

# 2-Mbit (128K x 18) Flow-through SRAM with NoBL™ Architecture

## Features

- Can support up to 117-MHz bus operations with zero wait states
  - Data is transferred on every clock
- Pin compatible and functionally equivalent to ZBT™ devices
- Internally self-timed output buffer control to eliminate the need to use OE
- Registered inputs for flow-through operation
- Byte Write capability
- 128K x 18 common I/O architecture
- Single 3.3V power supply
- Fast clock-to-output times
  - 7.5 ns (for 117-MHz device)
  - 8.5 ns (for 100-MHz device)
- Clock Enable (CEN) pin to suspend operation
- Synchronous self-timed writes
- Asynchronous Output Enable
- JEDEC-standard 100 TQFP package
- Burst Capability—linear or interleaved burst order
- Low standby power

## Functional Description<sup>[1]</sup>

The CY7C1231F is a 3.3V, 128K x 18 Synchronous Flow-through Burst SRAM designed specifically to support unlimited true back-to-back Read/Write operations without the insertion of wait states. The CY7C1231F is equipped with the advanced No Bus Latency™ (NoBL™) logic required to enable consecutive Read/Write operations with data being transferred on every clock cycle. This feature dramatically improves the throughput of data through the SRAM, especially in systems that require frequent Write-Read transitions.

All synchronous inputs pass through input registers controlled by the rising edge of the clock. The clock input is qualified by the Clock Enable (CEN) signal, which when deasserted suspends operation and extends the previous clock cycle. Maximum access delay from the clock rise is 7.5 ns (117-MHz device).

Write operations are controlled by the two Byte Write Select (BW<sub>[A:B]</sub>) and a Write Enable (WE) input. All writes are conducted with on-chip synchronous self-timed write circuitry.

Three synchronous Chip Enables (CE<sub>1</sub>, CE<sub>2</sub>, CE<sub>3</sub>) and an asynchronous Output Enable (OE) provide for easy bank selection and output three-state control. In order to avoid bus contention, the output drivers are synchronously three-stated during the data portion of a write sequence.

**Note:**

1. For best-practices recommendations, please refer to the Cypress application note *System Design Guidelines* on [www.cypress.com](http://www.cypress.com).

**Selection Guide**

	<b>CY7C1231F-117</b>	<b>CY7C1231F-100</b>	<b>Unit</b>
Maximum Access Time	7.5	8.5	ns
Maximum Operating Current	220	205	mA
Maximum CMOS Standby Current	40	40	mA

**Pin Configuration**
**100-lead TQFP**

**Pin Definitions** (100-pin TQFP Package)

Name	TQFP	I/O	Description
A <sub>0</sub> , A <sub>1</sub> , A	37,36,32,33,34, 35,44,45,46, 47,48,49,80,81, 82,99,100	Input- Synchronous	<b>Address Inputs used to select one of the 128K address locations.</b> Sampled at the rising edge of the CLK. A <sub>[1:0]</sub> are fed to the two-bit burst counter.
BW <sub>[A:B]</sub>	93,94	Input- Synchronous	<b>Byte Write Inputs, active LOW.</b> Qualified with WE to conduct writes to the SRAM. Sampled on the rising edge of CLK.
WE	88	Input- Synchronous	<b>Write Enable Input, active LOW.</b> Sampled on the rising edge of CLK if CEN is active LOW. This signal must be asserted LOW to initiate a write sequence.
ADV/LD	85	Input- Synchronous	<b>Advance/Load Input.</b> Used to <u>advance</u> the on-chip address counter or load a new address. When HIGH (and CEN is asserted LOW) the internal burst counter is advanced. When LOW, a new address can be loaded into the device for an access. After being deselected, ADV/LD should be driven LOW in order to load a new address.
CLK	89	Input-Clock	<b>Clock Input.</b> Used to capture all synchronous inputs to the device. CLK is qualified with CEN. CLK is only recognized if CEN is active LOW.
CE <sub>1</sub>	98	Input- Synchronous	<b>Chip Enable 1 Input, active LOW.</b> Sampled on the rising edge of CLK. Used in conjunction with CE <sub>2</sub> , and CE <sub>3</sub> to select/deselect the device.
CE <sub>2</sub>	97	Input- Synchronous	<b>Chip Enable 2 Input, active HIGH.</b> Sampled on the rising edge of CLK. Used in conjunction with CE <sub>1</sub> and CE <sub>3</sub> to select/deselect the device.
CE <sub>3</sub>	92	Input- Synchronous	<b>Chip Enable 3 Input, active LOW.</b> Sampled on the rising edge of CLK. Used in conjunction with CE <sub>1</sub> and CE <sub>2</sub> to select/deselect the device.
OE	86	Input- Asynchronous	<b>Output Enable, asynchronous input, active LOW.</b> Combined with the synchronous logic block inside the device to control the direction of the I/O pins. When LOW, the I/O pins are allowed to behave as outputs. When deasserted HIGH, I/O pins are three-stated, and act as input data pins. OE is masked during the data portion of a write sequence, during the first clock when emerging from a deselected state, when the device has been deselected.
CEN	87	Input- Synchronous	<b>Clock Enable Input, active LOW.</b> When asserted LOW the Clock signal is recognized by the SRAM. When deasserted HIGH the Clock signal is masked. Since deasserting CEN does not deselect the device, CEN can be used to extend the previous cycle when required.
ZZ	64	Input- Asynchronous	<b>ZZ “sleep” Input.</b> This active HIGH input places the device in a non-time critical “sleep” condition with data integrity preserved. During normal operation, this pin can be connected to V <sub>SS</sub> or left floating.
DQ <sub>s</sub>	58,59,62,63, 68,69,72,73,8, 9,12,13,18,19, 22,23	I/O- Synchronous	<b>Bidirectional Data I/O Lines.</b> As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by address during the clock rise of the read cycle. The direction of the pins is controlled by OE and the internal control logic. When OE is asserted LOW, the pins can behave as outputs. When HIGH, DQ <sub>s</sub> and DQP <sub>[A:B]</sub> are placed in a three-state condition. The outputs are automatically three-stated during the data portion of a write sequence, during the first clock when emerging from a deselected state, and when the device is deselected, regardless of the state of OE.
DQP <sub>[A:B]</sub>	74,24	I/O- Synchronous	<b>Bidirectional Data Parity I/O Lines.</b> Functionally, these signals are identical to DQ <sub>s</sub> . During write sequences, DQP <sub>[A:B]</sub> is controlled by BW <sub>x</sub> correspondingly.
Mode	31	Input Strap Pin	<b>Mode Input.</b> Selects the burst order of the device. When tied to Gnd selects linear burst sequence. When tied to V <sub>DD</sub> or left floating selects interleaved burst sequence.
V <sub>DD</sub>	15,16,41,65,91	Power Supply	<b>Power supply inputs to the core of the device.</b>
V <sub>DDQ</sub>	4,11,20,27,54, 61,70,77	I/O Power Supply	<b>Power supply for the I/O circuitry.</b>
V <sub>SS</sub>	5,10,14,17,21, 26,40,55,60, 66,67,71,76,90	Ground	<b>Ground for the device.</b>

**Pin Definitions** (100-pin TQFP Package) (continued)

Name	TQFP	I/O	Description
NC	1,2,3,6,7,25,28, 29,30,38,39, 42,43,50,51,52, 53,56,57,75,78, 79,83,84,95,96	–	<b>No Connects.</b> Not Internally connected to the die. 9M,18M,36M and 72M are address expansion pins and are not internally connected to the die.

**Functional Overview**

The CY7C1231F is a synchronous flow-through burst SRAM designed specifically to eliminate wait states during Write-Read transitions. All synchronous inputs pass through input registers controlled by the rising edge of the clock. The clock signal is qualified with the Clock Enable input signal ( $\overline{CEN}$ ). If  $\overline{CEN}$  is HIGH, the clock signal is not recognized and all internal states are maintained. All synchronous operations are qualified with  $\overline{CEN}$ . Maximum access delay from the clock rise ( $t_{CDV}$ ) is 7.5 ns (117-MHz device).

Accesses can be initiated by asserting all three Chip Enables ( $\overline{CE}_1$ ,  $\overline{CE}_2$ ,  $\overline{CE}_3$ ) active at the rising edge of the clock. If Clock Enable ( $\overline{CEN}$ ) is active LOW and  $\overline{ADV/LD}$  is asserted LOW, the address presented to the device will be latched. The access can either be a read or write operation, depending on the status of the Write Enable ( $\overline{WE}$ ).  $BW_{[A:B]}$  can be used to conduct Byte Write operations.

Write operations are qualified by the Write Enable ( $\overline{WE}$ ). All writes are simplified with on-chip synchronous self-timed write circuitry.

Three synchronous Chip Enables ( $\overline{CE}_1$ ,  $\overline{CE}_2$ ,  $\overline{CE}_3$ ) and an asynchronous Output Enable ( $\overline{OE}$ ) simplify depth expansion. All operations (Reads, Writes, and Deselects) are pipelined.  $\overline{ADV/LD}$  should be driven LOW once the device has been deselected in order to load a new address for the next operation.

**Single Read Accesses**

A read access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{CEN}$  is asserted LOW, (2)  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$  are ALL asserted active, (3) the Write Enable input signal  $\overline{WE}$  is deasserted HIGH, and 4)  $\overline{ADV/LD}$  is asserted LOW. The address presented to the address inputs is latched into the Address Register and presented to the memory array and control logic. The control logic determines that a read access is in progress and allows the requested data to propagate to the output buffers. The data is available within 7.5 ns (117-MHz device) provided  $\overline{OE}$  is active LOW. After the first clock of the read access, the output buffers are controlled by  $\overline{OE}$  and the internal control logic.  $\overline{OE}$  must be driven LOW in order for the device to drive out the requested data. On the subsequent clock, another operation (Read/Write/Deselect) can be initiated. When the SRAM is deselected at clock rise by one of the chip enable signals, its output will be three-stated immediately.

**Burst Read Accesses**

The CY7C1231F has an on-chip burst counter that allows the user the ability to supply a single address and conduct up to four Reads without reasserting the address inputs.  $\overline{ADV/LD}$  must be driven LOW in order to load a new address into the SRAM, as described in the Single Read Access section above. The sequence of the burst counter is determined by the MODE

input signal. A LOW input on MODE selects a linear burst mode, a HIGH selects an interleaved burst sequence. Both burst counters use A0 and A1 in the burst sequence, and will wrap around when incremented sufficiently. A HIGH input on  $\overline{ADV/LD}$  will increment the internal burst counter regardless of the state of Chip Enable inputs or  $\overline{WE}$ .  $\overline{WE}$  is latched at the beginning of a burst cycle. Therefore, the type of access (Read or Write) is maintained throughout the burst sequence.

**Single Write Accesses**

Write accesses are initiated when the following conditions are satisfied at clock rise: (1)  $\overline{CEN}$  is asserted LOW, (2)  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$  are ALL asserted active, and (3) the Write signal  $\overline{WE}$  is asserted LOW. The address presented to the address bus is loaded into the Address Register. The write signals are latched into the Control Logic block. The data lines are automatically three-stated regardless of the state of the OE input signal. This allows the external logic to present the data on DQs and  $DQP_{[A:B]}$ .

On the next clock rise the data presented to DQs and  $DQP_{[A:B]}$  (or a subset for Byte Write operations, see Truth Table for details) inputs is latched into the device and the write is complete. Additional accesses (Read/Write/Deselect) can be initiated on this cycle.

The data written during the Write operation is controlled by  $BW_{[A:B]}$  signals. The CY7C1231F provides Byte Write capability that is described in the Truth Table. Asserting the Write Enable input ( $\overline{WE}$ ) with the selected Byte Write Select input will selectively write to only the desired bytes. Bytes not selected during a Byte Write operation will remain unaltered. A synchronous self-timed write mechanism has been provided to simplify the Write operations. Byte Write capability has been included in order to greatly simplify Read/Modify/Write sequences, which can be reduced to simple byte write operations.

Because the CY7C1231F is a common I/O device, data should not be driven into the device while the outputs are active. The Output Enable ( $\overline{OE}$ ) can be deasserted HIGH before presenting data to the DQs and  $DQP_{[A:B]}$  inputs. Doing so will three-state the output drivers. As a safety precaution, DQs and  $DQP_{[A:B]}$  are automatically three-stated during the data portion of a write cycle, regardless of the state of  $\overline{OE}$ .

**Burst Write Accesses**

The CY7C1231F has an on-chip burst counter that allows the user the ability to supply a single address and conduct up to four Write operations without reasserting the address inputs.  $\overline{ADV/LD}$  must be driven LOW in order to load the initial address, as described in the Single Write Access section above. When  $\overline{ADV/LD}$  is driven HIGH on the subsequent clock rise, the Chip Enables ( $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$ ) and  $\overline{WE}$  inputs are ignored and the burst counter is incremented. The correct  $BW_{[A:B]}$  inputs must be driven in each cycle of the burst write, in order to write the correct bytes of data.

### Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ places the SRAM in a power conservation “sleep” mode. Two clock cycles are required to enter into or exit from this “sleep” mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the “sleep” mode are not considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the “sleep” mode.  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$ , must remain inactive for the duration of  $t_{ZZREC}$  after the ZZ input returns LOW.

### Interleaved Burst Sequence

First Address	Second Address	Third Address	Fourth Address
A1, A0	A1, A0	A1, A0	A1, A0
00	01	10	11
01	00	11	10
10	11	00	01
11	10	01	00

### Linear Burst Address Table (MODE = GND)

First Address A1, A0	Second Address A1, A0	Third Address A1, A0	Fourth Address A1, A0
00	01	10	11
01	10	11	00
10	11	00	01
11	00	01	10

### ZZ Mode Electrical Characteristics

Parameter	Description	Test Conditions	Min.	Max.	Unit
$I_{DDZZ}$	Snooze mode standby current	$ZZ \geq V_{DD} - 0.2V$		40	mA
$t_{ZZS}$	Device operation to ZZ	$ZZ \geq V_{DD} - 0.2V$		$2t_{CYC}$	ns
$t_{ZZREC}$	ZZ recovery time	$ZZ \leq 0.2V$	$2t_{CYC}$		ns
$t_{ZZI}$	ZZ Active to snooze current	This parameter is sampled		$2t_{CYC}$	ns
$t_{RZZI}$	ZZ inactive to exit snooze current	This parameter is sampled	0		ns

#### Notes:

- X = “Don’t Care.” H = Logic HIGH, L = Logic LOW.  $\overline{BW}_x = 0$  signifies at least one Byte Write Select is active,  $\overline{BW}_x = \text{Valid}$  signifies that the desired byte write selects are asserted, see Truth Table for details.
- Write is defined by  $\overline{BW}_{[A,B]}$ , and  $\overline{WE}$ . See Truth Table for Read/Write.
- When a write cycle is detected, all I/Os are three-stated, even during byte writes.
- The DQs and  $\overline{DQP}_{[A,B]}$  pins are controlled by the current cycle and the  $\overline{OE}$  signal.  $\overline{OE}$  is asynchronous and is not sampled with the clock.
- $\overline{CEN} = H$ , inserts wait states.
- Device will power-up deselected and the I/Os in a three-state condition, regardless of  $\overline{OE}$ .
- $\overline{OE}$  is asynchronous and is not sampled with the clock rise. It is masked internally during write cycles. During a read cycle DQs and  $\overline{DQP}_{[A,B]}$  = Three-state when  $\overline{OE}$  is inactive or when the device is deselected, and DQs and  $\overline{DQP}_{[A,B]}$  = data when  $\overline{OE}$  is active.

**Truth Table for Read/Write** [2, 3]

Function	$\overline{WE}$	$\overline{BW}_A$	$\overline{BW}_B$

**Notes:**

11. Tested initially and after any design or process changes that may affect these parameters.
12. Timing reference level is 1.5V when  $V_{DDQ} = 3.3\text{V}$ .
13. Test conditions shown in (a) of AC Test Loads, unless otherwise noted.
14. This part has a voltage regulator internally;  $t_{POWER}$  is the time that the power needs to be supplied above  $V_{DD}$  minimum initially before a read or write operation can be initiated.
15.  $t_{CHZ}$ ,  $t_{CLZ}$ ,  $t_{OELZ}$ , and  $t_{OEHZ}$  are specified with AC test conditions shown in (b) of AC Test Loads. Transition is measured  $\pm 200\text{ mV}$  from steady-state voltage.
16. At any given voltage and temperature,  $t_{OEHZ}$  is less than  $t_{OELZ}$  and  $t_{CHZ}$  is less than  $t_{CLZ}$  to eliminate bus contention between SRAMs when sharing the same data bus. These specifications do not imply a bus contention condition, but reflect parameters guaranteed over worst case user conditions. Device is designed to achieve Three-state prior to Low-Z under the same system conditions.
17. This parameter is sampled and not 100% tested.
