

SPI CONTROLLED H-BRIDGE

PRELIMINARY DATA

1 Features

- OPERATING SUPPLY VOLTAGE 5V TO 28V
- TYPICAL R_{DSon} = 150 mΩ FOR EACH OUTPUT TRANSISTOR (AT 25°C)
- CONTINOUS DC LOAD CURRENT 5A (T_{case} < 100 °C)
- OUTPUT CURRENT LIMITATION AT TYP. 8.6A
- SHORT CIRCUIT SHUT DOWN FOR OUTPUT CURRENTS OVER TYP. 10.6A
- LOGIC- INPUTS TTL/CMOS-COMPATIBLE
- OPERATING-FREQUENCY UP TO 30 kHz
- OVER TEMPERATURE PROTECTION
- SHORT CIRCUIT PROTECTION
- UNDERVOLTAGE DISABLE FUNCTION
- DIAGNOSTIC BY SPI OR STATUS-FLAG (CONFIGURABLE)
- ENABLE AND DISABLE INPUT
- SO20 POWER PACKAGE

2 Description

The L9929 is an SPI controlled H-Bridge, designed for the control of DC and stepper motors in safety critical applications and under extreme environmental conditions.

Figure 2. Block Diagram

Figure 1. Package

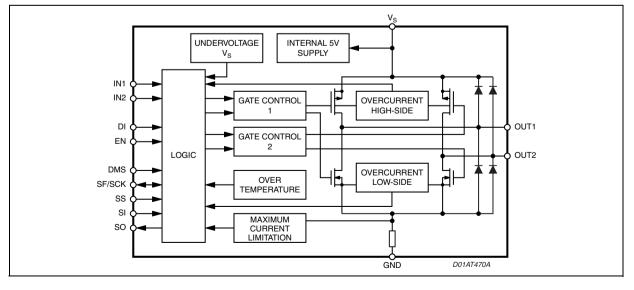

Table 1. Order Codes

| Part Number | Package |
|-------------|------------|
| L9929 | PowerSO20 |
| L9929XP | PowerSSO24 |

The H-Bridge is protected against over temperature and short circuits and has an under voltage lockout for all the supply voltages " V_S " (Main DC power supply). All malfunctions cause the output stages to go tristate.

The H-Bridge contains integrated free-wheel diodes. In case of free-wheeling condition, the low side transistor is switched on in parallel of its diode to reduce the current injected into the substrate. Switching in parallel is only allowed, if the voltage level of the according output-stage is below the ground-level. In this case it must be ensured, that the upper transistor is switched off.

This is preliminary information on a new product now in development or undergoing evaluation. Details are subject to change without notice.

| N° | NAME | Description |

Table 4. Absolute Maximum Ratings

The integrated circuit must not be destroyed by use at the limit values.

Each limit value can be used, as long as no other limit is violated.

Voltage reference point: Direction of current flow: Rise-, fall- and delaytimes: All values are, if not otherwise stated, relative to ground.

Current flow into a pin is positive.

If not otherwise stated, all rise times are between 10% and 90%, fall times between 90% and 10% and delay times at 50% of the relevant steps.

Table 5. Electrical Characteristics (continued)

Spi Interface

The timing of L9929 is defined as follows:

- The change at output (SO) is forced by the rising edge of the SCK signal.
- The input signal (SI) is taken over on the falling edge of the SCK signal.
- \overline{SS} = active without any clocks at SCK is not allowed
- The data received during a writing access is taken over into the internal registers on the rising edge of the \overline{SS} signal, if exactly 16 SPI clocks have been counted during \overline{SS} = active.

| 14. Overcurrent ^{2.)} | Х | х | Х | Х | Z | Z | L | |

- 1.) In case of undervoltage tristate and status-flag are reset automatically.
- 2.) Whenever overcurrent or overtemperature is detected, the fault is stored (i.e. status-flag remains low). The tristate conditions and the status-flag ³ are reset via DI or EN.
 - L = Low
 - H = High
 - X = High or Low
 - Z = High impedance

(all output stage transistors are switched off in static state. For more inform. see next page) Overcurrent: $I_{OUT1,2} > 10.6 \text{ A}$

 $Overtemperature: T_{j} > 175^{\circ}C$

Undervoltage: V_{Vs-GND} <4.5V (at least down to 2.5V)

- 3.) If Mode "Status-Flag" is selected (see chapter "Diagnostic / Status-Flag")
- 4.) If Mode "SPI-Diagnosis is selected (see chapter "Diagnostic / SPI-Interface")

Description of the state "Z"

The state "Z" has, depending on the previous operating condition different meaning.

1. dynamical

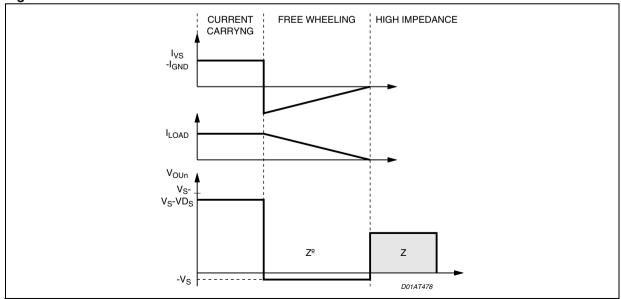

I. e. the inductive load is current carrying and is switched off according to Pos. 5, 6, 9, 10, 11, 12, 13, or 14 of the truth table

- a.) All output stage transistors are switched off.
- b.) The current flow is continued via the free wheeling diodes.
- c.) Free wheeling is detected by a negative voltage-level at OUn.
- d.) Switch on of the parallel-transistor of the current carrying diode.
- f.) Free wheeling is finshed, if the voltage-level on OUn is positive again.

2. statical

g.) all output-stages switched off.

4 Diagnostic

The Diagnosis-Mode can be selected between SPI-Diagnosis and Status-Flag Diagnosis.

The choise of the Diagnosis-Mode is selected by the voltage-level on pin 12 (DMS Diagnosis Mode Selection).

DMS = GND Status-Flag

DMS = Vcc SPI-Diagnostic

For the connection of pins SI, SO, SS and SCK/SF see Fig. 13 respectively Fig. 14.

4.1 Status-Flag

The Status-Flag showes the condition "tristate".

At the following fault-cases the output-stages switches in tristate and set the status-flag from high to low.

- Short circuit of OUT1 or OUT2 against V_S or GND
- Short circuit between OUT1 and OUT2
- Overcurrent
- Overtemperature
- Undervoltage on V_S

In cause of short circuit or overcurrent, the fault will be stored.

The output stage switches in tristate and the status-flag is set from high level to low-level if the specified value is exceeded.

If the voltage level changes from high to low on DI or from low to high on EN, the output stage switches on again and the status-flag is reset to high-level.

In cause of overtemperature the fault will be stored.

The output stage switches in tristate and the status-flag is set from high level to low-level if the specified value is exceeded.

If the voltage level changes from high to low on DI or from low to high on EN, the output stage switches on again and the status-flag is reset to high-level.

In cause of undervoltage on V_{Batt} the output stage switches in tristate and the status-flag is set from high level to low-level if the specified value is fallen. If the voltage has risen about the specified value again, the output stage switches on again and the status-flag is reset to high-level.

The maximum current which can flow under normal operating conditions is limited to typical $I_{max.} = 8.6A$. When the maximum current value is reached, the output stages are switched tristate for a fixed time. According to the time-constant the current decreases exponentially until the next switch-on occurs. At the end if the fixed time the output stage switches on again and the status-flag is reset to high-level.

5 SPI-INTERFACE

5.1 General Discription

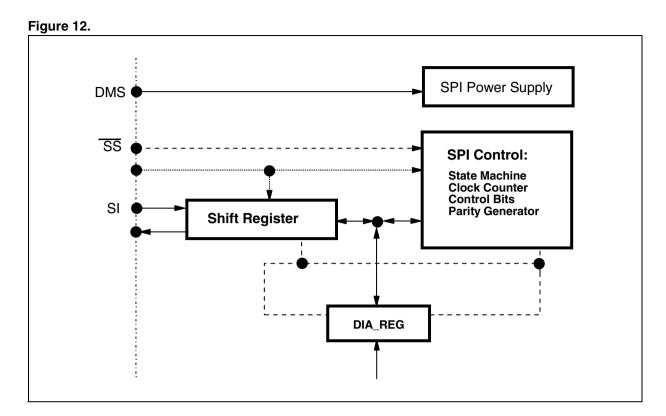

The serial SPI interface establishes a communication link between L9929 and the systems microcontroller. L9929 always operates in slave mode whereas the controller provides the master function.

The maximum baud rate is 2 MBaud (200pF).

Applying an active slave select signal at SS L9929 is selected by the SPI master. SI is the data input (Slave In), SO the data output (Slave Out). Via SCK (Serial Clock Input) the SPI clock is provided by the master.

In case of inactive slave select signal (High) the data output SO goes into tristate.

L9929

5.2 Power Supply of the SPI-Interface

SPI-Logic and I/O-Pins are alternativ supplied from DMS or Vcc internal, depending on which voltage is higher. That is why diagnosis of the EN-/DI-Pins is always possible, even in case of missing H-Bridge-power supply e.g. during "Vorlauf/Nauchlauf".

5.3 Characteristics of the SPI Interface

- 1) When DMS is > 3.1V, the SPI is active, independent of the state of EN or DI and the voltage on V_S. During active reset conditions (DMS < 2.5V) the SPI is driven into its default state. When reset becomes inactive, the state machine enters into a waitstate for the next instruction.
- 2) If the slave select signal at SS is inactive (high), the state machine is forced to enter the waitstate, i.e. the state machine waits for the following instruction.
- 3) During active (low) state of the select signal SS the falling edge of the serial clock signal SCK will be used to latch the input data at SI. Output data at SO are driven with the rising edge of SCK. Further processing of the data according to the instruction (i.e. modification of internal registers) will be triggered by the rising edge of the SS signal. (-> See Note)
- 4) Chipaddress: In order to establish the option of extended addressing the uppermost two bits of the instruction-byte (i.e the first two SI-bits of a Frame) are reserved to send a chipaddress. To avoid a busconflict the output SO must stay high impedant during the addressing phase of a frame (i.e. until the addressbits are recognised as valid chipaddress). This tristate behavior should be realised in any case, regardless wether the extended addressoption is used or not. If the chipaddress does not match, the according access will be ignored and SO remains high impedant for the complete frame regardless which frametype is applied.
- 5) Check byte: Simultaneously to the receipt of an SPI instruction L9929 transmitts a check byte via the output SO to the controller. This byte indicates regular or irregular operation of the SPI. It contains an initial bitpattern and a flag indicating an invalid instruction of the previous access.

- 6) On the read access the databits at the SPI input SI are rejected.
- 7) Invalid instruction/access: An instruction is invalid, if one of the following conditions is fulfilled:
 - An unused instruction code is detected (see tables with SPI instructions).
 - In case the previous transmission is not completed in terms of internal data processing. (Violation of the minimum Access-Time.)
 - In case of the previous transmission has detected more than 16 SCK pulses
 - Reset has occurred (Undervoltage on DMS)

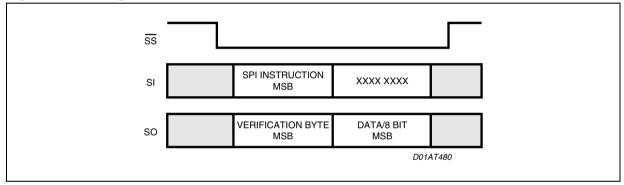

If an invalid instruction is detected, any modifications on registers of L9929 are not allowed.

In case an unused instruction code occured the databyte "ffh ex" will be transmitted after having sent the check byte.

In addition any access is invalid if the number of SPI clock pulses (falling edge) counted during active SS differs from exactly 16 clock pulses (-> See Note).

5.4 SPI Communication

Figure 13. Reading access / 8 bit

5.5 SPI Instruction

The uppermost 2 bit of the instruction byte contains the chipadress. The chipaddress of L9929 is 00.

| MSB | _ | | _ | | | _ | |
|-----|---|--------|--------|--------|--------|-------|-------|

| | | | | |
| RD_DIA | 00 | 001 001 | Read DIA_REG | |
| | | All others | No function | |

5.6 Reset of the Diagnostic Register DIA_REG

On the following conditions DIA_REG is reset:

- With the rising edge of the SS-signal after the SPI-Instruction RD_DIA (only if error free while SS, new errors will actualize DIA_REG with the rising edge of SS).
- When the voltage on DMS exceeds the threshold for detecting SPI-Mode. (after undervoltage condition or after power up)
- If VS rises over about the undervoltage level, the Bits of DIA_REG are restored (when VS internal or DMS > 3,1V)

Verification byte:

5.8 Device Identifier and Revision Number

The IC's identifier is used for production test purposes and features plug & play functionality depending on the systems software release. It is made up on a device-number and a revision number each one read-only accessible via standardised instructions.

The Device number is defined once to allow indentification of different IC-Types by software.

The Revision number may be utilised to distinguish different states of hardware. The contents is divided into an upper 4 bit field reserved to define revisions correspondending to specific softwarereleases. The lower 4 bit field is utilised to indentify the actual maskset.

Both (SWR and MSR) will start with 0000b and are increased by 1 every time an according modification of the hardware is introduced.

5.9 Reading the IC Identifier (SPI Instruction: RD_IDENT):

| IC Identifi | IC Identifier1 (Device ID) | | | | | | | |
|-------------|----------------------------|-----|-------------|----------|-----|-----|-----|--|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| ID7 | ID6 | ID5 | ID4 | ID3 | ID2 | ID1 | ID0 | |
| Bit | Name | | Description | | | | | |
| 70 | ID(70) | | ID-No.: 10 | 010 0001 | | | | |

5.10 Reading the IC revision number (SPI Instruction: RD_VERSION):

| IC's revisi | IC's revision number | | | | | | | | | |
|-------------|----------------------|------|--|---|------|------|------|--|--|--|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | | |
| SWR3 | SWR2 | SWR1 | SWR0 | MSR3 | MSR2 | MSR1 | MSR0 | | | |
| Bit | Name | | | Description | | | | | | |
| 74 | SWR(30) | | Revision corresponding to Software release: 0Hex | | | | | | | |
| 30 | MSR(30) | | Revision of | Revision corresponding to Maskset: 8Hex | | | | | | |

Figure 14. Application example with SPI-Interface

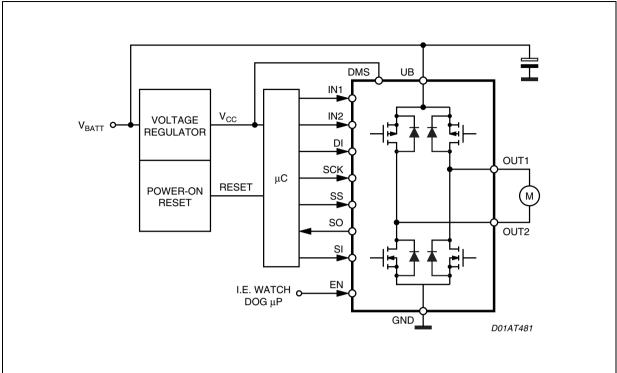

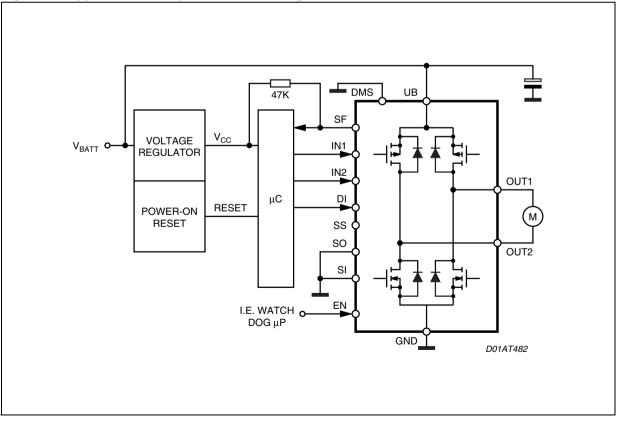

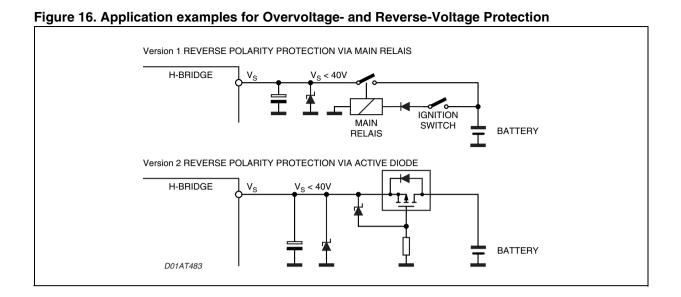

Figure 15. Application example with Status-Flag

6 ESD-SOLIDITY

The connection pins of the IC have to be protected against Electrostatic Discharge ESD) by suitable integrated protection structures.

The integrated circuit has to meet the demand of the "Human-Body-Model" with V_C = $\pm 4kV$

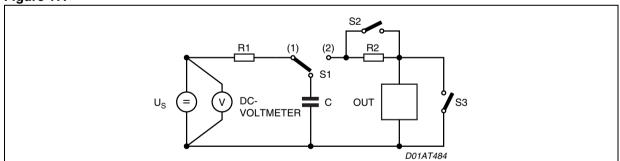

C = 100pF and R2 = $1,5k\Omega$ (330 Ω for OUT1 and OUT2).

Thereby any defect or destruction of the integrated circuit must not occur.

The protection structures realized to reach the ESD-strength have to be coordinated.

The ESD-strength has to be verified by the test circuit given as below.

Figure 17.

For the Pins 4, 5, 6, 7, 14 and 15

 $U_{\rm C} = \pm 4 \rm kV$ R₁ = 100kΩ

R₂ = 330Ω

C = 100pF

Number of pulses each pin: 18

Frequency: 1Hz

Arrangement and performance:

The requirements of MIL883D Methode 3015 have to be fulfilled.

7 ISO-PULSES

In the main-power-supply-system disturbance transients according to ISO 7637-1 First Edition 1990-06-01 may occur.

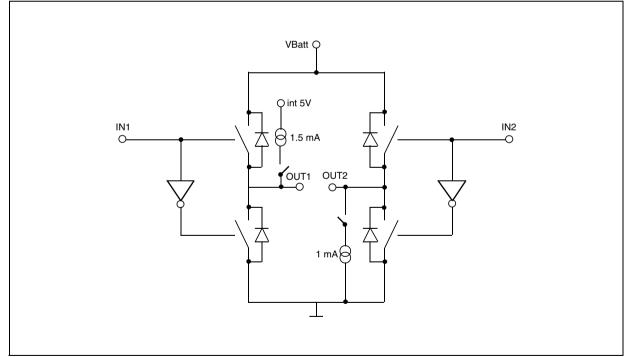

By means of external components (see Fig. 12) the following maximum ratings of the IC will not be exceeded.

statical -1V +40V dynamical for t < 500 ms -2V +40V

APPENDIX A

| | OUT1 | OUT2 | |
|-----------------------------|------|------|---------------------------------|
| Load available | 1 | 1 | |
| Open Load | 1 | 0 | |
| SC -> GND on OUT1 with Load | 0 | 0 | SC detected on normal operation |
| SC -> GND on OUT2 with Load | 0 | 0 | SC detected on normal operation |
| SC -> UB on OUT1 with Load | 1 | 1 | SC detected on normal operation |
| SC -> UB on OUT2 with Load | 1 | 1 | SC detected on normal operation |
| SC -> GND on OUT1 Open Load | 0 | 0 | OL not detected Double Fault |
| SC -> GND on OUT2 Open Load | 1 | 0 | OL detected |
| SC -> UB on OUT1 Open Load | 1 | 0 | OL detected |
| SC -> UB on OUT2 Open Load | 1 | 1 | OL not detected Double Fault |
