EVALUATION KIT AVAILABLE

MAXIM

250ksps, +3V, 8-/4-Channel, 12-Bit ADCs with +2.5V Reference and Parallel Interface

General Description

The MAX1291/MAX1293 low-power, 12-bit analog-to-digital converters (ADCs) feature a successive-approximation ADC, automatic power-down, fast wake-up (2µs), an on-chip clock, +2.5V internal reference, and a high-speed, byte-wide parallel interface. They operate with a single +3V analog supply and feature a V_{LOGIC} pin that allows them to interface directly with a +1.8V to +5.5V digital supply.

Power consumption is only 5.7mW (V_{DD} = V_{LOGIC}) at the maximum sampling rate of 250ksps. Two software-selectable power-down modes enable the MAX1291/MAX1293 to be shut down between conversions; accessing the parallel interface returns them to normal operation. Powering down between conversions can cut supply current to under 10µA at reduced sampling rates.

Both devices offer software-configurable analog inputs for unipolar/bipolar and single-ended/pseudo-differential operation. In single-ended mode, the MAX1291 has 8 input channels and the MAX1293 has 4 input channels (4 and 2 input channels, respectively, when in pseudo-differential mode).

Excellent dynamic performance and low power combined with ease of use and small package size make these converters ideal for battery-powered and data-acquisition applications or for other circuits with demanding power consumption and space requirements.

The MAX1291 is available in a 28-pin QSOP package, while the MAX1293 is available in a 24-pin QSOP. For pin-compatible +5V, 12-bit versions, refer to the MAX1290/MAX1292 data sheet.

Applications

Industrial Control Systems	Data Logging
Energy Management	Patient Monitoring
Data-Acquisition Systems	Touch Screens

Ordering Information

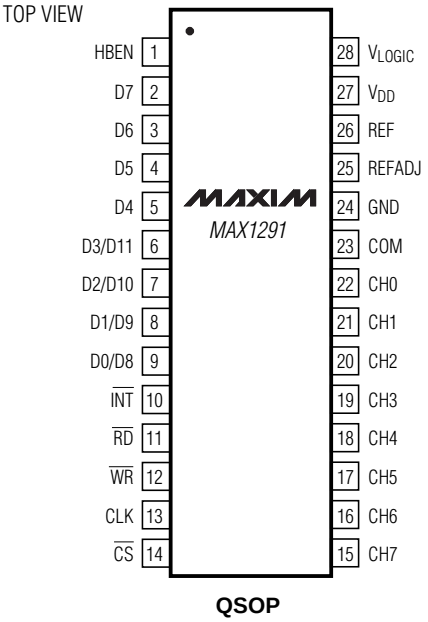
PART	TEMP. RANGE	PIN-PACKAGE	INL (LSB)
MAX1291ACEI	0°C to +70°C	28 QSOP	±0.5
MAX1291BCEI	0°C to +70°C	28 QSOP	±1
MAX1291AEEI	-40°C to +85°C	28 QSOP	±0.5
MAX1291BEEI	-40°C to +85°C	28 QSOP	±1

Ordering Information continued at end of data sheet.

Features

- **12-Bit Resolution, ±0.5LSB Linearity**
- **+3V Single Operation**
- **User-Adjustable Logic Level (+1.8V to +3.6V)**
- **Internal +2.5V Reference**
- **Software-Configurable, Analog Input Multiplexer**
  - **8-Channel Single-Ended/**
  - **4-Channel Pseudo-Differential (MAX1291)**
  - **4-Channel Single-Ended/**
  - **2-Channel Pseudo-Differential (MAX1293)**
- **Software-Configurable, Unipolar/Bipolar Inputs**
- **Low Power: 1.7mA (250ksps)**
  - **1.0mA (100ksps)**
  - **400µA (10ksps)**
  - **2µA (Shutdown)**
- **Internal 3MHz Full-Power Bandwidth Track/Hold**
- **Byte-Wide Parallel (8+4) Interface**
- **Small Footprint: 28-Pin QSOP (MAX1291)**
  - **24-Pin QSOP (MAX1293)**

Pin Configurations



QSOP

Pin Configurations continued at end of data sheet.

Typical Operating Circuits appear at end of data sheet.

$\overline{CS}$ Fall to Output Data Valid	t_{DO2}	C_{LOAD} = 20pF, Figure 1			110	ns

Note 1: Tested at V_{DD} = +3V, COM = GND, unipolar single-ended input mode.
Note 2: Relative accuracy is the deviation of the analog value at any code from its theoretical value after offset and gain errors have been removed.
Note 3: Offset nulled.
Note 4: On channel is grounded; sine wave applied to off channels.
Note 5: Conversion time is defined as the number of clock cycles times the clock period; clock has 50% duty cycle.
Note 6: Input voltage range referenced to negative input. The absolute range for the analog inputs is from GND to V_{DD}.
Note 7: External load should not change during conversion for specified accuracy.
Note 8: When bit 5 is set low for internal acquisition, $\overline{WR}$ must not return low until after the first falling clock edge of the conversion.

Pin Description

PIN		NAME	FUNCTION
MAX1291	MAX1293		
1	1	HBEN	High Byte Enable. Used to multiplex the 12-bit conversion result. 1: Four MSBs are multiplexed on the data bus. 0: Eight LSBs are available on the data bus.
2	2	D7	Three-State Digital I/O Line (D7)
3	3	D6	Three-State Digital I/O Line (D6)
4	4	D5	Three-State Digital I/O Line (D5)
5	5	D4	Three-State Digital I/O Line (D4)
6	6	D3/D11	Three-State Digital I/O Line (D3, HBEN = 0; D11, HBEN = 1)
7	7	D2/D10	Three-State Digital I/O Line (D2, HBEN = 0; D10, HBEN = 1)
8	8	D1/D9	Three-State Digital I/O Line (D1, HBEN = 0; D9, HBEN = 1)
9	9	D0/D8	Three-State Digital I/O Line (D0, HBEN = 0; D8, HBEN = 1
10	10	$\overline{INT}$	$\overline{INT}$ goes low when the conversion is complete and the output data is ready.
11	11	$\overline{RD}$	Active-Low Read Select. If $\overline{CS}$ is low, a falling edge on $\overline{RD}$ will enable the read operation on the data bus.
12	12	$\overline{WR}$	Active-Low Write Select. When $\overline{CS}$ is low in internal acquisition mode, a rising edge on $\overline{WR}$ latches in configuration data and starts an acquisition plus a conversion cycle. When $\overline{CS}$ is low in external acquisition mode, the first rising edge on $\overline{WR}$ ends acquisition and starts a conversion.
13	13	CLK	Clock Input. In external clock mode, drive CLK with a TTL/CMOS-compatible clock. In internal clock mode, connect this pin to either V_{DD} or GND.
14	14	$\overline{CS}$	Active-Low Chip Select. When $\overline{CS}$ is high, digital outputs ($\overline{INT}$, D7–D0) are high impedance.
15	—	CH7	Analog Input Channel 7
16	—	CH6	Analog Input Channel 6
17	—	CH5	Analog Input Channel 5
18	—	CH4	Analog Input Channel 4
19	15	CH3	Analog Input Channel 3
20	16	CH2	Analog Input Channel 2
21	17	CH1	Analog Input Channel 1
22	18	CH0	Analog Input Channel 0
23	19	COM	Ground Reference for Analog Inputs. Sets zero-code voltage in single-ended mode and must be stable to ±0.5LSB during conversion.
24	20	GND	Analog and Digital Ground
25	21	REFADJ	Bandgap Reference Output/Bandgap Reference Buffer Input. Bypass to GND with a 0.01µF capacitor. When using an external reference, connect REFADJ to V_{DD} to disable the internal bandgap reference.
26	22	REF	Bandgap Reference Buffer Output/External Reference Input. Add a 4.7µF capacitor to GND when using the internal reference.
27	23	V_{DD}	Analog +5V Power Supply. Bypass with a 0.1µF capacitor to GND.
28	24	V_{LOGIC}	Digital Power Supply. V_{LOGIC} powers the digital outputs of the data converter and can range from +1.8V to V_{DD} + 300mV.

Detailed Description

Converter Operation

The MAX1291/MAX1293 ADCs use a successive-approximation (SAR) conversion technique and an input track/hold (T/H) stage to convert an analog input signal to a 12-bit digital output. Their parallel 8+4 output format provides an easy interface to standard microprocessors (µPs). Figure 2 shows the simplified internal architecture of the MAX1291/MAX1293.

Single-Ended and Pseudo-Differential Operation

The sampling architecture of the ADC's analog comparator is illustrated in the equivalent input circuit in Figure 3. In single-ended mode, IN+ is internally switched to channels CH0–CH7 for the MAX1291 (Figure 3a) and to CH0–CH3 for the MAX1293 (Figure 3b), while IN- is switched to COM (Table 3).

In differential mode IN+ and IN- are selected from analog input pairs (Table 4) and are internally switched to either of the analog inputs. This configuration is pseudo-differential in that only the signal at IN+ is sampled. The return side (IN-) must remain stable within ±0.5LSB (±0.1LSB for best performance) with respect to GND during a conversion. To accomplish this, connect a 0.1µF capacitor from IN- (the selected input) to GND.

During the acquisition interval, the channel selected as the positive input (IN+) charges capacitor C_{HOLD}. At the end of the acquisition interval, the T/H switch opens, retaining charge on C_{HOLD} as a sample of the signal at IN+.

The conversion interval begins with the input multiplexer switching C_{HOLD} from the positive input (IN+) to the negative input (IN-). This unbalances node ZERO at the comparator's positive input. The capacitive digital-to-analog converter (DAC) adjusts during the remainder of the conversion cycle to restore node ZERO to 0V within the limits of 12-bit resolution. This action is equivalent to transferring a 12pF[(V_{IN+}) - (V_{IN-})] charge from C_{HOLD} to the binary-weighted capacitive DAC, which in turn forms a digital representation of the analog input signal.

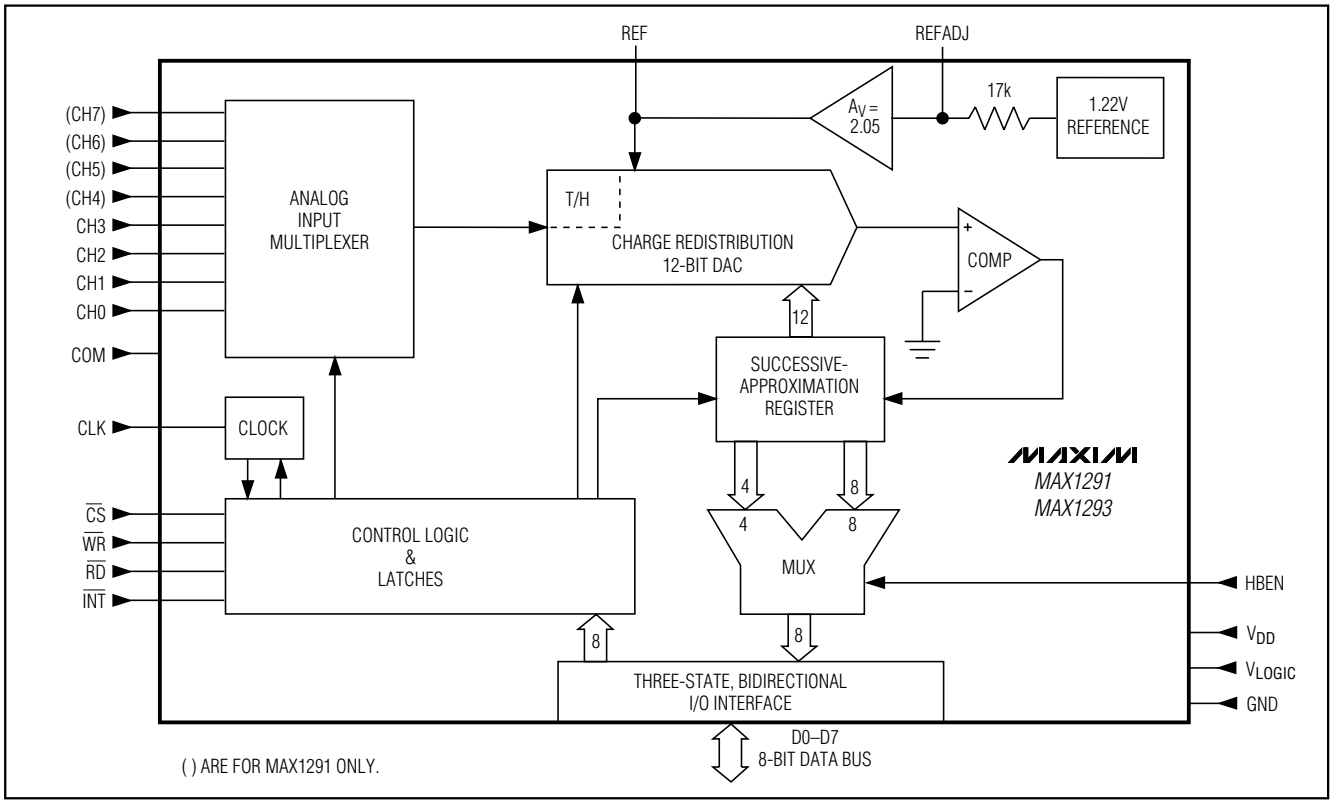

Figure 2. Simplified Internal Architecture for 8-/4-Channel MAX1291/MAX1293

250ksps, +3V, 8-/4-Channel, 12-Bit ADCs with +2.5V Reference and Parallel Interface

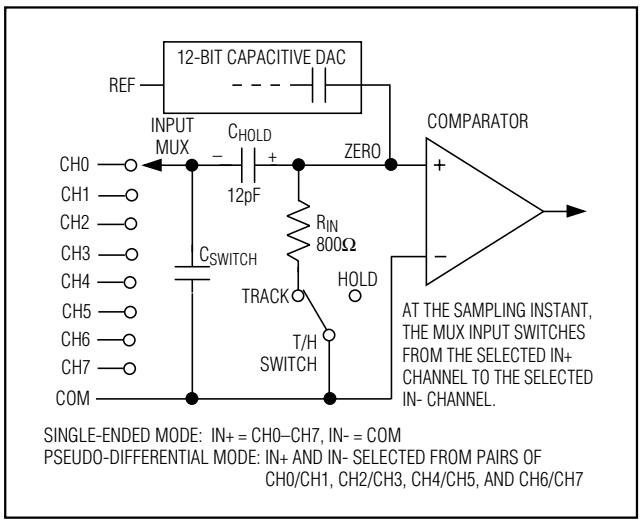

Figure 3a. MAX1291 Simplified Input Structure

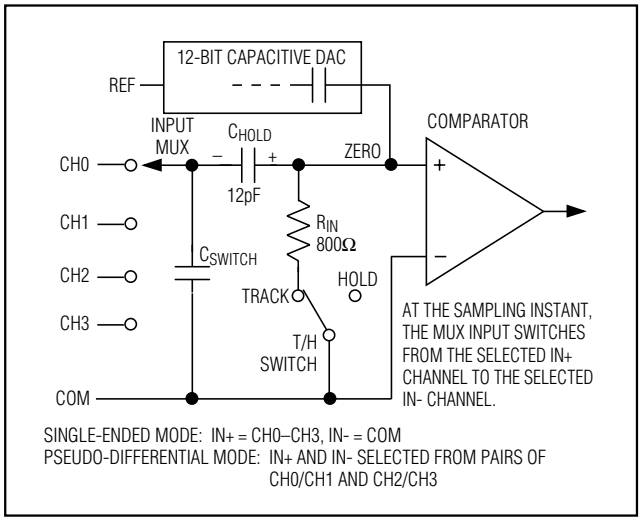

Figure 3b. MAX1293 Simplified Input Structure

Analog Input Protection

Internal protection diodes, which clamp the analog input to V_{DD} and GND, allow each input channel to swing within (GND - 300mV) to (V_{DD} + 300mV) without damage. However, for accurate conversions near full scale, both inputs must not exceed (V_{DD} + 50mV) or be less than (GND - 50mV).

If an off-channel analog input voltage exceeds the supplies by more than 50mV, limit the forward-bias input current to 4mA.

Track/Hold

The MAX1291/MAX1293 T/H stage enters its tracking mode on the rising edge of $\overline{WR}$. In external acquisition mode, the part enters its hold mode on the next rising edge of $\overline{WR}$. In internal acquisition mode, the part enters its hold mode on the fourth falling edge of clock after writing the control byte. Note that in internal clock mode this occurs approximately 1µs after writing the control byte. In single-ended operation, IN- is connected to COM and the converter samples the positive ("+") input. In pseudo-differential operation, IN- connects to the negative input ("-"), and the difference of |(IN+) - (IN-)| is sampled. At the beginning of the next conversion, the positive input connects back to IN+ and C_{HOLD} charges to the input signal.

The time required for the T/H stage to acquire an input signal depends on how quickly its input capacitance is charged. If the input signal's source impedance is high, the acquisition time lengthens, and more time must be allowed between conversions. The acquisition time, t_{ACQ}, is the maximum time the device takes to acquire the signal and is also the minimum time required for the signal to be acquired. Calculate this with the following equation:

$$t_{ACQ} = 9 (R_S + R_{IN}) C_{IN}$$

where R_S is the source impedance of the input signal, R_{IN} (800Ω) is the input resistance, and C_{IN} (12pF) is the ADC's input capacitance. Source impedances below 3kΩ have no significant impact on the MAX1291/MAX1293's AC performance.

Higher source impedances can be used if a 0.01µF capacitor is connected to the individual analog inputs. Together with the input impedance, this capacitor forms an RC filter, limiting the ADC's signal bandwidth.

Input Bandwidth

The MAX1291/MAX1293 T/H stage offers a 250kHz full-linear and a 3MHz full-power bandwidth, enabling these parts to use undersampling techniques to digitize high-speed transients and measure periodic signals with bandwidths exceeding the ADCs sampling rate. To avoid high-frequency signals being aliased into the frequency band of interest, anti-alias filtering is recommended.

Starting a Conversion

Initiate a conversion by writing a control byte that selects the multiplexer channel and configures the MAX1291/MAX1293 for either unipolar or bipolar operation. A write pulse ($\overline{WR}$ + $\overline{CS}$) can either start an acquisition interval or initiate a combined acquisition plus

conversion. The sampling interval occurs at the end of the acquisition interval. The ACQMOD (acquisition mode) bit in the input control byte (Table 1) offers two options for acquiring the signal: an internal and an external acquisition. The conversion period lasts for 13 clock cycles in either the internal or external clock or acquisition mode. Writing a new control byte during a conversion cycle will abort the conversion and start a new acquisition interval.

Internal Acquisition

Select internal acquisition by writing the control byte with the ACQMOD bit cleared (ACQMOD = 0). This causes the write pulse to initiate an acquisition interval whose duration is internally timed. Conversion starts when this acquisition interval ends (three external cycles or approximately 1µs in internal clock mode) (Figure 4). Note that when the internal acquisition is combined with the internal clock, the aperture jitter can be as high as 200ps. Internal clock users wishing to achieve the 50ps jitter specification should always use external acquisition mode.

External Acquisition

Use external acquisition mode for precise control of the sampling aperture and/or dependent control of acquisition and conversion times. The user controls acquisition and start-of-conversion with two separate write pulses. The first pulse, written with ACQMOD = 1, starts an acquisition interval of indeterminate length. The second write pulse, written with ACQMOD = 0, terminates acquisition and starts conversion on $\overline{WR}$'s rising edge (Figure 5).

The address bits for the input multiplexer must have the same values on the first and second write pulse. Power-down mode bits (PD0, PD1) can assume new values on the second write pulse (see the *Power-Down Modes* section). Changing other bits in the control byte will corrupt the conversion.

Reading a Conversion

A standard interrupt signal $\overline{INT}$ is provided to allow the MAX1291/MAX1293 to flag the microprocessor when the conversion has ended and a valid result is available. $\overline{INT}$ goes low when the conversion is complete and the output data is ready (Figures 4, 5). It returns high on the first read cycle or if a new control byte is written.

Table 1. Control Byte Functional Description

BIT	NAME	FUNCTION		
D7, D6	PD1, PD0	**PD1** and **PD0** select the various clock and power-down modes.		
		0	**0**	Full Power-Down Mode. Clock mode is unaffected.
		0	**1**	Standby Power-Down Mode. Clock mode is unaffected.
		1	**0**	Normal Operation Mode. Internal clock mode selected.
		1	**1**	Normal Operation Mode. External clock mode selected.
D5	ACQMOD	ACQMOD = 0: Internal Acquisition Mode ACQMOD = 1: External Acquisition Mode		
D4	SGL/$\overline{DIF}$	SGL/$\overline{DIF}$ = 0: Pseudo-Differential Analog Input Mode SGL/$\overline{DIF}$ = 1: Single-Ended Analog Input Mode In single-ended mode, input signals are referred to COM. In pseudo-differential mode, the voltage difference between two channels is measured (see Tables 2, 3).		
D3	UNI/$\overline{BIP}$	UNI/$\overline{BIP}$ = 0: Bipolar Mode UNI/$\overline{BIP}$ = 1: Unipolar Mode In unipolar mode, an analog input signal from 0 to V_{REF} can be converted; in bipolar mode, the signal can range from $-V_{REF}/2$ to $+V_{REF}/2$.		
D2, D1, D0	A2, A1, A0	Address bits A2–A0 select which of the 8/4 (MAX1291/MAX1293) channels are to be converted (see Tables 3, 4).		

250ksps, +3V, 8-/4-Channel, 12-Bit ADCs with +2.5V Reference and Parallel Interface

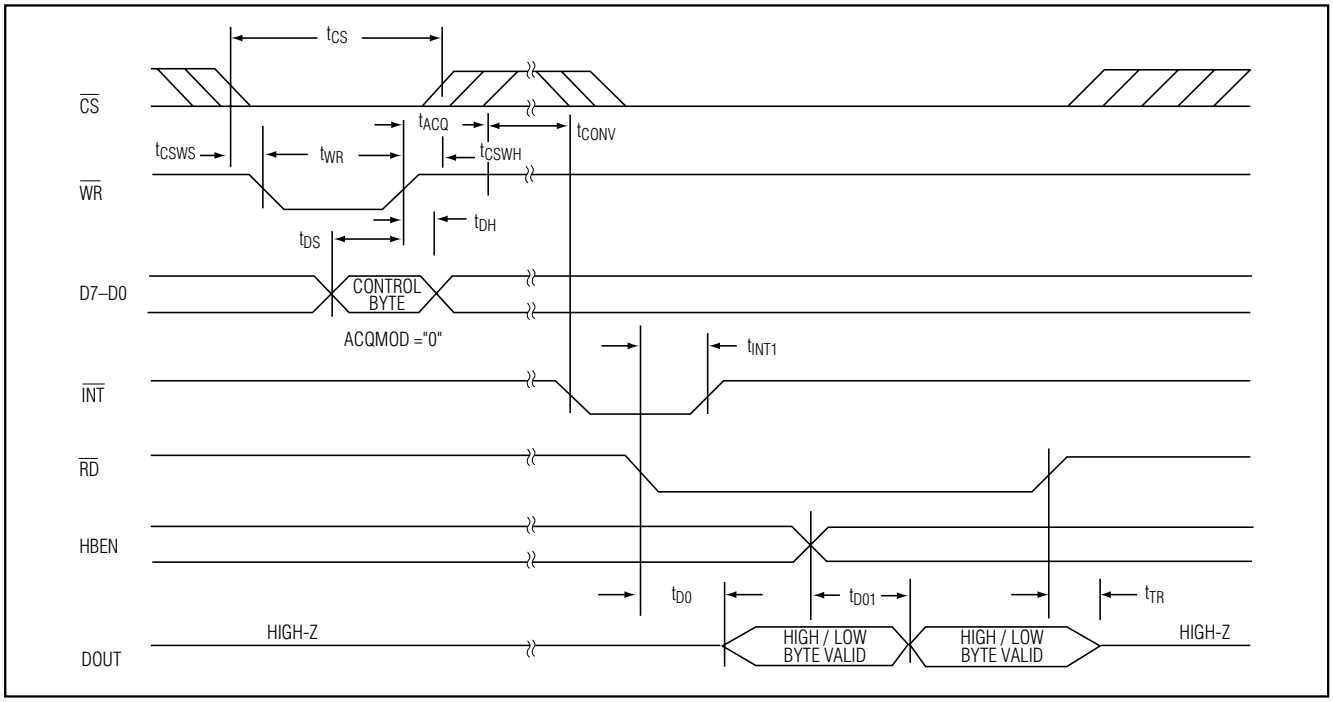

Figure 4. Conversion Timing Using Internal Acquisition Mode

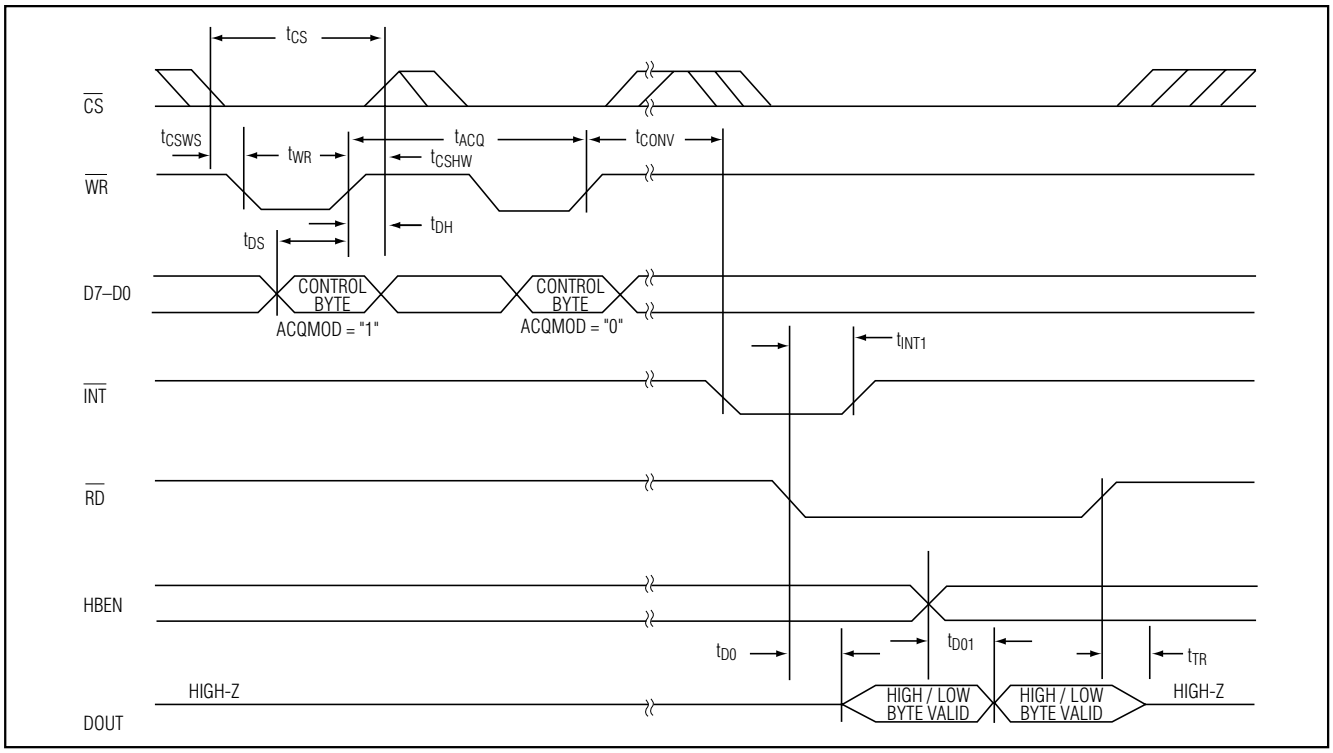

Figure 5. Conversion Timing Using External Acquisition Mode

Selecting Clock Mode

The MAX1291/MAX1293 operate with either an internal or an external clock. Control bits D6 and D7 select either internal or external clock mode. The parts retain the last requested clock mode if a power-down mode is selected in the current input word. For both internal and external clock mode, internal or external acquisition can be used. At power-up, the MAX1291/MAX1293 enter the default external clock mode.

Internal Clock Mode

Select internal clock mode to release the µP from the burden of running the SAR conversion clock. To select this mode, bits D6 and D7 of the control byte must be set to 1; the internal clock frequency is then selected, resulting in a conversion time of 3.6µs. When using the internal clock mode, tie the CLK pin either high or low to prevent the pin from floating.

External Clock Mode

To select the external clock mode, bits D6 and D7 of the control byte must be set to zero. Figure 6 shows the clock and $\overline{WR}$ timing relationship for internal (Figure 6a) and external (Figure 6b) acquisition modes with an external clock. For proper operation, a 100kHz to 4.8MHz clock frequency with 30% to 70% duty cycle is recommended. Operating the MAX1291/MAX1293 with clock frequencies lower than 100kHz is not recommended because it will cause a voltage droop across the hold capacitor in the T/H stage that will result in degraded performance.

Digital Interface

Input (control byte) and output data are multiplexed on a three-state parallel interface. This parallel interface (I/O) can easily be interfaced with standard µPs. The signals $\overline{CS}$, $\overline{WR}$, and $\overline{RD}$ control the write and read operations. $\overline{CS}$ represents the chip select signal, which enables a µP to address the MAX1291/MAX1293 as an I/O port. When high, $\overline{CS}$ disables the CLK $\overline{WR}$ and $\overline{RD}$ inputs and forces the interface into a high-impedance (high-Z) state.

Input Format

The control byte is latched into the device on pins D7–D0 during a write command. Table 2 shows the control byte format.

Output Format

The output format for both the MAX1291/MAX1293 is binary in unipolar mode and two's complement in bipolar mode. When reading the output data, $\overline{CS}$ and $\overline{RD}$ must be low. When HBEN = 0, the lower 8 bits are read. With HBEN = 1, the upper 4 bits are available and the output data bits D7–D4 are set either low in unipolar mode or set to the value of the MSB in bipolar mode (Table 5).

Applications Information

Power-On Reset

When power is first applied, internal power-on reset circuitry activates the MAX1291/MAX1293 in external clock mode and sets $\overline{INT}$ high. After the power supplies stabilize, the internal reset time is 10µs, and no conversions should be attempted during this phase. When using the internal reference, 500µs is required for V_{REF} to stabilize.

Internal and External Reference

The MAX1291/MAX1293 can be used with an internal or external reference voltage. An external reference can be connected directly to REF or REFADJ.

An internal buffer is designed to provide +2.5V at REF for the both the MAX1291 and the MAX1293. The internally trimmed +1.22V reference is buffered with a +2.05V/V gain.

Table 5. Data-Bus Output (8+4 Parallel Interface)

PIN	HBEN = 0	HBEN = 1	
D0	B0 (LSB)	B8	
D1	B1	B9	
D2	B2	B10	
D3	B3	B11 (MSB)	
D4	B4	UNIPOLAR (UNI/$\overline{BIP}$ = 1)	BIPOLAR (UNI/$\overline{BIP}$ = 0)
		B11	0
D5	B5	B11	0
D6	B6	B11	0
D7	B7	B11	0

Internal Reference

With the internal reference, the full-scale range is +2.5V with unipolar inputs and ±1.25V with bipolar inputs. The internal reference buffer allows for small adjustments (±100mV) in the reference voltage. See Figure 7.

Note that the reference buffer must be compensated with an external capacitor (4.7µF min) connected between REF and GND to reduce reference noise and switching spikes from the ADC. To further minimize noise on the reference, connect a 0.01µF capacitor between REFADJ and GND.

External Reference

With both the MAX1291 and MAX1293, an external reference can be placed at either the input (REFADJ) or the output (REF) of the internal reference buffer amplifier.

Using the REFADJ input makes buffering the external reference unnecessary. The REFADJ input impedance is typically 17kΩ.

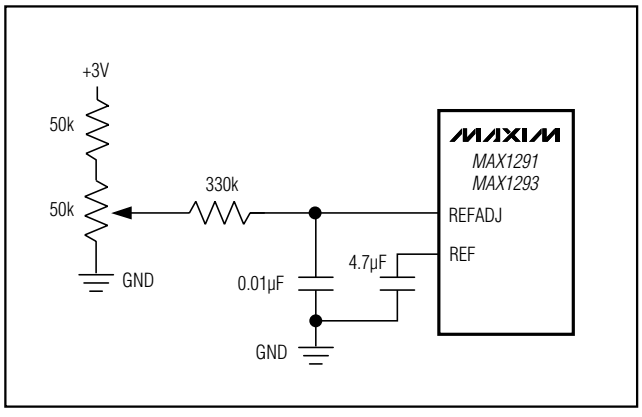

Figure 7. Reference Voltage Adjustment with External Potentiometer

250ksps, +3V, 8-/4-Channel, 12-Bit ADCs with +2.5V Reference and Parallel Interface

When applying an external reference to REF, disable the internal reference buffer by connecting REFADJ to V_{DD}. The DC input resistance at REF is 25kΩ. Therefore, an external reference at REF must deliver up to 200µA DC load current during a conversion and have an output impedance less than 10Ω. If the reference has higher output impedance or is noisy, bypass it close to the REF pin with a 4.7µF capacitor.

Power-Down Modes

Save power by placing the converter in a low-current shutdown state between conversions. Select standby mode or shutdown mode via bits D6 and D7 of the control byte (Tables 1 and 2). In both software power-down modes, the parallel interface remains active, but the ADC does not convert.

Standby Mode

While in standby mode, the supply current is 850µA (typ). The part will power up on the next rising edge on $\overline{WR}$ and is ready to perform conversions. This quick turn-on time allows the user to realize significantly reduced power consumption for conversion rates below 250ksps.

Shutdown Mode

Shutdown mode turns off all chip functions that draw quiescent current, reducing the typical supply current to 2µA immediately after the current conversion is completed. A rising edge on $\overline{WR}$ causes the MAX1291/MAX1293 to exit shutdown mode and return to normal operation. To achieve full 12-bit accuracy with a 4.7µF reference bypass capacitor, 500µs is required after power-up. Waiting this 500µs in standby mode instead of in full-power mode can reduce power consumption by a factor of 3 or more. When using an external reference, only 50µs is required after power-up. Enter standby mode by performing a dummy conversion with the control byte specifying standby mode.

Note: Bypassing capacitors larger than 4.7µF between REF and GND will result in longer power-up delays.

Transfer Function

Table 6 shows the full-scale voltage ranges for unipolar and bipolar modes.

Figure 8 depicts the nominal, unipolar input/output (I/O) transfer function and Figure 9 shows the bipolar I/O transfer function. Code transitions occur halfway between successive-integer LSB values. Output coding is binary, with 1LSB = (V_{REF}/4096).

Maximum Sampling Rate/ Achieving 300ksps

When running at the maximum clock frequency of 4.8MHz, the specified throughput of 250ksps is achieved by completing a conversion every 19 clock cycles: 1 write cycle, 3 acquisition cycles, 13 conver-

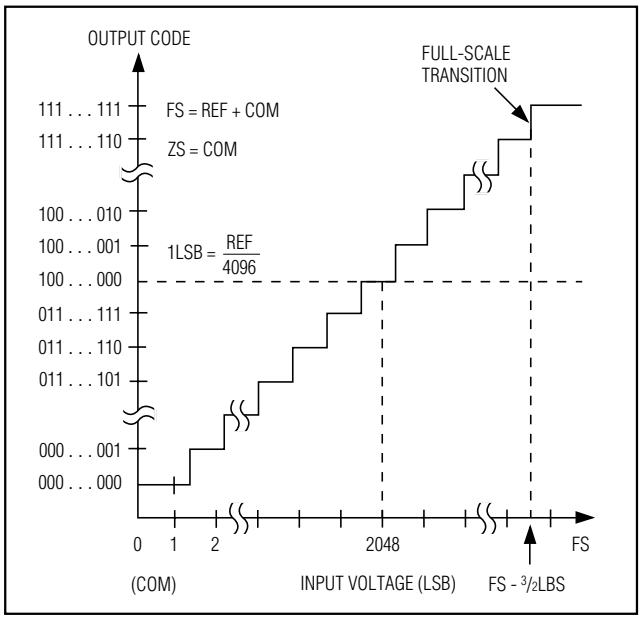

Figure 8. Unipolar Transfer Function

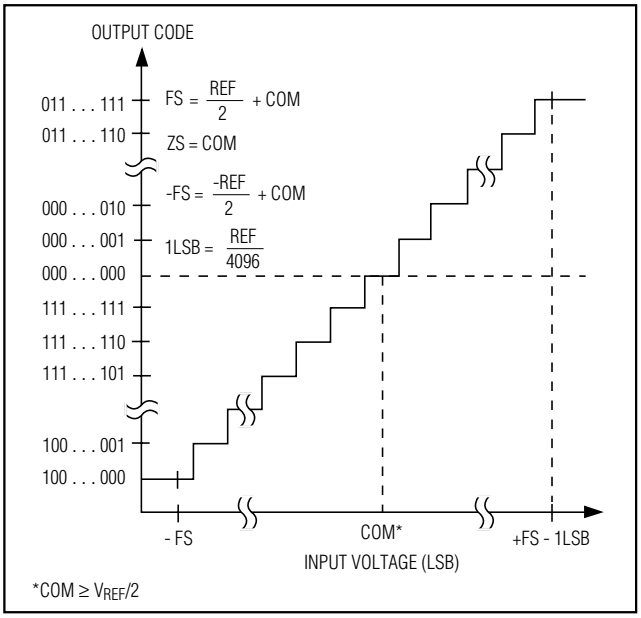

Figure 9. Bipolar Transfer Function

Table 6. Full-Scale and Zero-Scale for Unipolar and Bipolar Operation

UNIPOLAR MODE		BIPOLAR MODE	
Full Scale	V_{REF} + COM	Positive Full Scale	$V_{REF}/2$ + COM
Zero Scale	COM	Zero Scale	COM
—	—	Negative Full Scale	$-V_{REF}/2$ + COM

sion cycles, and 2 read cycles. This assumes that the results of the last conversion are read before the next control byte is written. Throughputs up to 300ksps can be achieved by first writing a control word to begin the acquisition cycle of the next conversion, and then reading the results of the previous conversion from the bus (Figure 10). This technique allows a conversion to be completed every 16 clock cycles. Note that the switching of the data bus during acquisition or conversion can cause additional supply noise, which may make it difficult to achieve true 12-bit performance.

Layout, Grounding, and Bypassing

For best performance use printed circuit (PC) boards. Wire-wrap configurations are not recommended since the layout should ensure proper separation of analog and digital traces. Do not run analog and digital lines parallel to each other, and don't lay out digital signal paths underneath the ADC package. Use separate analog and digital PC Board ground sections with only one starpoint (Figure 11) connecting the two ground systems (analog and digital). For lowest-noise operation, ensure the ground return to the star ground's power supply is low impedance and as short as possible. Route digital signals far away from sensitive analog and reference inputs.

High-frequency noise in the power supply (VDD) could influence the proper operation of the ADC's fast comparator. Bypass V_{DD} to the star ground with a network of two parallel capacitors, 0.1µF and 4.7µF, located as close as possible to the MAX1291/MAX1293s' power supply pin. Minimize capacitor lead length for best supply-noise rejection; add an attenuation resistor (5Ω) if the power supply is extremely noisy.

Definitions

Integral Nonlinearity

Integral nonlinearity (INL) is the deviation of the values on an actual transfer function from a straight line. This straight line can be either a best-straight-line fit or a line drawn between the endpoints of the transfer function, once offset and gain errors have been nullified. The static linearity parameters for the MAX1291/MAX1293 are measured using the endpoint method.

Differential Nonlinearity

Differential nonlinearity (DNL) is the difference between an actual step width and the ideal value of 1LSB. A DNL error specification of less than 1LSB guarantees no missing codes and a monotonic transfer function.

Aperture Definitions

Aperture jitter (t_{AJ}) is the sample-to-sample variation in the time between the samples. Aperture delay (t_{AD}) is the time between the rising edge of the sampling clock and the instant when an actual sample is taken.

Signal-to-Noise Ratio

For a waveform perfectly reconstructed from digital samples, signal-to-noise ratio (SNR) is the ratio of full-scale analog input (RMS value) to the RMS quantization error (residual error). The ideal, theoretical minimum analog-to-digital noise is caused by quantization error only and results directly from the ADC's resolution (N bits):

$$SNR = (6.02 \cdot N + 1.76)dB$$

In reality, there are other noise sources besides quantization noise: thermal noise, reference noise, clock jitter, etc. Therefore, SNR is computed by taking the ratio of the RMS signal to the RMS noise which includes all spectral components minus the fundamental, the first five harmonics, and the DC offset.

Signal-to-Noise Plus Distortion

Signal-to-noise plus distortion (SINAD) is the ratio of the fundamental input frequency's RMS amplitude to RMS equivalent of all other ADC output signals.

$$SINAD\ (dB) = 20 \cdot \log (Signal_{RMS} / Noise_{RMS})$$

250ksps, +3V, 8-/4-Channel, 12-Bit ADCs with +2.5V Reference and Parallel Interface

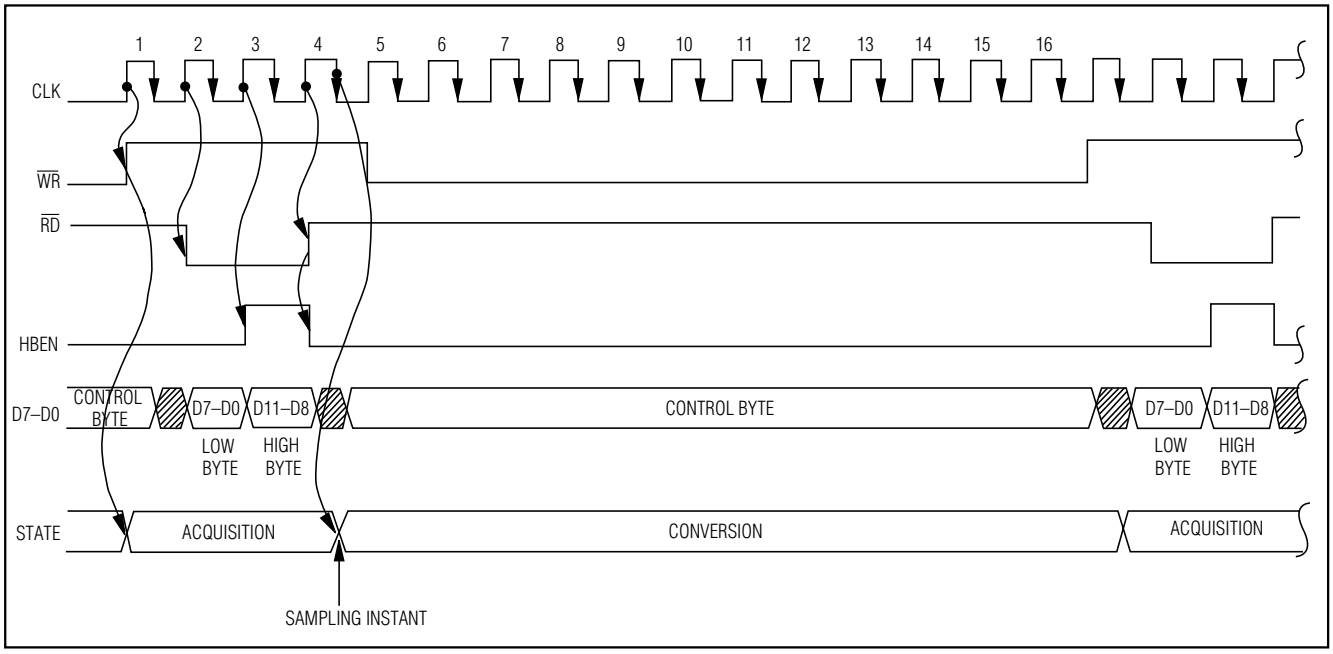

Figure 10. Timing Diagram for Fastest Conversion

Effective Number of Bits

Effective number of bits (ENOB) indicates the global accuracy of an ADC at a specific input frequency and sampling rate. An ideal ADC's error consists of quantization noise only. With an input range equal to the full-scale range of the ADC, calculate the effective number of bits as follows:

$$ENOB = (SINAD - 1.76) / 6.02$$

Total Harmonic Distortion

Total harmonic distortion (THD) is the ratio of the RMS sum of the first five harmonics of the input signal to the fundamental itself. This is expressed as:

$$THD = 20 \cdot \log\left(\sqrt{\left(V_2^2 + V_3^2 + V_4^2 + V_5^2\right)} / V_1\right)$$

where V_1 is the fundamental amplitude, and V_2 through V_5 are the amplitudes of the 2nd- through 5th-order harmonics.

Spurious-Free Dynamic Range

Spurious-free dynamic range (SFDR) is the ratio of RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next largest distortion component.
