SATURN USER NETWORK INTERFACE (622-MAX)

REVISION HISTORY

ISSUE	DATE	DETAIL
6	June 2000	Corrected block diagram.
		Corrected function name errors in Register 0x03: S/UNI-622 MAX Clock Monitors. Changed PTCLKI to PTCLK, REFCLKI to REFCLK, RFCLKI to RFCLK, RCLKI to RCLK and TCLKI to TCLK.
		Added line loopback operation information to RXDINV and TXDINV in Register 0x07: S/UNI-622-MAX Miscellaneous Configuration.
		Rewrote IINVCNT bit functionality for clarity. Register 0x30 (EXTD=1): RPOP Status/Control.
		Rewrote DOOLI bit functionality to indicate change to DOOLV bit and CRU out of lock conditions in Register 0.5C: CRSI Configuration.
		Rewrote DOOLE bit functionality to indicate change to DOOLV register events in Register 0x5D: CRSI Status.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

ISSUE	DATE	DETAIL
5	Dec, 1999	#1 Modified section 9.4 (UTOPIA pin description) and section 14.2 (Functional timing) to reflect operation of the RCA signal
		#2 DC characteristics update (Section 16)
		#3 Registers updated with correct defaults and descriptions:
		Register 0X01, Bit 4 (TFPEN), Defaults To 1, Not 0
		Register 0X08, Description Incorrect
		Register 0X09 Description Incorrect
		New Register 0XFC: Concatenation Status And Enable
		New Register 0XFD: Concatenation Interrupt Status
		New Register Bit Required For OC-3 Operation (Register 0X07)
		Register 0X5E Bit 5 (RTYPE) should be set to zero for improved Jitter Tolerance
		Register 0X00 Type Bits Incorrect
		Loss Of Multi-frame Tributary AIS (LOMTUAIS) Bit 2 Incorrectly Stated In Register 0X0D
		#4 APS pin description modified
		#6 Updated TFCLK timing specifications, RFCLK timing specifications
		#7 Diagnostic Loop-back Clarification
		#8 Bit Error Rate Monitor Table Update
		#9 Receive Data Requires 3 RFCLK Cycles Before Becoming Valid (Utopia Level 3 Only)
		#11 Receive Line AIS Insertion Is Not Gated By ALLONES
		#12 Large Power Supply Glitch (Beyond Specification) Can Cause Clock Synthesis Unit To Lose Lock To Reference.
4	January 4, 1999	Corrected wrong pin number assignments in pin description.
3	Dec 15, 1999	General update
2	Aug 30, 1998	Re-organized registers. Removed UDF. Update pin list and block diagram. Add preliminary simulation and test sections text.

1   FEATURES

1.1   General

- Single chip ATM over SONET/SDH Physical Layer Device operating at 622.08 Mbit/s.

- Implements the ATM Forum User Network Interface Specification and the ATM physical layer for Broadband ISDN according to CCITT Recommendation I.432.

- Processes duplex bit-serial 622.08 Mbit/s STS-12c/STM-4-4c data streams with on-chip clock and data recovery and clock synthesis.

- Supports a duplex byte-serial 77.76 Mbyte/s STS-12c/STM-4-4c line side interface for use in applications where by-passing clock recovery, clock synthesis, and serializer-deserializer functionality is desired.

- Supports a byte-serial 19.44 Mbyte/s STS-3c/STM-1 line side interface on the transmit and/or receive interface for use in applications where a 155.52 Mbit/s data rate is desired.

- Supports clock recovery by-pass for use in applications where external clock recovery is desired.

- Provides UTOPIA Level 2 16-bit wide System Interface (clocked up to 50 MHz) with parity support for ATM applications.

- Provides UTOPIA Level 3 compatible 8-bit wide System Interface (clocked up to 100 MHz) with parity support for ATM applications.

- Provides support functions for a two chip solution for 1+1 APS operation.

- Provides a standard 5 signal IEEE 1149.1 JTAG test port for boundary scan board test purposes.

- Provides a generic 8-bit microprocessor bus interface for configuration, control, and status monitoring.

- Low power 3.3V CMOS with TTL compatible digital inputs and CMOS/TTL digital outputs. PECL inputs and outputs are 3.3V and 5V compatible.

- Industrial temperature range (-40°C to +85°C).

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

- 304 pin Super BGA package.

1.2   The SONET Receiver

- Provides a serial interface at 622.08 Mbit/s with clock and data recovery.

- Frames to and de-scrambles the received STS-12c/STM-4-4c stream.

- Optionally frames to and de-scrambles a received STS-3c/STM-1 stream.

- Interprets the received payload pointer (H1, H2) and extracts the STS-12c/STM-4-4c or STS-3c/STM-1 synchronous payload envelope and path overhead.

- Filters and captures the automatic protection switch channel (APS) bytes in readable registers and detects APS byte failure.

- Captures and de-bounces the synchronization status (S1) nibble in a readable register.

- Detects signal degrade (SD) and signal fail (SF) threshold crossing alarms based on received B2 errors.

- Extracts the 16-byte or 64-byte section trace (J0/Z0) sequence and the 16-byte or 64-byte path trace (J1) sequence into internal register banks.

- Detects loss of signal (LOS), out of frame (OOF), loss of frame (LOF), line alarm indication signal (AIS-L), line remote defect indication (RDI-L), loss of pointer (LOP), path alarm indication signal (AIS-P), path remote defect indication (RDI-P), path extended remote defect indicator (extended RDI-P).

- Counts received section BIP-8 (B1) errors, received line BIP-96 (B2) errors, line remote error indicates (REI-L), received path BIP-8 (B3) errors and path remote error indications (REI-P) for performance monitoring purposes.

1.3   The Receive ATM Processor

- Extracts ATM cells from the received STS-12c/STM-4-4c or STS-3c/STM-1 payload using ATM cell delineation.

- Provides ATM cell payload de-scrambling.

- Performs header check sequence (HCS) error detection and correction, and idle/unassigned cell filtering.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

- Detects out of cell Delineation (OCD) and loss of cell delineation (LCD) alarms.

- Counts number of received cells, idle cells, errored cells and dropped cells.

- Provides a UTOPIA Level 2 compliant 16-bit wide datapath interface (clocked up to 50 MHz) with parity support to read extracted cells from an internal four-cell FIFO buffer.

- Provides a UTOPIA Level 3 compatible 8-bit wide datapath interface (clocked up to 100 MHz) with parity support to read extracted cells from an internal four-cell FIFO buffer.

1.4   The SONET Transmitter

- Synthesizes the 622.08 MHz transmit clock from a 77.76 MHz reference.

- Provides a differential PECL bit-serial interface at 622.08 Mbit/s.

- Inserts a register programmable path signal label (C2).

- Generates the transmit payload pointer (H1, H2) and inserts the path overhead.

- Optionally inserts the 16-byte or 64-byte section trace (J0/Z0) sequence and the 16-byte or 64-byte path trace (J1) sequence from internal register banks.

- Optionally inserts externally generated data communication channels (D1-D3, D4-D12) via a 192 kbit/s (D1-D3) serial stream and a 576 kbit/s (D4-D12) serial stream.

- Scrambles the transmitted STS-12c/STM-4-4c or STS-3c/STM-1 stream and inserts the framing bytes (A1, A2).

- Optionally inserts register programmable APS bytes.

- Provides a byte-serial transmit path data stream allowing two devices to implement 1+1 APS.

- Inserts path BIP-8 codes (B3), path remote error indications (REI-P), line BIP-96 codes (B2), line remote error indications (REI-L), and section BIP-8 codes (B1) to allow performance monitoring at the far end.

- Allows forced insertion of all-zeros data (after scrambling) and the corruption of the section, line, or path BIP-8 codes for diagnostic purposes.

- Inserts ATM cells into the transmitted STS-12c/STM-4-4c or STS-3c/STM-1 payload.

1.5   The Transmit ATM Processor

- Provides idle/unassigned cell insertion.

- Provides HCS generation/insertion, and ATM cell payload scrambling.

- Counts number of transmitted and idle cells.

- Provides a UTOPIA Level 2 compliant 16-bit wide datapath interface (clocked up to 50 MHz) with parity support for writing cells into an internal four-cell FIFO.

- Provides a UTOPIA Level 3 compatible 8-bit wide datapath interface (clocked up to 100 MHz) with parity support for writing cells into an internal four-cell FIFO.

4   DEFINITIONS

The following table defines the abbreviations for the S/UNI-622-MAX.

AIS	Alarm Indication Signal
APS	Automatic Protection Switching
ASSP	Application Specific Standard Product
ATM	Asynchronous Transfer Mode
BER	Bit Error Rate
BIP	Byte Interleaved Parity
CBI	Common Bus Interface
CMOS	Complementary Metal Oxide Semiconductor
CRC	Cyclic Redundancy Check
CRSI	CRU and Serial-In Parallel-Out
CRU	Clock Recovery Unit
CSPI	CSU and Parallel-In Serial-Out
CSU	Clock Synthesis Unit
ECL	Emitter Controlled Logic
ERDI	Enhanced Remote Defect Indication
ESD	Electrostatic Discharge
FEBE	Far-End Block Error
FIFO	First-In First-Out
GFC	Generic Flow Control
HCS	Header Check Sequence
LAN	Local Area Network
LCD	Loss of Cell Delineation
LOF	Loss of Frame
LOH	Line Overhead
LOP	Loss of Pointer
LOS	Loss of Signal

5   APPLICATION EXAMPLES

The PM5357 S/UNI-622-MAX is applicable to equipment implementing Asynchronous Transfer Mode (ATM) User-Network Interfaces (UNI) and ATM Network-Network Interfaces (NNI).

The S/UNI-622-MAX may find application at either end of switch-to-switch links or switch-to-terminal links, both in public network (WAN) and private network (LAN) situations. The S/UNI-622-MAX performs the mapping of ATM cells into the SONET/SDH STS-12c/STM-4-4c synchronous payload envelope (SPE) and processes applicable SONET/SDH section, line and path overheads.

In a typical STS-12c/STM-4-4c ATM application, the S/UNI-622-MAX performs clock and data recovery in the receive direction and clock synthesis in the transmit direction of the line interface. The S/UNI-622-MAX can also be configured to by-pass the clock recovery, clock synthesis, and serializer/de-serializer functions. In this mode, an external clock and data recovery/serial-to-parallel converter device is required in the receive direction, and an external serial-to-parallel converter/clock synthesis device is required in the transmit direction.

On the system side, the S/UNI-622-MAX interfaces directly with ATM layer processors and switching or adaptation functions using a UTOPIA Level 2 compliant 16-bit (clocked up to 50 MHz) or an UTOPIA Level 3 8-bit (clocked up to 100 MHz) synchronous FIFO style interface.

An application with a UTOPIA Level 2 system side interface is shown in Figure 1. An application with a UTOPIA Level 3 system side is shown in Figure 2. The initial configuration and ongoing control and monitoring of the S/UNI-622-MAX are normally provided via a generic microprocessor interface.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)
7   DESCRIPTION

The PM5357 S/UNI-622-MAX SATURN User Network Interface is a monolithic integrated circuit that implements SONET/SDH processing, ATM mapping over SONET/SDH mapping functions at the STS-12c/STM-4-4c 622.08 Mbit/s rate.

The S/UNI-622-MAX receives SONET/SDH streams using a bit serial interface, recovers the clock and data and processes section, line, and path overhead. The S/UNI-622-MAX can also be configured for clock and data recovery and clock synthesis by-pass where it receives SONET/SDH frames via a byte-serial interface. The S/UNI-622-MAX performs framing (A1, A2), de-scrambling, detects alarm conditions, and monitors section, line, and path bit interleaved parity (B1, B2, B3), accumulating error counts at each level for performance monitoring purposes. Line and path remote error indications (M1, G1) are also accumulated. The S/UNI-622-MAX interprets the received payload pointers (H1, H2) and extracts the synchronous payload envelope which carries the received ATM cell payload.

When used to implement an ATM UNI or NNI, the S/UNI-622-MAX frames to the ATM payload using cell delineation. HCS error correction is provided. Idle/unassigned cells may be optionally dropped. Cells are also dropped upon detection of an uncorrectable header check sequence error. The ATM cell payloads are descrambled and are written to a four-cell FIFO buffer. The received cells are read from the FIFO using a 16-bit wide UTOPIA Level 2 (clocked up to 50 MHz) or an 8-bit wide UTOPIA Level 3 (clocked up to 100 MHz) datapath interface. Counts of received ATM cell headers that are errored and uncorrectable and those that are errored and correctable are accumulated independently for performance monitoring purposes.

The S/UNI-622-MAX transmits SONET/SDH streams using a bit serial interface. The S/UNI-622-MAX can also be configured for clock and data recovery and clock synthesis by-pass where it transmits the SONET/SDH frames via a byte-serial interface. The S/UNI-622-MAX synthesizes the transmit clock from a 77.76MHz frequency reference and performs framing pattern insertion (A1, A2), scrambling, alarm signal insertion, and creates section, line, and path bit interleaved parity codes (B1, B2, B3) as required to allow performance monitoring at the far end. Line and path remote error indications (M1, G1) are also inserted. The S/UNI-622-MAX also supports the insertion of a large variety of errors into the transmit stream, such as framing pattern errors, bit interleaved parity errors, and illegal pointers, which are useful for system diagnostics and tester applications.

RELEASED
S/UNI-622-MAX
DATASHEET
PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

PMC-Sierra, Inc.   **PM5356**
S/UNI-622-MAX

When used to implement an ATM UNI or NNI, ATM cells are written to an internal four cell FIFO using a 16-bit wide UTOPIA Level 2 (clocked up to 50 MHz) or an 8-bit wide UTOPIA Level 3 (clocked up to 100 MHz) datapath interface. Idle/unassigned cells are automatically inserted when the internal FIFO contains less than one complete cell. The S/UNI-622-MAX provides generation of the header check sequence and scrambles the payload of the ATM cells. Each of these transmit ATM cell processing functions can be enabled or bypassed.

No line rate clocks are required directly by the S/UNI-622-MAX as it synthesizes the transmit clock and recovers the receive clock using a 77.76 MHz reference clock. The S/UNI-622-MAX outputs a differential PECL line data (TXD+/-).

The S/UNI-622-MAX is configured, controlled and monitored via a generic 8-bit microprocessor bus interface. The S/UNI-622-MAX also provides a standard 5 signal IEEE 1149.1 JTAG test port for boundary scan board test purposes.

The S/UNI-622-MAX is implemented in low power, +3.3 Volt, CMOS technology. It has TTL compatible digital inputs and TTL/CMOS compatible digital outputs. High speed inputs and outputs support 3.3V and 5.0V compatible pseudo-ECL (PECL). The S/UNI-622-MAX is packaged in a 304 pin SBGA package.

                                                         S/UNI-622-MAX
9   PIN DESCRIPTION

9.1   Serial Line Side Interface Signals

Pin Name	Type	Pin No.	Function
RBYP	Input	E21	The receive bypass (RBYP) input disables clock recovery. If RBYP is high, RXD+/- is sampled on the rising edge of RRCLK+/-. If RBYP is low, the receive clock is recovered from the RXD+/- bit stream. Please refer to the Operation section for a discussion of the operating modes.
PECLV	Input	D22	The PECL signal voltage select (PELCV) selects between 3.3V PECL signaling and 5V PECL signaling for the PECL inputs. When PECLV is low, the PECL inputs expect a 5V PECL signal. When PECLV is high, the PECL inputs expect a 3.3V PECL signal. The PECL biasing pins PBIAS should be set to the appropriate voltage to prevent latchup. Please refer to the Operation section for a discussion of PECL interfacing issues.
REFCLK+ REFCLK-	Differential PECL Input	Y2 AA1	The differential reference clock inputs (REFCLK+/-) provides a jitter-free 77.76 MHz reference clock for both the clock recovery and the clock synthesis circuits. REFCLK+/- is not required if the clock recovery and clock synthesis features are not used. Please refer to the Operation section for a discussion of PECL interfacing issues and reference clocks.
RXD+ RXD-	Differential PECL Input	W1 V2	The receive differential data PECL inputs (RXD+/-) contain the NRZ bit serial receive stream. The receive clock is recovered from the RXD+/- bit stream when RBYP is set low. RXD+/- is sampled on the rising edge of RRCLK+/- when RBYP is set high. Please refer to the Operation section for a discussion of PECL interfacing issues.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

Pin Name	Type	Pin No.	Function
RRCLK+ RRCLK-	Differential PECL Input	U1 U2	When clock recovery is bypassed (RBYP set high), RRCLK+/- is nominally a 622.08 MHz 50% duty cycle clock and provides timing for the S/UNI-622-MAX receive functions. In this case, RXD+/- is sampled on the rising edge of RRCLK+/-. RRCLK+/- is ignored when RBYP is set low. Please refer to the Operation section for a discussion of PECL interfacing issues.
SD	PECL Input	R2	The receive signal detect PECL input (SD) indicates the presence of valid receive signal power from the Optical Physical Medium Dependent Device. A PECL logic high indicates the presence of valid data. A PECL logic low indicates a loss of signal. Please refer to the Operation section for a discussion of PECL interfacing issues
TXD+ TXD-	Differential PECL Output	L2 L1	The transmit differential data PECL outputs (TXD+/-) contain the 622.08 Mbit/s transmit stream. The TXD+/- outputs are driven using the synthesized clock from the CSU-622. Please refer to the Operation section for a discussion of PECL interfacing issues.

SATURN USER NETWORK INTERFACE (622-MAX)

9.2   Parallel Line Side Interface Signals - CRU and CSU Bypass

Pin Name	Type	Pin No.	Function
LIFSEL	Input	C23	The line interface select (LIFSEL) selects between serial and parallel line interface modes of operation.
			When tied high, the parallel mode is selected by-passing the clock and data recovery, clock synthesis and the serializer/de-serializer functions.
			When tied low, serial mode is selected, enabling clock and data recovery, clock synthesis and the serializer/de-serializer functions. During this operation, the parallel interface may be used for 1+1 APS operation. See the Operation section for more discussion of 1+1 APS support.
PICLK	Input	AC19	The parallel input clock (PICLK) provides timing for S/UNI-622-MAX receive function operation when the device is configured for the parallel interface mode of operation.
			When the RSOC3 bit is set high, PICLK is a 19.44 MHz nominally 50% duty cycle clock. When the RSOC3 bit is set low, PICLK is a 77.76 MHz nominally 50% duty cycle clock.
			When parallel operation is not used, PICLK may be used for 1+1 APS operation. See the Operation section for more discussion of 1+1 APS.
OOF	Output	AA18	The out of frame (OOF) signal is high while the S/UNI-622-MAX is out of frame. OOF is set low while the S/UNI-622-MAX is in-frame. An out of frame declaration occurs when four consecutive errored framing patterns (A1 and A2 bytes) have been received.
			OOF is intended to enable an upstream framing pattern detector to search for the framing pattern. This alarm indication is also available via register access. OOF is an asynchronous output with a minimum period of one PICLK clock.

ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

Pin Name	Type	Pin No.	Function
FPIN	Input	AB17	The active-high framing position input (FPIN) signal indicates the SONET/SDH frame position on the PIN[7:0] bus. In parallel interface operation, the byte on the PIN[7:0] bus indicated by FPIN is the third A2 of the SONET/SDH framing pattern. FPIN is sampled on the rising edge of PICLK. When parallel interface operation is not used, FPIN may be used for 1+1 APS operation. In this mode, FPIN marks the first synchronous payload envelope byte after the J0/Z0 bytes on PIN[7:0]. See the Operation section for more discussion of 1+1 APS.
PIN[0] PIN[1] PIN[2] PIN[3] PIN[4] PIN[5] PIN[6] PIN[7]	Input	AB18 AA17 AB16 AA16 Y16 AC15 AB15 AA15	In parallel interface operation, the data input (PIN[7:0]) bus carries the byte-serial STS-12c/STM-4-4c or STS-3c/STM-1 stream. PIN[7] is the most significant bit (corresponding to bit 1 of each serial byte, the first bit received). PIN[0] is the least significant bit (corresponding to bit 8 of each serial byte, the last bit received). PIN[7:0] is sampled on the rising edge of PICLK. When parallel interface operation is not used, PIN[7:0] may be used for 1+1 APS operation. In this mode, PIN[7:0] carries the byte-serial STS-12c/STM-4-4c transmit path. See the Operation section for more discussion of 1+1 APS.
PTCLK	Input	Y14	The parallel transmit clock (PTCLK) provides timing for S/UNI-622-MAX transmit function operation when the device is configured for the parallel interface mode of operation. When TOC3 is low, PTCLK should be a 77.76 MHz nominally 50% duty cycle clock free-running (non gapped) clock. When TOC3 is high, PTCLK should be a 19.44 MHz nominally 50% duty cycle clock.

SATURN USER NETWORK INTERFACE (622-MAX)

Pin Name	Type	Pin No.	Function
FPOUT	Output	AC14	In parallel interface operation, the parallel outgoing stream frame pulse (FPOUT) marks the frame alignment on the POUT[7:0] bus. FPOUT marks the first synchronous payload envelope byte after the J0/Z0 bytes. FPOUT is updated on the rising edge of PTCLK. When parallel interface operation is not used, FPOUT may be used for 1+1 APS operation. In this mode, FPOUT marks the first synchronous payload envelope byte after the J0/Z0 bytes. FPOUT is updated on the rising edge of TCLK. See the Operation section for more discussion of 1+1 APS.
POUT[0] POUT[1] POUT[2] POUT[3] POUT[4] POUT[5] POUT[6] POUT[7]	Output	AA14 AB14 AC13 AB13 AA13 Y13 AB12 AA12	In parallel interface operation, the parallel outgoing stream, (POUT[7:0]) carries the scrambled STS-12c/STM-4-4c or STS-3c/STM-1 stream in byte-serial format. POUT[7] is the most significant bit (corresponding to bit 1 of each serial word, the first bit transmitted). POUT[0] is the least significant bit (corresponding to bit 8 of each serial word, the last bit transmitted). POUT[7:0] is updated on the rising edge of PTCLK. When parallel interface operation is not used, POUT[7:0] may be used for 1+1 APS operation. In this mode, POUT[7:0] carries the byte-serial STS-12c/STM-4-4c transmit path and updates on the rising edge of TCLK. See the Operation section for more discussion of 1+1 APS.

SATURN USER NETWORK INTERFACE (622-MAX)

9.3 Clocks and Alarms Signals

Pin Name	Type	Pin No.	Function
RCLK	Output	AC20	The receive clock (RCLK) provides a timing reference for the S/UNI-622-MAX receive function outputs. RCLK is a 77.76 MHz, 50% duty cycle clock.
RFPO	Output	AB19	The receive frame pulse output (RFPO), when the framing alignment has been found (the OOF register bit is low), is an 8 kHz signal derived from the receive clock RCLK. RFPO pulses high for one RCLK cycle every 9720 RCLK cycles (STS-12c / STM-4-4c). RFPO is updated on the rising edge of RCLK.
RALRM	Output	AA19	The receive alarm (RALRM) output indicates the state of the receive framing. RALRM is low if no receive alarms are active. RALRM is optionally high if line AIS (LAIS), path AIS (PAIS), line RDI (LRDI), path RDI (PRDI), enhanced path RDI (PERDI), loss of signal (LOS), loss of frame (LOF), out of frame (OOF), loss of pointer (LOP), loss of pointer concatenation (LOPC/AISC), loss of cell delineation (LCD), signal fail BER (SFBER), signal degrade BER (SDBER), path trace identification mismatch (TIM) or path signal label mismatch (PSLM) is detected . RALRM is an asynchronous output with a minimum period of one RCLK clock.
TCLK	Output	B19	The transmit clock (TCLK) provides timing for the S/UNI-622-MAX transmit function operation. TCLK is a 77.76 MHz, 50% duty cycle clock.
TFPO	Output	A20	The active-high framing position output (TFPO) signal is an 8 kHz signal derived from the transmit clock TCLK. TFPO pulses high for one TCLK cycle every 9720 TCLK cycles (STS-12c / STM-4-4c). TFPO is updated on the rising edge of TCLK.

SATURN USER NETWORK INTERFACE (622-MAX)

Pin Name	Type	Pin No.	Function
TFCLK	Input	M22	UTOPIA transmit FIFO write clock (TFCLK) is used to write ATM cells to the four cell transmit FIFO. When in 16-bit Level 2 ATM mode, TFCLK must cycle at a 50 MHz to 40 MHz instantaneous rate, and must be a free running clock (cannot be gapped). When in 8-bit Level 3 ATM mode, TFCLK must cycle at a 100 MHz to 60 MHz instantaneous rate, and must be a free running clock (cannot be gapped).
TDAT[0] TDAT[1] TDAT[2] TDAT[3] TDAT[4] TDAT[5] TDAT[6] TDAT[7] TDAT[8] TDAT[9] TDAT[10] TDAT[11] TDAT[12] TDAT[13] TDAT[14] TDAT[15]	Input	K22 K21 K20 J23 J22 J21 H22 H21 H20 G23 G22 G21 G20 F22 F21 E23	The UTOPIA transmit cell data (TDAT[15:0]) bus carries the ATM cell octets that are written to the transmit FIFO. In 16-bit Level 2 ATM mode, the TDAT[15:0] is considered valid only when TENB is simultaneously asserted. In 8-bit Level 3 ATM mode, the TDAT[7:0] bus is considered valid only when TENB is simultaneously asserted. TDAT[15:8] are ignored. TDAT[15:0] is sampled on the rising edge of TFCLK.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

Pin Name	Type	Pin No.	Function
TSOC	Input	L21	The UTOPIA transmit start of cell (TSOC) signal marks the start of a cell structure on the TDAT bus. In 16-bit Level 2 ATM mode, the first word of the cell structure is present on the TDAT[15:0] bus when TSOC is high. It is not necessary for TSOC to be present for each cell. In 8-bit Level 3 ATM mode, the first byte of the cell structure is present on the TDAT[7:0] bus when TSOC is high. TSOC must be present for each cell. TSOC is considered valid only when TENB is simultaneously asserted. TSOC is sampled on the rising edge of TFCLK.
TPRTY	Input	L20	The UTOPIA transmit bus parity (TPRTY) signal indicates the parity on the TDAT bus. A parity error is indicated by a status bit and a maskable interrupt. Cells with parity errors are inserted in the transmit stream, so the TPRTY input may be unused. In 16-bit Level 2 ATM mode, the TPRTY signal indicates the parity on the TDAT[15:0] bus. Odd or even parity selection is made in the TXCP registers. In 8-bit Level 3 ATM mode, the TPRTY signal indicates the parity on the TDAT[7:0] bus. Odd or even parity selection is made in the TUL3 registers. TPRTY is considered valid only when TENB is simultaneously asserted. TPRTY is sampled on the rising edge of TFCLK.
TENB	Input	L22	The UTOPIA transmit write enable (TENB) signal is an active low input which is used to initiate writes to the transmit FIFO's. When TENB is sampled high, the information sampled on the TDAT, TPRTY and TSOC signals are invalid. When TENB is sampled low, the information sampled on the TDAT, TPRTY and TSOC signals are valid and are written into the transmit FIFO. TENB is sampled on the rising edge of TFCLK.

ISSUE 6

PM5356
S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

Pin Name	Type	Pin No.	Function
TCA	Output	L23	The UTOPIA transmit cell available (TCA) signal provides direct status indication of when cell space is available in the transmit FIFO.
			When set high, TCA indicates that the corresponding transmit FIFO is not full and a complete cell may be written. TCA is set low to either indicate that the transmit FIFO is near full or that the transmit FIFO is full. To reduce FIFO latency, the FIFO depth at which TCA indicates "full" can be set to one, two, three or four cells. Note that regardless of what fill level TCA is set to indicate "full" at, the transmit cell processor can store 4 complete cells.
			In 16-bit Level 2 ATM mode, TCA will transition low one TFCLK cycle after the payload word 19 or 23 (depending of the configuration in TXCP) is sampled on the TDAT[15:0] bus.
			In 8-bit Level 3 ATM mode, TCA will transition low on the rising edge of TFCLK before the payload byte 45 is sampled on the TDAT[7:0] bus.
			TCA is updated on the rising edge of TFCLK.
RFCLK	Input	M21	The UTOPIA receive FIFO read clock (RFCLK). RFCLK is used to read ATM cells from the four cell receive FIFO.
			When in 16-bit Level 2 ATM mode, RFCLK must cycle at a 50 MHz to 40 MHz instantaneous rate, and must be a free running clock (cannot be gapped).
			When in 8-bit Level 3 ATM mode, RFCLK must cycle at a 100 MHz to 60 MHz instantaneous rate, and must be a free running clock (cannot be gapped).

PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

Pin Name	Type	Pin No.	Function
RSOC	Output	P23	The UTOPIA receive start of cell (RSOC) signal marks the start of a cell structure on the RDAT bus. In 16-bit Level 2 ATM mode, the first word of the cell structure is present on the RDAT[15:0] bus when RSOC is high. RSOC is tri-stated when RENB is sampled high. In 8-bit Level 3 ATM mode, the first byte of the cell structure is present on the RDAT[7:0] bus when RSOC is high. RDAT[15:8] are invalid and must be ignored. RSOC is updated on the rising edge of RFCLK.
RPRTY	Output	P21	The UTOPIA receive parity (RPRTY) signal indicates the parity of the RDAT bus. When in 16-bit Level 2 ATM mode, the RPRTY signal indicates the parity on the RDAT[15:0] bus. RPRTY is tri-stated when RENB is sampled high. Odd or even parity selection is made in the RXCP registers. When in 8-bit Level 3 ATM mode, the RPRTY signal indicates the parity on the RDAT[7:0] bus. Odd or even parity selection is made in the RUL3 registers. RPRTY is updated on the rising edge of RFCLK.

PMC-Sierra, Inc.

Pin Name	Type	Pin No.	Function
RENB	Input	N23	The UTOPIA receive read enable (RENB) is used to initiate reads from the receive FIFO. The system may de-assert RENB if it is unable to accept more data.
			In 16-bit Level 2 ATM mode, a read is not performed and RDAT[15:0], RPRTY and RSOC will tristate when RENB is sampled high. When RENB is sampled low, the word on the RDAT[15:0] bus is read from the receive FIFO and changes to the next value on the next clock cycle.
			In 8-bit Level 3 ATM mode, a read is not performed and RDAT[7:0] does not change when RENB is sampled high. When RENB is sampled low, the word on the RDAT[7:0] bus is read from the receive FIFO and changes to the next value on the next clock cycle.
			RENB is sampled on the rising edge of RFCLK.
RCA	Output	N20	The UTOPIA receive cell available (RCA) provides direct status indication of when a cell is available in the receive FIFO.
			In 16-bit Level 2 mode, RCA can be configured to de-assert when either zero or four bytes remain in the FIFO. RCA will thus transition low on the rising edge of RFCLK after payload word 24 or 19 is output on the RDAT[15:0] bus depending on the RXCP registers.
			In 8-bit Level 3 mode, RCA is ignored as the RVAL signal identifies valid data on the RDAT[7:0] bus.
			RCA is updated on the rising edge of RFCLK.

SATURN USER NETWORK INTERFACE (622-MAX)

9.5   Microprocessor Interface Signals

Pin Name	Type	Pin No.	Function
CSB	Input	C11	The active-low chip select (CSB) signal is low during S/UNI-622-MAX register accesses. When CSB is high, the RDB and WRB inputs are ignored. When CSB is low, the RDB and WRB are valid. CSB must be high when RSTB is low to properly reset the chip. If CSB is not required (i.e., registers accesses are controlled using the RDB and WRB signals only), CSB must be connected to an inverted version of the RSTB input.
RDB	Input	B11	The active-low read enable (RDB) signal is low during S/UNI-622-MAX register read accesses. The S/UNI-622-MAX drives the D[7:0] bus with the contents of the addressed register while RDB and CSB are low.
WRB	Input	A11	The active-low write strobe (WRB) signal is low during a S/UNI-622-MAX register write accesses. The D[7:0] bus contents are clocked into the addressed register on the rising WRB edge while CSB is low.
D[0] D[1] D[2] D[3] D[4] D[5] D[6] D[7]	I/O	B17 A17 C16 B16 C15 B15 A15 D14	The bi-directional data bus D[7:0] is used during S/UNI-622-MAX register read and write accesses.
A[0] A[1] A[2] A[3] A[4] A[5] A[6] A[7]	Input	B14 A14 D13 C13 B13 A13 C12 B12	The address bus A[7:0] selects specific registers during S/UNI-622-MAX register accesses.

PMC-Sierra, Inc.

S/UNI-622-MAX

Pin Name	Type	Pin No.	Function
A[8]	Input	D11	The test register select (A[8]) signal selects between normal and test mode register accesses. A[8] is high during test mode register accesses, and is low during normal mode register accesses. A[8] may be tied low.
RSTB	Input	B10	The active-low reset (RSTB) signal provides an asynchronous S/UNI-622-MAX reset. RSTB is a Schmitt triggered input with an integral pull-up resistor. CSB must be held high when RSTB is low in order to properly reset this chip.
ALE	Input	A10	The address latch enable (ALE) is active-high and latches the address bus A[8:0] when low. When ALE is high, the internal address latches are transparent. It allows the S/UNI-622-MAX to interface to a multiplexed address/data bus. ALE has an integral pull-up resistor.
INTB	Output	C14	The active-low interrupt (INTB) signal is set low when a S/UNI-622-MAX interrupt source is active and that source is unmasked. The S/UNI-622-MAX may be enabled to report many alarms or events via interrupts. Examples of interrupt sources are loss of signal (LOS), loss of frame (LOF), line AIS, line remote defect indication (LRDI) detect, loss of pointer (LOP), path AIS, path remote defect indication and others. INTB is tri-stated when the all enabled interrupt sources are acknowledged via an appropriate register access. INTB is an open drain output.

S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

Notes on Pin Description:

1. All S/UNI-622-MAX inputs and bi-directional signals present minimum capacitive loading and operate at TTL logic levels except the inputs marked as Analog or differential pseudo-ECL (PECL).

2. The RDAT[15:0], RPRTY, RSOC/RSOP, REOP, RMOD, RERR, RCA/RPA, RVAL, RCLK, RFPO, TCA/TPA, TCLK, TFPO, POUT[7:0], FPOUT and OOF outputs have a 8mA drive capability. The TDO and INTB outputs have a 2mA drive capability. All other digital outputs and bi-directional signals have 4mA drive capability.

3. The system interface inputs RFCLK, RENB, TFCLK, TENB, TDAT[15:0], TMOD, TERR, TSOC/TSOP, TEOP and TPRTY do not use the ESD bias voltages (VBIAS and PBIAS pins) and are 3.3V tolerate only. All other digital inputs (excluding inputs marked Analog), may operate with 5V signalling with appropriate ESD biasing.

4. The differential pseudo-ECL inputs and outputs should be terminated in a passive network and interface at PECL levels as described in the Operation section.

5. It is mandatory that every digital ground pin (VSS) be connected to the printed circuit board ground plane to ensure reliable device operation.

6. It is mandatory that every digital power pin (VDD) be connected to the printed circuit board power plane to ensure reliable device operation.

7. All analog power and ground pins can be sensitive to noise. They must be isolated from the digital power and ground. Care must be taken to correctly decouple these pins. Please refer to the Operation section and the S/UNI-622-MAX reference design (PMC-981070) for more information.

8. Due to ESD protection structures in the pads it is necessary to exercise caution when powering a device up or down. ESD protection devices behave as diodes between power supply pins and from I/O pins to power supply pins. Under extreme conditions it is possible to damage these ESD protection devices or trigger latch up. Please adhere to the recommended power supply sequencing as described in the Operation section of this document.

                                                         S/UNI-622-MAX

10 FUNCTIONAL DESCRIPTION

10.1 Receive Line Interface (CRSI-622)

The Receive Line Interface allows direct interface of the S/UNI-622-MAX to optical modules (ODLs) or other medium interfaces. This block performs clock and data recovery on the incoming 622.08 Mbit/s data stream and SONET/SDH A1/A2 pattern framing.

Clock Recovery

The clock recovery unit recovers the clock from the incoming bit serial data stream and is compliant with SONET and SDH jitter tolerance requirements. The clock recovery unit utilizes a low frequency reference clock to train and monitor its clock recovery PLL. Under loss of transition conditions, the clock recovery unit continues to output a line rate clock that is locked to this reference for keep alive purposes. The clock recovery unit utilizes a 77.76 MHz reference clock. The clock recovery unit provides status bits that indicate whether it is locked to data or the reference and also supports diagnostic loopback and a loss of signal input that squelches normal input data.

Initially upon start-up, the PLL locks to the reference clock, REFCLK. When the frequency of the recovered clock is within 488 ppm of the reference clock, the PLL attempts to lock to the data. Once in data lock, the PLL reverts to the reference clock if no data transitions occur in 96 bit periods or if the recovered clock drifts beyond 488 ppm of the reference clock.

When the transmit clock is derived from the recovered clock (loop timing), the accuracy of the transmit clock is directly related to the REFCLK reference accuracy in the case of a loss of transition condition. To meet the Bellcore GR-253-CORE SONET Network Element free-run accuracy specification, the reference must be within +/-20 ppm. For LAN applications, the REFCLK accuracy may be relaxed to +/-50 ppm.

The loop filter transfer function is optimized to enable the PLL to track the jitter, yet tolerate the minimum transition density expected in a received SONET/SDH data signal. The total loop dynamics of the clock recovery PLL yield a jitter tolerance that exceeds the minimum tolerance specified for SONET/SDH equipment by GR-253-CORE.

Note that for frequencies below 300Hz, the jitter tolerance is greater than 22 UIpp; 22UIpp is the maximum jitter tolerance of the test equipment. The dip in

RELEASED

DATASHEET
PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

PMC-Sierra, Inc.   **PM5356**
                                                                    S/UNI-622-MAX

the jitter tolerance curve between 10 kHz and 30 kHz is due to the clock difference detector.

The typical jitter tolerance performance of the S/UNI-622-MAX is shown in Figure 3 with the GR-253-CORE jitter tolerance specification limits. The jitter tolerance setup used a Hewlett Packard HFBR-5208M multi-mode fiber optic transceiver with approximately -10 dBm input power. The RTYPE register bit in CRSI-622 was set to logic zero.

Note that for frequencies below 300Hz, the jitter tolerance is greater than 22 UIpp; 22UIpp is the maximum jitter tolerance of the test equipment. The dip in the jitter tolerance curve between 10 kHz and 30 kHz is due to the clock difference detector.

Figure 3: Typical STS-12c/STM-4-4c S/UNI-622-MAX Jitter Tolerance
Serial to Parallel Converter

The Serial to Parallel Converter (SIPO) converts the received bit serial stream to a byte serial stream. The SIPO searches for the initial SONET/SDH framing pattern in the receive stream, and performs serial to parallel conversion on octet boundaries.

PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

While out of frame, the CRSI-622 block monitors the bit-serial STS-12c/STM-4-4c data stream for an occurrence of a A1 byte. The CRSI-622 adjusts its byte alignment of the serial-to-parallel converter when three consecutive A1 bytes followed by three consecutive A2 bytes occur in the data stream. The CRSI informs the RSOP Framer block when this framing pattern has been detected to reinitializes the RSOP to the new frame alignment.

While in frame, the CRSI-622 maintains the byte alignment of the serial-to-parallel converter until RSOP declares out of frame.

10.2 Receive Section Overhead Processor (RSOP)

The Receive Section Overhead Processor (RSOP) provides frame synchronization, descrambling, section level alarm and performance monitoring. In addition, it extracts the section data communication channel from the section overhead and provides it serially on output RSD.

Framer

The Framer Block determines the in-frame/out-of-frame status of the receive stream. While in-frame, the framing bytes (A1, A2) in each frame are compared against the expected pattern. Out-of-frame is declared when four consecutive frames containing one or more framing pattern errors have been received.

While out of frame, the CRSI-622 block monitors the bit-serial STS-12c/STM-4-4c data stream for an occurrence of the framing pattern (A1, A2). The CRSI-622 informs the RSOP Framer block when three A1 bytes followed by three A2 bytes has been detected to reinitializes the frame byte counter to the new alignment. The Framer block declares frame alignment on the next SONET/SDH frame when either all A1 and A2 bytes are seen error-free or when only the first A1 byte and the first four bits of the last A2 byte are seen error-free depending upon the selected framing algorithm.

Once in frame, the Framer block monitors the framing pattern sequence and declares out of frame (OOF) when one or more bit errors in each framing pattern are detected for four consecutive frames. Again, depending upon the algorithm either 24 framing bytes are examined for bit errors each frame, or only the first A1 byte and the first four bits of the last A2 byte are examined for bit errors each frame.

When the parallel line interface PIN[7:0] is used, upstream circuitry monitors the receive stream for an occurrence of the three A1 bytes followed by three A2 bytes framing pattern while out-of-frame. The upstream circuitry is expected to pulse input FPIN when the third A2 byte has been detected. RSOP monitors the

S/UNI-622-MAX

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

receive data stream on PIN[7:0] for the framing pattern as before. Once in frame, RSOP monitors the framing pattern sequence and sets the OOF pin when one or more bit errors in each framing pattern are detected for four consecutive frames.

Descramble

The Descramble Block utilizes a frame synchronous descrambler to process the receive stream. The generating polynomial is $x^7 + x^6 + 1$ and the sequence length is 127. Details of the descrambling operation are provided in the references. Note that the framing bytes (A1 and A2) and the trace/growth bytes (J0/Z0) are not descrambled. A register bit is provided to disable the descrambling operation.

Error Monitor

The Error Monitor Block calculates the received section BIP-8 error detection code (B1) based on the scrambled data of the complete STS-12c/STM-4-4c frame. The section BIP-8 code is based on a bit interleaved parity calculation using even parity. The calculated BIP-8 code is compared with the BIP-8 code extracted from the B1 byte of the following frame. Differences indicate that a section level bit error has occurred. Up to 64000 (8 x 8000) bit errors can be detected per second. The Error Monitor Block accumulates these section level bit errors in a 16-bit saturating counter that can be read via the microprocessor interface. Circuitry is provided to latch this counter so that its value can be read while simultaneously resetting the internal counter to 0 or 1, if appropriate, so that a new period of accumulation can begin without loss of any events. It is intended that this counter be polled at least once per second so as not to miss bit error events.

Loss of Signal

The Loss of Signal Block monitors the scrambled data of the receive stream for the absence of 1's or 0's. When 20 ± 3 μs of all zeros patterns or all ones patterns are detected, a loss of signal (LOS) is declared. Loss of signal is cleared when two valid framing words are detected and during the intervening time, no loss of signal condition is detected.   The LOS signal is optionally reported on the RALRM output pin when enabled by the LOSEN Receive Alarm Control Register bit.

Loss of Frame

The Loss of Frame Block monitors the in-frame / out-of-frame status of the Framer Block. A loss of frame (LOF) is declared when an out-of-frame (OOF) condition persists for 3 ms. The LOF is cleared when an in-frame condition

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

persists for a period of 3 ms. To provide for intermittent out-of-frame (or in-frame) conditions, the 3 ms timer is not reset to zero until an in-frame (or out-of-frame) condition persists for 3 ms. The LOF and OOF signals are optionally reported on the RALRM output pin when enabled by the LOFEB and OOFEN Receive Alarm Control Register bits.

10.3 Receive Line Overhead Processor (RLOP)

The Receive Line Overhead Processor (RLOP) provides line level alarm and performance monitoring.

Line RDI Detect

The Line RDI Detect Block detects the presence of Line Remote Defect Indication (LRDI) in the receive stream. Line RDI is declared when a 110 binary pattern is detected in bits 6, 7, and 8 of the K2 byte, for three or five consecutive frames. Line RDI is removed when any pattern other than 110 is detected in bits 6, 7, and 8 of the K2 byte for three or five consecutive frames. The LRDI signal is optionally reported on the RALRM output pin when enabled by the LRDIEN Receive Alarm Control Register bit.

Line AIS Detect

The Line AIS Block detects the presence of a Line Alarm Indication Signal (LAIS) in the receive stream. Line AIS is declared when a 111 binary pattern is detected in bits 6, 7, and 8 of the K2 byte, for three or five consecutive frames. Line AIS is removed when any pattern other than 111 is detected in bits 6, 7, and 8 of the K2 byte for three or five consecutive frames. The LAIS signal is optionally reported on the RALRM output pin when enabled by the LAISEN Receive Alarm Control Register bit.

Error Monitor Block

The Error Monitor Block calculates the received line BIP-8 error detection codes based on the Line Overhead bytes and synchronous payload envelopes of the STS-12c/STM-4-4c stream. The line BIP-8 code is a bit interleaved parity calculation using even parity. Details are provided in the references. The calculated BIP-8 codes are compared with the BIP-8 codes extracted from the following frame. Any differences indicate that a line layer bit error has occurred. Optionally the RLOP can be configured to count a maximum of only one BIP error per frame.

This block also extracts the line FEBE code from the M1 byte. The FEBE code is contained in bits 2 to 8 of the M1 byte, and represents the number of line BIP-8

RELEASED
S/UNI-622-MAX
DATASHEET

PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

errors that were detected in the last frame by the far end. The FEBE code value has 97 legal values (0 to 96) for an STS-12c/STM-4-4c stream.   Illegal values are interpreted as zero errors.

The Error Monitor Block accumulates B2 error events and FEBE events in two 20-bit saturating counters that can be read via the CBI. The contents of these counters may be transferred to internal holding registers by writing to any one of the counter addresses, or by using the TIP register bit feature. During a transfer, the counter value is latched and the counter is reset to 0 (or 1, if there is an outstanding event). Note, these counters should be polled at least once per second to avoid saturation.

The B2 error event counters optionally can be configured to accumulate only "word" errors. A B2 word error is defined as the occurrence of one or more B2 bit error events during a frame. The B2 error counter is incremented by one for each frame in which a B2 word error occurs.

In addition the FEBE events counters optionally can be configured to accumulate only "word" events. A FEBE word event is defined as the occurrence of one or more FEBE bit events during a frame. The FEBE event counter is incremented by one for each frame in which a FEBE event occurs. If the extracted FEBE value is in the range 1 to 4 the FEBE event counter will be incremented for each and every FEBE bit. If the extracted FEBE value is greater than 4 the FEBE event counter will be incremented by 4.

10.4 The Receive APS, Synchronization Extractor and Bit Error Monitor (RASE)

Automatic Protection Switch Control

The Automatic Protection Switch (APS) control block filters and captures the receive automatic protection switch channel bytes (K1 and K2) allowing them to be read via the RASE APS K1 Register and the RASE APS K2 Register. The bytes are filtered for three frames before being written to these registers. A protection switching byte failure alarm is declared when twelve successive frames have been received, where no three consecutive frames contain identical K1 bytes. The protection switching byte failure alarm is removed upon detection of three consecutive frames containing identical K1 bytes. The detection of invalid APS codes is done in software by polling the RASE APS K1 Register and the RASE APS K2 Register.

Bit Error Rate Monitor

The Bit Error Monitor Block (BERM) calculates the received line BIP-96 error detection code (B2) based on the line overhead and synchronous payload

S/UNI-622-MAX
DATASHEET
PMC-1980589

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

envelope of the receive data stream. The line BIP-96 code is a bit interleaved parity calculation using even parity. Details are provided in the references. The calculated BIP code is compared with the BIP-96 code extracted from the B2 bytes of the following frame. Any differences indicate that a line layer bit error has occurred. Up to 768,000 (96 BIP/frame x 8000 frames/second) bit errors can be detected per second for STS-12c/STM-4-4c rate.

The BERM accumulates these line layer bit errors in a 20 bit saturating counter that can be read via the microprocessor interface. During a read, the counter value is latched and the counter is reset to 0 (or 1, if there is an outstanding event). Note, this counter should be polled at least once per second to avoid saturation that in turn may result in missed bit error events.

The BERM block is able to simultaneously monitor for signal fail (SF) or signal degrade (SD) threshold crossing and provide alarms through software interrupts. The bit error rates associated with the SF or SD alarms are programmable over a range of 10^{-3} to 10^{-9}. Details are provided in the Operation section.

Synchronization Status Extraction

The Synchronization Status Extraction (SSE) Block extracts the synchronization status (S1) byte from the line overhead. The SSE block can be configured to capture the S1 nibble after three or after eight frames with the same value (filtering turned on) or after any change in the value (filtering turned off). The S1 nibble can be read via the CBI interface.

10.5 Receive Path Overhead Processor (RPOP)

The Receive Path Overhead Processor (RPOP) provides pointer interpretation, extraction of path overhead, extraction of the synchronous payload envelope, and path level alarm indication and performance monitoring.

Pointer Interpreter

The Pointer Interpreter interprets the incoming pointer (H1, H2) as specified in the references. The pointer value is used to determine the location of the path overhead (the J1 byte) in the incoming STS-12c/STM-4-4c stream. The algorithm can be modeled by a finite state machine. Within the pointer interpretation algorithm three states are defined as shown below:

NORM_state (NORM)
AIS_state (AIS)
LOP_state (LOP)

RELEASED
S/UNI-622-MAX
DATASHEET

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

The transition between states will be consecutive events (indications), e.g., three consecutive AIS indications to go from the NORM_state to the AIS_state. The kind and number of consecutive indications activating a transition is chosen such that the behavior is stable and insensitive to low BER. The only transition on a single event is the one from the AIS_state to the NORM_state after receiving a NDF enabled with a valid pointer value. It should be noted that, since the algorithm only contains transitions based on consecutive indications, this implies that, for example, non-consecutively received invalid indications do not activate the transitions to the LOP_state.

Figure 4: Pointer Interpretation State Diagram
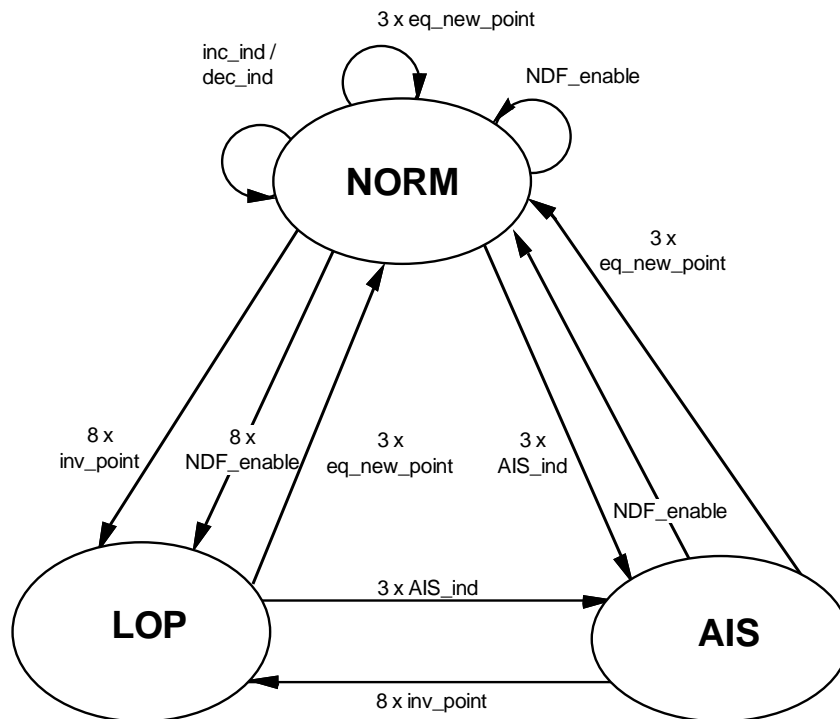

The following table defines the events (indications) shown in the state diagram.

Table 1: Pointer Interpreter Event (Indications) Description

Event (Indication)	Description
norm_point	disabled NDF + ss + offset value equal to active offset
NDF_enable	enabled NDF + ss + offset value in range of 0 to 782 or enabled NDF + ss, if NDFPOR bit is set (Note that the current pointer is not updated by an enabled NDF if the

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

	pointer is out of range).
AIS_ind	H1 = 'hFF, H2 = 'hFF
inc_ind	disabled NDF + ss + majority of I bits inverted + no majority of D bits inverted + previous NDF_enable, inc_ind or dec_ind more than 3 frames ago
dec_ind	disabled NDF + ss + majority of D bits inverted + no majority of I bits inverted + previous NDF_enable, inc_ind or dec_ind more than 3 frames ago
inv_point	not any of above (i.e., not norm_point, and not NDF_enable, and not AIS_ind, and not inc_ind and not dec_ind)
new_point	disabled_NDF + ss + offset value in range of 0 to 782 but not equal to active offset
inc_req	majority of I bits inverted + no majority of D bits inverted
dec_req	majority of D bits inverted + no majority of I bits inverted

Note 1-   active offset is defined as the accepted current phase of the SPE (VC) in the NORM_state and is undefined in the other states.

Note 2 -   enabled NDF is defined as the following bit patterns: 1001, 0001, 1101, 1011, 1000.

Note 3 -   disabled NDF is defined as the following bit patterns: 0110, 1110, 0010, 0100, 0111.

Note 4 -   the remaining six NDF codes (0000, 0011, 0101, 1010, 1100, 1111) result in an inv_ndf indication.

Note 5 -   ss bits are unspecified in SONET and has bit pattern 10 in SDH

Note 6 -   the use of ss bits in definition of indications may be optionally disabled.

Note 7 -   the requirement that previous NDF_enable, inc_ind or dec_ind be more than 3 frames ago may be optionally disabled.

Note 8 -   new_point is also an inv_point.

Note 9 -   LOP is not declared if all the following conditions exist:
• the received pointer is out of range (>782),
• the received pointer is static,

PMC-Sierra, Inc.

**PM5356
S/UNI-622-MAX**

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

- the received pointer can be interpreted, according
  to majority voting on the I and D bits, as a
  positive or negative justification indication,
- after making the requested justification, the received
  pointer continues to be interpretable as a
  pointer justification.

When the received pointer returns to an in-range value, the S/UNI-622-MAX will interpret it correctly.

Note 10 -   LOP will exit at the third frame of a three frame sequence consisting of one frame with NDF enabled followed by two frames with NDF disabled, if all three pointers have the same legal value.

The transitions indicated in the state diagram are defined in the following table.

Table 2: Pointer Interpreter Transition Description

Transition	Description
inc_ind/dec_ind	offset adjustment (increment or decrement indication)
3 x eq_new_point	three consecutive equal new_point indications
NDF_enable	single NDF_enable indication
3 x AIS_ind	three consecutive AIS indications
8 x inv_point	eight consecutive inv_point indications
8 x NDF_enable	eight consecutive NDF_enable indications

Note 1 -   the transitions from NORM_state to NORM_state do not represent state changes but imply offset changes.

Note 2 -   3 x new_point takes precedence over other events and if the IINVCNT bit is set resets the inv_point count.

Note 3 -   all three offset values received in 3 x eq_new_point must be identical.

Note 4 -   "consecutive event counters" are reset to zero on a change of state except for consecutive NDF count.

The Pointer Interpreter detects loss of pointer (LOP) in the incoming STS-12c/STM-4-4c stream. LOP is declared on entry to the LOP_state as a result of eight consecutive invalid pointers or eight consecutive NDF enabled indications. The alarm condition is reported in the receive alarm port and is optionally

S/UNI-622-MAX**

ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

returned to the source node by signaling the corresponding Transmit Path Overhead Processor in the local S/UNI-622-MAX to insert a path RDI indication.

The Pointer Interpreter detects path AIS in the incoming STS-12c/STM-4-4c stream. PAIS is declared on entry to the AIS_state after three consecutive AIS indications. The alarm condition reported in the receive alarm port and is optionally returned to the source node by signaling the corresponding Transmit Path Overhead Processor in the local SONET/SDH equipment to insert a path RDI indication.

Invalid pointer indications (inv_point), invalid NDF codes, new pointer indications (new_point), discontinuous change of pointer alignment, and illegal pointer changes are also detected and reported by the Pointer Interpreter block via register bits. An invalid NDF code is any NDF code that does not match the NDF enabled or NDF disabled definitions. The third occurrence of equal new_point indications (3 x eq_new_point) is reported as a discontinuous change of pointer alignment event (DISCOPA) instead of a new pointer event and the active offset is updated with the receive pointer value. An illegal pointer change is defined as a inc_ind or dec_ind indication that occurs within three frames of the previous inc_ind, dec_ind or NDF_enable indications. Illegal pointer changes may be optionally disabled via register bits.

The active offset value is used to extract the path overhead from the incoming stream and can be read from an internal register.

SPE Timing

The SPE Timing Block provides SPE timing information to the Error Monitor and the Extract blocks. The block contains a free running timeslot counter that is initialized by a J1 byte identifier (which identifies the first byte of the SPE). Control signals are provided to the Error Monitor and the Extract blocks to identify the Path Overhead bytes and to downstream circuitry to extract the ATM cell payload.

Error Monitor

The Error Monitor Block contains two 16-bit counters that are used to accumulate path BIP-8 errors (B3), and far end block errors (FEBEs). The contents of the two counters may be transferred to holding registers, and the counters reset under microprocessor control.

Path BIP-8 errors are detected by comparing the path BIP-8 byte (B3) extracted from the current frame, to the path BIP-8 computed for the previous frame.

PM5356
S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

FEBEs are detected by extracting the 4-bit FEBE field from the path status byte (G1). The legal range for the 4-bit field is between 0000 and 1000, representing zero to eight errors. Any other value is interpreted as zero errors.

Path RDI alarm is detected by extracting bit 5 of the path status byte. The PRDI signal is set high when bit 5 is set high for five/ten consecutive frames. PRDI is set low when bit 5 is low for five/ten consecutive frames. Auxiliary RDI alarm is detected by extracting bit 6 of the path status byte. The Auxiliary RDI alarm is indicated when bit 6 is set high for five/ten consecutive frames. The Auxiliary RDI alarm is removed when bit 6 is low for five/ten consecutive frames. The Enhanced RDI alarm is detected when the enhanced RDI code in bits 5,6,7 of the path status byte indicates the same error codepoint for five/ten consecutive frames. The Enhanced RDI alarm is removed when the enhanced RDI code in bits 5,6,7 of the path status byte indicates the same non error codepoint for five/ten consecutive frames. The ERDII maskable interrupt is set high when bits 5, 6 & 7 of the path status byte (G1) byte are set to a new codepoint for five or ten consecutive frames. The ERDIV[2:0] signal reflects the state of the filtered ERDI value (G1 byte bits 5, 6, & 7).

10.6 Receive ATM Cell Processor (RXCP)

The Receive ATM Cell Processor (RXCP) performs ATM cell delineation, provides cell filtering based on idle/unassigned cell detection and HCS error detection, and performs ATM cell payload descrambling. The RXCP also provides a four-cell deep receive FIFO. This FIFO is used to separate the STS-12c/STM-4-4c line timing from the higher layer ATM system timing.

Cell Delineation

Cell Delineation is the process of framing to ATM cell boundaries using the header check sequence (HCS) field found in the cell header. The HCS is a CRC-8 calculation over the first 4 octets of the ATM cell header. When performing delineation, correct HCS calculations are assumed to indicate cell boundaries. Cells are assumed to be byte-aligned to the synchronous payload envelope. The cell delineation algorithm searches the 53 possible cell boundary candidates individually to determine the valid cell boundary location. While searching for the cell boundary location, the cell delineation circuit is in the HUNT state. When a correct HCS is found, the cell delineation state machine locks on the particular cell boundary, corresponding to the correct HCS, and enters the PRESYNC state. The PRESYNC state validates the cell boundary location. If the cell boundary is invalid, an incorrect HCS will be received within the next DELTA cells, at which time a transition back to the HUNT state is executed. If no HCS errors are detected in this PRESYNC period, the SYNC state is entered. While in the SYNC state, synchronization is maintained until ALPHA consecutive incorrect

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

HCS patterns are detected. In such an event a transition is made back to the HUNT state. The state diagram of the delineation process is shown in Figure 5.

Figure 5: Cell Delineation State Diagram
The values of ALPHA and DELTA determine the robustness of the delineation process. ALPHA determines the robustness against false misalignments due to bit errors. DELTA determines the robustness against false delineation in the synchronization process. ALPHA is chosen to be 7 and DELTA is chosen to be 6. These values result in an average time to delineation of 8 µs for the STS-12c/STM-4-4c rate.

Descrambler

The self-synchronous descrambler operates on the 48 byte cell payload only. The circuitry descrambles the information field using the $x^{43} + 1$ polynomial. The descrambler is disabled for the duration of the header and HCS fields and may optionally be disabled for the payload.

Cell Filter and HCS Verification

Cells are filtered (or dropped) based on HCS errors and/or a cell header pattern. Cell filtering is optional and is enabled through the RXCP registers. Cells are

S/UNI-622-MAX

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

passed to the receive FIFO while the cell delineation state machine is in the SYNC state as described above. When both filtering and HCS checking are enabled, cells are dropped if uncorrectable HCS errors are detected, or if the corrected header contents match the pattern contained in the RXCP Match Header Pattern and RXCP Match Header Mask registers. Idle or unassigned cell filtering is accomplished by writing the appropriate cell header pattern into the RXCP Match Header Pattern and RXCP Match Header Mask registers. Idle/Unassigned cells are assumed to contain the all zeros pattern in the VCI and VPI fields. The RXCP Match Header Pattern and RXCP Match Header Mask registers allow filtering control over the contents of the GFC, PTI, and CLP fields of the header.

The HCS is a CRC-8 calculation over the first 4 octets of the ATM cell header. The RXCP block verifies the received HCS using the polynomial, $x^8 + x^2 + x + 1$. The coset polynomial, $x^6 + x^4 + x^2 + 1$, is added (modulo 2) to the received HCS octet before comparison with the calculated result. While the cell delineation state machine in Figure 5 is in the SYNC state, the HCS verification circuit implements the state machine shown in Figure 6.

In normal operation, the HCS verification state machine remains in the 'Correction Mode' state. Incoming cells containing no HCS errors are passed to the receive FIFO. Incoming single-bit errors are corrected, and the resulting cell is passed to the FIFO. Upon detection of a single-bit error or a multi-bit error, the state machine transitions to the 'Detection Mode' state. In this state, programmable HCS error filtering is provided. The detection of any HCS error causes the corresponding cell to be dropped. The state machine transitions back to the 'Correction Mode' state when M (where M = 1, 2, 4, 8) cells are received with correct HCSs. The Mth cell is not discarded.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

Figure 6: HCS Verification State Diagram
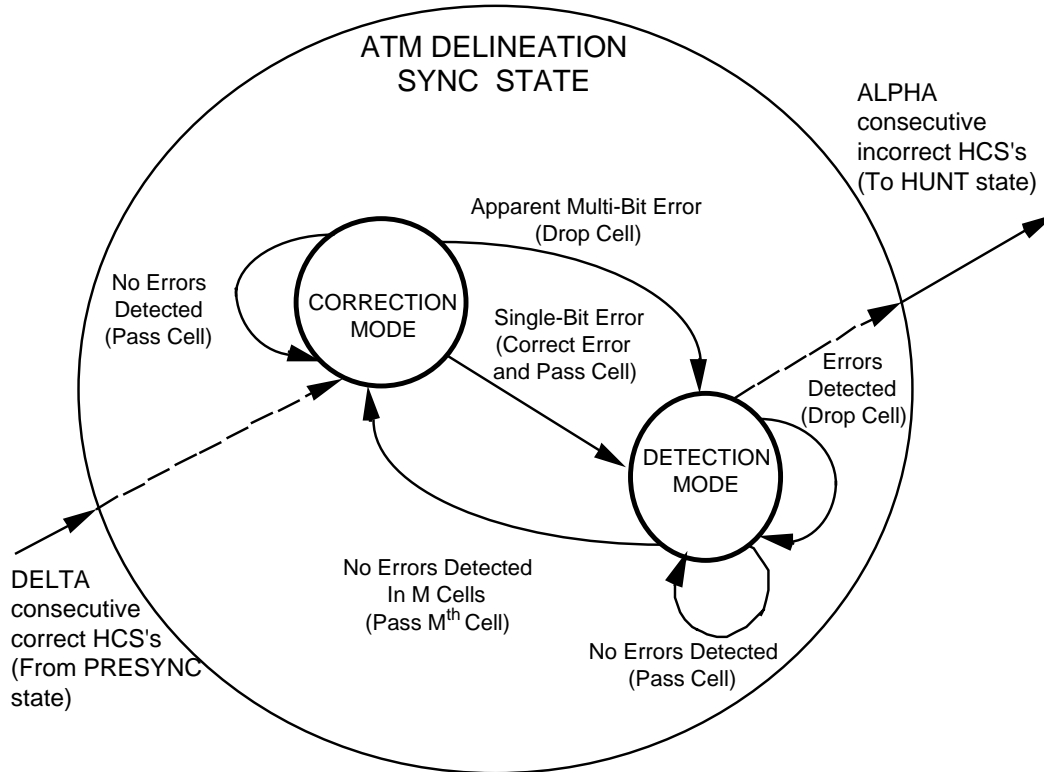

Performance Monitor

The Performance Monitor consists of two 8-bit saturating HCS error event counters and a 24-bit saturating receive cell counter. The first error counter accumulates correctable HCS errors, which are HCS single-bit errors, detected and corrected while the HCS Verification state machine is in the 'Correction Mode' state. The second error counter accumulates uncorrectable HCS errors, which are HCS bit errors detected while the HCS Verification state machine is in the 'Detection Mode' state or HCS bit errors detected but not corrected while the state machine is in the 'Correction Mode' state. The 24-bit receive cell counter counts all cells written into the receive FIFO. Filtered cells are not counted.

Each counter may be read through the microprocessor interface. Circuitry is provided to latch these counters so that their values can be read while simultaneously resetting the internal counters to 0 or 1, if appropriate, so that a new period of accumulation can begin without loss of any events. It is intended that the counter be polled at least once per second so as not to miss any counted events.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

Receive FIFO

The Receive FIFO block contains storage for 4 cells, along with management circuitry for reading and writing the FIFO. The receive FIFO provides for the separation of the physical layer timing from the system timing.

Receive FIFO management functions include filling the receive FIFO, indicating when cells are available to be read from the receive FIFO, maintaining the receive FIFO read and write pointers, and detecting FIFO overrun conditions. Upon detection of an overrun, the FIFO discards the current cell and discards the incoming cells until there is room in the FIFO. FIFO overruns are indicated through a maskable interrupt and register bit and are considered a system error.

10.7 Transmit Line Interface (CSPI-622)

The Transmit Line Interface allows to directly interface the S/UNI-622-MAX with optical modules (ODLs) or other medium interfaces. This block performs clock synthesis and performs parallel to serial conversion on the incoming outgoing 622.08 Mbit/s data stream.

Clock Synthesis

The transmit clock is synthesized from a 77.76 MHz reference by the clock synthesis unit (CSU). The transfer function yields a typical low pass corner of 1 MHz, above which reference jitter is attenuated at least 20 dB per octave. The design of the loop filter and PLL is optimized for minimum intrinsic jitter. With a jitter free 77.76 MHz reference, the intrinsic jitter is typically less than 0.07 UI RMS when measured using a high pass filter with a 12 kHz cutoff frequency.

The REFCLK reference should be within ±20 ppm to meet the SONET/SDH free-run accuracy requirements specified in GR-253-CORE. The CSU may require a software reset when the supply voltage drops below the minimum operating level. See the CSPI-622 register description for more information.

Parallel to Serial Converter

The Parallel to Serial Converter (PISO) converts the transmit byte serial stream to a bit serial stream. The transmit bit serial stream appears on the TXD+/-PECL output. When the parallel transmit interface mode is used, the PISO block is not used.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

10.8 Transmit Section Overhead Processor (TSOP)

The Transmit Section Overhead Processor (TSOP) provides frame pattern insertion (A1, A2), scrambling, section level alarm signal insertion, and section BIP-8 (B1) insertion. In addition, it inserts the section data communication channel provided serially on input TSD.

Line AIS Insert

Line AIS insertion results in all bits of the SONET/SDH frame being set to 1 before scrambling except for the section overhead. The Line AIS Insert Block substitutes all ones as described when enabled by the TLAIS input or through an internal register accessed through the microprocessor interface. Activation or deactivation of line AIS insertion is synchronized to frame boundaries.

BIP-8 Insert

The BIP-8 Insert Block calculates and inserts the BIP-8 error detection code (B1) into the transmit stream.

The BIP-8 calculation is based on the scrambled data of the complete STS-12c/STM-4-4c frame. The section BIP-8 code is based on a bit interleaved parity calculation using even parity. Details are provided in the references. The calculated BIP-8 code is then inserted into the B1 byte of the following frame before scrambling. BIP-8 errors may be continuously inserted under register control for diagnostic purposes.

Framing and Identity Insert

The Framing and Identity Insert Block inserts the framing bytes (A1, A2) and trace/growth bytes (J0/Z0) into the STS-12c/STM-4-4c frame. Framing bit errors may be continuously inserted under register control for diagnostic purposes.

Scrambler

The Scrambler Block utilizes a frame synchronous scrambler to process the transmit stream when enabled through an internal register accessed via the microprocessor interface. The generating polynomial is $x^7 + x^6 + 1$. Precise details of the scrambling operation are provided in the references. Note that the framing bytes and the identity bytes are not scrambled. All zeros may be continuously inserted (after scrambling) under register control for diagnostic purposes.

                                                         S/UNI-622-MAX

The POUT[7:0] outputs are provided by the Scrambler block and are updated with timing aligned to TCLK. It also provides the FPOUT signal.

10.9 Transmit Line Overhead Processor (TLOP)

The Transmit Line Overhead Processor (TLOP) provides line level alarm signal insertion, and line BIP-96 insertion (B2). In addition, it inserts the line data communication provided serially on input TLD.

APS Insert

The APS Insert Block inserts the two automatic protection switch (APS) channel bytes in the Line Overhead (K1 and K2) into the transmit stream when enabled by an internal register.

Line BIP Calculate

The Line BIP Calculate Block calculates the line BIP-96 error detection code (B2) based on the line overhead and synchronous payload envelope of the transmit stream. The line BIP-96 code is a bit interleaved parity calculation using even parity. Details are provided in the references. The calculated BIP-96 code is inserted into the B2 byte positions of the following frame. BIP-96 errors may be continuously inserted under register control for diagnostic purposes.

Line RDI Insert

The Line RDI Insert Block controls the insertion of line remote defect indication. Line RDI insertion is enabled through register control. Line RDI is inserted by transmitting the code 110 (binary) in bit positions 6, 7, and 8 of the K2 byte contained in the transmit stream.

Line FEBE Insert

The Line FEBE Insert Block accumulates line BIP-96 errors (B2) detected by the Receive Line Overhead Processor and encodes far end block error indications in the transmit Z2 byte.

10.10 Transmit Path Overhead Processor (TPOP)

The Transmit Path Overhead Processor (TPOP) provides transport frame alignment generation, pointer generation (H1, H2), path overhead insertion and the insertion of path level alarm signals.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

Pointer Generator

The Pointer Generator Block generates the outgoing payload pointer (H1, H2) as specified in the references. The concatenation indication (the NDF field set to 1001, I-bits and D-bits set to all ones, and unused bits set to all zeros) is inserted in the second and third pointer byte locations in the transmit stream.

(1) A "normal pointer value" locates the start of the SPE. Note: $0 \leq$ "normal pointer value" ≤ 782, and the new data flag (NDF) field is set to 0110. Note that values greater than 782 may be inserted, using internal registers, to generate a loss of pointer alarm in downstream circuitry.

(2) Arbitrary "pointer values" may be generated using internal registers. These new values may optionally be accompanied by a programmable new data flag. New data flags may also be generated independently using internal registers.

(3) Positive pointer movements may be generated using a bit in an internal register. A positive pointer movement is generated by inverting the five I-bits of the pointer word. The SPE is not inserted during the positive stuff opportunity byte position, and the pointer value is incremented by one. Positive pointer movements may be inserted once per frame for diagnostic purposes.

(4) Negative pointer movements may be generated using a bit in an internal register. A negative pointer movement is generated by inverting the five D-bits of the pointer word. The SPE is inserted during the negative stuff opportunity byte position, the H3 byte, and the pointer value is decremented by one. Negative pointer movements may be inserted once per frame for diagnostic purposes.

The pointer value is used to insert the path overhead into the transmit stream. The current pointer value may be read via internal registers.

BIP-8 Calculate

The BIP-8 Calculate Block performs a path bit interleaved parity calculation on the SPE of the transmit stream. Details are provided in the references. The resulting parity byte is inserted in the path BIP-8 (B3) byte position of the subsequent frame. BIP-8 errors may be continuously inserted under register control for diagnostic purposes.

FEBE Calculate

The FEBE Calculate Block accumulates far end block errors on a per frame basis, and inserts the accumulated value (up to maximum value of eight) in the FEBE bit positions of the path status (G1) byte. The FEBE information is derived from path BIP-8 errors detected by the receive path overhead processor, RPOP.

Far end block errors may be inserted under register control for diagnostic purposes.

10.11 Transmit ATM Cell Processor (TXCP)

The Transmit ATM Cell Processor (TXCP) provides rate adaptation via idle/unassigned cell insertion, provides HCS generation and insertion, and performs ATM cell scrambling. The TXCP contains a four cell transmit FIFO. An idle or unassigned cell is transmitted if a complete ATM cell has not been written into the FIFO.

Transmit FIFO

The Transmit FIFO is responsible for holding cell provided through the Transmit System Interface until they are transmitted. The transmit FIFO can accommodate a maximum of 4 cells. The cells are written in with a single 16 bit data bus running off TFCLK and are read out using the SONET/SDH clock. Internal read and write pointers track the cells and indicate the fill status of the Transmit FIFO. Separate read and write clock domains provide for separation of the physical layer line timing from the System Link layer timing (TFCLK).

Idle/Unassigned Cell Generator

The Idle/Unassigned Cell Generator inserts idle or unassigned cells into the cell stream when enabled. Registers are provided to program the GFC, PTI, and CLP fields of the idle cell header and the idle cell payload. The idle cell HCS is automatically calculated and inserted.

Scrambler

The Scrambler scrambles the 48 octet information field. Scrambling is performed using a parallel implementation of the self-synchronous scrambler ($x^{43} + 1$ polynomial). The cell headers are transmitted unscrambled, and the scrambler may optionally be disabled.

HCS Generator

The HCS Generator performs a CRC-8 calculation over the first four header octets. A parallel implementation of the polynomial, x^8+x^2+x+1, is used. The coset polynomial, $x^6+x^4+x^2+1$, is added (modulo 2) to the residue. The HCS Generator optionally inserts the result into the fifth octet of the header.

                                                        S/UNI-622-MAX

10.12 ATM UTOPIA System Interfaces

The S/UNI-622-MAX system interface can be configured for ATM cell data. The system interface provides either a UTOPIA level 2 compliant bus or a UTOPIA Level 3 compatible bus to allow the transfer of ATM cells between the ATM layer device and the S/UNI-622-MAX.

10.12.1   Receive ATM Interface

The Receive ATM FIFO (RXCP) provides FIFO management at the S/UNI-622-MAX receive cell interface. The receive FIFO contains four cells. The FIFO provides the cell rate decoupling function between the transmission system physical layer and the ATM layer.

In general, the management functions include filling the receive FIFO, indicating when the receive FIFO contains cells, maintaining the receive FIFO read and write pointers, and detecting FIFO overrun and underrun conditions.

UTOPIA Level 2 Interface

The UTOPIA Level 2 compliant interface accepts a read clock (RFCLK) and read enable signal (RENB). The interface indicates the start of a cell (RSOC) and the receive cell available status (RCA) when data is read from the receive FIFO (using the rising edges of RFCLK). The RCA status changes from available to unavailable when the FIFO is either empty (when RCALEVEL0 is high) or near empty (when RCALEVEL0 is low). This interface also indicates FIFO overruns via a maskable interrupt and register bits. Read accesses while RCA is a logic zero will output invalid data. The FIFO is reset on FIFO overrun, causing up to 4 cells to be lost.

UTOPIA Level 3 Interface

The UTOPIA Level 3 compliant interface accepts a read clock (RFCLK) and read enable signal (RENB). The interface indicates the start of a cell (RSOC) when data is read from the receive FIFO (using the rising edges of RFCLK). The RVAL signal indicates when data on the receive data bus RDAT[7:0] is valid. The RPRTY signal reports the parity on the RDAT[7:0] bus (selectable as odd or even parity). RVAL will not assert until RENB is asserted. This interface also indicates FIFO overruns via a maskable interrupt and register bits. Read accesses while RVAL is low are ignored and will output invalid data. The FIFO is reset on FIFO overrun, causing up to 4 cells to be lost.

ISSUE 6
SATURN USER NETWORK INTERFACE (622-MAX)

10.12.2 Transmit ATM Interface

The ATM Transmit FIFO (TXCP) provides FIFO management and the S/UNI-622-MAX transmit cell interface. The transmit FIFO contains four cells. The FIFO depth may be programmed to four, three, two, or one cells. The FIFO provides the cell rate decoupling function between the transmission system physical layer and the ATM layer.

In general, the management functions include emptying cells from the transmit FIFO, indicating when the transmit FIFO is full, maintaining the transmit FIFO read and write pointers and detecting a FIFO overrun condition.

The interface can be configured either as a 16-bit UTOPIA Level 2 interface, or as an 8-bit UTOPIA Level 3 interface.

UTOPIA Level 2 Interface

The UTOPIA Level 2 compliant interface accepts a write clock (TFCLK), a write enable signal (TENB), the start of a cell (TSOC) indication, and the parity bit (TPRTY), when data is written to the transmit FIFO (using the rising edges of TFCLK). The interface provides the transmit cell available status (TCA) which can transition from "available" to "unavailable" when the transmit FIFO is near full (when TCALEVEL0 is low) or when the FIFO is full (when TCALEVEL0 is high) and can accept no more writes. To reduce FIFO latency, the FIFO depth at which TCA indicates "full" can be set to one, two, three or four cells by the FIFODP[1:0] bits of the TXCP Configuration 2 register. If the programmed depth is less than four, more than one cell may be written after TCA is asserted as the TXCP still allows four cells to be stored in its FIFO.

This interface also indicates FIFO overruns via a maskable interrupt and register bit, but write accesses while TCA is low are not processed. The TXCP automatically transmits idle cells until a full cell is available to be transmitted.

UTOPIA Level 3 Interface

The UTOPIA Level 3 compliant interface accepts a write clock (TFCLK), a write enable signal (TENB), the start of a cell (TSOC) indication and the parity bit (TPRTY) when data is written to the transmit FIFO (using the rising edges of the TFCLK). To reduce FIFO latency, the FIFO depth at which TCA indicates "full" can be set to one, two, three or four cells by the FIFODP[1:0] bits of the TXCP Configuration 2 register. If the programmed depth is less than four, more than one cell may be written after TCA is asserted as the TXCP still allows four cells to be stored in its FIFO.

S/UNI-622-MAX

11 NORMAL MODE REGISTER DESCRIPTION

Normal mode registers are used to configure and monitor the operation of the S/UNI-622-MAX. Normal mode registers (as opposed to test mode registers) are selected when TRS (A[8]) is low.

Notes on Normal Mode Register Bits:

1.   Writing values into unused register bits has no effect. However, to ensure software compatibility with future, feature-enhanced versions of the product, unused register bits must be written with logic zero. Reading back unused bits can produce either a logic one or a logic zero; hence, unused register bits should be masked off by software when read.

2.   All configuration bits that can be written into can also be read back. This allows the processor controlling the S/UNI-622-MAX to determine the programming state of the block.

3.   Writable normal mode register bits are cleared to logic zero upon reset unless otherwise noted.

4.   Writing into read-only normal mode register bit locations does not affect S/UNI-622-MAX operation unless otherwise noted. Performance monitoring counter registers are a common exception.

5.   Certain register bits are reserved. These bits are associated with megacell functions that are unused in this application. To ensure that the S/UNI-622-MAX operates as intended, reserved register bits must be written with their default value as indicated by the register bit description.

6.   Writing any data to the Master Reset and Identity register (0x00) simultaneously loads all the performance monitoring registers in RSOP, RLOP, RPOP, SPTB, SSTB, RXCP, TXCP, RXFP and TXFP blocks in the device.

Writing any data to the performance register in question may individually trigger the performance registers in each block. In some cases, all performance registers in the block are loaded. In other cases, only the specific register being written will load. See the register descriptions for the performance register in question for more information.

PM5356
S/UNI-622-MAX

Register 0x00: S/UNI-622-MAX Master Reset and Identity

Bit	Type	Function	Default
Bit 7	R/W	RESET	0
Bit 6	R	TYPE[3]	0
Bit 5	R	TYPE[2]	1
Bit 4	R	TYPE[1]	1
Bit 3	R	TYPE[0]	1
Bit 2	R	ID[2]	0
Bit 1	R	ID[1]	1
Bit 0	R	ID[0]	0

This register allows the revision number of the S/UNI-622-MAX to be read by software permitting graceful migration to newer, feature-enhanced versions of the S/UNI-622-MAX.

In addition, writing to this register simultaneously loads all the performance monitor registers in the RSOP, RLOP, RPOP, SPTB, SSTB, RXCP, TXCP, RXFP, and TXFP blocks.

ID[2:0]:

The ID bits can be read to provide a binary S/UNI-622-MAX revision number.

TYPE[3:0]:

The TYPE bits can be read to distinguish the S/UNI-622-MAX from the other members of the S/UNI family of devices.

RESET:

The RESET bit allows the S/UNI-622-MAX to be reset under software control. If the RESET bit is a logic one, the entire S/UNI-622-MAX is held in reset. This bit is not self-clearing. Therefore, a logic zero must be written to bring the S/UNI-622-MAX out of reset. Holding the S/UNI-622-MAX in a reset state places it into a low power, stand-by mode. A hardware reset clears the RESET bit, thus negating the software reset. Otherwise, the effect of a software reset is equivalent to that of a hardware reset.

ISSUE 6

PM5356
S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x01: S/UNI-622-MAX Master Configuration #1

Bit	Type	Function	Default
Bit 7	R/W	Reserved	0
Bit 6	R/W	Reserved	0
Bit 5	R/W	SDH_J0/Z0	0
Bit 4	R/W	TFPEN	1
Bit 3	R/W	DLE	0
Bit 2	R/W	PDLE	0
Bit 1	R/W	PCM	0
Bit 0	R	TIP	X

TIP:

The TIP bit is set to a logic one when the performance meter registers are being loaded. Writing to the S/UNI-622-MAX Master Reset and Identity register initiates an accumulation interval transfer and loads all the performance meter registers in the RSOP, RLOP, RPOP, SPTB, RXCP, TXCP and TXFP blocks.

TIP remains high while the transfer is in progress, and is set to a logic zero when the transfer is complete. TIP can be polled by a microprocessor to determine when the accumulation interval transfer is complete.

PCM:

The pointer concatenation mode select (PCM) determines the number of H1/H2 pointer pairs used to determine loss of pointer concatenation (LOPC) and pointer AIS (AISC). When PCM is set high, all H1/H2 pointer pairs are processed. When PCM is set low, only four H1/H2 pointer pairs (corresponding to the active STM-4-4c pointers) are processed.

PDLE:

The Parallel Diagnostic Loopback, PDLE bit enables the S/UNI-622-MAX diagnostic loopback where the S/UNI-622-MAX's Transmit Section Overhead Processor (TSOP) is directly connected to its Receive Section Overhead Processor (RSOP). When PDLE is logic one, loopback is enabled. Under this operating condition, the S/UNI-622-MAX continues to operate normally in the transmit direction. When PDLE is logic zero, the S/UNI-622-MAX operates normally in both directions.

PMC-Sierra, Inc.

**PM5356
S/UNI-622-MAX**

PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

DLE:

The Diagnostic Loopback, DLE bit enables the S/UNI-622-MAX diagnostic loopback where the S/UNI-622-MAX's Transmit ATM (TXCP) are directly connected to the Receive ATM (RXCP). When DLE is logic one, loopback is enabled. Under this operating condition, the S/UNI-622-MAX does not operate normally in the transmit direction or receive direction. When DLE is logic zero, the S/UNI-622-MAX operates normally.

TFPEN:

The Transmit Frame Pulse Enable (TFPEN) enables the TFPI input. When TFPEN is set low, the TFPI input is disabled. When TFPEN is set high, the TFPI input is enabled.

SDH_J0/Z0

The SDH_J0/Z0 bit selects whether to insert SONET or SDH format J0/Z0 section overhead bytes into the transmit stream. When SDH_J0/Z0 is set high, SDH format J0/Z0 bytes are selected for insertion. For this case, all the J0/Z0 bytes are forced to the value programmed in the S/UNI-622-MAX Transmit J0/Z0 register. When SDH_J0/Z0 is set low, SONET format J0/Z0 bytes are selected for insertion. For this case, the J0/Z0 bytes of a STS-N signal are numbered incrementally from 1 to N.

When SDH_J0/Z0 is set high, the transmit section trace buffer enable bit, TSTBEN can be used to overwrite the first J0/Z0 byte of a STS-N signal.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x02: S/UNI-622-MAX Master Configuration #2

Bit	Type	Function	Default
Bit 7	R/W	SLLE	0
Bit 6	R/W	SDLE	0
Bit 5	R/W	LOOPT	0
Bit 4	R/W	DPLE	0
Bit 3	R/W	AUTOLRDI	1
Bit 2	R/W	AUTOPRDI	1
Bit 1	R/W	AUTOLFEBE	1
Bit 0	R/W	AUTOPFEBE	1

AUTOPFEBE

The AUTOPFEBE bit determines if the remote path block errors are sent upon detection of an incoming path BIP error event. When AUTOPFEBE is set to logic one, one path FEBE is inserted for each path BIP error event, respectively. When AUTOPFEBE is set to logic zero, incoming path BIP error events do not generate FEBE events.

AUTOLFEBE

The AUTOLFEBE bit determines if remote line block errors are sent upon detection of an incoming line BIP error event. When AUTOLFEBE is set to logic one, one line FEBE is inserted for each line BIP error event, respectively. When AUTOLFEBE is set to logic zero, incoming line BIP error events do not generate FEBE events.

AUTOPRDI

The AUTOPRDI bit determines whether STS path remote defect indication (RDI) is sent immediately upon detection of an incoming alarm. When AUTOPRDI is set to logic one, STS path RDI is inserted immediately upon declaration of several alarms. Each alarm can individually be enabled and disabled using the S/UNI-622-MAX Path RDI Control Registers.

AUTOLRDI

The AUTOLRDI bit determines if line remote defect indication (RDI) is sent immediately upon detection of an incoming alarm. When AUTOLRDI is set to logic one, line RDI is inserted immediately upon declaration of several alarms.

PMC-Sierra, Inc.   **PM5356**
                                                                S/UNI-622-MAX

Each alarm can individually be enabled and disabled using the S/UNI-622-MAX Line RDI Control Registers.

DPLE:

The Diagnostic Path Loopback, DPLE bit enables the S/UNI-622-MAX diagnostic loopback where the S/UNI-622-MAX's Transmit Path Overhead Processor (TPOP) is directly connected to its Receive Path Overhead Processor (RPOP). When DPLE is logic one, loopback is enabled. Under this operating condition, the S/UNI-622-MAX continues to operates normally in the transmit direction. When DPLE is logic zero, the S/UNI-622-MAX operates normally.

LOOPT:

The LOOPT bit selects the source of timing for the transmit section of the channel. When LOOPT is a logic zero, the transmitter timing is derived from input REFCLK (Clock Synthesis Unit). When LOOPT is a logic one, the transmitter timing is derived from the recovered clock (Clock Recovery Unit). LOOPT should not be set if the WANS is being used. The SDLE, SLLE or LOOPT bits should not be set high simultaneously.

SDLE:

The SDLE bit enables the serial diagnostic loopback. When SDLE is a logic one, the transmit serial stream on the TXD+/- differential outputs is internally connected to the received serial RXD+/- differential inputs. Under this operating condition, the S/UNI-622-MAX continues to operates normally in the transmit direction. The SDLE, SLLE or LOOPT bits should not be set high simultaneously.

SLLE:

The SLLE bit enables the S/UNI-622-MAX line loopback mode when the device is configured for 622.08 Mbit/s serial line interface mode of operation. When SLLE is a logic one, the recovered data from the receive serial RXD+/- differential inputs is mapped to the TXD+/- differential outputs. Under this operating condition, the S/UNI-622-MAX continues to operates normally in the receive direction. The SDLE, SLLE or LOOPT bits should not be set high simultaneously.

S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x03: S/UNI-622-MAX Clock Monitors

Bit	Type	Function	Default
Bit 7	R	TCLKA	X
Bit 6	R	RCLKA	X
Bit 5	R	RFCLKA	X
Bit 4	R	TFCLKA	X
Bit 3	R	Unused	X
Bit 2	R	REFCLKA	X
Bit 1	R	PICLKA	X
Bit 0	R	PTCLKA	X

This register provides activity monitoring of the S/UNI-622-MAX clocks. When a monitored clock signal makes a low to high transition, the corresponding register bit is set high. The bit will remain high until this register is read, at which point all the bits in this register are cleared. A lack of transitions is indicated by the corresponding register bit reading low. This register should be read at periodic intervals to detect clock failures.

PTCLKA:

The PTCLK active (PTCLKA) bit monitors for low to high transition on the PTCLK parallel transmit clock input. PTCLKA is set high on a rising edge of PTCLK and is set low when this register is read.

PICLKA:

The PICLK active (PICLKA) bit monitors for low to high transition on the PICLK parallel receive clock input. PICLKA is set high on a rising edge of PICLK and is set low when this register is read.

REFCLKA:

The REFCLK active (REFCLKA) bit monitors for low to high transition on the REFCLK CSU-622 and CRU-622 reference clock input. REFCLKA is set high on a rising edge of REFCLK and is set low when this register is read.

TFCLKA:

The TFCLK active (TFCLKA) bit monitors for low to high transition on the TFCLK transmit system interface clock input. TFCLKI is set high on a rising edge of PTLCK and is set low when this register is read.

RFCLKA:

The RFCLK active (RFCLKA) bit monitors for low to high transition on the RFCLK receive system interface clock input. RFCLKA is set high on a rising edge of RFCLK and is set low when this register is read.

RCLKA:

The RCLK active (RCLKA) bit monitors for low to high transition on the RCLK receive line rate clock. RCLKA is set high on a rising edge of RCLK and is set low when this register is read.

TCLKA:

The TCLK active (TCLKA) bit monitors for low to high transition on the TCLK transmit line rate clock. TCLKA is set high on a rising edge of TCLK and is set low when this register is read.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x04: S/UNI-622-MAX Master Interrupt Status #1

Bit	Type	Function	Default
Bit 7		Unused	X
Bit 6	R	CONCATI	X
Bit 5	R	RASEI	X
Bit 4	R	TXCPI	X
Bit 3	R	RXCPI	X
Bit 2	R	RPOPI	X
Bit 1	R	RLOPI	X
Bit 0	R	RSOPI	X

When the interrupt output INTB goes low, this register allows the source of the active interrupt to be identified down to the block level. Further register accesses are required for the block in question to determine the cause of an active interrupt and to acknowledge the interrupt source.

RSOPI:

   The RSOPI bit is high when an interrupt request is active from the RSOP block. The RSOP interrupt sources are enabled in the RSOP Control/Interrupt Enable Register.

RLOPI:

   The RLOPI bit is high when an interrupt request is active from the RLOP block. The RLOP interrupt sources are enabled in the RLOP Interrupt Enable/Status Register.

RPOPI:

   The RPOPI bit is high when an interrupt request is active from the RPOP block. The RPOP interrupt sources are enabled in the RPOP Interrupt Enable Register.

RXCPI:

   The RXCPI bit is high when an interrupt request is active from the RXCP block. The RXCP interrupt sources are enabled in the RXCP Interrupt Enable/Status Register.

When the interrupt output INTB goes low, this register allows the source of the active interrupt to be identified down to the block level. Further register accesses are required for the block in question to determine the cause of an active interrupt and to acknowledge the interrupt source.

CRSII:

> The CRSII bit is high when an interrupt request is active from the Clock Recovery and SIPO block (CRSI-622). The CRSI interrupt sources are enabled in the Clock Recovery Interrupt Control/Status Register.

CSPII:

> The CSPII bit is high when an interrupt request is active from the Clock Synthesis and PISO block (CSPI-622). The CSPII interrupt sources are enabled in the Clock Synthesis Interrupt Control/Status Register.

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

Register 0x06: S/UNI-622-MAX APS Configuration and Control

Bit	Type	Function	Default
Bit 7	R/W	APSFRST	0
Bit 6	R	APSI	X
Bit 5		Unused	X
Bit 4	R/W	APSFEBE	0
Bit 3	R/W	APSRDI	0
Bit 2	R/W	APSPD	0
Bit 1	R/W	APSOE	0
Bit 0	R/W	APSEN	0

This register controls the APS transmit path override and the transmit path RDI and FEBE controls for 1+1 APS operation. See the Operation section for more discussion

APSEN:

The APSEN bit controls the 1+1 APS mode of the S/UNI-622-MAX. When APSEN is set high, the S/UNI-622-MAX transmit path data stream may be supplied to another S/UNI-622-MAX using the POUT[7:0] bus. When APSEN is set low, the S/UNI-622-MAX operates normally and POUT[7:0] is held at a constant value.

APSOE:

The APSOE bit controls the direction of the APS[4:0] pins. When APSOE is set low, the APS[4:0] pins are inputs and supply path RDI and FEBE information to TPOP. When APSEN is set high, the APS[4:0] pins are outputs and supply the receive path RDI and FEBE information from RPOP.

APSPD:

The APSPD bit controls overwriting of the transmit path data stream. When APSPD is set high, the transmit path data stream from TPOP is overwritten from the data sampled on the parallel input PIN[7:0] bus. A four-byte FIFO is used to handle minor phase variations between the transmit clock TCLK and the parallel input clock PICLK. When APSPD is set low, the TPOP path data stream is used.

RELEASED
S/UNI-622-MAX
DATASHEET
PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

APSRDI:

The APSRDI bit control the overwriting of the transmit path RDI values. When APSRDI is set high, the RDI information on the APS[4:0] pins is transmitted by TPOP. When APSRDI is set low, the RDI information from RPOP is transmitted by TPOP. The APSOE bit must be set low when APSRDI is set high.

APSFEBE

The APSFEBE bit controls the overwriting of the transmit path FEBE values. When APSFEBE is set high, the FEBE information on the APS[4:0] pins is transmitted by TPOP. When APSFEBE is set low, the FEBE information from RPOP is transmitted by TPOP. The APSOE bit must be set low when APSFEBE is set high.

APSI:

The APS FIFO interrupt indicates if the APS FIFO has underrun or overrun. The APSI register is set high when a FIFO underrun or overrun has occurred since the register was last read. The APSI register is set low when the register is read. This interrupt register should be periodically polled to ensure the APS FIFO is operating normally when configured for 1+1 APS operation.

APSFRST:

The APS FIFO Reset bit controls the four-byte FIFO which handles minor phase variations between the parallel input clock PTCLK and the transmit clock TCLK. When APSFRST is set high, the FIFO is held in reset. When APSFRST is set low, the FIFO may be reset during system reset. The APSFRST should be set high for at least 4 TCLK cycles when either S/UNI-622-MAX devices in the 1+1 APS configuration are reset.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x07: S/UNI-622-MAX Miscellaneous Configuration

Bit	Type	Function	Default
Bit 7		Unused	X
Bit 6		Unused	X
Bit 5	R/W	TX_LIFINV	0
Bit 4	R/W	RX_LIFINV	0
Bit 3	R/W	TSOC3	0
Bit 2	R/W	RSOC3	0
Bit 1	R/W	TXDINV	0
Bit 0	R/W	RXDINV	0

RXDINV:

The receive inversion RXDINV controls the polarity of the receive data. When RXDINV is set high, the polarity of the RXD+/- is inverted. When RXDINV is set low, the RXD+/- inputs operate normally.

RXDINV and TXDINV are ignored during line loopback operation (SLLE set high).

TXDINV:

The transmit inversion TXDINV controls the polarity of the transmit data. When TXDINV is set high, the polarity of the TXD+/- is inverted. When TXDINV is set low, the TXD+/- outputs operate normally.

RXDINV and TXDINV are ignored during line loopback operation (SLLE set high).

RSOC3:

The Receive SONET/SDH OC3 enable allows the S/UNI-622-MAX to process receive STS-3c/STM-1 data streams using the parallel line interface. When RSOC3 is set high, the SONET/SDH receive processors RSOP/RLOP/RPOP are configured for STS-3c/STM-1 operation. When RSOC3 is set low, the receive side of the S/UNI-622-MAX is configured for STS-12c/STM-4-4c operation. Setting RSOC3 high when LIFSEL is low is invalid as the analog interface only operates at STS-12c/STM-4-4c line rates.

RELEASED

PMC-1980589   ISSUE 6

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

TSOC3:

The Transmit SONET/SDH OC3 enable allows the S/UNI-622-MAX to process transmit STS-3c/STM-1 data streams using the parallel line interface. When TSOC3 is set high, the SONET/SDH transmit processors TSOP/TLOP/TPOP are configured for STS-3c/STM-1 operation. When TSOC3 is set low, the transmit side of the S/UNI-622-MAX is configured for STS-12c/STM-1 operation. Setting TSOC3 high when LIFSEL is low is invalid as the analog interface only operates at STS-12c/STM-4-4c line rates.

RX_LIFINV:

The Receive LIFSEL Inversion select (RX_LIFINV) controls the interpretation of the LIFSEL pin for the receive side. When RX_LIFINV is set high, the polarity of the LIFSEL input is inverted. When RX_LIFINV is set low, the LIFSEL input operates normally for the receive side.

TX_LIFINV:

The Transmit LIFSEL Inversion select (TX_LIFINV) controls the interpretation of the LIFSEL pin for the transmit side. When TX_LIFINV is set high, the polarity of the LIFSEL input is inverted. When TX_LIFINV is set low, the LIFSEL input operates normally for the transmit side.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x08: S/UNI-622-MAX Auto Line RDI Control

Bit	Type	Function	Default
Bit 7	R/W	SDLRDI	0
Bit 6	R/W	SFLRDI	0
Bit 5	R/W	LOFLRDI	1
Bit 4	R/W	LOSLRDI	1
Bit 3	R/W	Reserved	0
Bit 2	R/W	Reserved	0
Bit 1	R/W	LAISLRDI	1
Bit 0		Unused	X

This register controls the auto assertion of the line RDI in TLOP for the entire SONET/SDH stream.

LAISLRDI:

The Line Alarm Indication Signal LRDI (LAISLRDI) controls the insertion of a Line RDI in the transmit data stream upon detection of this alarm condition. When LAISLRDI is set high, the transmit line RDI will be inserted. When LAISLRDI is set low, no action is taken. This register bit is used only if the AUTOLRDI register bit is also set high.

LOSLRDI:

The Loss of Signal LRDI (LOSLRDI) controls the insertion of a Line RDI in the transmit data stream upon detection of this alarm condition. When LOSLRDI is set high, the transmit line RDI will be inserted. When LOSLRDI is set low, no action is taken. This register bit is used only if the AUTOLRDI register bit is also set high.

LOFLRDI:

The Loss of Frame LRDI (LOFLRDI) controls the insertion of a Line RDI in the transmit data stream upon detection of this alarm condition. When LOFLRDI is set high, the transmit line RDI will be inserted. When LOFLRDI is set low, no action is taken. This register bit is used only if the AUTOLRDI register bit is also set high.

SATURN USER NETWORK INTERFACE (622-MAX)

SFLRDI:

The Signal Fail BER LRDI (SFLRDI) controls the insertion of a Line RDI in the transmit data stream upon detection of this alarm condition. When SFLRDI is set high, the transmit line RDI will be inserted. When SFLRDI is set low, no action is taken. This register bit is used only if the AUTOLRDI register bit is also set high.

SDLRDI:

The Signal Degrade BER LRDI (SDLRDI) controls the insertion of a Line RDI in the transmit data stream upon detection of this alarm condition. When SDLRDI is set high, the transmit line RDI will be inserted. When SDLRDI is set low, no action is taken. This register bit is used only if the AUTOLRDI register bit is also set high.

Register 0x09: S/UNI-622-MAX Auto Path RDI Control

Bit	Type	Function	Default
Bit 7	R/W	LCDPRDI	0
Bit 6	R/W	ALRMPRDI	0
Bit 5	R/W	PAISPRDI	1
Bit 4	R/W	Reserved	1
Bit 3	R/W	LOPPRDI	1
Bit 2	R/W	LOPCONPRDI	1
Bit 1	R/W	Reserved	1
Bit 0	R/W	Reserved	1

This register controls the auto assertion of path RDI (G1 bit 5) in the TPOP for the entire SONET/SDH stream. Also see the Auto Enhanced Path RDI register.

LOPCONPRDI:

The Loss of Pointer Concatenation Indication PRDI (LOPCONPRDI) controls the insertion of a Path RDI in the transmit data stream upon detection of this alarm condition. When LOPCONPRDI is set high, the transmit line RDI will be inserted. When LOPCONPRDI is set low, no action is taken. This register bit is used only if the AUTOPRDI register bit is also set high.

LOPPRDI:

The Loss of Pointer Indication PRDI (LOPPRDI) controls the insertion of a Path RDI in the transmit data stream upon detection of this alarm condition. When LOPPRDI is set high, the transmit line RDI will be inserted. When LOPPRDI is set low, no action is taken. This register bit is used only if the AUTOPRDI register bit is also set high.

PAISPRDI:

The Path Alarm Indication Signal PRDI (PAISPRDI) controls the insertion of a Path RDI in the transmit data stream upon detection of this alarm condition. When PAISPRDI is set high, the transmit line RDI will be inserted. When PAISPRDI is set low, no action is taken. This register bit is used only if the AUTOPRDI register bit is also set high.

ALRMPRDI:

The Line Alarm Indication Signal PRDI (ALRMPRDI) controls the insertion of a Path RDI in the transmit data stream upon detection of one of the following alarm conditions: Loss of Signal (LOS), Loss of Frame (LOF) and Line Alarm Indication Signal (LAIS). When ALRMPRDI is set high, the transmit line RDI will be inserted When ALRMPRDI is set low, no action is taken. This register bit is used only if the AUTOPRDI register bit is also set high.

LCDPRDI:

The Loss of ATM Cell Delineation Signal PRDI (LCDPRDI) controls the insertion of a Path RDI in the transmit data stream upon detection of this alarm. When LCDPRDI is set high, the transmit path RDI will be inserted. When LCDPRDI is set low, no action is taken. This register bit is used only if the AUTOPRDI register bit is also set high.

Register 0x0A: S/UNI-622-MAX Auto Enhanced Path RDI Control

Bit	Type	Function	Default
Bit 7	R/W	LCDEPRDI	0
Bit 6	R/W	NOALMEPRDI	0
Bit 5	R/W	NOPAISEPRDI	0
Bit 4	R/W	Reserved	1
Bit 3	R/W	NOLOPEPRDI	0
Bit 2	R/W	NOLOPCONEPRDI	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	Reserved	1

This register controls the auto assertion of enhanced path RDI (G1 bit 5, 6 and 7) in the TPOP for the entire SONET/SDH stream.

NOLOPCONEPRDI:

When set high, the NOLOPCONEPRDI bit disables enhanced path RDI assertion when loss of pointer concatenation (LOPCON) events are detected in the receive stream. When NOLOPCONEPRDI is set high and LOPCON occurs, bit 6 of the G1 byte is set low while bit 7 of the G1 byte is set high. NOLOPCONEPRDI has precedence over PSLMERDI, TIUEPRDI, TIMEPRDI and UNEQERDI.

When NOLOPCONEPRDI is set low, reporting of enhanced RDI is according to PSLMERDI, TIUEPRDI, TIMEPRDI and UNEQERDI and the associated alarm states.

NOLOPEPRDI:

When set high, the NOLOPEPRDI bit disables enhanced path RDI assertion when loss of pointer (LOP) events are detected in the receive stream. When NOLOPEPRDI is set high and LOP occurs, bit 6 of the G1 byte is set low while bit 7 of the G1 byte is set high. NOLOPEPRDI has precedence over PSLMERDI, TIUEPRDI, TIMEPRDI and UNEQERDI.

When NOLOPEPRDI is set low, reporting of enhanced RDI is according to PSLMERDI, TIUEPRDI, TIMEPRDI and UNEQERDI and the associated alarm states.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

NOPAISEPRDI:

When set high, the NOPAISEPRDI bit disables enhanced path RDI assertion when the path alarm indication signal state (PAIS) is detected in the receive stream. When NOPAISEPRDI is set high and PAIS occurs, bit 6 of the G1 byte is set low while bit 7 of the G1 byte is set high. NOPAISEPRDI has precedence over PSLMERDI, TIUEPRDI, TIMEPRDI and UNEQERDI.

When NOPAISEPRDI is set low, reporting of enhanced RDI is according to PSLMERDI, TIUEPRDI, TIMEPRDI and UNEQERDI and the associated alarm states.

NOALMEPRDI:

When set high, the NOALMEPRDI bit disables enhanced path RDI assertion when loss of signal (LOS), loss of frame (LOF) or line alarm indication signal (LAIS) events are detected in the receive stream. When NOALMEPRDI is set high and one of the listed events occur, bit 6 of the G1 byte is set low while bit 7 of the G1 byte is set high. NOALMEPRDI has precedence over PSLMERDI, TIUEPRDI, TIMEPRDI and UNEQERDI.

When NOALMEPRDI is set low, reporting of enhanced RDI is according to PSLMERDI, TIUEPRDI, TIMEPRDI and UNEQERDI and the associated alarm states.

LCDEPRDI:

When set high, the LCDEPRDI bit enables enhanced path RDI assertion when loss of ATM cell delineation (LCD) events are detected in the receive stream. If enabled, when the event occurs, bit 6 of the G1 byte is set high while bit 7 of the G1 byte is set low.

When LCDEPRDI is set low, loss of ATM cell delineation has no effect on path RDI. In addition, this bit has no effect when EPRDI_EN is set low.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x0B: S/UNI-622-MAX Receive RDI and Enhanced RDI Control

Bit	Type	Function	Default
Bit 7	R/W	PAISCONPRDI	0
Bit 6	R/W	NOPAISCONEPRDI	0
Bit 5		Unused	X
Bit 4		Unused	X
Bit 3		Unused	X
Bit 2	R/W	EPRDI_EN	0
Bit 1	R/W	UNEQPRDI	1
Bit 0	R/W	UNEQEPRDI	1

This register along with the Enhanced Path RDI Control register controls the auto assertion of path RDI (G1 bit 5, 6 and 7) in the TPOP for the entire SONET/SDH stream.

UNEQEPRDI:

When set high, the UNEQEPRDI bit enables enhanced path RDI assertion when the path signal label in the receive stream indicates unequipped status. When UNEQEPRDI is set high and the path signal label indicates unequipped, bit 6 of the G1 byte is set high while bit 7 of the G1 byte is set low.

When UNEQEPRDI is set low, path signal label unequipped status has no effect on enhanced path RDI.

UNEQPRDI:

When set high, the UNEQPRDI bit enables path RDI assertion when the path signal label in the receive stream indicates unequipped status. When UNEQPRDI is set low, the path signal label unequipped status has no effect on path RDI.

EPRDI_EN:

The EPRDI_EN bit enables the automatic insertion of enhanced RDI in the local transmitter. When EPRDI_EN is a logic one, auto insertion is enabled using the event enable bits in this register. When EPRDI_EN is a logic zero, enhanced path RDI is not automatically inserted in the transmit stream.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x0C: S/UNI-622-MAX Received Line AIS Control

Bit	Type	Function	Default
Bit 7	R/W	SDINS	0
Bit 6	R/W	SFINS	0
Bit 5	R/W	LOFINS	1
Bit 4	R/W	LOSINS	1
Bit 3	R/W	Reserved	0
Bit 2	R/W	Reserved	0
Bit 1		Unused	X
Bit 0	R/W	Reserved	0

This register controls the auto assertion of the receive line AIS for the entire SONET/SDH stream.

LOSINS:

The LOSINS bit enables the insertion of path AIS in the receive direction upon the declaration of loss of signal (LOS). If LOSINS is a logic one, path AIS is inserted into the SONET/SDH frame when LOS is declared. Path AIS is terminated when LOS is removed.

LOFINS:

The LOFINS bit enables the insertion of path AIS in the receive direction upon the declaration of loss of frame (LOF). If LOFINS is a logic one, path AIS is inserted into the SONET/SDH frame when LOF is declared. Path AIS is terminated when LOF is removed.

SFINS:

The SFINS bit enables the insertion of path AIS in the receive direction upon the declaration of signal fail (SF). If SFINS is a logic one, path AIS is inserted into the SONET/SDH frame when SF is declared. Path AIS is terminated when SF is removed.

SDINS:

The SDINS bit enables the insertion of path AIS in the receive direction upon the declaration of signal degrade (SD). If SDINS is a logic one, path AIS is

Bit 3	R/W	LOPPAIS	1
Bit 2	R/W	Reserved	1
Bit 1	R/W	Reserved	1
Bit 0	R/W	Reserved	1

This register controls the auto assertion of path AIS, which will force a loss of cell delineation by the receive cell processor.

LOPPAIS:

When set high, the LOPPAIS bit enables path AIS insertion when loss of pointer (LOP) events are detected in the receive stream. When LOPPAIS is set low, loss of pointer events will not assert path AIS.

LOPCONPAIS:

When set high, the LOPCONPAIS bit enables path AIS insertion when loss of pointer concatenation (LOPCON) events are detected in the receive stream. When LOPCONPAIS is set low, loss of pointer concatenation events will not assert path AIS.

PAISCONPAIS:

When set high, the PAISCONPAIS bit enables path AIS insertion when Path AIS concatenation (PAISCON) events are detected in the receive direction. When PAISCONPAIS is set low, Path AIS concatenation events will not assert path AIS.

Reserved:

The reserved bit must be programmed to logic zero for proper operation.

Register 0x10: RSOP Control/Interrupt Enable

Bit	Type	Function	Default
Bit 7	R/W	BLKBIP	0
Bit 6	R/W	DDS	0
Bit 5	W	FOOF	X
Bit 4	R/W	ALGO2	0
Bit 3	R/W	BIPEE	0
Bit 2	R/W	LOSE	0
Bit 1	R/W	LOFE	0
Bit 0	R/W	OOFE	0

OOFE:

The OOFE bit is an interrupt enable for the out-of-frame alarm. When OOFE is set to logic one, an interrupt is generated when the out-of-frame alarm changes state.

LOFE:

The LOFE bit is an interrupt enable for the loss of frame alarm. When LOFE is set to logic one, an interrupt is generated when the loss of frame alarm changes state.

LOSE:

The LOSE bit is an interrupt enable for the loss of signal alarm. When LOSE is set to logic one, an interrupt is generated when the loss of signal alarm changes state.

BIPEE:

The BIPEE bit is an interrupt enable for the section BIP-8 errors. When BIPEE is set to logic one, an interrupt is generated when a section BIP-8 error (B1) is detected.

ALGO2:

The ALGO2 bit position selects the framing algorithm used to determine and maintain the frame alignment. When a logic one is written to the ALGO2 bit position, the framer is enabled to use the second of the framing algorithms where only the first A1 framing byte and the first 4 bits of the last A2 framing

RELEASED
S/UNI-622-MAX
DATASHEET
PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

PMC-Sierra, Inc.   PM5356
                                                                 S/UNI-622-MAX

byte (12 bits total) are examined. This algorithm examines only 12 bits of the framing pattern regardless; all other framing bits are ignored. When a logic zero is written to the ALGO2 bit position, the framer is enabled to use the first of the framing algorithms where all the A1 framing bytes and all the A2 framing bytes are examined.

FOOF:

The FOOF bit controls the framing of the RSOP. When a logic one is written to FOOF, the RSOP is forced out of frame at the next frame boundary. The FOOF bit is a write only bit.   Register reads may yield a logic one or a logic zero.

DDS:

The DDS bit is set to logic one to disable the descrambling of the STS-12c/STM-4-4c stream. When DDS is a logic zero, descrambling is enabled.

BLKBIP:

The BLKBIP bit position enables the accumulating of section BIP word errors. When a logic one is written to the BLKBIP bit position, one or more errors in the BIP-8 byte result in a single error being accumulated in the B1 error counter. When a logic zero is written to the BLKBIP bit position, all errors in the B1 byte are accumulated in the B1 error counter.

Bit 4	R	LOFI	X
Bit 3	R	OOFI	X
Bit 2	R	LOSV	X
Bit 1	R	LOFV	X
Bit 0	R	OOFV	X

OOFV:

The OOFV bit is read to determine the out-of-frame state of the RSOP. When OOFV is high, the RSOP is out of frame. When OOFV is low, the RSOP is in-frame.

LOFV:

The LOFV bit is read to determine the loss of frame state of the RSOP. When LOFV is high, the RSOP has declared loss of frame.

LOSV:

The LOSV bit is read to determine the loss of signal state of the RSOP. When LOSV is high, the RSOP has declared loss of signal.

OOFI:

The OOFI bit is the out-of-frame interrupt status bit. OOFI is set high when a change in the out-of-frame state occurs. This bit is cleared when this register is read.

LOFI:

The LOFI bit is the loss of frame interrupt status bit. LOFI is set high when a change in the loss of frame state occurs. This bit is cleared when this register is read.

Bit 2	R	SBE[10]	X
Bit 1	R	SBE[9]	X
Bit 0	R	SBE[8]	X

SBE[15:0]:

Bits SBE[15:0] represent the number of section BIP-8 errors (individual or block) that have been detected since the last time the error count was polled. The error count is polled by writing to either of the RSOP Section BIP-8 Register addresses. Such a write transfers the internally accumulated error count to the Section BIP-8 registers within approximately 7 µs and simultaneously resets the internal counter to begin a new cycle of error accumulation. This transfer and reset is carried out in a manner that ensures that coincident events are not lost.

Register 0x14: TSOP Control

Bit	Type	Function	Default
Bit 7		Unused	X
Bit 6	R/W	DS	0
Bit 5	R/W	Reserved	0
Bit 4	R/W	Reserved	0
Bit 3	R/W	Reserved	0
Bit 2	R/W	Reserved	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	LAIS	0

LAIS:

The LAIS bit controls the insertion of line alarm indication signal (AIS). When LAIS is set to logic one, the TSOP inserts AIS into the transmit SONET/SDH stream. Activation or deactivation of line AIS insertion is synchronized to frame boundaries. Line AIS insertion results in all bits of the SONET/SDH frame being set to 1 prior to scrambling except for the section overhead.

DS:

The DS bit is set to logic one to disable the scrambling of the STS-12c/STM-4-4c stream. When DS is a logic zero, scrambling is enabled.

Reserved:

The reserved bits must be programmed to logic zero for proper operation.

Register 0x15: TSOP Diagnostic

Bit	Type	Function	Default
Bit 7		Unused	X
Bit 6		Unused	X
Bit 5		Unused	X
Bit 4		Unused	X
Bit 3		Unused	X
Bit 2	R/W	DLOS	0
Bit 1	R/W	DBIP8	0
Bit 0	R/W	DFP	0

DFP:

> The DFP bit controls the insertion of a single bit error continuously in the most significant bit (bit 1) of the A1 section overhead framing byte. When DFP is set to logic one, the A1 bytes are set to 0x76 instead of 0xF6.

DBIP8:

> The DBIP8 bit controls the insertion of bit errors continuously in the section BIP-8 byte (B1). When DBIP8 is set to logic one, the B1 byte is inverted.

DLOS:

> The DLOS bit controls the insertion of all zeros in the STS-12c/STM-4-4c stream. When DLOS is set to logic one, the transmit stream is forced to 0x00.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x18: RLOP Control/Status

Bit	Type	Function	Default
Bit 7	R/W	BIPWORD	0
Bit 6	R/W	ALLONES	0
Bit 5	R/W	AISDET	0
Bit 4	R/W	LRDIDET	0
Bit 3	R/W	BIPWORDO	0
Bit 2	R/W	FEBEWORD	0
Bit 1	R	LAISV	X
Bit 0	R	LRDIV	X

LRDIV:

The LRDIV bit is read to determine the remote defect indication state of the RLOP. When LRDIV is high, the RLOP has declared line RDI.

LAISV:

The LAISV bit is read to determine the line AIS state of the RLOP. When LAISV is high, the RLOP has declared line AIS.

FEBEWORD:

The FEBEWORD bit controls the accumulation of FEBEs. When FEBEWORD is high, if the FEBE event has a value from 1 to 4, the FEBE event counter is incremented for each and every FEBE bit. However, if the FEBE event has a value greater than 4 and is valid, the FEBE event counter is incremented by 4. When FEBEWORD is low, the FEBE event counter is incremented for each and every FEBE bit that occurs during that frame (the counter can be incremented up to 24.).

BIPWORDO:

The BIPWORDO bit controls the indication of B2 errors reported to the TLOP block for insertion as FEBEs. When BIPWORDO is logic one, the BIP errors are indicated once per frame whenever one or more B2 bit errors occur during that frame. When BIPWORDO is logic zero, BIP errors are indicated once for every B2 bit error that occurs during that frame. The accumulation of B2 error events functions independently and is controlled by the BIPWORD register bit.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

LRDIDET:

The LRDIDET bit determines the line RDI alarm detection algorithm. When LRDIDET is set to logic one, line RDI is declared when a 110 binary pattern is detected in bits 6, 7 and 8 of the K2 byte for three consecutive frames. When LRDIDET is set to logic zero, line RDI is declared when a 110 binary pattern is detected in bits 6, 7 and 8 of the K2 byte for five consecutive frames.

AISDET:

The AISDET bit determines the line AIS alarm detection algorithm. When AISDET is set to logic one, line AIS is declared when a 111 binary pattern is detected in bits 6, 7 and 8 of the K2 byte for three consecutive frames. When AISDET is set to logic zero, line AIS is declared when a 111 binary pattern is detected in bits 6, 7 and 8 of the K2 byte for five consecutive frames.

ALLONES:

The ALLONES bit controls automatically forcing the SONET/SDH frame passed to downstream blocks to logical all-ones whenever line AIS is detected. When ALLONES is set to logic one, the SONET/SDH frame is forced to logic one immediately when the line AIS alarm is declared. When line AIS is removed, the downstream data stream is immediately returned to carrying the receive data. When ALLONES is set to logic zero, the downstream data stream always carries the receive data regardless of the line AIS alarm state.

BIPWORD:

The BIPWORD bit controls the accumulation of B2 errors. When BIPWORD is logic one, the B2 error event counter is incremented only once per frame whenever one or more B2 bit errors occur during that frame. When BIPWORD is logic zero, the B2 error event counter is increment for each and every B2 bit error that occurs during that frame.

Register 0x19: RLOP Interrupt Enable/Interrupt Status

Bit	Type	Function	Default
Bit 7	R/W	FEBEE	0
Bit 6	R/W	BIPEE	0
Bit 5	R/W	LAISE	0
Bit 4	R/W	LRDIE	0
Bit 3	R	FEBEI	X
Bit 2	R	BIPEI	X
Bit 1	R	LAISI	X
Bit 0	R	LRDII	X

LRDII:

The LRDII bit is the remote defect indication interrupt status bit. LRDII is set high when a change in the line RDI state occurs. This bit is cleared when this register is read.

LAISI:

The LAISI bit is the line AIS interrupt status bit. LAISI is set high when a change in the line AIS state occurs. This bit is cleared when this register is read.

BIPEI:

The BIPEI bit is the line BIP-96 interrupt status bit. BIPEI is set high when a line layer (B2) bit error is detected. This bit is cleared when this register is read.

FEBEI:

The FEBEI bit is the line far end block error interrupt status bit. FEBEI is set high when a line layer FEBE (M1) is detected. This bit is cleared when this register is read.

LRDIE:

The LRDIE bit is an interrupt enable for the line remote defect indication alarm. When LRDIE is set to logic one, an interrupt is generated when the line RDI state changes.

LBE[19:0]

Bits LBE[19:0] represent the number of line BIP-96 errors (individual or block) that have been detected since the last time the error count was polled. The error count is polled by writing to any of the RLOP Line BIP-96 Register or Line FEBE Register addresses. Such a write transfers the internally accumulated error count to the Line BIP-96 Registers within approximately 7 µs and simultaneously resets the internal counter to begin a new cycle of error accumulation.

The count can also be polled by writing to the S/UNI-622-MAX Master Reset and Identity register (0x00). Writing to register address 0x00 loads all the counter registers in the RSOP, RLOP, RPOP, SPTB, SSTB, RXCP, TXCP, RXFP and TXFP blocks.

Register 0x20: TLOP Control

Bit	Type	Function	Default
Bit 7	R/W	Reserved	0
Bit 6	R/W	Reserved	0
Bit 5	R/W	APSREG	0
Bit 4	R/W	Reserved	0
Bit 3	R/W	Reserved	0
Bit 2	R/W	Reserved	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	LRDI	0

LRDI:

The LRDI bit controls the insertion of line remote defect indication (LRDI).
When LRDI is set to logic one, the TLOP inserts line RDI into the transmit
SONET/SDH stream. Line RDI is inserted by transmitting the code 110 in bit
positions 6, 7 and 8 of the K2 byte of the STS-12c stream.

APSREG:

The APSREG bit selects the source for the transmit APS channel K1/K2
bytes. When APSREG is a logic zero, 0x0000 is inserted in the transmit APS
K1 and K2 bytes. When APSREG is a logic one, the transmit APS channel is
inserted from the TLOP Transmit K1 Register and the TLOP Transmit K2
Register.

Reserved:

The reserved bits must be programmed to logic zero for proper operation.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x22: TLOP Transmit K1

Bit	Type	Function	Default
Bit 7	R/W	K1[7]	0
Bit 6	R/W	K1[6]	0
Bit 5	R/W	K1[5]	0
Bit 4	R/W	K1[4]	0
Bit 3	R/W	K1[3]	0
Bit 2	R/W	K1[2]	0
Bit 1	R/W	K1[1]	0
Bit 0	R/W	K1[0]	0

K1[7:0]:

The K1[7:0] bits contain the value inserted in the K1 byte when the APSREG bit in the TLOP Control Register is logic one. K1[7] is the most significant bit corresponding to bit 1, the first bit transmitted. K1[0] is the least significant bit, corresponding to bit 8, the last bit transmitted. The bits in this register are double buffered so that register writes do not need to be synchronized to SONET/SDH frame boundaries. The insertion of a new APS code value is initiated by a write to this register. The contents of this register, and the TLOP Transmit K2 Register are inserted in the SONET/SDH stream starting at the next frame boundary. Successive writes to this register must be spaced at least two frames (250 µs) apart.

Bit 4		Unused	X
Bit 3	R	PAISV	X
Bit 2	R	PRDIV	X
Bit 1	R	NEWPTRI	X
Bit 0	R/W	NEWPTRE	0

NOTE: To facilitate additional register mapping, shadow registers have been added to registers 0x30, 0x31 and 0x33. These shadow registers are accessed in the same way as the normal registers.

The EXTD (extend register) bit must be set in register 0x36 to allow switching between accessing the normal registers and the shadow registers.

This register allows the status of path level alarms to be monitored.

NEWPTRE:

   The NEWPTRE bit is the interrupt enable for the receive new pointer status. When NEWPTRE is a logic one, an interrupt is generated when the pointer interpreter validates a new pointer.

NEWPTRI:

   The NEWPTRI bit is the receive new pointer interrupt status bit. NEWPTRI is a logic one when the pointer interpreter has validated a new pointer value (H1, H2). NEWPTRI is cleared when this register is read.

PRDIV:

   The PRDIV bit is read to determine the remote defect indication state. When PRDIV is a logic one, the S/UNI-622-MAX has declared path RDI.

PAISV:

   The PAISV bit is read to determine the path AIS state. When PAISV is a logic one, the S/UNI-622-MAX has declared path AIS.

Bit	Type	Function	Default
Bit 7	R/W	Reserved	0
Bit 6	R/W	IINVCNT	0
Bit 5	R/W	PSL5	0
Bit 4	R/W	Reserved	0
Bit 3		Unused	X
Bit 2	R	ERDIV[2]	X
Bit 1	R	ERDIV[1]	X
Bit 0	R/W	ERDIV[0]	X

NOTE: To facilitate additional register mapping, shadow registers have been added to registers 0x30, 0x31 and 0x33. These shadow registers are accessed in the same way as the normal registers.

The EXTD (extend register) bit must be set in register 0x36 to allow switching between accessing the normal registers and the shadow registers.

The Status Register is provided at RPOP read address 0, if the extend register (EXTD) bit is set in register 6.

ERDIV[2:0]:

The ERDIV[2:0] bits reflect the current state of the detected enhanced RDI, (filtered G1 bits 5, 6, & 7).

IINVCNT:

When IINVCNT (Intuitive Invalid Pointer Counter) bit is set to 1, if the RPOP pointer interpreter state machine is in the LOP state, a new pointer received 3 consecutive times resets the inv_point count. If this bit is set to 0, the inv_point count will not be reset if pointer interpreter is in the LOP state and a new pointer received 3 consecutive times.

PSL5:

The PSL5 bit controls the filtering of the path signal label byte (C2). When PSL5 is set high, the PSL is updated when the same value is received for 5 consecutive frames. When the PSL5 is set low, the PSL is updated when the same value is received for 3 consecutive frames.

Bit 4	R	INVNDFI	X
Bit 3	R	ILLPTRI	X
Bit 2	R	NSEI	X
Bit 1	R	PSEI	X
Bit 0	R	NDFI	X

This register allows identification and acknowledgment of pointer event interrupts.

NDFI:

The NDFI bit is set to logic one when the RPOP detects an active NDF event to a valid pointer value. NDFI is cleared when the RPOP Pointer Interrupt Status register is read.

PSEI:

The PSEI bit is set to logic one when the RPOP detects a positive stuff event. PSEI is cleared when the RPOP Pointer Interrupt Status register is read.

NSEI:

The NSEI bit is set to logic one when the RPOP detects a negative stuff event. NSEI is cleared when the RPOP Pointer Interrupt Status register is read.

ILLPTRI:

The ILLPTRI bit is set to logic one when the RPOP detects an illegal pointer event. ILLPTRI is cleared when the RPOP Pointer Interrupt Status register is read.

Register 0x33 (EXTD=0): RPOP Interrupt Enable

Bit	Type	Function	Default
Bit 7	R/W	PSLE	0
Bit 6	R/W	Reserved	0
Bit 5	R/W	LOPE	0
Bit 4	R/W	Reserved	0
Bit 3	R/W	PAISE	0
Bit 2	R/W	PRDIE	0
Bit 1	R/W	BIPEE	0
Bit 0	R/W	FEBEE	0

NOTE: To facilitate additional register mapping, shadow registers have been added to registers 0x30, 0x31 and 0x33. These shadow registers are accessed in the same way as the normal registers.

The EXTD (extend register) bit must be set in register 0x36 to allow switching between accessing the normal registers and the shadow registers.

This register allows interrupt generation to be enabled for path level alarm and error events.

FEBEE:

The FEBEE bit is the interrupt enable for path FEBEs. When FEBEE is a logic one, an interrupt is generated when a path FEBE is detected.

BIPEE:

The BIPEE bit is the interrupt enable for path BIP-8 errors. When BIPEE is a logic one, an interrupt is generated when a B3 error is detected.

PRDIE:

The PRDIE bit is the interrupt enable for path RDI. When PRDIE is a logic one, an interrupt is generated when the path RDI state changes.

PAISE:

The PAISE bit is the interrupt enable for path AIS. When PAISE is a logic one, an interrupt is generated when the path AIS state changes.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x34: RPOP Pointer Interrupt Enable

Bit	Type	Function	Default
Bit 7	R/W	ILLJREQE	0
Bit 6	R/W	Reserved	0
Bit 5	R/W	DISCOPAE	0
Bit 4	R/W	INVNDFE	0
Bit 3	R/W	ILLPTRE	0
Bit 2	R/W	NSEE	0
Bit 1	R/W	PSEE	0
Bit 0	R/W	NDFE	0

This register is used to enable pointer event interrupts.

NDFE:

When a logic one is written to the NDFE interrupt enable bit position, an interrupt is generated when a change in active offset due to the reception of an enabled NDF (NDF_enabled indication) occurs.

PSEE:

When a logic one is written to the PSEE interrupt enable bit position, an interrupt is generated when a positive pointer adjustment event is received.

NSEE:

When a logic one is written to the NSEE interrupt enable bit position, an interrupt is generated when a negative pointer adjustment is received.

ILLPTRE:

When a logic one is written to the ILLPTRE interrupt enable bit position, an interrupt is generated when an illegal pointer is received.

INVNDFE:

When a logic one is written to the INVNDFE interrupt enable bit position, an interrupt is generated when an invalid NDF code is received.

Register 0x36: RPOP Pointer MSB

Bit	Type	Function	Default
Bit 7	R/W	NDFPOR	0
Bit 6	R/W	EXTD	0
Bit 5	R/W	RDI10	0
Bit 4		Unused	X
Bit 3	R	S1	X
Bit 2	R	S0	X
Bit 1	R	PTR[9]	X
Bit 0	R	PTR[8]	X

PTR[9:0]:

The PTR[7:0] bits contain the current pointer value as derived from the H1 and H2 bytes. To ensure reading a valid pointer, the NDFI, NSEI and PSEI bits of the RPOP Pointer Interrupt Status register should be read before and after reading this register to ensure that the pointer value did not changed during the register read.

S0, S1:

The S0 and S1 bits contain the two S bits received in the last H1 byte. These bits should be software debounced to ensure the proper values are received.

S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

RDI10:

The RDI10 bit controls the filtering of the remote defect indication and the auxiliary remote defect indication. When RDI10 is set to logic one, the PRDI and ARDI statuses are updated when the same value is received in the corresponding bit of the G1 byte for 10 consecutive frames. When PRDI10 is set to logic zero, the PRDI and ARDI statuses are updated when the same value is received for 5 consecutive frames.

NDFPOR:

The NDFPOR (new data flag pointer outside range) bit allows an NDF counter enable, if the pointer value is outside the range (0-782). If this bit is set high the definition for NDF counter enable is enabled NDF + ss. If this bit is set low the definition for NDF counter enable is enabled NDF + ss + offset in the range of 0 to 782. Note that this bit only allows the NDF counter to count towards LOP when the pointer is out of range and no active offset change will occur.

EXTD:

The EXTD bit extends the registers to facilitate additional mapping. If this bit is set high, the register mapping, for registers 0x30, 0x31 and 0x33, are extended.

Bit 5	R/W	Reserved	0
Bit 4	R/W	BLKFEBE	0
Bit 3		Unused	X
Bit 2	R/W	Reserved	0
Bit 1	R/W	ARDIE	0
Bit 0	R	ARDIV	X

ARDIV:

The auxiliary RDI bit (ARDIV) reports the current state of the path auxiliary RDI within the receive path overhead processor.

ARDIE:

When a logic one is written to the ARDIE interrupt enable bit position, an interrupt is generated when a change in the path auxiliary RDI state occurs.

BLKFEBE:

When set high, the block FEBE bit (BLKFEBE) causes path FEBE errors to be reported and accumulated on a block basis. A single path FEBE error is accumulated for a block if the received FEBE code for that block is between 1 and 8 inclusive. When BLKFEBE is set low, path FEBE errors are accumulated on a error basis.

Reserved:

The reserved bits must be programmed to logic zero for proper operation.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x3D: RPOP Ring Control

Bit	Type	Function	Default
Bit 7	R/W	SOS	0
Bit 6	R/W	ENSS	0
Bit 5	R/W	BLKBIP	0
Bit 4	R/W	Reserved	0
Bit 3	R/W	BLKBIPO	0
Bit 2	R/W	Reserved	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	Reserved	0

BLKBIPO:

When set high, the block BIP-8 output bit (BLKBIPO) indicates that path BIP-8 errors are to be reported on a block basis to the transmit path overhead processor (TPOP) block. A single path BIP error is reported to the return transmit path overhead processor if any of the path BIP-8 results indicates a mismatch. When BLKBIP is set low, BIP-8 errors are reported on a bit basis.

BLKBIP:

When set high, the block BIP-8 bit (BLKBIP) indicates that path BIP-8 errors are to be accumulated on a block basis. A single BIP error is accumulated if any of the BIP-8 results indicates a mismatch. When BLKBIP is set low, BIP-8 errors are accumulated on a bit basis.

ENSS:

The enable size bit (ENSS) controls whether the SS bits in the payload pointer are used to determine offset changes in the pointer interpreter state machine. When a logic one is written to this bit, an incorrect SS bit pattern (i.e., not equal to 10) will prevent RPOP from issuing NDF_enable, inc_ind, new_point and dec_ind indications. When a logic zero is written to this bit, the received SS bits do not affect active offset change events.

SOS:

The stuff opportunity spacing control bit (SOS) controls the spacing between consecutive pointer justification events on the receive stream. When a logic one is written to this bit, the definition of inc_ind and dec_ind indications

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x40: TPOP Control/Diagnostic

Bit	Type	Function	Default
Bit 7		Unused	X
Bit 6	R/W	EPRDIEN	0
Bit 5	R/W	EPRDISRC	0
Bit 4	R/W	PERSIST	0
Bit 3	R/W	Reserved	0
Bit 2	R/W	Reserved	0
Bit 1	R/W	DBIP8	0
Bit 0	R/W	PAIS	0

PAIS:

The PAIS bit controls the insertion of STS path alarm indication signal. When a logic one is written to this bit position, the complete SPE, and the pointer bytes (H1, H2, and H3) are overwritten with the all-ones pattern. When a logic zero is written to this bit position, the pointer bytes and the SPE are processed normally.DBIP8:

The DBIP8 bit controls the insertion of bit errors continuously in the B3 byte. When DBIP8 is a logic one, the B3 byte is inverted.

PERSIST

The path far end receive failure alarm persistence bit (PERSIST) controls the persistence of the RDI asserted into the transmit stream. When PERSIST is a logic one, the RDI code inserted into the transmit stream as a result of consequential actions is asserted for a minimum of 20 frames in non-enhanced RDI mode, or the last valid RDI code before an idle code (idle codes are when bits 5,6,7 are 000, 001, or 011) is asserted for 20 frames in enhanced RDI mode. When PERSIST is logic zero, the transmit RDI code changes immediately based on received alarm conditions.

 EPRDISRC

The enhanced path receive defect indication alarm source bit (EPRDISRC) controls the source of RDI input to be inserted onto the G1 byte. When EPRDIEN is logic zero, the extended RDI bits of the G1 byte not overwritten by the TPOP block, regardless of EPRDISRC. When EPRDIEN is logic one and EPRDISCR is logic zero, the extended RDI bits of the G1 byte, bits 6 and

S/UNI-622-MAX

7, are inserted according to the value in the G1[1:0] register bits (register 0x49). When EPRDIEN is logic one and EPRDISCR is logic one, the value register 0x49 G1[1:0] is ignored and the EPRDI bits in the G1 byte are set according to the setting of the Channel Auto Enhanced Path RDI Control registers (0x92 and 0x93).

EPRDIEN

The enhanced path receive defect indication alarm enable bit (EPRDIEN) controls the use of 3-bit RDI mode. When EPRDIEN is set to logic zero, the basic path RDI scheme is used and only G1[5] is used to indicate PRDI. When EPRDIEN is set to logic one, the enhanced path RDI scheme is used and the three G1[7:5] bits are used to indicate PRDI. The actual three bit code will be controlled according to the EPRDISRC.

Reserved:

The reserved bits must be programmed to logic zero for proper operation.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x41: TPOP Pointer Control

Bit	Type	Function	Default
Bit 7	R/W	Reserved	0
Bit 6	R/W	FTPTR	0
Bit 5	R/W	SOS	0
Bit 4	R/W	PLD	0
Bit 3	R/W	NDF	0
Bit 2	R/W	NSE	0
Bit 1	R/W	PSE	0
Bit 0	R/W	Reserved	0

This register allows control over the transmitted payload pointer for diagnostic purposes.

PSE:

The PSE bit controls the insertion of positive pointer movements. A zero to one transition on this bit enables the insertion of a single positive pointer justification in the outgoing stream. This register bit is automatically cleared when the pointer movement is inserted.

NSE:

The NSE bit controls the insertion of negative pointer movements. A zero to one transition on this bit enables the insertion of a single negative pointer justification in the outgoing stream. This register bit is automatically cleared when the pointer movement is inserted.

NDF:

The NDF bit controls the insertion of new data flags in the inserted payload pointer. When a logic one is written to this bit position, the pattern contained in the NDF[3:0] bit positions in the TPOP Arbitrary Pointer MSB Register is inserted continuously in the payload pointer. When a logic zero is written to this bit position, the normal pattern (0110) is inserted in the payload pointer.

PLD:

The PLD bit controls the loading of the pointer value contained in the TPOP Arbitrary Pointer Registers. Normally the TPOP Arbitrary Pointer Registers

S/UNI-622-MAX

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

are written to set up the arbitrary new pointer value, the S-bit values, and the NDF pattern. A logic one is then written to this bit position to load the new pointer value. The new data flag bit positions are set to the programmed NDF pattern for the first frame; subsequent frames have the new data flag bit positions set to the normal pattern (0110) unless the NDF bit described above is set to a logic one.

Note: When loading an out of range pointer (that is a pointer with a value greater than 782), the TPOP continues to operate with timing based on the last valid pointer value. The out of range pointer value will of course be inserted in the STS-12c/STM-4-4c stream. Although a valid SPE will continue to be generated, it is unlikely to be extracted by downstream circuitry, which should be in a loss of pointer state.

This bit is automatically cleared after the new payload pointer has been loaded.

SOS:

The SOS bit controls the stuff opportunity spacing between consecutive SPE positive or negative stuff events. When SOS is a logic zero, stuff events may be generated every frame as controlled by the PSE and NSE register bits described above. When SOS is a logic one, stuff events may be generated at a maximum rate of once every four frames.

FTPTR:

The force transmit pointer bit (FTPTR) enables the insertion of the pointer value contained in the Arbitrary Pointer Registers into the POUT[7:0] stream for diagnostic purposes. This allows the ATM payload mapping circuitry to continue functioning normally and a valid SPE to continue to be generated, although it is unlikely to be extracted by downstream circuitry as the downstream pointer processor should be in a loss of pointer state.

If FTPTR is set to logic one, the APTR[9:0] bits of the Arbitrary Pointer Registers are inserted into the H1 and H2 bytes of the transmit stream. At least one corrupted pointer is guaranteed to be sent. If FTPTR is a logic zero, a valid pointer is inserted.

Reserved:

The reserved bits must be programmed to logic zero for proper operation.

Bit 2	R/W	APTR[2]	0
Bit 1	R/W	APTR[1]	0
Bit 0	R/W	APTR[0]	0

This register allows an arbitrary pointer to be inserted for diagnostic purposes.

APTR[7:0]:

The APTR[7:0] bits, along with the APTR[9:8] bits in the TPOP Arbitrary Pointer MSB Register are used to set an arbitrary payload pointer value. The arbitrary pointer value is inserted in the outgoing stream by writing a logic one to the PLD bit in the TPOP Pointer Control Register.

If the FTPTR bit in the TPOP Pointer Control register is a logic one, the current APTR[9:0] value is inserted into the payload pointer bytes (H1 and H2) in the transmit stream.

Register 0x46: TPOP Arbitrary Pointer MSB

Bit	Type	Function	Default
Bit 7	R/W	NDF[3]	1
Bit 6	R/W	NDF[2]	0
Bit 5	R/W	NDF[1]	0
Bit 4	R/W	NDF[0]	1
Bit 3	R/W	S[1]	1
Bit 2	R/W	S[0]	0
Bit 1	R/W	APTR[9]	0
Bit 0	R/W	APTR[8]	0

This register allows an arbitrary pointer to be inserted for diagnostic purposes.

APTR[9:8]:

The APTR[9:8] bits, along with the APTR[7:0] bits in the TPOP Arbitrary Pointer LSB Register are used to set an arbitrary payload pointer value. The arbitrary pointer value is inserted in the outgoing stream by writing a logic one to the PLD bit in the TPOP Pointer Control Register.

If the FTPTR bit in the TPOP Pointer Control register is a logic one, the current APTR[9:0] value is inserted into the payload pointer bytes (H1 and H2) in the transmit stream.

S[1:0]:

The S[1:0] bits contain the value inserted in the S[1:0] bit positions (also referred to as the unused bits) in the payload pointer. These bits are continuously inserted into the transmit stream.

NDF[3:0]:

The NDF[3:0] bits contain the value inserted in the NDF bit positions when an arbitrary new payload pointer value is inserted (using the PLD bit in the TPOP Pointer Control Register) or when new data flag generation is enabled using the NDF bit in the TPOP Pointer Control Register.

Bit 4	R/W	FEBE[0]	0
Bit 3	R/W	PRDI	0
Bit 2	R/W	APRDI	0
Bit 1	R/W	G1[1]	0
Bit 0	R/W	G1[0]	0

This register allows control over the path status byte.

G1[1:0]:

The G1[1:0] bits are inserted in bits 1 and 2 of the Path Status Byte G1. These bits are ignored when EPRDIEN is logic zero or when EPRDIEN and EPRDISRC are both logic one. See the description of EPRDIEN and EPRDISRC for more details on how G1 can be controlled.

APRDI:

The APRDI bit controls the insertion of the auxiliary path remote defect indication. When APRDI is a logic one, the APRDI bit position in the path status byte is set high. When APRDI is a logic zero, the APRDI bit position in the path status byte is set low.

PRDI:

The PRDI bit controls the insertion of the path remote defect indication. When a logic one is written to this bit position, the PRDI bit position in the path status byte is set high. When a logic zero is written to this bit position, the PRDI bit position in the path status byte is set low. This bit is ignored when EPRDIEN is logic zero or when EPRDIEN and EPRDISRC are both logic one.

FEBE[3:0]:

The FEBE[3:0] bits are inserted in the FEBE bit positions in the path status byte. The value contained in FEBE[3:0] is cleared after being inserted in the

Bit 1	R/W	Reserved	0
Bit 0	R/W	Reserved	0

The CSU Control register provides direct access to the CSU. When the CSU does not lock properly (ROOLV remains high), the CSU may be re-initialized using this register.

When the AVD power supply of the S/UNI-622-MAX is subjected to a change greater than the ±5% tolerance specified for the 3.3V analog supply pins, the Clock Synthesis Unit may lose lock to the reference clock. When this occurs, the ROOLV will remain high until the CSU is reset using the CSURESETLPF and CSURSET registers.

The S/UNI-622-MAX will operate normally if the power supply does not vary beyond the specified ±5% tolerance.

CSURESETLPF:

The CSU low pass filter (LPF) reset control CSURESETLPF bit provides a software reset for the CSU-622 ABC. When CSURESETLPF is set high, the CSU RESETLPF input is set high forcing the CSU LPF into reset. When CSURESETLPF is set low, the CSU RESETLPF input is controlled by the system reset.

The CSURESETLPF and CSURESET should be held high for 10ms to properly reset the CSU.

CSURESET:

The CSU reset control CSURESET bit provides a software reset for the CSU-622 ABC. When CSURESET is set high, the CSU RESET input is set high

Bit 2	R	LOTI	X
Bit 1	R	ROOLI	X
Bit 0	R	DOOLI	X

DOOLI:

The DOOLI bit is the data out of lock interrupt status bit. DOOLI is set high when the DOOLV bit goes high, indicating the CRU has gone out of lock. DOOLI is cleared when this register is read.

ROOLI:

The ROOLI bit is the reference out of lock interrupt status bit. ROOLI is set high when the ROOLV register changes state, indicating that either the PLL is locked to the reference clock REFCLK or is in out of lock. ROOLI is cleared when this register is read.

LOTI:

The LOTI bit is the loss of transition interrupt status bit. LOTI is set high when a loss of transition event occurs. A loss of transition is defined as either the SD input set low or more than 96 consecutive ones or zeros received. LOTI is cleared when this register is read.

SENB:

The loss of signal transition detector enable (SENB) bit enables the declaration of loss of transition (LOT) when more than 96 consecutive ones or zeros occurs in the receive data. When SENB is a logic zero, a loss of transition is declared when more than 96 consecutive ones or zeros occurs in the receive data or when the SD input is low. When SENB is a logic one, a loss of transition is declared only when the SD input is low.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

PFPEN:

The parallel frame pulse enable (PFPEN) enables the parallel frame pulse operation when the parallel data interface is enabled (LIFSEL is set high). When PFPEN is a logic zero, the FPIN input is ignored and the SONET/SDH framing is performed on the PIN[7:0] data. When PFPEN is logic one, the SONET/SDH framer is ignored and the PIN[7:0] bus is assumed to be byte aligned marked with the FPIN frame pulse. PFPEN is ignored when the LIFSEL input is set low.

SDINV:

The signal detect input invert (SDINV) controls the polarity of the SD input. The value of the SD input is logically XOR'ed with the value of the SDINV register. Therefore, when SDINV is a logic zero, valid signal power is indicated by the SD input high. When SDINV is a logic one, valid signal power is indicated by the SD input low.

Bit 3		Unused	X
Bit 2	R/W	LOTE	0
Bit 1	R/W	ROOLE	0
Bit 0	R/W	DOOLE	0

DOOLE:

The DOOLE bit is an interrupt enable for the recovered data out of lock
status. When DOOLE is set to logic one, an interrupt is generated upon
assertion events of the DOOLV register. When ROOLE is set low, changes in
the DOOL status do not generate an interrupt.

ROOLE:

The ROOLE bit enables the reference out of lock indication interrupt. When
ROOLE is set high, an interrupt is generated upon assertion and negation
events of the ROOLV register. When ROOLE is set low, changes in the
ROOL status do not generate an interrupt.

LOTE:

The LOTE bit enables the loss of transition indication interrupt. When LOTE
is set high, an interrupt is generated upon assertion events of the LOTV
register. When LOTE is set low, changes in the LOTV status do not generate
an interrupt.

DOOLV:

The recovered data out of lock status indicates the clock recovery phase
locked loop is unable to recover and lock to the input data stream. DOOLV is
a logic one if the divided down recovered clock frequency is not within
approximately 488ppm of the REFCLK frequency or if no transitions have
occurred on the RXD input for more than 96 bits.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x60: RXCP Configuration 1

Bit	Type	Function	Default
Bit 7	R/W	DDSCR	0
Bit 6	R/W	HDSCR	0
Bit 5		Unused	X
Bit 4		Unused	X
Bit 3		Unused	X
Bit 2	R/W	HCSADD	1
Bit 1	R/W	Reserved	0
Bit 0	R/W	DISCOR	0

DISCOR:

The DISCOR bit controls the HCS error correction algorithm. When DISCOR is a logic zero, the error correction algorithm is enabled, and single-bit errors detected in the cell header are corrected. When DISCOR is a logic one, the error correction algorithm is disabled, and any error detected in the cell header is treated as an uncorrectable HCS error.

HCSADD:

The HCSADD bit controls the addition of the coset polynomial, $x^6+x^4+x^2+1$, to the HCS octet prior to comparison. When HCSADD is a logic one, the polynomial is added, and the resulting HCS is compared. When HCSADD is a logic zero, the polynomial is not added, and the unmodified HCS is compared.

HDSCR:

HDSCR enables the self-synchronous $x^{43} + 1$ descrambler to continue running through the bytes which should contain the ATM cell headers. When HSCR is set low, the descrambling polynomial will function only over the ATM payload bytes. When HDSCR is set high, the descrambling polynomial will function over all bytes, including the 5 ATM header bytes. This function is available for use with PPP packets and flags which are scrambled at the source to prevent the generation of "killer" sequences.

Bit	Type	Function	Default
Bit 7	R/W	CCDIS	0
Bit 6	R/W	HCSPASS	0
Bit 5	R/W	IDLEPASS	0
Bit 4	R/W	Reserved	0
Bit 3	R/W	Reserved	0
Bit 2	R/W	Reserved	0
Bit 1	R/W	HCSFTR[1]	0
Bit 0	R/W	HCSFTR[0]	0

HCSFTR[1:0]:

The HCS filter bits, HCSFTR[1:0] indicate the number of consecutive error-free cells required, while in detection mode, before reverting back to correction mode.

HCSFTR[1:0]	Cell Acceptance Threshold
00	One ATM cell with correct HCS before resumption of cell acceptance. This cell is accepted.
01	Two ATM cells with correct HCS before resumption of cell acceptance. The last cell is accepted.
10	Four ATM cells with correct HCS before resumption of cell acceptance. The last cell is accepted.
11	Eight ATM cells with correct HCS before resumption of cell acceptance. The last cell is accepted.

IDLEPASS:

The IDLEPASS bit controls the function of the Idle Cell filter. When IDLEPASS is written with a logic zero, all cells that match the Idle Cell Header Pattern and Idle Cell Header Mask are filtered out. When IDLEPASS is a logic one, the Idle Cell Header Pattern and Mask registers are ignored. The default state of this bit and the bits in the Idle Cell Header Mask and Idle Cell Header Pattern Registers enable the dropping of idle cells.

RELEASED
S/UNI-622-MAX
DATASHEET

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

PMC-1980589   *ISSUE 6*   *SATURN USER NETWORK INTERFACE (622-MAX)*

HCSPASS:

The HCSPASS bit controls the dropping of cells based on the detection of an uncorrectable HCS error. When HCSPASS is a logic zero, cells containing an uncorrectable HCS error are dropped. When HCSPASS is a logic one, cells are passed to the receive FIFO regardless of errors detected in the HCS. Additionally, the HCS verification finite state machine never exits the correction mode.

Regardless of the programming of this bit, cells are always dropped while the cell delineation state machine is in the 'HUNT' or 'PRESYNC' states unless the CCDIS bit in this register is set high.

CCDIS:

The CCDIS bit can be used to disable all cell filtering and cell delineation. All payload data read from the RXCP is passed into its FIFO without the requirement of having to find cell delineation first.

Reserved:

The reserved bits must be programmed to logic zero for proper operation.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x62: RXCP FIFO/UTOPIA Control and Configuration

Bit	Type	Function	Default
Bit 7	R/W	RXPTYP	0
Bit 6		Unused	X
Bit 5	R/W	RCAINV	0
Bit 4	R/W	RCALEVEL0	1
Bit 3		Unused	X
Bit 2		Unused	X
Bit 1		Unused	X
Bit 0	R/W	FIFORST	0

FIFORST:

The FIFORST bit is used to reset the four-cell receive FIFO. When FIFORST is set low, the FIFO operates normally. When FIFORST is set high, the FIFO is immediately emptied and ignores writes. The FIFO remains empty and continues to ignore writes until a logic zero is written to FIFORST. Activating this bit during a cell transfer may result in a truncated cell on the System Interface.

RCALEVEL0:

The RCA level 0 bit, RCALEVEL0, determines when the RCA transitions low for Level 2 operation. When RCALEVEL0 is set high, a high-to-low transition on output RCA indicates that the receive FIFO is empty and RCA will de-assert on the rising RFCLK edge after word 27 (of the 27 word cell structure) is output. When RCALEVEL0 is set low, a high-to-low transition on output RCA indicates that the receive FIFO is near empty and RCA will de-assert on the rising RFCLK edge after word 13 (of the 27 word cell structure) is output.

RCALEVEL0 must be set high when the system interface is configured for Level 3 operation.

RCAINV:

The RCAINV bit inverts the polarity of the RCA output signal for Level 2 operation. When RCAINV is a logic one, the polarity of RCA is inverted (RCA at logic zero means there is a receive cell available to be read). When RCAINV is a logic zero, the polarity of RCA is not inverted.

RELEASED

Bit 3	R/W	OOCDE	0
Bit 2	R/W	HCSE	0
Bit 1	R/W	FOVRE	0
Bit 0	R/W	LCDE	0

LCDE:

The LCDE bit enables the generation of an interrupt due to a change in the LCD state. When LCDE is set high, the interrupt is enabled.

FOVRE:

The FOVRE bit enables the generation of an interrupt due to a FIFO overrun error condition. When FOVRE is set high, the interrupt is enabled.

HCSE:

The HCSE bit enables the generation of an interrupt due to the detection of a corrected or an uncorrected HCS error. When HCSE is set high, the interrupt is enabled.

OOCDE:

The OOCDE bit enables the generation of an interrupt due to a change in cell delineation state. When OOCDE is set high, the interrupt is enabled.

XFERE:

The XFERE bit enables the generation of an interrupt when an accumulation interval is completed and new values are stored in the RXCP Count registers. When XFERE is set high, the interrupt is enabled.

OVR:

The OVR bit is the overrun status of the RXCP Performance Monitoring Count registers. A logic one in this bit position indicates that a previous transfer

(indicated by XFERI being logic one) has not been acknowledged before the next accumulation interval has occurred and that the contents of the RXCP Count registers have been overwritten. OVR is set low when this register is read.

XFERI:

The XFERI bit indicates that a transfer of RXCP Performance Monitoring Count data has occurred. A logic one in this bit position indicates that the RXCP Count registers have been updated. This update is initiated by writing to one of the RXCP Count register locations or to the S/UNI-622-MAX, Master Reset and Identity register. XFERI is set low when this register is read.

Register 0x64: RXCP Status/Interrupt Status

Bit	Type	Function	Default
Bit 7	R	OOCDV	X
Bit 6	R	LCDV	X
Bit 5		Unused	X
Bit 4	R	OOCDI	X
Bit 3	R	CHCSI	X
Bit 2	R	UHCSI	X
Bit 1	R	FOVRI	X
Bit 0	R	LCDI	X

LCDI:

The LCDI bit is set high when there is a change in the loss of cell delineation (LCD) state. This bit is reset immediately after a read to this register.

FOVRI:

The FOVRI bit is set high when an attempt is made to write into the FIFO when it is already full. This bit is reset immediately after a read to this register. Continuous over-writing of the FIFO results in only one interrupt.

UHCSI:

The UHCSI bit is set high when an uncorrected HCS error is detected. This bit is reset immediately after a read to this register.

CHCSI:

The CHCSI bit is set high when a corrected HCS error is detected. This bit is reset immediately after a read to this register.

OOCDI:

The OOCDI bit is set high when the RXCP enters or exits the SYNC state. The OOCDV bit indicates whether the RXCP is in the SYNC state or not. The OOCDI bit is reset immediately after a read to this register.

LCDV:

The LCDV bit gives the Loss of Cell Delineation state. When LCD is high, an out of cell delineation (OCD) defect has persisted for the number of cells

specified in the LCD Count Threshold register. When LCD is low, no OCD has persisted for the number of cells specified in the LCD Count Threshold register. The cell time period can be varied by using the LCDC[7:0] register bits in the RXCP LCD Count Threshold register.

OOCDV:

The OOCDV bit indicates the cell delineation state. When OOCDV is high, the cell delineation state machine is in the 'HUNT' or 'PRESYNC' state and is hunting for the cell boundaries. When OOCDV is low, the cell delineation state machine is in the 'SYNC' state and cells are passed through the receive FIFO.

Bit 5	R/W	LCDC[5]	1
Bit 4	R/W	LCDC[4]	0
Bit 3	R/W	LCDC[3]	1
Bit 2	R/W	LCDC[2]	0
Bit 1	R/W	LCDC[1]	0
Bit 0	R/W	LCDC[0]	0

LCDC[10:0]:

 The LCDC[10:0] bits represent the number of consecutive cell periods the receive cell processor must be out of cell delineation before loss of cell delineation (LCD) is declared. Likewise, LCD is not de-asserted until receive cell processor is in cell delineation for the number of cell periods specified by LCDC[10:0].

 The default value of LCD[10:0] is 360, which translates to an average cell period of 0.71 µs and a default LCD integration period of 255 µs.

Register 0x67: RXCP Idle Cell Header Pattern

Bit	Type	Function	Default
Bit 7	R/W	GFC[3]	0
Bit 6	R/W	GFC[2]	0
Bit 5	R/W	GFC[1]	0
Bit 4	R/W	GFC[0]	0
Bit 3	R/W	PTI[3]	0
Bit 2	R/W	PTI[2]	0
Bit 1	R/W	PTI[1]	0
Bit 0	R/W	CLP	1

GFC[3:0]:

The GFC[3:0] bits contain the pattern to match in the first, second, third, and fourth bits of the first octet of the 53-octet cell, in conjunction with the Idle Cell Header Mask Register. The IDLEPASS bit in the RXCP Configuration 2 Register must be set to logic zero to enable dropping of cells matching this pattern. Note that an all-zeros pattern must be present in the VPI and VCI fields of the idle or unassigned cell.

PTI[2:0]:

The PTI[2:0] bits contain the pattern to match in the fifth, sixth, and seventh bits of the fourth octet of the 53-octet cell, in conjunction with the Idle Cell Header Mask Register. The IDLEPASS bit in the RXCP Configuration 2 Register must be set to logic zero to enable dropping of cells matching this pattern.

CLP:

The CLP bit contains the pattern to match in the eighth bit of the fourth octet of the 53-octet cell, in conjunction with the Match Header Mask Register. The IDLEPASS bit in the RXCP Configuration 2 Register must be set to logic zero to enable dropping of cells matching this pattern.

Bit 2	R/W	MPTI[2]	1
Bit 1	R/W	MPTI[1]	1
Bit 0	R/W	MCLP	1

MGFC[3:0]:

The MGFC[3:0] bits contain the mask pattern for the first, second, third, and fourth bits of the first octet of the 53-octet cell. This mask is applied to the Idle Cell Header Pattern Register to select the bits included in the cell filter. A logic one in any bit position enables the corresponding bit in the pattern register to be compared. A logic zero causes the masking of the corresponding bit.

MPTI[3:0]:

The MPTI[3:0] bits contain the mask pattern for the fifth, sixth, and seventh bits of the fourth octet of the 53-octet cell. This mask is applied to the Idle Cell Header Pattern Register to select the bits included in the cell filter. A logic one in any bit position enables the corresponding bit in the pattern register to be compared. A logic zero causes the masking of the corresponding bit.

MCLP:

The CLP bit contains the mask pattern for the eighth bit of the fourth octet of the 53-octet cell. This mask is applied to the Idle Cell Header Pattern Register to select the bits included in the cell filter. A logic one in this bit position enables the MCLP bit in the pattern register to be compared. A logic zero causes the masking of the MCLP bit.

PM5356
S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x80: TXCP Configuration 1

Bit	Type	Function	Default
Bit 7	R/W	TPTYP	0
Bit 6	R/W	TCALEVEL0	0
Bit 5	R/W	HSCR	0
Bit 4	R/W	Reserved	0
Bit 3	R/W	HCSB	0
Bit 2	R/W	HCSADD	1
Bit 1	R/W	DSCR	0
Bit 0	R/W	FIFORST	0

FIFORST:

The FIFORST bit is used to reset the four cell transmit FIFO. When FIFORST is set to logic zero, the FIFO operates normally. When FIFORST is set to logic one, the FIFO is immediately emptied and ignores writes. The FIFO remains empty and continues to ignore writes until a logic zero is written to FIFORST. Null/unassigned cells are transmitted until a subsequent cell is written to the FIFO.

DSCR:

The DSCR bit controls the scrambling of the cell payload. When DSCR is a logic one, cell payload scrambling is disabled. When DSCR is a logic zero, payload scrambling is enabled.

HCSADD:

The HCSADD bit controls the addition of the coset polynomial, $x^6+x^4+x^2+1$, to the HCS octet prior to insertion in the synchronous payload envelope. When HCSADD is a logic one, the polynomial is added, and the resulting HCS is inserted. When HCSADD is a logic zero, the polynomial is not added, and the unmodified HCS is inserted. HCSADD takes effect unconditionally regardless of whether a null/unassigned cell is being transmitted or whether the HCS octet has been read from the FIFO.

HCSB:

The active low HCSB bit enables the internal generation and insertion of the HCS octet into the transmit cell stream. When HCSB is logic zero, the HCS is

RELEASED

S/UNI-622-MAX

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

generated and inserted internally. If HCSB is logic one, then no HCS octet is inserted in the transmit data stream.

HSCR:

The Header Scramble enable bit, HSCR, enables scrambling of the ATM five octet header along with the payload. When set to logic one, the ATM header and payload are both scrambled. When set to logic zero, the header is left unscrambled and payload scrambling is determined by the DSCR bit.

TCALEVEL0:

The TCA level control (TCALEVEL0) determines when the TCA will transition low as the FIFO fills for Level 2 operation. When TCALEVEL0 is logic zero, TCA will deassert on the same rising TFCLK edge that samples word 21 of the 27 word ATM cell structure. When TCALEVEL0 is logic one, TCA will deassert on the same rising TFCLK edge that samples word 26 of the 27 word ATM cell structure.

TCALEVEL0 must be set low when the system interface is configured for Level 3 operation.

TPTYP:

The TPTYP bit selects even or odd parity for input TPRTY for Level 2 operation. When set to logic one, input TPRTY is the even parity bit for the TDAT input bus. When set to logic zero, input TPRTY is the odd parity bit for the TDAT input bus.

TPTYP must be set low when the system interface is configured for Level 3 operation.

Reserved:

The reserved bits must be programmed to logic zero for proper operation.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x81: TXCP Configuration 2

Bit	Type	Function	Default
Bit 7		Unused	X
Bit 6		Unused	X
Bit 5		Unused	X
Bit 4	R/W	TCAINV	0
Bit 3	R/W	FIFODP[1]	0
Bit 2	R/W	FIFODP[0]	0
Bit 1	R/W	DHCS	0
Bit 0	R/W	HCSCTLEB	0

HCSCTLEB:

The active low HCS control enable, HCSCTLEB bit enables the XORing of the HCS Control byte with the generated HCS. When set to logic zero, the HCS Control byte provided in the third word of the 27 word data structure is XORed with the generated HCS. When set to logic one, XORing is disabled and the HCS Control byte is ignored.

For normal operation, the HCS Control byte in the ATM cell structure transferred on the system interface should always be 0x00. If not, the HCSCTLEB register should be set to logic one to prevent corruption of the HCS byte.

DHCS:

The DHCS bit controls the insertion of HCS errors for diagnostic purposes. When DHCS is set to logic one, the HCS octet is inverted prior to insertion in the synchronous payload envelope. DHCS takes effect unconditionally regardless of whether a null/unassigned cell is being transmitted or whether the HCS octet has been read from the FIFO. DHCS occurs after any error insertion caused by the Control Byte in the 27-word data structure.

FIFODP[1:0]:

The FIFODP[1:0] bits determine the transmit FIFO cell depth at which TCA is de-asserted. FIFO depth control may be important in systems where the cell latency through the TXCP must be minimized. When the FIFO is filled to the specified depth, the transmit cell available signal, TCA is deasserted.   Note that regardless of what fill level FIFODP[1:0] is set to, the transmit cell

RELEASED

processor can store 4 complete cells. The selectable FIFO cell depths are shown below:

FIFODP[1]	FIFODP[0]	FIFO DEPTH
0	0	4 cells
0	1	3 cells
1	0	2 cells
1	1	1 cell

TCAINV:

The TCAINV bit inverts the polarity of the TCA output signal for Level 2 operation. When TCAINV is a logic one, the polarity of TCA is inverted (TCA at logic zero means there is transmit cell space available to be written to). When TCAINV is a logic zero, the polarity of TCA is not inverted.

TCAINV must be set low when the system interface is configured for Level 3 operation.

Bit 3	R/W	Reserved	1
Bit 2	R/W	Reserved	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	Reserved	0

XFERI:

The XFERI bit indicates that a transfer of Transmit Cell Count data has occurred. A logic one in this bit position indicates that the Transmit Cell Count registers have been updated. This update is initiated by writing to one of the Transmit Cell Count register locations or to the S/UNI-622-MAX, Master Reset and Identity register. XFERI is set low when this register is read.

OVR:

The OVR bit is the overrun status of the Transmit Cell Count registers. A logic one in this bit position indicates that a previous transfer (indicated by XFERI being logic one) has not been acknowledged before the next accumulation interval has occurred and that the contents of the Transmit Cell Count registers have been overwritten. OVR is set low when this register is read.

XFERE:

The XFERE bit enables the generation of an interrupt when an accumulation interval is completed and new values are stored in the Transmit Cell Count registers. When XFERE is set high, the interrupt is enabled.

Reserved:

These bits should be set to their default values for proper operation.

Bit 4		Unused	X
Bit 3		Unused	X
Bit 2	R	TPRTYI	X
Bit 1	R	FOVRI	X
Bit 0	R	TSOCI	X

TSOCI:

The TSOCI bit is set high when the TSOC input is sampled high during any position other than the first word of the selected data structure. The write address counter is reset to the first word of the data structure when TSOC is sampled high. This bit is reset immediately after a read to this register.

FOVRI:

The FOVRI bit is set high when an attempt is made to write into the FIFO when it is already full. This bit is reset immediately after a read to this register.

TPRTYI:

The TPRTYI bit indicates if a parity error was detected on the TDAT input bus. When logic one, the TPRTYI bit indicates a parity error over the active TDAT bus. This bit is cleared when this register is read. Odd or even parity is selected using the TPTYP bit.

TSOCE:

The TSOCE bit enables the generation of an interrupt when the TSOC input is sampled high during any position other than the first word of the selected data structure. When TSOCE is set to logic one, the interrupt is enabled.

Bit 4	R/W	PAYLD[4]	0
Bit 3	R/W	PAYLD[3]	1
Bit 2	R/W	PAYLD[2]	0
Bit 1	R/W	PAYLD[1]	1
Bit 0	R/W	PAYLD[0]	0

PAYLD[7:0]:

The PAYLD[7:0] bits contain the pattern inserted in the idle cell payload. Idle cells are inserted when the TXCP detects that the transmit FIFO contains no outstanding cells. PAYLD[7] is the most significant bit and is the first bit transmitted. PAYLD[0] is the least significant bit.

Bit	Type	Function	Default
Bit 7	R	TCELL[23]	X
Bit 6	R	TCELL[22]	X
Bit 5	R	TCELL[21]	X
Bit 4	R	TCELL[20]	X
Bit 3	R	TCELL[19]	X
Bit 2	R	TCELL[18]	X
Bit 1	R	TCELL[17]	X
Bit 0	R	TCELL[16]	X

TCELL[23:0]:

The TCELL[23:0] bits indicate the number of cells read from the transmit FIFO and inserted into the transmission stream during the last accumulation interval. Idle cells inserted into the transmission stream are not counted.

A write to any one of the TXCP Transmit Cell Counter registers or to the S/UNI-622-MAX Master Reset and Identity register loads the registers with the current counter value and resets the internal 19 bit counter to 1 or 0. The counter reset value is dependent on if there was a count event during the transfer of the count to the Transmit Cell Counter registers. The counter should be polled every second to avoid saturating. The contents of these registers are valid after a maximum of 67 TCLK cycles after a transfer is triggered by a write to a TXCP Transmit Cell count Register or the S/UNI-622-MAX Master Reset and Identity register.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0x90: RUL3 Configuration

Bit	Type	Function	Default
Bit 7		Unused	X
Bit 6		Unused	X
Bit 5		Unused	X
Bit 4	R/W	RL3PP	0
Bit 3		Unused	X
Bit 2	R/W	RMOVR	0
Bit 1	R/W	Reserved	X
Bit 0	R/W	RSYSSEL	X

RSYSSEL:

The Receive System Interface Select RSYSSEL allows the SYSSEL pin to be observed and overridden by software. When the RMOVR bit is set low, the RSYSSEL bit is read-only and reports the status of the SYSSEL pin. When RMOVR is set high, the value of the RSYSSEL bit is used to determine the system mode and the SYSEL pin is ignored.

When RMOVR is set high and RSYSSEL is set low, the receive side of the system interface is configured for Level 2 operation. When RMOVR is set high and RSYSSEL is set high, the receive side of the system interface is configured for Level 3 operation.

RMOVR:

The Receive Mode Over-Ride bit RMOVR enables the RSYSSEL bit to override the mode selected by the SYSSEL pin. When RMOVR is low, the receive side of the system interface is selected by the external pins, and can be read from the RSYSSEL register bit. When RMOVR is high, the mode is controlled by writing to the RSYSSEL bit, and the external mode pins are ignored.

RL3PP:

The Receive Level 3 Parity RL3PP bit selects even or odd parity for output RPRTY when the system interface is configured for Level 3 operation. When set high, output RPRTY is the even parity bit for outputs RDAT[7:0]. When RL3PP is set to low, RPRTY is the odd parity bit for outputs RDAT[7:0].

Register 0x92: TUL3 Configuration

Bit	Type	Function	Default
Bit 7		Unused	X
Bit 6		Unused	X
Bit 5		Unused	X
Bit 4	R/W	TL3PP	0
Bit 3		Unused	X
Bit 2	R/W	TMOVR	0
Bit 1	R/W	Reserved	X
Bit 0	R/W	TSYSSEL	X

TSYSSEL:

The Transmit System Interface Select TSYSSEL allows the SYSSEL pin to be observed and overridden by software. When the TMOVR bit is set low, the TSYSSEL bit is read-only and reports the status of the SYSSEL pin. When TMOVR is set high, the value of the TSYSSEL bit is used to determine the system mode and the SYSEL pin is ignored.

When TMOVR is set high and TSYSSEL is set low, the transmit side of the system interface is configured for Level 2 operation. When TMOVR is set high and TSYSSEL is set high, the transmit side of the system interface is configured for Level 3 operation.

TMOVR:

The Transmit Mode Over-Ride bit TMOVR enables the TSYSSEL bit to override the mode selected by the SYSSEL pin. When TMOVR is low, the system interface mode is selected by the external pins, and can be read from the TSYSSEL register bit. When TMOVR is high, the mode is controlled by writing to the TSYSSEL bit, and the external mode pins are ignored.

TL3PP:

The Transmit Level 3 Parity TL3PP bit selects even or odd parity for input RPRTY when the system interface is configured for Level 3 operation. When set high, input TPRTY is the even parity bit for inputs TDAT[7:0]. When TL3PP is set to low, TPRTY is the odd parity bit for input RDAT[7:0]. TL3PP is ignored when the system interface is configured for Level 2 operation.

PMC-Sierra, Inc.

TL3PP is ignored when the system interface is configured for Level 2 operation.

Register 0x97: DLL RUL3 Control Status

Bit	Type	Function	Default
Bit 7	R	RFCLKI	X
Bit 6	R	Reserved	X
Bit 5	R	ERRORI	X
Bit 4	R	Reserved	X
Bit 3		Unused	X
Bit 2	R	ERROR	X
Bit 1	R	Reserved	X
Bit 0	R	RUN	X

The DLL Control Status Register provides information of the DLL operation.

RUN:

The DLL lock status register bit RUN indicates the DLL has found an initial lock condition. When the phase detector first indicates lock, RUN is set high. The RUN register bit is cleared only by a system reset or a software reset.

ERROR:

The delay line error register ERROR indicates the DLL is currently at the end of the delay line. ERROR is set high when the DLL tries to move beyond the end of the delay line.

ERRORI:

The error event register bit ERRORI indicates the ERROR register bit has been a logic one. When the ERROR register changes from a logic zero to a logic one, the ERRORI register bit is set to logic one. The ERRORI register bit is cleared immediately after it is read, thus acknowledging the event has been recorded.

RFCLKI:

The clock event register bit RFCLKI provides a method to monitor activity on the RFCLK clock. When the RFCLK input changes from a logic zero to a logic one, the RFCLKI register bit is set to logic one. The RFCLKI register bit is cleared immediately after it is read, thus acknowledging the event has been recorded.

Bit 4	R/W	OVERRIDE	0
Bit 3		Unused	X
Bit 2		Unused	X
Bit 1	R/W	Reserved	0
Bit 0	R/W	Reserved	0

The DLL Configuration Register controls the basic operation of the DLL for the receive system interface clock PTCLK.

OVERRIDE:

The override control (OVERRIDE) disables the DLL operation. When OVERRIDE is set low, the DLL generates the internal clock by delaying the PTCLK to ensure the best possible output propagation on the system interface. When OVERRIDE is set high, the system interface output propagation will not meet the specified timing. This feature provides a back-up strategy for very low frequency PTCLK operation.

Bit 3	R/W	SDBERE	0
Bit 2		Unused	X
Bit 1		Unused	X
Bit 0		Unused	X

SDBERE:

The SDBERE bit is the interrupt enable for the signal degrade threshold alarm. When SDBERE is a logic one, an interrupt is generated when the SD alarm is declared or removed.

SFBERE:

The SFBERE bit is the interrupt enable for the signal fail threshold alarm. When SFBERE is a logic one, an interrupt is generated when the SF alarm is declared or removed.

Z1/S1E:

The Z1/S1 interrupt enable is an interrupt mask for changes in the received synchronization status. When Z1/S1E is a logic one, an interrupt is generated when a new synchronization status message is extracted into the Receive Z1/S1 register.

COAPSE:

The COAPS interrupt enable is an interrupt mask for changes in the received APS code. When COAPSE is a logic one, an interrupt is generated when a new K1/K2 code value is extracted into the RASE Receive K1 and RASE Receive K2 registers.

Register 0xE1: RASE Interrupt Status

Bit	Type	Function	Default
Bit 7	R	PSBFI	X
Bit 6	R	COAPSI	X
Bit 5	R	Z1/S1I	X
Bit 4	R	SFBERI	X
Bit 3	R	SDBERI	X
Bit 2	R	SFBERV	X
Bit 1	R	SDBERV	X
Bit 0	R	PSBFV	X

PSBFV:

The PSBFV bit indicates the protection switching byte failure alarm state. The alarm is declared (PSBFV is set high) when twelve successive frames have been received without three consecutive frames containing identical K1 bytes. The alarm is removed (PSBFV is set low) when three consecutive frames containing identical K1 bytes have been received.

SDBERV:

The SDBERV bit indicates the signal degrade threshold crossing alarm state. The alarm is declared (SDBERV is set high) when the bit error rate exceeds the threshold programmed in the RASE SD Declaring Threshold registers. The alarm is removed (SDBERV is set low) when the bit error rate is below the threshold programmed in the RASE SD Clearing Threshold registers.

SFBERV:

The SFBERV bit indicates the signal failure threshold crossing alarm state. The alarm is declared (SFBERV is set high) when the bit error rate exceeds the threshold programmed in the RASE SF Declaring Threshold registers. The alarm is removed (SFBERV is set low) when the bit error rate is below the threshold programmed in the RASE SF Clearing Threshold registers.

SDBERI:

The SDBERI bit is set high when the signal degrade threshold crossing alarm is declared or removed. This bit is cleared when the RASE Interrupt Status register is read.

SATURN USER NETWORK INTERFACE (622-MAX)

<u>SFBERI:</u>

The SFBERI bit is set high when the signal failure threshold crossing alarm is declared or removed. This bit is cleared when the RASE Interrupt Status register is read.

<u>Z1/S1I:</u>

The Z1/S1I bit is set high when a new synchronization status message has been extracted into the RASE Receive Z1/S1 register. This bit is cleared when the RASE Interrupt Status register is read.

<u>COAPSI:</u>

The COAPSI bit is set high when a new APS code value has been extracted into the RASE Receive K1 and RASE Receive K2 registers. This bit is cleared when the RASE Interrupt Status register is read.

<u>PSBFI:</u>

The PSBFI bit is set high when the protection switching byte failure alarm is declared or removed. This bit is cleared when the RASE Interrupt Status register is read.

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

Register 0xE2: RASE Configuration/Control

Bit	Type	Function	Default
Bit 7	R/W	Z1/S1_CAP	0
Bit 6	R/W	SFBERTEN	0
Bit 5	R/W	SFSMODE	0
Bit 4	R/W	SFCMODE	0
Bit 3	R/W	SDBERTEN	0
Bit 2	R/W	SDSMODE	0
Bit 1	R/W	SDCMODE	0
Bit 0	R/W	Reserved	0

SDCMODE:

The SDCMODE alarm bit selects the RASE window size to use for clearing the SD alarm. When SDCMODE is a logic zero, the RASE clears the SD alarm using the same window size used for declaration. When SDCMODE is a logic one, the RASE clears the SD alarm using a window size that is 8 times longer than the alarm declaration window size. The declaration window size is determined by the RASE SD Accumulation Period registers.

SDSMODE:

The SDSMODE bit selects the RASE saturation mode. When SDSMODE is a logic zero, the RASE limits the number of B2 errors accumulated in one frame period to the RASE SD Saturation Threshold register value. When SDSMODE is a logic one, the RASE limits the number of B2 errors accumulated in one window subtotal accumulation period to the RASE SD Saturation Threshold register value. Note that the number of frames in a window subtotal accumulation period is determined by the RASE SD Accumulation Period register value.

SDBERTEN:

The SDBERTEN bit selects automatic monitoring of line bit error rate threshold events by the RASE. When SDBERTEN is a logic one, the RASE continuously monitors line BIP errors over a period defined in the RASE configuration registers. When SDBERTEN is a logic zero, the RASE BIP accumulation logic is disabled, and the RASE logic is reset to the declaration monitoring state.

RELEASED
S/UNI-622-MAX
DATASHEET

PMC-1980589

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

All RASE accumulation period and threshold registers should be set up before SDBERTEN is written.

SFCMODE:

The SFCMODE alarm bit selects the RASE window size to use for clearing the SF alarm. When SFCMODE is a logic zero, the RASE clears the SF alarm using the same window size used for declaration. When SFCMODE is a logic one, the RASE clears the SF alarm using a window size that is 8 times longer than the alarm declaration window size. The declaration window size is determined by the RASE SF Accumulation Period registers.

SFSMODE:

The SFSMODE bit selects the RASE saturation mode. When SFSMODE is a logic zero, the RASE limits the number of B2 errors accumulated in one frame period to the RASE SF Saturation Threshold register value. When SFSMODE is a logic one, the RASE limits the number of B2 errors accumulated in one window subtotal accumulation period to the RASE SF Saturation Threshold register value. Note that the number of frames in a window subtotal accumulation period is determined by the RASE SF Accumulation Period register value.

SFBERTEN:

The SFBERTEN bit enables automatic monitoring of line bit error rate threshold events by the RASE. When SFBERTEN is a logic one, the RASE continuously monitors line BIP errors over a period defined in the RASE configuration registers. When SFBERTEN is a logic zero, the RASE BIP accumulation logic is disabled, and the RASE logic is reset to the declaration monitoring state.

All RASE accumulation period and threshold registers should be set up before SFBERTEN is written.

Z1/S1_CAP:

The Z1/S1_CAP bit enables the Z1/S1 Capture algorithm. When Z1/S1_CAP is a logic one, the Z1/S1 clock synchronization status message nibble must have the same value for eight consecutive frames before writing the new value into the RASE Receive Z1/S1 register. When Z1/S1_CAP is logic zero, the Z1/S1 nibble value is written directly into the RASE Receive Z1/S1 register.

Reserved:

The reserved bits must be programmed to logic zero for proper operation.

SATURN USER NETWORK INTERFACE (622-MAX)

Register 0xF7: RASE Receive Z1/S1

Bit	Type	Function	Default
Bit 7	R	Z1/S1[7]	X
Bit 6	R	Z1/S1[6]	X
Bit 5	R	Z1/S1[5]	X
Bit 4	R	Z1/S1[4]	X
Bit 3	R	Z1/S1[3]	X
Bit 2	R	Z1/S1[2]	X
Bit 1	R	Z1/S1[1]	X
Bit 0	R	Z1/S1[0]	X

Z1/S1[3:0]:

The lower nibble of the first Z1/S1 byte contained in the receive stream is extracted into this register. The Z1/S1 byte is used to carry synchronization status messages between line terminating network elements. Z1/S1[3] is the most significant bit corresponding to bit 5, the first bit received. Z1/S1[0] is the least significant bit, corresponding to bit 8, the last bit received. An interrupt may be generated when a byte value is received that differs from the value extracted in the previous frame (using the Z1/S1E bit in the RASE Interrupt Enable Register). In addition, debouncing can be performed where the register is not loaded until eight of the same consecutive nibbles are received. Debouncing is controlled using the Z1/S1_CAP bit in the RASE Configuration/Control register.

Z1/S1[7:4]:

The upper nibble of the first Z1/S1 byte contained in the receive stream is extracted into this register. No interrupt is asserted on the change of this nibble. In addition, when the Z1/S1_CAP bit in the RASE Configuration/Control register selects debouncing, the upper nibble is only updated when eight of the same consecutive lower nibbles are received.

Bit 3		Unused	X
Bit 2		Unused	X
Bit 1	R/W	AISCE	0
Bit 0	R/W	LOPCE	0

<u>LOPCE:</u>

The LOPCE bit is the interrupt enable for the Loss of Pointer Concatenation event. When LOPCE is a logic one, an interrupt is generated when the state of the Loss of Pointer Concatenation indicator changes.

<u>AISCE:</u>

The AISCE bit is the interrupt enable for the Pointer AIS event. When AISCE is a logic one, an interrupt is generated when the state of the Pointer AIS indicator changes.

<u>LOPCV:</u>

The LOPCV bit is the Loss of Pointer Concatenation indicator. When LOPCV is logic one, the STS-12c/STM-4-4c pointers do not indicate a concatenated payload. When LOPCV and AISCV are both logic zero, a STS-12c/STM-4-4c payload is indicated.

<u>AISCV:</u>

The ASICV bit is the Pointer AIS indicator. When AISCV is logic one, the STS-12c/STM-4-4c pointer indicates a pointer AIS condition. When LOPC and AISCV are both logic zero, a STS-12c/STM-4-4c payload is indicated.

12 TEST FEATURES DESCRIPTION

Simultaneously asserting (low) the CSB, RDB and WRB inputs causes all digital output pins and the data bus to be held in a high-impedance state. This test feature may be used for board testing.

Test mode registers are used to apply test vectors during production testing of the S/UNI-622-MAX. Test mode registers (as opposed to normal mode registers) are selected when TRS (A[8]) is high.

In addition, the S/UNI-622-MAX also supports a standard IEEE 1149.1 five-signal JTAG boundary scan test port for use in board testing. All digital device inputs may be read and all digital device outputs may be forced via the JTAG test port.

Table 4: Test Mode Register Memory Map

Address	Register
0x000-0x0FF	Normal Mode Registers
0x100	Master Test Register
0x101-0x1FF	Reserved For Production Test

12.1 Master Test and Test Configuration Registers

Notes on Test Mode Register Bits:

1. Writing values into unused register bits has no effect. However, to ensure software compatibility with future, feature-enhanced versions of the product, unused register bits must be written with logic zero. Reading back unused bits can produce either a logic one or a logic zero; hence, unused register bits should be masked off by software when read.

2. Writable test mode register bits are not initialized upon reset unless otherwise noted.

Register 0x100: Master Test Register

Bit	Type	Function	Default
Bit 7		Unused	X
Bit 6	W	Reserved	X
Bit 5	W	PMCATST	X
Bit 4	W	PMCTST	X
Bit 3	W	DBCTRL	X
Bit 2		Reserved	0
Bit 1	W	HIZDATA	X
Bit 0	R/W	HIZIO	0

This register is used to enable S/UNI-622-MAX test features. All bits, except PMCTST andPMCATST are reset to zero by a reset of the S/UNI-622-MAX using either the RSTB input or the Master Reset register. PMCTST and PMCATST can also be reset by writing a logic zero to the corresponding register bit.

HIZIO, HIZDATA:

The HIZIO and HIZDATA bits control the tri-state modes of the S/UNI-622-MAX . While the HIZIO bit is a logic one, all output pins of the S/UNI-622-MAX except the data bus and output TDO are held tri-state. The microprocessor interface is still active. While the HIZDATA bit is a logic one, the data bus is also held in a high-impedance state which inhibits microprocessor read cycles. The HIZDATA bit is overridden by the DBCTRL bit.

DBCTRL:

The DBCTRL bit is used to pass control of the data bus drivers to the CSB pin. When the DBCTRL bit is set to logic one and PMCTST is set to logic one, the CSB pin controls the output enable for the data bus. While the DBCTRL bit is set, holding the CSB pin high causes the S/UNI-622-MAX to drive the data bus and holding the CSB pin low tri-states the data bus. The DBCTRL bit overrides the HIZDATA bit. The DBCTRL bit is used to measure the drive capability of the data bus driver pads.

PMCTST:

The PMCTST bit is used to configure the S/UNI-622-MAX for PMC's manufacturing tests. When PMCTST is set to logic one, the S/UNI-622-MAX

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

microprocessor port becomes the test access port used to run the PMC "canned" manufacturing test vectors. The PMCTST bit can be cleared by setting CSB to logic one and RSTB to logic zero or by writing logic zero to the bit.

PMCATST:

The PMCATST bit is used to configure the analog portion of the S/UNI-622-MAX for PMC's manufacturing tests. The PMCTST bit can be cleared by setting CSB to logic one and RSTB to logic zero or by writing logic zero to the bit.

12.2 JTAG Test Port

The JTAG Test Access Port (TAP) allows access to the TAP controller and the 4
TAP registers: instruction, bypass, device identification and boundary scan.
Using the TAP, device input logic levels can be read, device outputs can be
forced, the device can be identified and the device scan path can be bypassed.
For more details on the JTAG port, please refer to the Operation section.

NOTES:

1. Enable "pinname_OEN" tristates pin "pinname" when set high.

2. ROEN is the active low output enable for RDAT[15:0], RSOC, RVAL and RPRTY.

3. HIZ is the active low output enable for all OUT_CELL types except D[7:0], RDAT[15:0], RSOC, RVAL, RPRTY, APS[4:0] and INTB.

4. RSTB is the first bit of the boundary scan chain closest to the TDI TAP input.

12.2.1 Boundary Scan Cells

In the following diagrams, CLOCK-DR is equal to TCK when the current controller state is SHIFT-DR or CAPTURE-DR, and unchanging otherwise. The multiplexer in the center of the diagram selects one of four inputs, depending on the status of select lines G1 and G2. The ID Code bit is as listed in the Boundary Scan Register table located above.

SATURN USER NETWORK INTERFACE (622-MAX)
13 OPERATION

13.1 SONET/SDH Frame Mappings and Overhead Byte Usage

13.1.1 ATM Mapping

The S/UNI-622-MAX processes the ATM cell mapping for STS-12c/STM-4-4c as shown below in Figure 11. The S/UNI-622-MAX processes the transport and path overhead required to support ATM UNIs and NNIs. In addition, the S/UNI-622-MAX provides support for the APS bytes, the data communication channels and provides full control and observability of the transport and path overhead bytes through register access. In Figure 11, the STS-12c/STM-4-4c mapping is shown. In this mapping, three stuff columns are included in the SPE. No other options are provided.

Figure 11: ATM Mapping into the STS-12c/STM-4-4c SPE

13.1.2 Transport and Path Overhead Bytes

Under normal operating conditions, the S/UNI-622-MAX processes a subset of the complete transport overhead present in an STS-12c/STM-4-4c stream. The byte positions processed by the S/UNI-622-MAX are indicated in Figure 12.

Transport Overhead Bytes

A1, A2:   The frame alignment bytes (A1, A2) locate the SONET/SDH frame in the STS-12c/STM-4-4c serial stream.

J0   The J0 byte is currently defined as the STS-12c/STM-4-4c section trace byte for SONET/SDH. J0 byte is not scrambled by the frame synchronous scrambler.

Z0:   The Z0 bytes are currently defined as the STS-12c/STM-4-4c section growth bytes for SONET/SDH. Z0 bytes are not scrambled by the frame synchronous scrambler.

B1:   The section bit interleaved parity byte provides a section error monitoring function.

In the transmit direction, the S/UNI-622-MAX calculates the B1 byte over all bits of the previous frame after scrambling. The calculated code is then placed in the current frame before scrambling.

In the receive direction, the S/UNI-622-MAX calculates the B1 code over the current frame and compares this calculation with the B1 byte received in the following frame. B1 errors are accumulated in an error event counter.

PM5356
S/UNI-622-MAX

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

H1, H2: The pointer value bytes locate the path overhead column in the SONET/SDH frame.

In the transmit direction, the S/UNI-622-MAX inserts a fixed pointer value, with a normal new data flag indication in the first H1-H2 pair. The concatenation indication is inserted in the remaining H1-H2 pairs (STS-12c/STM-4-4c). Pointer movements can be induced using the TPOP registers.

In the receive direction, the pointer is interpreted to locate the SPE. The loss of pointer state is entered when a valid pointer cannot be found. Path AIS is detected when H1, H2 contain an all ones pattern.

H3: The pointer action bytes contain synchronous payload envelope data when a negative stuff event occurs. The all zeros pattern is inserted in the transmit direction. This byte is ignored in the receive direction unless a negative stuff event is detected.

B2: The line bit interleaved parity bytes provide a line error monitoring function.

In the transmit direction, the S/UNI-622-MAX calculates the B2 values. The calculated code is then placed in the next frame.

In the receive direction, the S/UNI-622-MAX calculates the B2 code over the current frame and compares this calculation with the B2 code receive in the following frame. Receive B2 errors are accumulated in an error event counter.

K1, K2: The K1 and K2 bytes provide the automatic protection switching channel. The K2 byte is also used to identify line layer maintenance signals. Line RDI is indicated when bits 6, 7, and 8 of the K2 byte are set to the pattern '110'. Line AIS is indicated when bits 6, 7, and 8 of the K2 byte are set to the pattern '111'.

In the transmit direction, the S/UNI-622-MAX provides register control for the K1 and K2 bytes.

In the receive direction, the S/UNI-622-MAX provides register access to the filtered APS channel. Protection switch byte failure alarm detection is provided. The K2 byte is examined to determine the presence of the line AIS, or the line RDI maintenance signals

PM5356
S/UNI-622-MAX

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

S1: The S1 byte provides the synchronization status byte. Bits 5 through 8 of the synchronization status byte identifies the synchronization source of the STS-12c/STM-4-4c signal. Bits 1 through 4 are currently undefined.

In the transmit direction, the S/UNI-622-MAX provides register control for the synchronization status byte.

In the receive direction, the S/UNI-622-MAX provides register access to the synchronization status byte. The SSTB block also provides circuitry to detect synchronization status mismatch and unstable alarms.

Z1: The Z1 bytes are located in the second and third STS-1's locations of an STS-12c/STM-4-4c and are allocated for future growth.

M1: The M1 byte is located in the third STS-1 locations of a STS-12c/STM-4-4c and provides a line far end block error function for remote performance monitoring.

Z2: The Z2 bytes are located in the first and second STS-1's locations of a STS-12c/STM-4-4c and are allocated for future growth.

In the transmit direction, Z2 byte is internally generated. The number of B2 errors detected in the previous interval is inserted.

In the receive direction, a legal Z2 byte value is added to the line FEBE event counter.

Path Overhead Bytes

J1: The Path Trace byte is used to repetitively transmit a 64-byte CLLI message (for SONET/SDH networks), or a 16-byte E.164 address (for SDH networks). When not used, this byte should be set to transmit continuous null characters. Null is defined as the ASCII code, 0x00.

In the transmit direction, characters can be inserted using the TPOP Path Trace register or the SPTB block. The register is the default selection and resets to 0x00 to enable the transmission of NULL characters from a reset state.

In the receive direction, the path trace message is optionally extracted into the 16 or 64 byte path trace message buffer.

PM5356
S/UNI-622-MAX

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

B3:   The path bit interleaved parity byte provides a path error monitoring function.

In the transmit direction, the S/UNI-622-MAX calculates the B3 bytes. The calculated code is then placed in the next frame.

In the receive direction, the S/UNI-622-MAX calculates the B3 code and compares this calculation with the B3 byte received in the next frame. B3 errors are accumulated in an error event counter.

C2:   The path signal label indicator identifies the equipped payload type. For ATM payloads, the identification code is 0x13.

In the transmit direction, the S/UNI-622-MAX inserts the value 0x13 or 0x16 using the TPOP Path Signal Label register.

In the receive direction, the code is available in the RPOP Path Signal Label register. In addition, the SPTB block also provides circuitry to detect path signal label mismatch and unstable alarms.

G1:   The path status byte provides a path FEBE function, and a path remote defect indication function. Three bits are allocated for remote defect indications: bit 5 (the path RDI bit), bit 6 (the auxiliary path RDI bit) and bit 7 (Enhanced RDI bit). Taken together these bits provide a eight state path RDI code that can be used to categorize path defect indications.

In the transmit direction, the S/UNI-622-MAX provides register bits to control the path RDI (bit 5) and auxiliary path RDI (bit 6) states. For path FEBE, the number of B3 errors detected in the previous interval is inserted either automatically or using a register. This path FEBE code has 9 legal values, namely 0 to 8 errors.

In the receive direction, a legal path FEBE value is accumulated in the path FEBE event counter. In addition, the path RDI and auxiliary path RDI signal states are available in internal registers.

H4:   The multi-frame indicator byte is a payload specific byte, and is not used for ATM payloads. This byte is forced to 0x00 in the transmit direction, and is ignored in the receive direction.

Z3 - Z5:   The path growth bytes provide three unused bytes for future use.

In the transmit direction, the growth bytes may be inserted from the three TPOP Path Growth byte registers.

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

13.2 ATM Cell Data Structure

ATM cells may be passed to/from the S/UNI-622-MAX using a 27 word, 16-bit UTOPIA level 2 compliant data structure or using a 54 byte, 8-bit UTOPIA level 3 compliant data structure. The former data structure is shown in Figure 13 and described below.

Figure 13: 16-bit Wide, 27 Word ATM Cell Structure

	Bit 15 Bit 8	Bit 7 Bit 0
Word 1	H1	H2
Word 2	H3	H4
Word 3	H5	HCS Status/Control
Word 4	Payload 1	Payload 2
Word 5	Payload 3	Payload 4
Word 6	Payload 5	Payload 6
Word 7	Payload 7	Payload 8
Word 8	Payload 9	Payload 10
	⋮	⋮
Word 27	Payload 47	Payload 48

Bit 15 of each word is the most significant bit (which corresponds to the first bit transmitted or received). The header check sequence octet (HCS) is passed through this structure. The start of cell indication input and output (TSOC and RSOC) are coincident with Word 1 (containing the first two header octets). Word 3 of this structure contains the HCS octet in bits 15 to 8.

In the receive direction, the lower 8 bits of Word 3 contain the HCS status octet. An all-zeros pattern in these 8 bits indicates that the associated header is error free. An all-ones pattern indicates that the header contains an uncorrectable error (if the HCSPASS bit in the RXCP Control Register is set to logic zero, the all-ones pattern will never be passed in this structure). An alternating ones and zeros pattern (0xAA) indicates that the header contained a correctable error. In this case the header passed through the structure is the "corrected" header.

DATASHEET
PMC-1980589

PMC-Sierra, Inc.

ISSUE 6

PM5356
S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

In the transmit direction, the HCS bit in the TXCP Control register determines whether the HCS is calculated internally or is inserted directly from the upper 8 bits of Word 3. The lower 8 bits of Word 3 contain the HCS control octet. The HCS control octet is an error mask that allows the insertion of one or more errors in the HCS octet. A logic one in a given bit position causes the inversion of the corresponding HCS bit position (for example a logic one in bit 7 causes the most significant bit of the HCS to be inverted). The HDCL control octet may be disabled by setting the HCSCTLEB register in the TXCP.

ATM cells can also be passed to/from the S/UNI-622-MAX using a 54 byte, 8-bit UTOPIA level 3 compliant data structure shown in Figure 14.

Figure 14: 8-bit Wide, 54 Byte ATM Cell Structure

Byte	Content
Byte 1	H1
Byte 2	H2
Byte 3	H3
Byte 4	H4
Byte 5	H5
Byte 6	HCS Status/Control
Byte 7	Payload 1
Byte 8	Payload 2
Byte 9	Payload 3
⋮	⋮
Byte 54	Payload 48

Bit 7 of each byte is the most significant bit (which corresponds to the first bit transmitted or received). The header check sequence octet (HCS) is passed through this structure. The start of cell indication input and output (TSOC and RSOC) are coincident with Byte 1.

13.3 Setting SONET or SDH Mode of Operation

The SONET and SDH standard for optical networking are very similar with only minor difference in overhead processing. The main difference between the SONET (Bellcore GR-253-CORE) and SDH (ITU.707) standards lies in the

RELEASED
S/UNI-622-MAX
DATASHEET
PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

PMC-Sierra, Inc.   **PM5356**
                                                         S/UNI-622-MAX

handling of some of the overhead bytes. Other details, like framing and data payload mappings are equivalent in SONET and SDH.

The bit error rate (BER) monitoring requirements are also slightly different between SONET and SDH. An application note, PMC-950820, explains the different parameters in detail for the RASE block.

The list below shows the various register setting to configure the S/UNI-16x155 for either SONET or SDH operation.

Table 8: Settings for SONET or SDH Operation

Configuration Registers	SONET	SDH
SDH_J0/Z0 (register offset 0x004)	0	X
ENSS (register offset 0x03D)	0	1
Path LEN16 (register offset 0x028)	0	1
Section LEN16 (register offset 0x050)	0	1
S[1:0] (register offset 0x46)	00	10

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

Notes:

1. SONET requires Z0 bytes to be set to the number corresponding to the STS-1 column number. SDH considers those bytes reserved.

2. When forcing a constant Z0 pattern (SDH_J0/ZO is high), the Z0 bytes must be DC balanced (approximately the same number of ones and zeros) as the bytes are not scrambled. Failure to do so may cause downstream clock recovery to lose lock.

3. SONET uses 64 byte trace messages while SDH uses 16 byte trace messages.

4. SDH specification requires the detector of SS bits to be "10".

5. The SS bits are undefined for SONET, but must be set to "10" for SDH.

13.4 Bit Error Rate Monitor

The S/UN-622-MAX provides two BERM blocks. One can be dedicated to monitor at the Signal Degrade (SD) error rate and the other dedicated to monitor at the Signal Fail (SF) error rate.

The Bit Error Rate Monitor (BERM) block counts and monitors line BIP errors over programmable periods of time (window size). It can monitor to declare an alarm or to clear it if the alarm is already set. A different threshold and accumulation period must be used to declare or clear the alarm, whether or not those two operations are not performed at the same BER. The following table lists the recommended content of the BERM registers for different error rates (BER). Both BERMs in the TSB are equivalent and are programmed similarly. In a normal application they will be set to monitor different BER.

When the SF/SD CMODE bit is set to one, the clearing monitoring is recommended to be performed using a window size that is 8 times longer than the declaration window size. When the SF/SD CMODE bit is set to zero, the clearing monitoring is recommended to be performed using a window size equal to the declaration window size. In all cases the clearing threshold is calculated for a BER that is 10 times lower than the declaration BER, as required in the references. The table indicates the declare BER and evaluation period only.

The saturation threshold is not listed in the table, and should be programmed with the value 0xFFF by default, deactivating saturation. Saturation capabilities are provided to allow the user to address issues associated with error bursts.

For additional information, please refer to the BERM application note (PMC-950820) for more detailed information.

13.5 Auto Alarm Control Configuration

The S/UNI-622-MAX supports the automatic generation of transmit alarm information based on the detected receive alarms. This functionality is controlled by the master AUTOxx register bits in register 0x02 and the Auto Path and Line Configuration registers 0x08 to 0x0F.

When consequential action is enabled for a given alarm condition, other S/UNI-622-MAX configuration registers become important. For instance, if consequential action for signal degrade is enabled, the RASE must be configured for the desired alarm thresholds. The following table lists register settings for path RDI and extended path RDI interfaces.

Table 10: Path RDI and Extended RDI Register Settings

13.6 Clocking Options

The S/UNI-622-MAX supports several clocking modes. Figure 15 is an abstraction of the clocking topology. The S/UNI-622-MAX can operate in source time, internally loop timed and externally loop timed.

Figure 15: Clocking Structure
Source timed operation is used for all public user network interfaces (UNIs) and for private UNIs and private network node interfaces (NNIs) that are not synchronized to the recovered clock.

The transmit clock in a public UNI must conform to SONET/SDH Network Element (NE) requirements specified in Bellcore GR-253-CORE. These requirements include jitter generation, short term clock stability, phase transients during synchronization failure, and holdover. The 77.76 MHz clock source is

                                                                         S/UNI-622-MAX

typically a VCO (or temperature compensated VCXO) locked to a primary reference source for public UNI applications. The accuracy of this clock source should be within ±20 ppm of 77.76 MHz to comply with the SONET/SDH network element free-run accuracy requirements.

The transmit clock in a private UNI or a private NNI may be locked to an external reference or may free-run. The simplest implementation requires an oscillator free-running at 77.76 MHz.

Source timed operation is selected by clearing the LOOPT bit of the Master Configuration register. REFCLK is multiplied by 8 to become the 622.08 MHz transmit clock. REFCLK must be jitter free. The source REFCLK is also internally used as the clock recovery reference during receive loss of transition conditions.

Internally loop timed operation is used for private UNIs and private NNIs that require synchronization to the recovered clock. This mode is selected by setting the LOOPT bit of the Master Control register to logic one. Normally, the transmit clock is locked to the receive data. In the event of a loss of signal/transition condition, the transmit clock is synthesized from REFCLK.

13.7 Loopback Operation

The S/UNI-622-MAX supports five loopback functions: path loopback, line loopback, data diagnostic loopback, parallel diagnostic loopback and serial diagnostic loopback. Each channel's loopback modes operate independently. The loopback modes are activated by the PDLE, SLLE, DLE, DPLE and SDLE bits contained in the S/UNI-622-MAX Master Configuration registers.

The line loopback, see Figure 16, connects the high speed receive data and clock to the high speed transmit data and clock, and can be used for line side investigations (including clock recovery and clock synthesis). While in this mode, the entire receive path is operating normally and cells can be received through the FIFO interface.

The serial diagnostic loopback, see Figure 17, connects the high speed transmit data and clock to the high speed receive data and clock. While in this mode, the entire transmit path is operating normally and data is transmitted on the TXD+/- outputs.

The parallel diagnostic loopback, see Figure 18, connects the byte wide transmit data and clock to the byte wide receive data and clock. While in this mode, the entire transmit path is operating normally and data is transmitted on the TXD+/- outputs.

SATURN USER NETWORK INTERFACE (622-MAX)
13.8 1+1 APS Support

The S/UNI-622-MAX has the ability to exchange transmit path data in order to implement a 1+1 APS interface. In order to use this capability, the serial line side interface must be used (1+1 APS support is not available in OC3 operation) as the parallel line side interface is used as the transmit path APS port.

The diagram in Figure 21 shows how to connect two S/UNI-622-MAX devices for 1+1 APS operation. The working device is the source of transmit path for both the working and the protection channels. The transmit path process TPOP as well as the TXCP and TXFP processors are unused in the protection device. The working device sends the transmit path data steam to the protection device using the parallel line interface pins. The protection device adds section and line overhead to the transmit path data stream using its TSOP and TLOP units. Thus, each channel has unique K1/K2 byte control and monitoring.

Figure 21: 1+1 APS Architecture
A 4-byte FIFO is used to handle wander between the TCLK of the working device and the TCLK of the protection device. Both transmit clocks TCLK must be the same frequency in order for this FIFO to operate normally. Therefore, the clock synthesis units (CSU) of both device must have the same reference clock input

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

REFCLK. The working and protection devices cannot operate in loop time as the frequency difference between the receive clock and the reference clock will cause the FIFO to underrun or overrun corrupting the protection transmit path. In order to perform loop-time operation, an external clocking source must be used.

The APS FIFO must be reset after both CSU units lock to the reference clock in order to center the FIFO. This the APSRST bit must be toggled when the ROOLV in the CSPI-622 indicates a CSU has lost lock or after a system reset. The ASPI register will indicate when the FIFO has corrupted data due to an overrun or an underrun.

The active channel is selected using the receive ATM System Interface. Thus, if the protection device is active, the receive System Interface of the protection device is used. If the working device is active, the receive System Interface of the working device is used. In all cases, the transmit System Interface of the working device is used for the transmit data stream.

In order for the S/UNI-622-MAX to support path AUTORDI and AUTOPFEBE functions, the APS[4:0] pins are used to exchange alarm information from the protection device to the TPOP of the working device. Thus, when the protection device is active, the working device must be configured to use the receive path alarm information from the protection device. Table 11 shows the register configurations for both normal operation and protection operation for both devices.

Table 11: 1+1 APS Register 0x06 Settings

Bit	Work Device (Normal)	Protect Device (Normal)	Work Device (Protection)	Protect Device (Protection)
APSEN	1	1	1	1
APSOE	0	1	0	1
APSPD	0	1	0	1
APSFEBE	0	X	1	X
APSRDI	0	X	1	X

13.9 JTAG Support

The S/UNI-622-MAX supports the IEEE Boundary Scan Specification as described in the IEEE 1149.1 standards. The Test Access Port (TAP) consists of the five standard pins, TRSTB, TCK, TMS, TDI and TDO used to control the TAP

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

controller and the boundary scan registers. The TRSTB input is the active-low reset signal used to reset the TAP controller. TCK is the test clock used to sample data on input, TDI and to output data on output, TDO. The TMS input is used to direct the TAP controller through its states. The basic boundary scan architecture is shown below.

Figure 22: Boundary Scan Architecture
The boundary scan architecture consists of a TAP controller, an instruction register with instruction decode, a bypass register, a device identification register and a boundary scan register. The TAP controller interprets the TMS input and generates control signals to load the instruction and data registers. The instruction register with instruction decode block is used to select the test to be executed and/or the register to be accessed. The bypass register offers a single-bit delay from primary input, TDI to primary output, TDO. The device identification register contains the device identification code.

The boundary scan register allows testing of board inter-connectivity. The boundary scan register consists of a shift register place in series with device inputs and outputs. Using the boundary scan register, all digital inputs can be

SATURN USER NETWORK INTERFACE (622-MAX)
13.9.2 States

Test-Logic-Reset

The test logic reset state is used to disable the TAP logic when the device is in normal mode operation. The state is entered asynchronously by asserting input, TRSTB. The state is entered synchronously regardless of the current TAP controller state by forcing input, TMS high for 5 TCK clock cycles. While in this state, the instruction register is set to the IDCODE instruction.

Run-Test-Idle

The run test/idle state is used to execute tests.

Capture-DR

The capture data register state is used to load parallel data into the test data registers selected by the current instruction. If the selected register does not allow parallel loads or no loading is required by the current instruction, the test register maintains its value. Loading occurs on the rising edge of TCK.

Shift-DR

The shift data register state is used to shift the selected test data registers by one stage. Shifting is from MSB to LSB and occurs on the rising edge of TCK.

Update-DR

The update data register state is used to load a test register's parallel output latch. In general, the output latches are used to control the device. For example, for the EXTEST instruction, the boundary scan test register's parallel output latches are used to control the device's outputs. The parallel output latches are updated on the falling edge of TCK.

Capture-IR

The capture instruction register state is used to load the instruction register with a fixed instruction. The load occurs on the rising edge of TCK.

Shift-IR

The shift instruction register state is used to shift both the instruction register and the selected test data registers by one stage. Shifting is from MSB to LSB and occurs on the rising edge of TCK.

PM5356
S/UNI-622-MAX

Update-IR

The update instruction register state is used to load a new instruction into the instruction register. The new instruction must be scanned in using the Shift-IR state. The load occurs on the falling edge of TCK.

The Pause-DR and Pause-IR states are provided to allow shifting through the test data and/or instruction registers to be momentarily paused.

Boundary Scan Instructions

The following is a description of the standard instructions. Each instruction selects a serial test data register path between input, TDI and output, TDO.

13.9.3 Instructions

BYPASS

The bypass instruction shifts data from input, TDI to output, TDO with one TCK clock period delay. The instruction is used to bypass the device.

EXTEST

The external test instruction allows testing of the interconnection to other devices. When the current instruction is the EXTEST instruction, the boundary scan register is placed between input, TDI and output, TDO. Primary device inputs can be sampled by loading the boundary scan register using the Capture-DR state. The sampled values can then be viewed by shifting the boundary scan register using the Shift-DR state. Primary device outputs can be controlled by loading patterns shifted in through input TDI into the boundary scan register using the Update-DR state.

SAMPLE

The sample instruction samples all the device inputs and outputs. For this instruction, the boundary scan register is placed between TDI and TDO. Primary device inputs and outputs can be sampled by loading the boundary scan register using the Capture-DR state. The sampled values can then be viewed by shifting the boundary scan register using the Shift-DR state.

IDCODE

The identification instruction is used to connect the identification register between TDI and TDO. The device's identification code can then be shifted out using the Shift-DR state.

DATASHEET
PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

STCTEST

The single transport chain instruction is used to test out the TAP controller and the boundary scan register during production test. When this instruction is the current instruction, the boundary scan register is connected between TDI and TDO. During the Capture-DR state, the device identification code is loaded into the boundary scan register. The code can then be shifted out output, TDO using the Shift-DR state.

13.10 Board Design Recommendations

The noise environment and signal integrity are often the limiting factors in system performance. Therefore, the following board design guidelines must be followed in order to ensure proper operation:

1. Use a single plane for both digital and analog grounds.

2. Provide separate +3.3 volt analog and +3.3 volt digital supplies, but otherwise connect the supply voltages together at one point close to the connector where +3.3 volts is brought to the card.

3. VBIAS biasing supply must be driven at a higher potential than the expected maximum digital input level. For 3.3 volt designs where all digital inputs are 3.3 volt TTL levels, VBIAS may be set to 3.3 volts or greater. For designs with 5.0 volt TTL levels, VBIAS must be set to 5.0 volts.

    PBIAS biasing supplies operate similarly. For designs using optical modules with 3.3 volt PECL levels, the PBIAS pins may be set to 3.3 volts or greater. For designs using optical modules with 5.0 volt PECL levels, the PBIAS pins must be set to 5.0 volts. If the serial interface is not being used, the PBIAS pins may be set to 3.3 volts. See the section on interfacing to ECL and PECL devices for more details

4. Ferrite beads are not advisable in digital switching circuits because inductive spiking (di/dt noise) is introduced into the power rail. Simple RC filtering is the best approach provided care is taken to ensure the IR drop in the resistance does not lower the supply voltage below the recommended operating voltage.

5. High-frequency decoupling capacitors are recommended for each biasing pins (VBIAS, PBIAS and QAVD) as close to the package pin as possible. Separate decoupling is required to prevent the transmitter from coupling noise into the receiver and to prevent power supply transients from coupling into some internal reference circuitry. See the section on Power Supplies for more details.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

6. Low-pass filtering networks are recommended for analog power supplies as close to the package pin as possible. Separate decoupling is required to prevent the transmitter from coupling noise into the receiver and to prevent power supply transients from coupling into some internal reference circuitry. See the section on Power Supplies for more details.

7. The high speed serial streams (TXD+/-, RXD+/, and RRCLK+/-) must be routed with 50 ohm controlled impedance circuit board traces and must be terminated with a matched load. Normal TTL-type design rules are not recommended and will reduce the performance of the device. See the section on interfacing to ECL and PECL devices for more details.

8. PECL traces between the S/UNI-622-MAX and optical modules should not exceed 4 cm for proper jitter operation.

Please refer to the S/UNI-622-MAX reference design (PMC-981070) for further recommendations

13.11 Power Supplies

Due to ESD protection structures in the pads it is necessary to exercise caution when powering a device up or down. ESD protection devices behave as diodes between power supply pins and from I/O pins to power supply pins. Under extreme conditions it is possible to blow these ESD protection devices or trigger latch up. The recommended power supply sequencing follows:

1. The VBIAS supply must be equal to or greater than the VDD supply during power up. By placing a decoupled 1 kohm in series with VBIAS as shown in Figure 24, this restriction may be ignored.

2. The PBIAS supplies must be equal to or greater than the AVD supply during power up. By placing a decoupled 1 kohm in series with the PBIAS supply as shown in Figure 24, this restriction may be ignored.

3. The VDD supply must be applied before or at the same time as QAVD and AVD supplies (the voltage difference between any two pins must be less than 0.5 volts).

4. VDD and VBIAS supplies must be applied before digital input pins are driven or the current per pin limited to less than the maximum DC input current specification.

ISSUE 6

PM5356
S/UNI-622-MAX

SATURN USER NETWORK INTERFACE (622-MAX)

5. AVD and PBIAS supplies must be applied before analog input pins are driven or the current per pin limited to less than the maximum DC input current specification.

6. The differential voltage between VDD and AVD must be less than 1.0 volts including peak to peak noise.. The differential voltage between VDD and QAVD must be less than 0.5 volts including peak to peak noise. Otherwise, digital noise on VDD will be coupled into the sensitive analog circuitry.

7. Power down the device in the reverse sequence. Use the above current limiting technique for the analog power supplies. Small offsets in VDD / AVD discharge times will not damage the device.

Analog circuitry is particularly susceptible to noise and thus we recommend the following analog power filter scheme shown Figure 24 and Figure 25. Sensitive analog power pins require RC filter networks in order to meet SONET/SDH jitter specifications. Some recommended notes follows:

8. Place each 0.1uF capacitor as close to its associated power pin as possible as shown in Figure 25.

9. The 0.1uF capacitors are ceramic X7R or X5R.

10. The 10uF capacitors are 10V X5R ceramic, 1210 size, from Tayio-Yuden, LMK325BJ106MN (visit their web site at www.t-yuden.com).

11. The 10uF capacitors and resistors do not have to be very close to power pins as they are filtering the power supply and not decoupling it.

12. The two 10uF X5R capacitors on pin C4 can be replaced by one 22uF, 10V, X5R LMK432BJ226MM from Tayio Yuden.

13. All resistors shown are 1/10 watt.

14. All other power pins not mentioned do not need any extra filtering or decoupling.

Please refer to the S/UNI-622-MAX reference design (PMC-981070) for further recommendations.

Figure 25: Power Supply Component Layout
13.12 Interfacing to ECL or PECL Devices

In normal operation, the S/UNI-622-MAX performs clock and data recovery on the incoming serial stream. As an option, internal clock and data recovery may be bypassed by setting the RBYP pin high and use an externally recovered receive clock on the RRCLK+/- pins. In this mode RXD+/- is sampled on the rising edge of RRCLK+/-. For example, Hewlett Packard provides HFCT/HFBR-5207 optical transceivers with clock and data recovery and HFCT/HFBR-5208 transceivers without clock and data recovery. The HFCT-5207 has a 2x9 pin out having one 9 pin row matching the pin out of the HFCT-5208 and another 9 pin row which provides extra signals for the recovered clock. By using a footprint that will fit both devices, either device may be used.

ISSUE 6

SATURN USER NETWORK INTERFACE (622-MAX)

Only a few passive components are required to convert the optical transceivers signals to ECL (or PECL) logic levels. Figure 26 and Figure 27 illustrate the recommended configurations for both types of ECL voltage levels. The PECLV pin must be set appropriately for the selected configuration.

Each PECL input and output has an associated ESD biasing pin PBIAS[3:0]. These biasing pins should be biased at the proper level to ensure the internal ESD diode structure is not forward biased. This means for 3.3V volt ECL logic levels (PECLV set high), the PBIAS pins may be biased from 3.3 volts to 5.0 volts. For 5.0 volt ECL logic levels (PECLV set low), the PBIAS pins must be biased at 5.0 volts. The bias pins should be high-frequency decoupled to prevent noise from coupling through the ESD structures and affecting the high-speed signals.

The 50 ohm control impedance traces must be less than 4 cm in length to reduce the effect of signal reflections between the optical module and the S/UNI-622-MAX. Vias should be avoided on the signal path between the optical module and the S/UNI-622-MAX as they can affect the jitter performance of the interface. Vias may be used for the termination networks as the inductive effective of a via will not significantly affect the termination performance.

PM5356
S/UNI-622-MAX
Figure 27: Interfacing S/UNI-622-MAX PECL Pins to 5.0V Devices
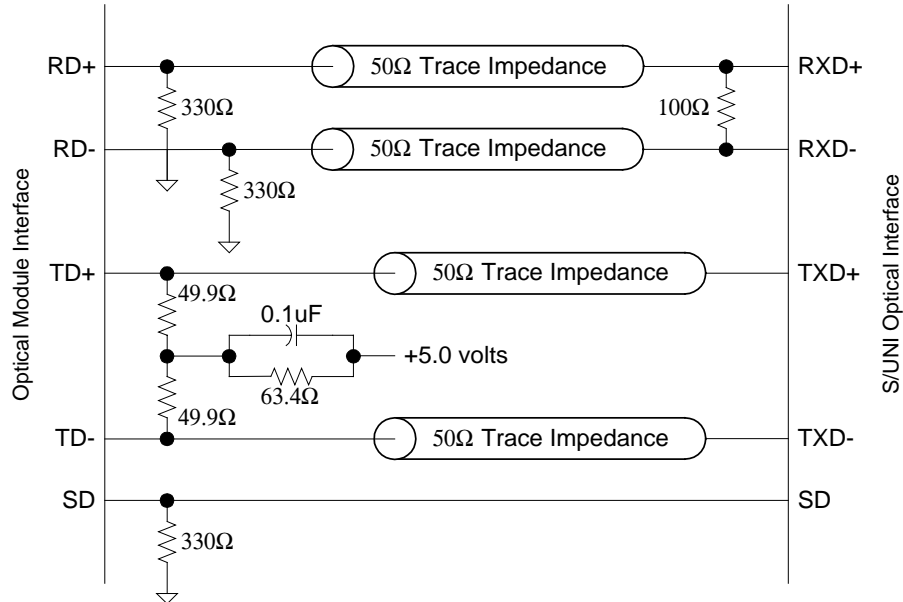

When a PECL input is not being used, the positive differential input must be tied to analog power (AVD) and the negative differential input must be tied to analog ground (AVS). In all cases, the PECL inputs must be driven with a differential voltage (do not connect both pins to AVD or AVS).

When the PECL output is not being used, the external reference resistor TDREF1 may be tied to analog power (AVD) and TDREF0 may be tied to analog group (AVS) to disable the PECL output. Both positive and negative differential outputs of the PECL output may be tied both to analog ground (AVS).

Please refer to the S/UNI-622-MAX reference design (PMC-981070) for further recommendations.

13.13 Clock Synthesis and Recovery

The Clock Synthesizer unit (CSU) in the S/UNI-622-MAX requires an external reference clock REFCLK to generate the 622 MHz transmit clock. The REFCLK input is a PECL input in order to reduce the amount of noise coupled into the CSU. In most cases, the reference clock must be generated and propagated using PECL logic in order for the CSU to meet SONET/SDH intrinsic jitter specifications.

RELEASED
S/UNI-622-MAX
DATASHEET
PMC-1980589   ISSUE 6   SATURN USER NETWORK INTERFACE (622-MAX)

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

In general, the reference clock REFCLK is supplied by a crystal oscillator with PECL outputs. The oscillator must have at least -115dBc/√Hz between 12 kHz and 5 MHz frequency offset in order for the CSU to meet SONET/SDH intrinsic jitter specifications. Do not use a TTL type crystal oscillator with a TTL to PECL converter as the TTL signal conversion will generate significant jitter on the reference clock.

Please refer to the S/UNI-622-MAX reference design (PMC-981070) for further recommendations.

13.14 System Interface DLL Operation

The S/UNI-622-MAX use digital delay lock loop (DLL) units to improve the output propagation timing on certain digital output pins. The TFCLK, RFCLK and PTCLK clock inputs each have a DLL to improve the timing on their associated interfaces.

The DLL compensate for internal timing and output pad delays by adaptively delaying the input clock signal by approximately one clock period (1 UI) to create a new clock which controls the internal device logic. A side effect is that the DLL units imposes a minimum clock rate on each of the clock signals. For certain operation modes, such as 19.44MHz OC3 clocking on PTCLK, the DLL is bypassed.

When the S/UNI-622-MAX is reset, the DLL units find the initial delay lock. This process may take up to 3100 clock cycles to identify the lock position. During this intial lock period, device interface timing will not meet the timing specifications listed in A.C. Timing section. The TCA/TPA pin is held low when the TFCLK DLL is finding lock. If the clock inputs are not stable during this period (for instance, a clock is generated using an external PLL), the S/UNI-622-MAX should be held in reset until the clocks are stable or the DLL should be reset using software control.

The RFCLK, TFCLK and PTCLK DLL software resets are performed by writing 0x00 to registers 0x96, 0x9A and 0x9E respectively. When resetting the RFCLK or TFCLK DLL units, the associated FIFOs in the RXCP, RXFP, TXCP and RXCP must also be reset using the their FIFORST register bits. The RUN register bit is set high when the DLL finds lock after a system or software reset.

The DLL units are sensitive to jitter on the clock inputs. The reason is that the DLL must track the changes in clock edges cause by changes in clock frequency, temperature, voltage and jitter. While the DLL may tolerate up to 0.4UIpp of clock jitter without losing phase lock, the output timing may degrade with

14 FUNCTIONAL TIMING

All functional timing diagrams assume that polarity control is not being applied to input and output data and clock lines (i.e. polarity control bits in the S/UNI-622-MAX registers are set to their default states).

14.1 Parallel Line Interface

The In Frame Declaration Timing diagram (Figure 28) illustrates the declaration of the in-frame state by the SUNI-622-MAX when processing a 77.76 Mbyte/s STS-12c/STM-4-4c stream on PIN[7:0]. An upstream serial-to-parallel converter indicates the location of the SONET/SDH frame using the FPIN input. The frame verification is initialized by a pulse on FPIN when the SUNI-622-MAX is out of frame. The in-frame state is declared if the framing pattern is observed in the correct byte positions in the following frame, and in the intervening period (125 us) no additional pulse were present of FPIN. The SUNI-622-MAX ignores pulses of FPIN while in frame. The algorithm results in a maximum average reframe time of 250 us in the absence of mimic framing patterns.

Figure 28: In Frame Declaration Timing
The Out of Frame Declaration Timing diagram (Figure 29) illustrates the declaration of out of frame for a STS-12c stream. The framing pattern is a 196-bit pattern that repeats once per frame. For the purposes of OOF declaration, the framing pattern may be modified using the ALGO2 bit in the RSOP Control register. Out of frame is declared when one or more errors are detected in this pattern for four consecutive frames as illustrated. In the presence of random data, out of frame will normally be declared within 500 us.

The FPOUT signal marks the SONET/SDH frame alignment on the POUT[7:0] bus. FPOUT pulses high during the first synchronous payload envelope byte after the J0/Z0 bytes.

Figure 30: Parallel Transmit Interface Timing
14.2 ATM UTOPIA Level 2 System Interface

The ATM UTOPIA Level 2 System Interface is compatible with the UTOPIA Level 2 specification (see References). The S/UNI-622-MAX only supports the 16-bit mode of operation.

The Transmit UTOPIA Level 2 System Interface Timing diagram (Figure 31) illustrates the operation of the system side transmit FIFO interface. Assertion of the transmit cell available output, TCA, indicates that there is space available in the transmit FIFO for at least one ATM cell structure. Deassertion of TCA occurs when the FIFO is filled with the number of ATM cells indicated by the register bits FIFODP[1:0]. If the TCA is configured to deassert early before the FIFO is truly full, the FIFO will accept additional cells even if TCA is inactive. At any time, if the upstream does not have a word to write, it must deassert TENB.

As well, the TCA may be configured to deassert after the last word of a cell is written into the FIFO (FIFO is full) or as the cell is being written into the FIFO (FIFO is near full). In addition, the register bit TCAINV can be used to invert the polarity of TCA.

S/UNI-622-MAX

TSOC must be high during the first word of the ATM cell structure and must be present for the start of each cell. When TSOC is asserted and the previous word transfer was not the end of an ATM cell structure, the system interface realigns itself to the new timing, and the previous partially transferred cell is dropped.
Figure 31: Transmit UTOPIA Level 2 System Interface Timing
The Receive UTOPIA Level 2 System Interface Timing diagram (Figure 32) illustrates the operation of the system side receive interface. The RXCP indicates that a cell is available by asserting the receive cell available output RCA. RCA remains high until the receive FIFO is empty. After RCA is deasserted, it remains low for a minimum of one RFCLK clock cycle and can then reassert to indicate that there are additional cells available in the FIFO.

At any time, the downstream reader can throttle back the reception of words by deasserting RENB. The RDAT[15:0], RPRTY and RSOC signals tri-state when RENB is sampled deasserted. RSOC is high during the first word of the cell and is present for each cell.

**Figure 32: Receive UTOPIA Level 2 System Interface Timing**

14.3 ATM UTOPIA Level 3 System Interface

The ATM UTOPIA Level 3 System Interface is compatible with the UTOPIA Level 3 specification (see References). The S/UNI-622-MAX only supports the 8-bit mode of operation.

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

The Transmit UTOPIA Level 3 System Interface Timing diagram (Figure 33) illustrates the operation of the system side transmit FIFO interface. Assertion of the transmit cell available output, TCA, indicates that there is space available in the transmit FIFO for at least one ATM cell structure. Deassertion of TCA occurs when the FIFO is filled with the number of ATM cells indicated by the register bits FIFODP[1:0]. If the TCA is configured to deassert early before the FIFO is truly full, the FIFO will accept additional cells even if TCA is inactive. At any time, if the upstream does not have a byte to write, it must deassert TENB. When TCA desserts, it will do so within 4 clocks cycles before the last byte of the cell.

TSOC must be high during the first byte of the ATM cell structure and must be present for the start of each cell. Thus, TSOC will mark the H1 byte. When TSOC is asserted and the previous byte transferred was not the end of an ATM cell structure, the system interface realigns itself to the new timing, and the previous partially transferred cell is dropped.

**Figure 33: Transmit UTOPIA Level 3 System Interface Timing**

The Receive UTOPIA Level 3 System Interface Timing diagram (Figure 34) illustrates the operation of the system side receive interface. Unlike traditional UTOPIA interfaces, the SUNI-622-MAX controls the bus. Because the bus is point to point, the SUNI-622-MAX pushes received data to the downstream reader. As well, the control of RENB is pipelined to improve the speed of the interface.

When a cell is available, the RVAL signal is asserted and the first byte of the cell appears on the RDAT[7:0] bus when RENB is low. The first byte of the structure is marked with RSOC being set high. Thus, RSOC will identify the H1 byte. The downstream reader may control the flow of data using RENB. If RENB is sampled low on the rising edge of RFCLK, the data on RDAT[7:0], RVAL and RSOC signals will be updated on the next rising edge of RFCLK. When RENB is sampled high on the rising edge of RFCLK, the data on RDAT[7:0], RVAL and RSOC will not change on the next rising edge of RFCLK. RENB must be low for at least 3 RFCLK clock cycles before RVAL will assert for the first byte of the first ATM cell.

ISSUE 6   *SATURN USER NETWORK INTERFACE (622-MAX)*

After the end of a cell, the SUNI-622-MAX will keep the RVAL signal high and mark the first byte of the next cell with RSOC asserted if the receive FIFO contained more than one cell.

15 ABSOLUTE MAXIMUM RATINGS

Maximum rating are the worst case limits that the device can withstand without sustaining permanent damage. They are not indicative of normal mode operation conditions.

Table 12: Absolute Maximum Ratings

Ambient Temperature under Bias	-40°C to +85°C
Storage Temperature	-40°C to +125°C
Supply Voltage	-0.3V to +4.6V
Bias Voltage (V_{BIAS})	(V_{DD} - .3) to +5.5V
Voltage on PECL Pin	-0.3V to V_{PBIAS}+0.3V
Voltage on 3.3V Tolerant Digital Pin	-0.3V to V_{VDD}+0.3V
Voltage on 5.0V Tolerant Digital Pin	-0.3V to V_{VBIAS}+0.3V
Static Discharge Voltage	±1000 V
Latch-Up Current per Pin	±100 mA
DC Input Current	±20 mA
Lead Temperature	+230°C
Absolute Maximum Junction Temperature	+150°C

SATURN USER NETWORK INTERFACE (622-MAX)
Notes on Microprocessor Interface Read Timing:

15. Output propagation delay time is the time in nanoseconds from the 1.4 Volt point of the reference signal to the 1.4 Volt point of the output.

16. Maximum output propagation delays are measured with a 100 pF load on the Microprocessor Interface data bus, (D[7:0]).

17. A valid read cycle is defined as a logical OR of the CSB and the RDB signals.

18. In non-multiplexed address/data bus architectures, ALE should be held high so parameters tS_{ALR}, tH_{ALR}, tV_L, tS_{LR}, and tH_{LR} are not applicable.

19. Parameter tH_{AR} is not applicable if address latching is used.

20. When a set-up time is specified between an input and a clock, the set-up time is the time in nanoseconds from the 1.4 Volt point of the input to the 1.4 Volt point of the clock.

21. When a hold time is specified between an input and a clock, the hold time is the time in nanoseconds from the 1.4 Volt point of the input to the 1.4 Volt point of the clock.

22. Output tri-state delay is the time in nanoseconds from the 1.4 Volt of the reference signal to the point where the total current delivered through the output is less than or equal to the leakage current.

PMC-Sierra, Inc.

PM5356
S/UNI-622-MAX

2. When a hold time is specified between an input and a clock, the hold time is the time in nanoseconds from the 1.4 Volt point of the clock to the 1.4 Volt point of the input.

Notes on Output Timing:

1. Output propagation delay time is the time in nanoseconds from the 1.4 Volt point of the reference signal to the 1.4 Volt point of the output.

2. Maximum output propagation delays are measured with a 50 pF load on the outputs.

3. Output tri-state delay is the time in nanoseconds from the 1.4 Volt of the reference signal to the point where the total current delivered through the output is less than or equal to the leakage current.
