# 74ACTQ841 Quiet Series<sup>™</sup> 10-Bit Transparent Latch with 3-STATE Outputs

### **General Description**

The ACTQ841 bus interface latch is designed to eliminate the extra packages required to buffer existing latches and provide extra data width for wider address/data paths or buses carrying parity. The 841 is a 10-bit transparent latch, a 10-bit version of the 373. The ACTQ841 utilizes Fairchild Quiet Series™ technology to guarantee quiet output switching and improved dynamic threshold performance. FACT Quiet Series features GTO™ output control and undershoot corrector in addition to a split ground bus for superior performance.

#### Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
- Inputs and outputs on opposite sides of package allow easy interface with microprocessors
- Improved latch-up immunity
- Outputs source/sink 24 mA
- Has TTL-compatible inputs

### **Ordering Code:**

| Order Number | Package Number | Package Description   |
|--------------|----------------|---|
| 74ACTQ841SC  | M24B           | 24-Lead Small Outline Integrated Circuit (SOIC), JEDEC MS-013, 0.300" Wide Body |

Device also available in Tape and Reel. Specify by appending suffix letter "X" to the ordering code.

### **Functional Description**

The ACTQ841 consists of ten D-type latches with 3-STATE outputs. The flip-flops appear transparent to the data when Latch Enable (LE) is HIGH. This allows asynchronous operation, as the output transition follows the data in transition.

On the LE HIGH-to-LOW transition, the data that meets the setup and hold time is latched. Data appears on the bus when the Output Enable  $(\overline{OE})$  is LOW. When  $\overline{OE}$  is HIGH the bus output is in the high impedance state.

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. Fairchild does not recommend operation of FACT™ circuits outside databook specifications.

Note 7: Voltage Range 5.0 is 5.0V  $\pm$  0.5V.

Note 8: Skew is defined as the absolute value of the difference between the actual propagation delay for any two outputs within the same packaged device. The specification applies to any outputs switching in the same direction, either HIGH to LOW (toSHL) or LOW to HIGH (toSLH). Parameter guaranteed by design. Not tested.

### **FACT Noise Characteristics**

The setup of a noise characteristics measurement is critical to the accuracy and repeatability of the tests. The following is a brief description of the setup used to measure the noise characteristics of FACT.

Equipment:

Hewlett Packard Model 8180A Word Generator

PC-163A Test Fixture

Tektronics Model 7854 Oscilloscope

Procedure:

- Verify Test Fixture Loading: Standard Load 50 pF, 500Ω.
- Deskew the HFS generator so that no two channels have greater than 150 ps skew between them. This requires that the oscilloscope be deskewed first. It is important to deskew the HFS generator channels before testing. This will ensure that the outputs switch simultaneously.
- Terminate all inputs and outputs to ensure proper loading of the outputs and that the input levels are at the correct voltage.
- Set the HFS generator to toggle all but one output at a frequency of 1 MHz. Greater frequencies will increase DUT heating and effect the results of the measurement.
- Set the HFS generator input levels at 0V LOW and 3V HIGH for ACT devices and 0V LOW and 5V HIGH for AC devices. Verify levels with an oscilloscope.

**Note A:**  $V_{OHV}$  and  $V_{OLP}$  are measured with respect to ground reference. **Note B:** Input pulses have the following characteristics: f = 1 MHz,  $t_r = 3$  ns,  $t_r = 3$  ns, skew < 150 ps.

FIGURE 1. Quiet Output Noise Voltage Waveforms

 $V_{OLP}/V_{OLV}$  and  $V_{OHP}/V_{OHV}$ :

- Determine the quiet output pin that demonstrates the greatest noise levels. The worst case pin will usually be the furthest from the ground pin. Monitor the output voltages using a 50 $\Omega$  coaxial cable plugged into a standard SMB type connector on the test fixture. Do not use an active FET probe.
- Measure V<sub>OLP</sub> and V<sub>OLV</sub> on the quiet output during the worst case transition for active and enable. Measure V<sub>OHP</sub> and V<sub>OHV</sub> on the quiet output during the worst case active and enable transition.
- Verify that the GND reference recorded on the oscilloscope has not drifted to ensure the accuracy and repeatability of the measurements.

 $V_{\text{ILD}}$  and  $V_{\text{IHD}}$ :

- Monitor one of the switching outputs using a  $50\Omega$  coaxial cable plugged into a standard SMB type connector on the test fixture. Do not use an active FET probe.
- First increase the input LOW voltage level, V<sub>IL</sub>, until the output begins to oscillate or steps out of a min of 2 ns. Oscillation is defined as noise on the output LOW level that exceeds V<sub>IL</sub> limits, or on output HIGH levels that exceed V<sub>IH</sub> limits. The input LOW voltage level at which oscillation occurs is defined as V<sub>ILD</sub>.
- Next decrease the input HIGH voltage level, V<sub>IH</sub>, until the output begins to oscillate or steps out a min of 2 ns. Oscillation is defined as noise on the output LOW level that exceeds V<sub>IL</sub> limits, or on output HIGH levels that exceed V<sub>IH</sub> limits. The input HIGH voltage level at which oscillation occurs is defined as V<sub>IHD</sub>.
- Verify that the GND reference recorded on the oscilloscope has not drifted to ensure the accuracy and repeatability of the measurements.
