

2-Phase Stepper-Motor Driver Bipolar-IC

TLE 4729 G

Features

- 2 × 0.7 amp. full bridge outputs
- Integrated driver, control logic and current control (chopper)
- Very low current consumption in inhibit mode
- Fast free-wheeling diodes
- Max. supply voltage 45 V
- Output stages are free of crossover current
- Offset-phase turn-ON of output stages
- All outputs short-circuit proof
- Error-flag for overload, open load, over-temperature
- SMD package P-DSO-24-3

Functional Description

TLE 4729 G is a bipolar, monolithic IC for driving bipolar stepper motors, DC motors and other inductive loads that operate by constant current. It is fully pin and function compatible except the current programming is inverse to the TLE 4729 G with an additional inhibit feature. The control logic and power output stages for two bipolar windings are integrated on a single chip which permits switched current control of motors with 0.7 A per phase at operating voltages up to 16 V.

The direction and value of current are programmable for each phase via separate control inputs. In the case of low at all four current program inputs the device is switched to inhibit mode automatically. A common oscillator generates the timing for the current control and turn-on with phase offset of the two output stages. The two output stages in full-bridge configuration include fast integrated freewheeling diodes and are free of crossover current. The device can be driven directly by a microprocessor in several modes by programming phase direction and current control of each bridge independently.

With the two error outputs the TLE 4729 G signals malfunction of the device. Setting the control inputs high resets the error flag and by reactivating the bridges one by one the location of the error can be found.

Diagrams

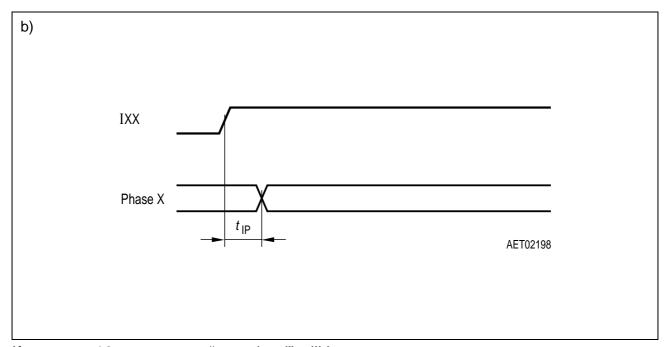

Timing between IXX and Phase X to prevent setting the error flag

Operating conditions:

+
$$V_{\rm S}$$
 = 14 V, $T_{\rm j}$ = 25 °C, $I_{\rm err}$ = 1 mA, load = 3.3 mH, 1 Ω

If t_{Pl} < typ. 5 μ s, an error "open load" will be set.

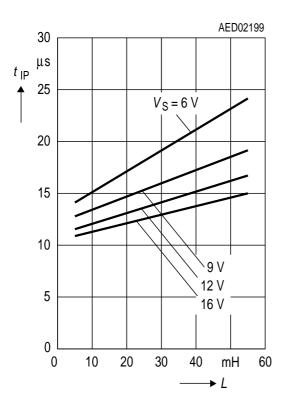

If t_{IP} < typ. 12 µs, an error "open load" will be set.

This time strongly depends on + $V_{\rm S}$ and inductivity of the load, see diagram below.

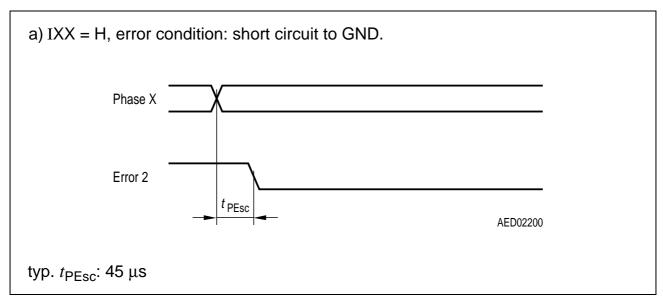

Time t_{IP} vs. Load Inductivity

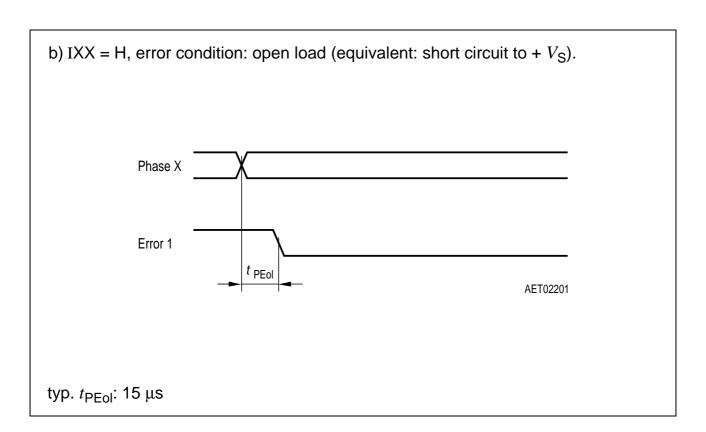

Propagation Delay of the Error Flag

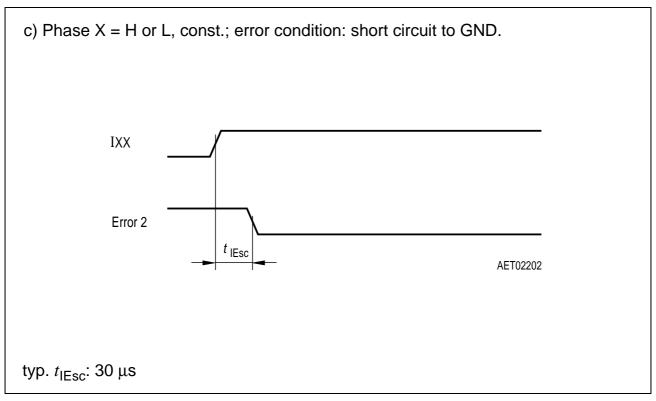

Operating conditions:

+
$$V_{\rm S}$$
 = 14 V, $T_{\rm j}$ = 25 °C, $I_{\rm err}$ = 1 mA, load = 3.3 mH, 1 Ω

 t_{IEsc} is also measured under the condition: begin of short circuit to GND till error flag set.

Calculation of Power Dissipation

The total power dissipation P_{tot} is made up of

Saturation losses P_{sat} (transistor saturation voltage and diode forward voltages),

Quiescent losses P_{q} (quiescent current times supply voltage) and

Switching losses P_s (turn-ON / turn-OFF operations).

The following equations give the power dissipation for chopper operation without phase reversal.

This is the worst case, because full current flows for the entire time and switching losses occur in addition.

$$P_{\text{tot}} = 2 \times P_{\text{sat}} + P_{\text{q}} + 2 \times P_{\text{s}}$$
 where

$$P_{\text{sat}} \cong I_{\text{N}} \{V_{\text{satI}} \times d + V_{\text{Fu}} (1 - d) + V_{\text{satuC}} \times d + V_{\text{satuD}} (1 - d)\}$$

 $P_{\text{q}} = I_{\text{q}} \times V_{\text{S}}$

$$P_{q} \cong \frac{V_{S}}{T} \left\{ \frac{i_{D} \times t_{DON}}{2} + \frac{(i_{D} + i_{R}) \times t_{ON}}{4} + \frac{I_{N}}{2} (t_{DOFF} + t_{OFF}) \right\}$$

 I_N = Nominal current (mean value)

 I_{c} = Quiescent current

 i_D = Reverse current during turn-on delay

 i_{R} = Peak reverse current

 t_p = Conducting time of chopper transistor

 t_{ON} = Turn-ON time t_{OFF} = Turn-OFF time

 t_{DON} = Turn-ON delay

 t_{DOFF} = Turn-OFF delay T = Cycle duration

 $d = \text{Duty cycle } t_{\text{D}} / T$

 V_{satl} = Saturation voltage of sink transistor (TX3, TX4)

 V_{satuC} = Saturation voltage of source transistor (TX1, TX2) during charge cycle

 $V_{\rm satuD}$ = Saturation voltage of source transistor (TX1, TX2) during discharge cycle

 V_{Fu} = Forward voltage of free-wheeling diode (DX1, DX2)

 V_{S} = Supply voltage

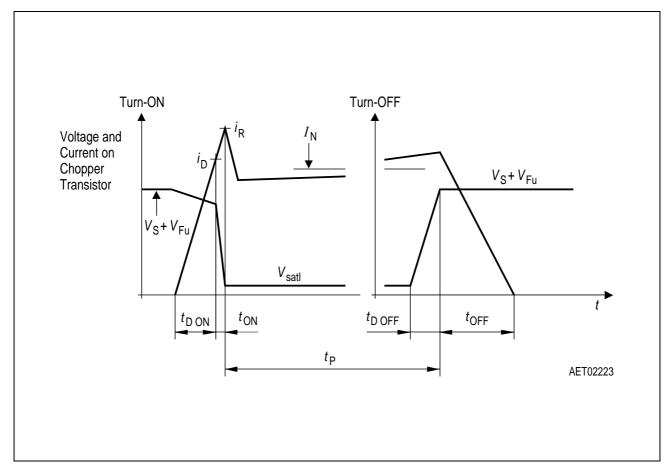

Figure 10 Voltage and Current on Chopper Transistor

Application Hints

The TLE 4729 G is intended to drive both phases of a stepper motor. Special care has been taken to provide high efficiency, robustness and to minimize external components.

Power Supply

The TLE 4729 G will work with supply voltages ranging from 5 V to 16 V at pin $V_{\rm S}$. Surges exceeding 16 V at $V_{\rm S}$ wont harm the circuit up to 45 V, but whole function is not guaranteed. As soon as the voltage drops below approximately 16 V the TLE 4729 G works promptly again.

As the circuit operates with chopper regulation of the current, interference generation problems can arise in some applications. Therefore the power supply should be decoupled by a $0.1\,\mu\text{F}$ ceramic capacitor located near the package. Unstabilized supplies may even afford higher capacities.

Inhibit Mode

In the case of low at all four current program inputs IXX the device will switch into inhibit condition; the current consumption is reduced to very low values.

When starting operation again, i.e. putting at least one IXX to high potential, the Error 1 output signals an open load error if the corresponding phase input is high. The error is reset by first recirculation in chop mode.

Current Sensing

The current in the windings of the stepper motor is sensed by the voltage drop across $R_{\rm sense}$. Depending on the selected current internal comparators will turn off the sink transistor as soon as the voltage drop reaches certain thresholds (typical 0 V, 0.07 V, 0.45 V and 0.7 V). These thresholds are not affected by variations of $V_{\rm S}$. Consequently instabilized supplies will not affect the performance of the regulation. For precise current level it must be considered, that internal bounding wire (typ. 60 m Ω) is a part of $R_{\rm sense}$.

Due to chopper control fast current rises (up to 10 A/ μ s) will occur at the sensing resistors. To prevent malfunction of the current sensing mechanism $R_{\rm sense}$ should be pure ohmic. The resistors should be wired to GND as directly as possible. Capacitive loads such as long cables (with high wire to wire capacity) to the motor should be avoided for the same reason.

Synchronizing Several Choppers

In some applications synchrone chopping of several stepper motor drivers may be desirable to reduce acoustic interference. This can be done by forcing the oscillator of the TLE 4729 G by a pulse generator overdriving the oscillator loading currents (approximately \pm 120 μA). In these applications low level should be between 0 V and 0.8 V while high level should between 3 V and 5 V.

Application Hints (cont'd)

Optimizing Noise Immunity

Unused inputs should always be wired to proper voltage levels in order to obtain highest possible noise immunity.

To prevent crossconduction of the output stages the TLE 4729 G uses a special break before make timing of the power transistors. This timing circuit can be triggered by short glitches (some hundred nanoseconds) at the phase inputs causing the output stage to become high resistive during some microseconds. This will lead to a fast current decay during that time. To achieve maximum current accuracy such glitches at the phase inputs should be avoided by proper control signals.

To lower EMI a ceramic capacitor of max. 3 nF is advisable from each output to GND.

Thermal Shut Down

To protect the circuit against thermal destruction, thermal shut down has been implemented.

Error Monitoring

The error outputs signal corresponding to the logic table the errors described below.

Logic Table

Kir	nd of Error	Error Output				
		Error 1	Error 2			
a)	No error	Н	Н			
b)	Short circuit to GND	Н	L			
c)	Open load ¹⁾	L	Н			
d)	b) and c) simultaneously	Н	L			
e)	Temperature prealarm	L	L			

¹⁾ Also possible: short circuit to + V_S or short circuit of the load.

Over-Temperature is implemented as pre-alarm; it appears approximately 20 K before thermal shut down. To detect an **open load**, the recirculation of the inductive load is watched. If there is no recirculation after a phase change-over, an internal error flipflop is set. Because in most kinds of **short circuits** there won't flow any current through the motor, there will be no recirculation after a phase change-over, and the error flipflop for open load will be set, too. Additionally an **open load error** is signaled after a phase change-over during hold mode.

Only in the case of a **short circuit to GND**, the most probably kind of a short circuit in automotive applications, the malfunction is signaled dominant (see d) in logic table) by a separate error flag. Simultaneously the output current is disabled after 30 μ s to prevent disturbances.

A phase change-over or putting both current control inputs of the affected bridge on low potential resets the error flipflop. Being a separate flipflop for every bridge, the error can be located in easy way.
