Battery charge level indicator

SAA1501T

FEATURES

- High level of integration to allow assembly in intelligent battery packs
- Accurate charge and discharge account
- Large dynamic range of charge and discharge currents
- Independent settings of charge and discharge efficiency
- 2 V minimum supply voltage (2 cell operation)
- Temperature protection of batteries during charging
- Temperature controlled self-discharge
- Accurate charge current regulation
- Two charge amount display modes, LCD and LED.

GENERAL DESCRIPTION

The SAA1501T is intended to be used as a battery monitor and charge current control circuit in rechargeable battery systems.

The SAA1501T is processed in BiCMOS technology where the benefits of mixed bipolar and CMOS technology is fully utilized to achieve high accuracy measurements and digital signal processing in the same device. The general function of the integrated circuit is a Coulomb counter. During battery charging, the charge current and charge time are registered in a Coulomb counter. During discharge, the discharge current and time are recorded. The momentary charge amount of the batteries can be displayed either on an LCD screen or on an LED bargraph. Using the SAA1501T, intelligent batteries or intelligent battery powered systems can be easily designed with only a few external components.

Battery charge level indicator

SAA1501T

FUNCTIONAL DESCRIPTION

The most important function of the SAA1501T is the charge account in rechargeable battery systems. Both NiCd and NiMH batteries in all sizes can be used. The system can operate alone as a charge monitor with a charge amount display function or, can operate in conjunction with a charger. If the SAA1501T operates together with a charger, it delivers a control signal at output EN, for charge current regulation or for battery voltage regulation.

Fast charging systems and charge current regulation

The SAA1501T is especially designed to be used in fast charging systems. In fast charging systems, the charge time is lowered by raising the charge current. Signal EN controls the charger current. The counters register the state of charge of the batteries and at the 80% level the charge current is reduced via a smaller duty cycle regulation of signal EN. The second (slow) level fully charges the batteries which is not possible with the first (fast) level. After the slow charge mode the counter switches over to an even smaller duty cycle of EN and thus enters the third (trickle) charge mode, to overcome the self-discharge of the batteries.

Current sensing and charge account

The charge current is sensed by means of a very low resistance (e.g. 70 mΩ) sense resistor R_{sc} (see Fig.8) to save power at high charge rates. Via the V/I charge converter and external resistor R_{CCC} (see Fig.8), the sensed voltage is converted into a charge current I_c (the same is applicable for the discharge current). In the I/F converter the charge current is converted into a frequency for up-counting the counter. For the discharge current (I_d) the converted frequency is used for down-counting. The up and down counting is registered in counters CNT1 and CNT2, depending on the actual charge and discharge current levels of the batteries. This is called dynamic charge account.

Charge display

The charge amount represented by the Coulomb counter can be displayed via an LCD screen or via an LED bargraph. If the charge amount is reduced to 0%, the battery low indicator (BLI) LED is turned on at the end of a battery discharge session. A flashing BLI, in combination with a repeating buzzer alarm, informs the user about the low charge state. A new charge session should then be started.

Protections

In the temperature control block, the absolute temperature is used as a protection to end the fast charge cycle. Fast charging at high temperature is not permitted because of degradation of the battery cells. If the batteries are disconnected, an open-battery condition is recognized and the SAA1501T enters the standby mode.

Mode detection

The mode detector detects whether there are any charge or discharge currents, whether the system is powered, whether loads are connected or whether the system is in the standby mode. If power is connected, the power-on LED (POL) is on. In the standby mode, the Coulomb counter will count down in accordance with the self-discharge speed of the batteries, which is temperature controlled. The following subsections describe the various blocks of the block diagram in more detail.

Supply and reference

During the period when V_{CC} rises from 0 V to the internal reset level, all counters are reset. The internal reset is released before V_{CC} reaches 1.7 V. The operating supply voltage ranges from 2 V to the open battery level of 4.3 V (min). The characteristics are guaranteed at $V_{CC} = 3$ V. In order to protect the SAA1501T against high supply voltages during open battery in a flyback converter, a voltage clamp circuit is made active at 6.35 V (typ). The clamping current must not exceed 80 mA. A band gap reference block is included to generate accurate voltages i.e. for the oscillator. Moreover, together with R_{ref} , accurate currents are generated which are used in the I/F and V/I converters and the oscillator block. In the standby mode only the oscillator and the digital parts are active to limit the discharge current of the batteries to a current level of less than 100 mA. The circuits that are needed temporarily are switched on and off during standby (see "Timing characteristics" t_{som}).

Voltage-to-current charge and discharge

In the V/I converter, the input charge current is translated into acceptable levels for the circuit. The conversion formula is:

$$I_c = \frac{(I_{charge} \times R_{sc})}{R_{CCC}} ; \text{ where } R_{CCC} > R_{sc} \text{ (see Fig.7)}$$

Battery charge level indicator

SAA1501T

With R_{CCC} , the charge efficiency can be manipulated depending on the charge level. The restriction of the SAA1501T is a maximum average charge current of 60 μA and a minimum momentary charge current of 0.6 μA . The same formula is applicable for the discharge current. The discharge efficiency can now also be changed by R_{DCC} depending on the discharge current levels, but independent of the charge current. As both sense levels are referenced to ground, the sensing elements could be combined into one. The outputs are used combined as $\frac{1}{6} \times (I_c - I_d)$ in the I/F converter and combined as $(I_c - I_d)$ in the pulse width modulator block and made separately available in the mode detector. The conversion is made lower by a factor of 6 in the I/F converter block, thereby enabling the use of poor leakage capacitors on pin 4. All V/I converter pins are sensitive to capacitive loading ($C_{out} \times R_{conv} < 1 \text{ ms}$), the conversion resistors should be mounted as close as possible to the output pins.

I/F converter

This block produces up-counts while charging and down-counts while discharging. The I/F converter translates the charge/discharge currents into a frequency. This frequency is determined by

$$f = \frac{(I_{c(d)} \times R_{sense} \times 6)}{(C_{CC} \times \Delta V_{osc} \times R_{CCC} (RDCC))}$$

During the time period 't', the charge current, expressed as a 'Charge Parcel', will be counted in the Coulomb counters (CNT1 and CNT2). During discharge the 'Charge Parcel' is the product of the discharge current and the 't' from the I/F converter generated frequency. The momentary contents of the Coulomb counter is a multiple of the 'Charge Parcels'.

Coulomb counters CNT1 and CNT2

The SAA1501T has been designed for average maximum charge and discharge current levels of 5 C and minimum charge and discharge current levels of 0.05 C. This means that counter CNT1 will be full, or empty, after a minimum time period of 12 minutes at maximum charge and discharge currents at the recommended oscillator frequency. Higher charge and discharge rates than 5 C are possible, but only by changing the oscillator frequency. It should be noted that the self-discharge time and the display functions are influenced by a higher oscillator frequency. The SAA1501T enables top-up charging in order to account for the decrease of charge efficiency at high charge rates. The SAA1501T switches to the slow charge mode at full recognition when CNT1 is at its maximum. As soon as the batteries are completely full (when CNT2 is at its maximum), the SAA1501T switches

to the trickle charge mode to overcome the self-discharge of the batteries. The top-up charge volume of $CNT2 = 0.2 \times CNT1 = 0.2 \text{ C}$ (where Q is rated as Ampere hours of the battery). The slow and trickle charge current levels are dependent on the k-factor. Signal EN controls the external charger e.g. TEA1400 (see Fig.8). When an LED bargraph display is used, the LED currents are also considered as a battery discharge current, and therefore influence the duty cycle of the charge current regulation signal EN. The SAA1501T also enables temperature protection. In the event that the battery temperature exceeds a certain maximum temperature level ($T_{battery} > T_{max}$), which can be set by an external NTC resistor, the SAA1501T switches to the slow charge mode. In the standby mode (self-discharge mode), which is recognized by the SAA1501T in the mode detector when both the charge and discharge currents are zero ($I_c = I_d = 0$), the self-discharge of the batteries is registered by counting down in 200 days (based on $f_{osc} = 4 \text{ kHz}$) if $T_{battery} < T_{self}$ or in 100 days (based on $f_{osc} = 4 \text{ kHz}$) if $T_{battery} > T_{self}$. T_{self} is also set by means of an external NTC resistor.

Band gap generation

From the band gap voltage block, two reference voltages are derived V_{ref} and V_{max} . Voltage V_{ref} at pin R_{ref} sets the reference currents, I_{ref1} (I/F converter); I_{ref2} (mode detector) and I_{ref3} (oscillator). Voltage V_{max} sets the current I_{max} which is used in the pulse width modulation block to accurately control the charge current.

Charge current regulation

While charging, the SAA1501T produces a charge current regulation signal EN in the pulse width modulation block which is used for controlling an external charger. This digital signal EN is derived from the signal produced at pin C_{cy} . The duty cycle is determined by

$$\delta = \frac{k \times I_{max}}{I_c - I_d}$$

in which the value of k depends on the state of the counters CNT1 and CNT2:

- CNT1 is not full; $k = 1$ (fast charging).
- CNT1 is full; CNT2 is not full; $k = 0.1$ (slow charging).
- CNT1 and CNT2 are full; $k = 0.025$ (trickle charging).

Battery charge level indicator

SAA1501T

Mode detector

This block differentiates between the available modes of operation. The modes are given below:

- Charge mode; power charge (POCH).
- Discharge mode; battery load (BATLD).
- Power load mode (POLD); the batteries are charged while the load is also active.
- Self discharge mode; (STANDBY).

To detect power in a regulated system (see Fig.8) the EN signal is used for sensing. The POCH mode is recognized when the converted charge current $I_c > I_{ref2}$ (when in the power mode, change of mode can only be recognised if EN is HIGH). The BATLD mode is recognized when $I_d > I_{ref2}$; the POLD mode is recognized when $I_c > I_{ref2}$ and $I_d > I_{ref2}$; the standby mode is recognized when $I_c < I_{ref2}$ and $I_d < I_{ref2}$. In the standby mode, if the advised frequency (4 kHz) is applied, it takes 0.5 s to determine another mode (in all other modes, a change of mode is sensed continuously). In all other modes an eventual change of mode is done continuously. To save supply current during standby, the V/I converters are switched off. With the specific fixed intervals, the SAA1501T checks whether power or load is connected again. This checking is synchronized by the sensing signal of the V/I converters. The SAA1501T can handle a DC charge current as well as a discontinuous charge current (SMSP charger). The load current can also be DC or interrupted, e.g. produced by a motor. The digital filtering of both signals, to overcome faulty mode detections, restricts the conditions in which power and load are recognized. Because of the very sensitive input detection level of the mode detector for a charge current (power) in combination with the high interference levels of motor driving, the detection level for power ($I_c > I_{ref2}$) is raised by a factor of 25 when the batteries are loaded.

Oscillator

As the oscillator has to operate in all modes, including the standby mode, the current consumption of the oscillator must be very low. The same applies for the band gap generator block, because the band gap delivers accurate reference voltages and currents to the oscillator block. Apart from the low current consumption, the accuracy of the period time is important. The period time of the oscillator is:

$$t_{osc} = 2 \times C_{osc} \times \frac{(V_H - V_L)}{I_{ref3}} = 5.6 \times C_{osc} \times R_{ref}$$

Prescaler/controller

In the prescaler, a new system clock is created (CLK) which is used for all timing blocks. Many frequencies are derived from the basic oscillator at the standard frequency of 4 kHz ($1/T_{osc}$), such as the self-discharge times and the modulation frequency for the buzzer, the drive voltage frequency for the LCD screen and the pulse trains for temperature measurements and power/load sensing measurements in the mode detector.

Temperature

In the temperature control block two temperature measurements are performed. In order to switch off fast charging when the battery temperature exceeds an adjustable maximum temperature (T_{max}), a maximum temperature measurement is performed. A second temperature measurement is performed in the standby mode. This temperature measurement is input to the temperature control block to switch over the self-discharge rate from a count down of 200 days (based on $f_{osc} = 4$ kHz) if $T_{battery} < T_{self}$, to a count down rate of 100 days (based on $f_{osc} = 4$ kHz) if $T_{battery} > T_{self}$. In all modes the temperature is measured periodical. The temperature circuit which controls the above mentioned functions is a bridge configuration synthesis, as illustrated in Fig.3.

Fig.3 Temperature circuit.

Battery charge level indicator

SAA1501T

Display decoder driver

The counters are used to output the battery charge amount via a decoder and driver stage to the display outputs L100, L80, L60, L40 and L20 to drive an LCD screen or an LED bargraph. A 64 Hz (based on $f_{osc} = 4 \text{ kHz}$) block signal at output BP (back plane) must be connected to the back plane of the LCD bar. If pin BP is connected to ground, the display outputs L20 to L100 will produce signals for an LED bargraph. Output signal POL (power-on LED) indicates when the batteries are in the charge mode. When the counter is not at its maximum state, POL is on and flickers at 2 Hz (based on $f_{osc} = 4 \text{ kHz}$) when the counter is at its maximum. The waveforms illustrated in Fig.4 depict operation of the monitor display. The outputs BLI (battery low indication), BUZ (buzzer) and FULL indicate the extreme status (empty or full) of the counters and the batteries. The waveforms of the signals BLI and BUZ if one switches over from BATLD to standby when BLI is active, are given in Fig.4.

The BLI sequence is as follows. If during discharge the charge state falls below 0%, the red BLI LED is turned on. Changing mode from discharge to standby means that the BLI LED and the buzzer (BUZ) are activated as indicated in Fig.4. If after a 0% passing recharge is activated, the red BLI LED is turned on again for as long as the counter remains below 10%. Switch-over in the 0 to 10% range to standby will activate BLI and BUZ again.

The LEDs of the LED bargraph are activated as a result of each operational mode change, starting with a step-up pattern. Step-up means that LEDs are activated successively one after the other, in accordance with the charge status each $\frac{1}{8} \text{ s}$ (based on $f_{osc} = 4 \text{ kHz}$). After the step-up, the LEDs will be on for 8 s (based on $f_{osc} = 4 \text{ kHz}$), except for the POCH mode, where the LEDs will be on continuously to inform the user about the charge state of the batteries. The LCD display is, apart from the LED mode, always visible.

Figure 5 shows the legend for Fig.6. Figure 6 shows the operation of the monitor display.

Fig.4 BLI and buzzer timing.

Battery charge level indicator

SAA1501T

Open battery protection

Open battery protection is active when $V_{CC} = 4.5\text{ V}$ (typ.). The SAA1501T will then react as if the system is in the standby mode. This means that the LEDs are turned off in the LED mode, in the LCD mode the flickering is stopped and the enable pin (EN) is switched to floating.

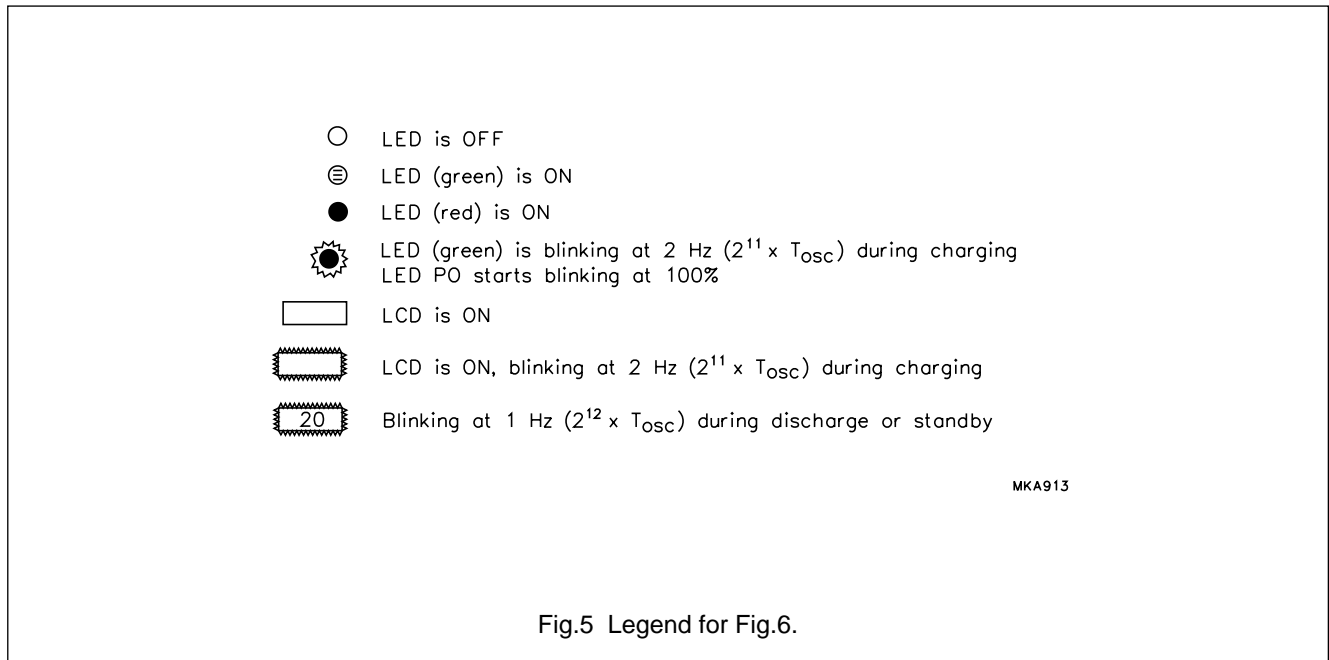

Testing

A user test facility is built-in for checking if the LCD and/or LED displays are mounted correctly. Pin R_{CC} is used as

a test pin. Raising the voltage above 1 V during the set-up time will activate the test. The test mode can only be started in the standby mode. In the test mode all counters are reset and will be active successively in the sequence BLI, L20, L40, L60, L80, L100 and FULL with an interval period determined by T_{OSC} . The test mode can be exited via the following methods:

Power-on; the Coulomb counter retains the latest data displayed.

Automatically after the test cycle time; the Coulomb counter is reset.

SYMBOL	PARAMETER	CONDITIONS	MIN.	TYP.	MAX.	UNIT
$V_{OH(14)}$	HIGH level output current (pin 14)	$V_{OH} = 2 \text{ V}; V_{CC} = 2.4 \text{ V}$	0.7	1.6	2.5	μA
$I_{OH(15)}$	HIGH level output current (pin 15)	$V_{OH} = 2 \text{ V}; V_{CC} = 2.4 \text{ V}$	0.99	1.67	2.69	mA
$I_{OH(22,23)}$	HIGH level output current (pins 22 and 23)	$V_{OH} = 2.4 \text{ V}; V_{CC} = 2.4 \text{ V}$	260	450	708	μA
I_{LO}	output leakage current (pin 21)	$V_{OH} = 0 \text{ to } V_{CC}$	–	–	± 1	μA

Notes

1. Not measured by the industrial measuring program, but guaranteed by design.
2. Internally detected from band gap generator.

Battery charge level indicator

SAA1501T

TIMING CHARACTERISTICS

SYMBOL	PARAMETER	CONDITIONS	VALUE
T _{osc}	oscillator cycle time	note 1	T _{osc} = 2C _{osc} × V _{osc} /I _{ref3}
T _{clk}	clock cycle time		64t _{osc}
t _{som}	sense operation mode time	note 2	1.5 × 2 ⁷ T _{osc}
t _{som(p)}	sense operation mode period time	note 2	2 ¹² T _{osc}
t _{rec}	recognition time	power; note 3	>32t _{osc}
		load; note 4	>20t _{osc}
t _{self}	self discharge counter time	T _{battery} > T _{self} (100 days at f _{osc} = 4 kHz)	2 ³⁵ T _{osc}
		T _{battery} > T _{self} (200 days at f _{osc} = 4 kHz)	2 ³⁶ T _{osc}
t _{battery(s)}	battery temperature measurement sense time		2 ⁷ T _{osc}
t _{battery(p)}	battery temperature measurement period time		2 ¹⁶ T _{osc}
t _{su}	display test set-up time		2 ¹¹ T _{osc} < t < 1.5 × 2 ¹⁸ T _{osc}
t _{id}	interval display test time		2 ¹⁰ T _{osc}
t _{pd}	period display test time		1.5 × 2 ¹⁸ T _{osc}
t _{su:LED}	LED set-up time		2 ⁹ T _{osc}
t _{LED(ON)}	LEDs-on time	after change of mode (except POCH mode)	2 ¹⁵ T _{osc}
f _{BP}	drive voltage frequency for back plane		2 ⁻⁴ T _{osc}
f _{BUZ}	modulation frequency for auto buzzer		1/2 T _{osc}

Notes

1. $t_{osc} = 2C_{osc} \times \frac{V_{osc}}{I_{ref3}}$; where V_{osc} = 440 mV and I_{ref3} = 0.75.
2. Applies to all converters and enable signal.
3. For charge current AC or DC: f > 1/2f_{osc}.
4. For discharge current AC: f > 1/4f_{osc}.

SOLDERING

Plastic small-outline packages

BY WAVE

During placement and before soldering, the component must be fixed with a droplet of adhesive. After curing the adhesive, the component can be soldered. The adhesive can be applied by screen printing, pin transfer or syringe dispensing.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder bath is 10 s, if allowed to cool to less than 150 °C within 6 s. Typical dwell time is 4 s at 250 °C.

A modified wave soldering technique is recommended using two solder waves (dual-wave), in which a turbulent wave with high upward pressure is followed by a smooth laminar wave. Using a mildly-activated flux eliminates the need for removal of corrosive residues in most applications.

BY SOLDER PASTE REFLOW

Reflow soldering requires the solder paste (a suspension of fine solder particles, flux and binding agent) to be

applied to the substrate by screen printing, stencilling or pressure-syringe dispensing before device placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt, infrared, and vapour-phase reflow. Dwell times vary between 50 and 300 s according to method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 min at 45 °C.

REPAIRING SOLDERED JOINTS (BY HAND-HELD SOLDERING IRON OR PULSE-HEATED SOLDER TOOL)

Fix the component by first soldering two, diagonally opposite, end pins. Apply the heating tool to the flat part of the pin only. Contact time must be limited to 10 s at up to 300 °C. When using proper tools, all other pins can be soldered in one operation within 2 to 5 s at between 270 and 320 °C. (Pulse-heated soldering is not recommended for SO packages.)

For pulse-heated solder tool (resistance) soldering of VSO packages, solder is applied to the substrate by dipping or by an extra thick tin/lead plating before package placement.

DEFINITIONS

Data sheet status	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
Limiting values	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
Application information	
Where application information is given, it is advisory and does not form part of the specification.	

LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
