system clock from either to or to divide-by-two or divide-by-16, you must follow the instruction with two NOP's in order to avoid clock conflicts during the internal system clock frequency change.

Stop-Mode Recovery Source (D2, D3, and D4). These three bits of the SMR specify the wake up source of the STOP recovery (Figure 34 and Table 5).

Table 5. Stop-Mode Recovery Source

SMR: 432			Operation
D4	**D3**	**D2**	**Description of Action**
0	0	0	POR and/or external reset recovery
0	0	1	Reserved
0	1	0	P31 transition
0	1	1	P32 transition
1	0	0	P33 transition
1	0	1	P27 transition
1	1	0	Logical NOR of P20 through P23
1	1	1	Logical NOR of P20 through P27

Stop-Mode Recovery Delay Select (D5). This bit, if High, disables the 5 ms /RESET delay after Stop-Mode Recovery. The default configuration of this bit is one. If the "fast" wake up is selected, the Stop-Mode Recovery source needs to be kept active for at least 5TpC.

Stop-Mode Recovery Edge Select (D6). A 1 in this bit position indicates that a High level on any one of the recovery sources wakes the Z86L7X from STOP mode. A 0 indicates Low level recovery. The default is 0 on POR (Figure 36).

Cold or Warm Start (D7). This bit is set by the device upon entering STOP mode. A 0 in this bit (cold) indicates that the device will be reset by POR/WDT Reset. A 1 in this bit (warm) indicates that the device awakens by a SMR source. This is a READ only bit.

Watch-Dog Timer Mode Register (WDTMR). The WDT is a retriggerable one-shot timer that resets the Z8 if it reaches its terminal count. The WDT must initially be enabled by executing the WDT instruction and refreshed on subsequent executions of the WDT instruction. The WDT circuit is driven by an on-board RC oscillator or external oscillator from the XTAL1 pin. The WDT instruction affects the Zero (Z), Sign (S), and Overflow (V) flags.

The POR clock source is selected with bit 4 of the WDT register. Bit 0 and 1 control a tap circuit that determines the time-out period. Bit 2 determines whether the WDT is active during HALT and Bit 3 determines WDT activity during STOP. Bits 5 through 7 are reserved (Figure 33). This register is accessible only during the first 64 processor cycles (64 internal system clocks) from the execution of the first instruction after Power-On-Reset, Watch-Dog Reset, or a Stop-Mode Recovery (Figure 40). After this point, the register cannot be modified by any means, intentional or otherwise. The WDTMR cannot be read and is located in Bank F of the Expanded Register Group at address location 0FH. It is organized as follows:

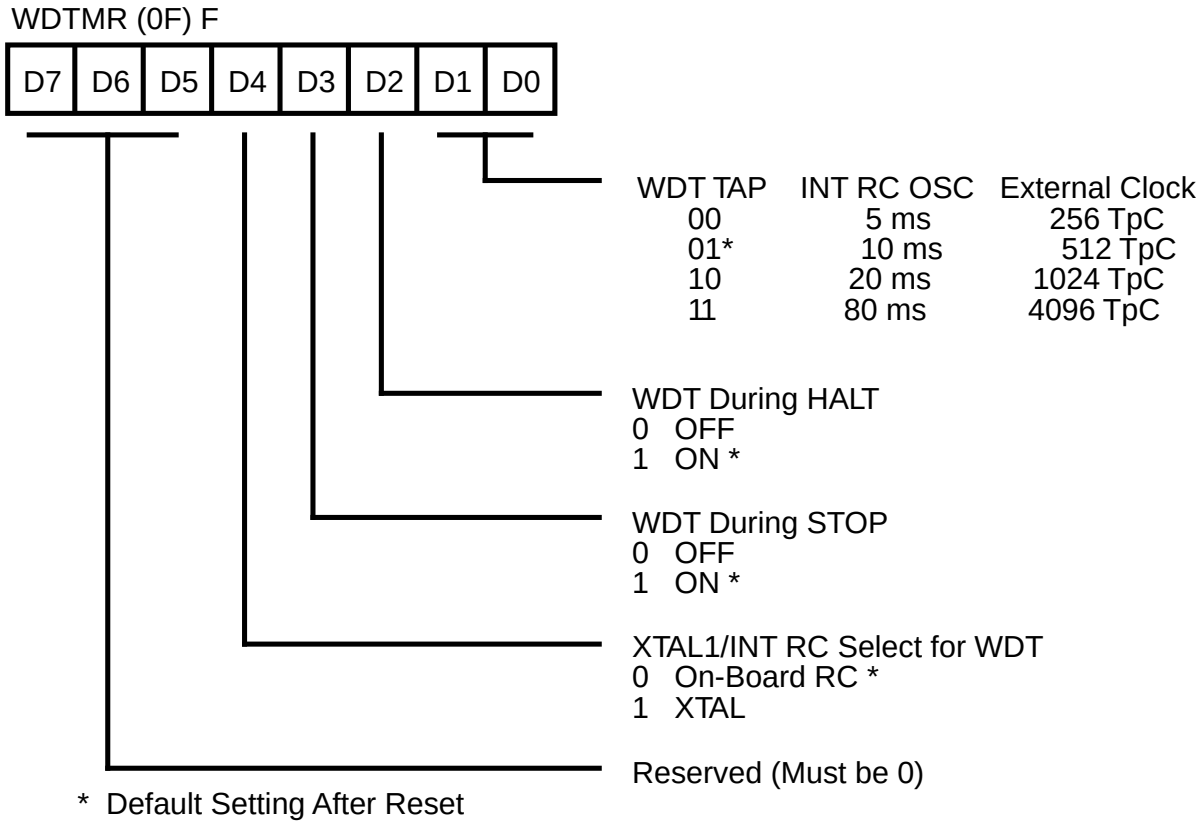

Figure 37. Watch-Dog Timer Mode Register (Write Only)

FUNCTIONAL DESCRIPTION (Continued)

WDT Time Select (D0, D1). Selects the WDT time period. It is configured as shown in Table 6.

Table 6. WDT Time Select

D1	D0	Time-Out of Internal RC OSC	Time-Out of XTAL Clock
0	0	5 ms min	256 TpC
0	1	10 ms min	512 TpC
1	0	20 ms min	1024 TpC
1	1	80 ms min	4096 TpC

Notes:
TpC = XTAL clock cycle.
The default on reset is 10 ms.

Note: The WDT can be permanently enabled through a mask programming option. The option is selected by the customer at the time of ROM code submittal. In this mode, WDT is always activated when the device comes out of reset. Execution of the WDT instruction serves to refresh the WDT time-out period. WDT operation in the HALT and STOP modes is controlled by WDTMR programming. If this mask option is not selected at the time of ROM code submission, the WDT must be activated by the user through the WDT instruction and is always disabled by any reset to the device.

WDTMR During HALT (D2). This bit determines whether or not the WDT is active during HALT mode. A 1 indicates active during HALT. The default is 1.

WDTMR During STOP (D3). This bit determines whether or not the WDT is active during STOP mode. Since the XTAL clock is stopped during STOP mode, the on-board RC has to be selected as the clock source to the WDT/POR counter. A 1 indicates active during STOP. The default is 1.

Note: A WDT time-out during STOP mode will have the same effect like a recovery from any programmed STOP mode recovery source except the reset delay will occur.

Clock Source for WDT (D4). This bit determines which oscillator source is used to clock the internal POR and WDT counter chain. If the bit is a 1, the internal RC oscillator is bypassed and the POR and WDT clock source is driven from the external pin, XTAL1. The default configuration of this bit is 0, which selects the RC oscillator.

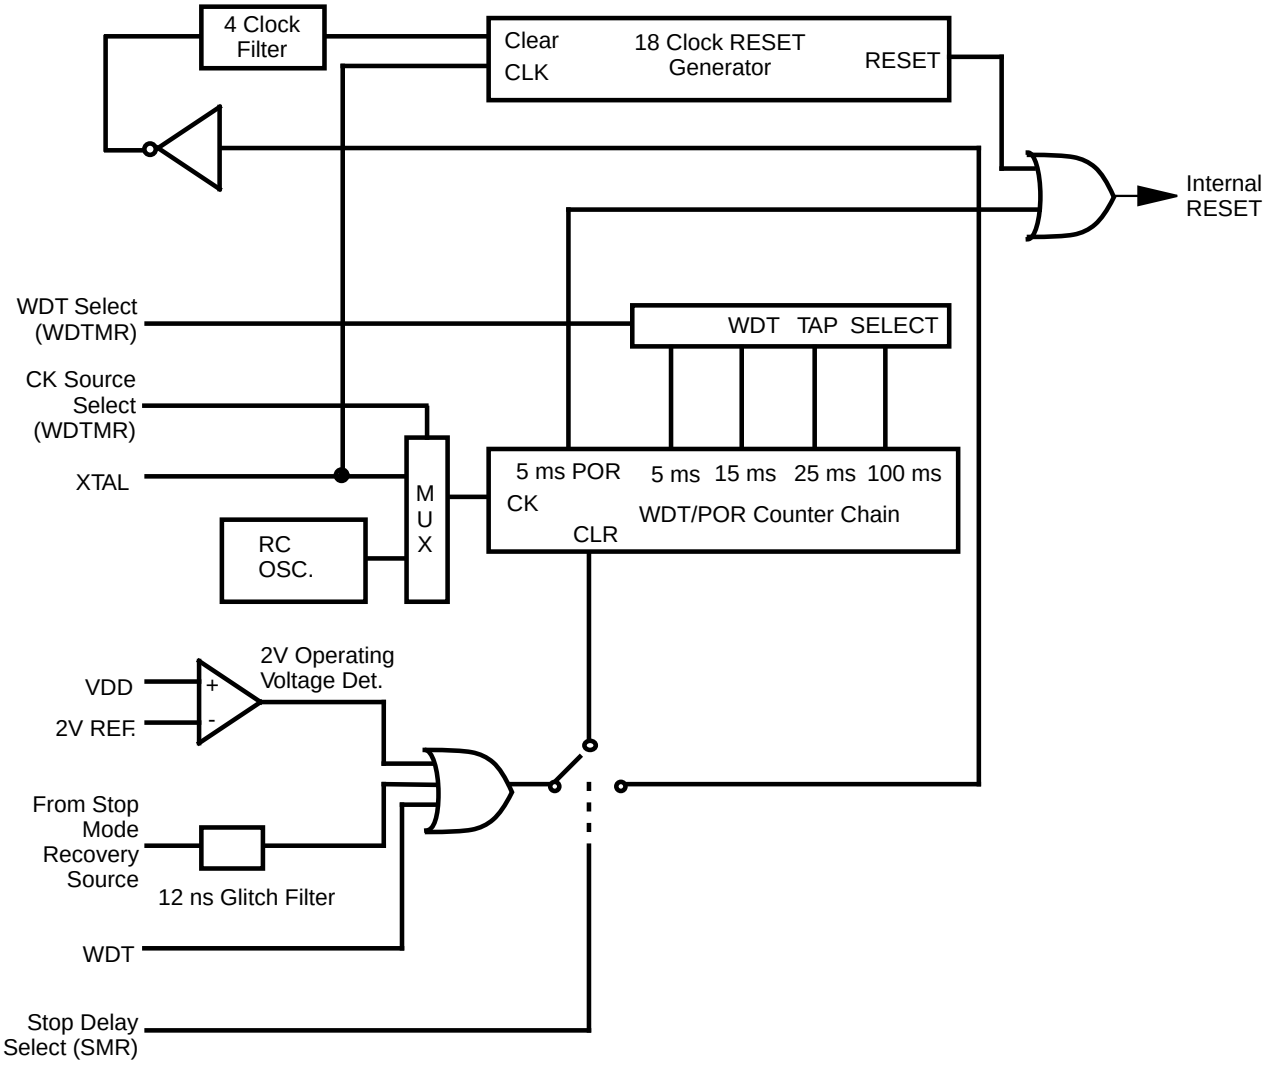

Figure 38. Resets and WDT

FUNCTIONAL DESCRIPTION (Continued)

Low Voltage Protection. An on-board Voltage Comparator checks that V_{CC} is at the required level to ensure correct operation of the device. Reset is globally driven if V_{CC} is below V_{LV} (Low Voltage). The minimum operating voltage varies with the temperature and operating frequency, while V_{LV} varies with temperature only.

Mask Selectable Options. There are six Mask Selectable Options to choose from based on ROM code requirements. These are:

Clock Source	RC/Other
Port 0 Pull-ups (lower nibble)	On/Off
Port 0 Pull-ups (upper nibble)	On/Off
Port 2 Pull-ups	On/Off
Port 3 Pull-ups	On/Off
Mouse/Normal	M/N
WDT Always On	On/Off*

*When WDT is selected as always on, the WDT will run in HALT or STOP mode regardless of the settings in the WDTMR Register Bits D2&D3.

The Low Voltage trip voltage (V_{LV}) is less than 2.1V under the following conditions:

Maximum (V_{LV}) Conditions:

T_A = 0°C, +55°C Internal clock frequency equal to or less than 4.0 MHz

Note: The internal clock frequency is one-half the external clock frequency.

The device functions normally at or above 2.0V under all conditions. Below 2.0V, the device is guaranteed to function normally until the Low Voltage Protection trip point V_{LV} is reached, below which reset is globally driven and then the device is put in a low current stand by mode with the oscillator stopped. The device is guaranteed to function normally at supply voltages above the V_{LV} trip point for the temperatures and operating frequencies in maximum V_{LV} conditions. The actual V_{LV} trip point is a function of temperature and process parameters (Figure 39).
