

MC524 • MC574
MC424 • MC474

These devices are dual clocked flip-flops that trigger on the negative edge of the clock pulse and perform the J-K logic function. Each flip-flop in the package has one clocked J, one clocked K, and one direct SET input. A direct RESET and the CLOCK input are common to both flip-flops. Both Q and \bar{Q} outputs are available on each flip-flop.

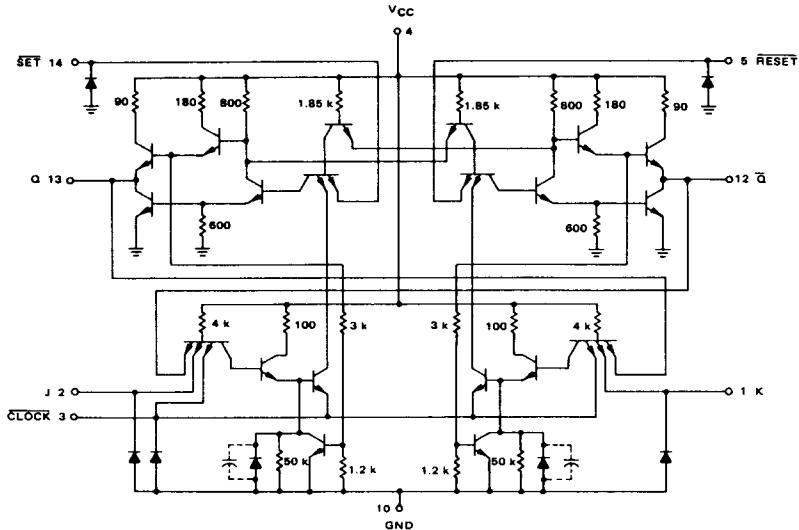

Information is changed on the J and K inputs while the clock is in the low state, since the inputs are inhibited in this condition. Information is transferred into a temporary

memory when the clock goes to the high state. When the clock returns low, the information is transferred to the bistable section and the Q and \bar{Q} outputs. The information on the J and K inputs should not be changed while the clock is in the high state. Each flip-flop can be set or reset directly by applying the low state to the direct SET or RESET inputs.

Since these flip-flops are charge-storage devices, there is a restriction on the clock fall time that must be observed.

* Prime Fan-Out

¹ Momentarily ground pin prior to taking measurement to set flip-flop in desired state, then release or set to the indicated voltage prior to taking measurement.

MC524, MC574/MC424, MC474 (continued)

OPERATING CHARACTERISTICS

Clock fall time ≤ 100 ns.

Triggers on clock pulse widths ≥ 12 ns.

Provides direct SET and RESET inputs. The application of a "0" state to the SET will cause Q to go to the "1" state; application of a "0" state to the RESET will cause both Qs to go to the "0" state. The SET or RESET can be applied 20 ns after the clock has changed to the low state. It should not be applied when the clock is in the high state.

Data at the J and K inputs must be present before the clock goes to a high state. If the information on the J and K inputs is changed while the clock is in a high state, the flip-flop will require typically 1.0 μ s to recognize a "1" state to "0" state information change on the J and K terminals. The flip-flop typically requires 10 ns to recognize a "0" state to a "1" state change.

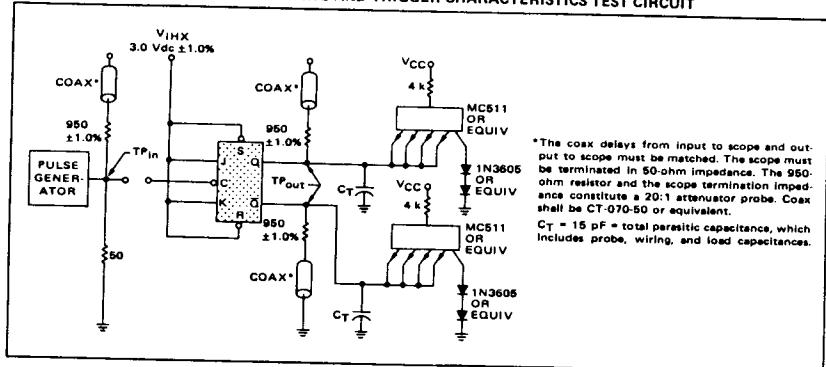

Negative edge triggering - When the clock changes from the high state to the low state, the information in the temporary storage section is transferred to the bistable network and the Q and Q outputs. While the clock is in a low state, the J and K terminals are inhibited.

Unused J and K inputs should be tied to the clock or to a voltage between 2.0 and 5.0 Vdc. Unused SET or RESET inputs must be tied to a voltage between 2.0 and 5.0 Vdc.

The maximum allowable skew time for these devices is 9.0 ns. This is the total of the minimum propagation delay (5.0 ns) and the minimum time to recognize a "0" to "1" state information change (4.0 ns).

Operating frequency of the flip-flops is not significantly affected by capacitive loading due to the buffered outputs.

FIGURE 1 – SWITCHING AND TRIGGER CHARACTERISTICS TEST CIRCUIT

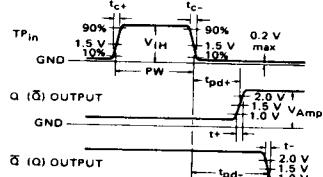

SWITCHING TIMES

| TEST | TEST SYMBOL | INPUT PULSE | MIN | MAX | UNIT |
