

POWER MANAGEMENT

Description

The SC4911 is a highly integrated bias/primary side PWM controller designed for off-line or isolated dc-dc converters in telecommunication and data communication applications. The high degree of integration minimizes the amount of discrete parts needed and leads to substantial cost and space saving converter designs.

The circuitry of the SC4911 includes line voltage UVLO featuring startup current less than 50 μ A and programmable switching frequency. The device supply is derived from an auxiliary winding on the transformer. The auxiliary winding could also provide output feedback information if an optocoupler is not used.

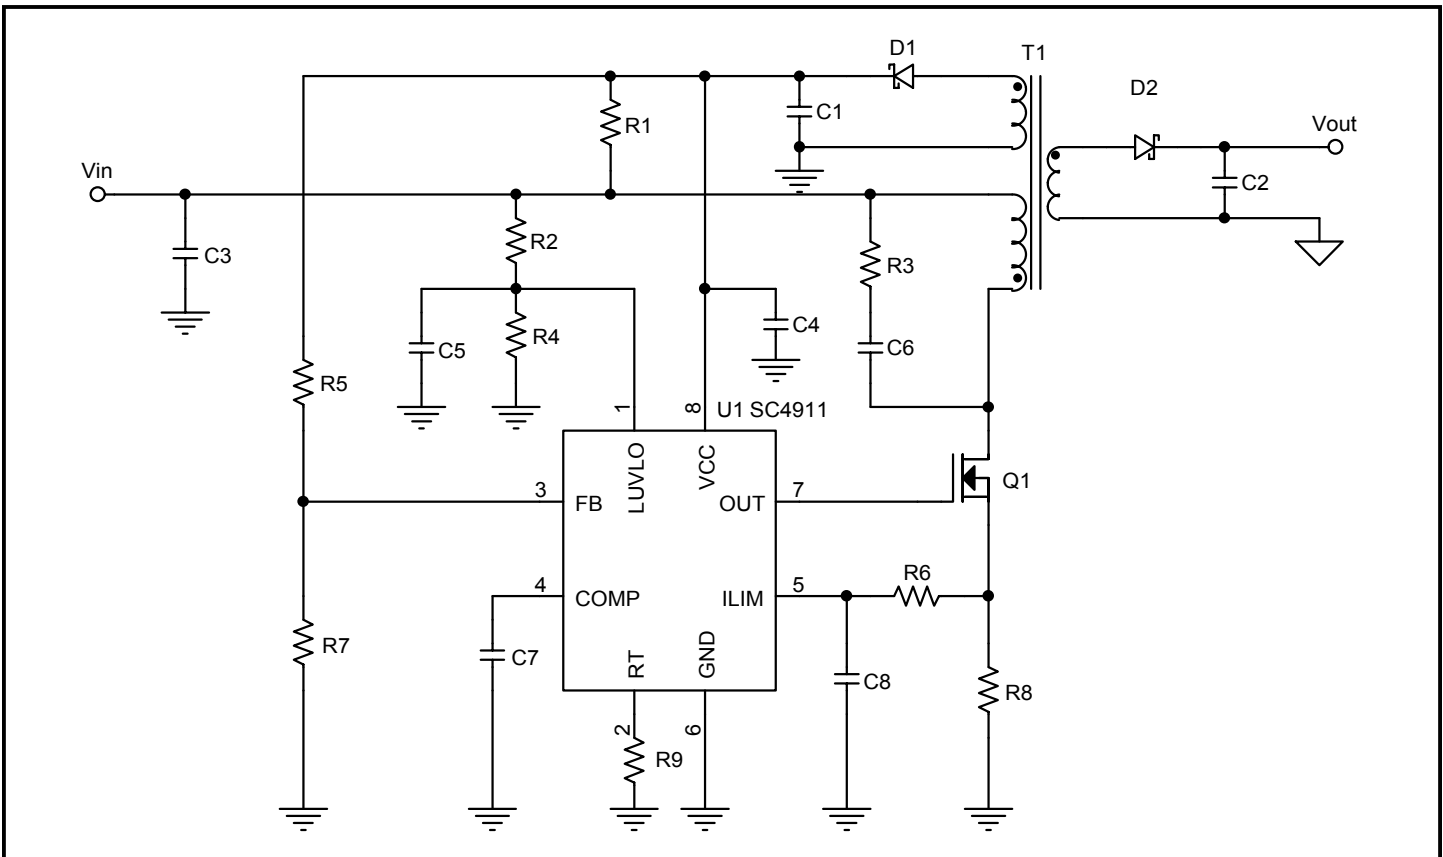

Features

- ◆ Programmable switching frequency up to 500kHz
- ◆ Line UVLO Protection
- ◆ Undervoltage Lockout
- ◆ Low startup current (45 μ A)
- ◆ Cycle by cycle current limit
- ◆ 8 pin MSOP. Available in Lead-free, fully WEEE and RoHS compliant

Applications

- ◆ Telecom isolated converters
- ◆ Offline isolated power supplies
- ◆ Instrumentation power supplies
- ◆ Battery chargers

Typical Application Circuit

POWER MANAGEMENT
Absolute Maximum Ratings

Exceeding the specifications below may result in permanent damage to the device, or device malfunction. Operation outside of the parameters specified in the Electrical Characteristics section is not implied.

Parameter	Symbol	Maximum	Units
Supply Voltage	V_{CC}	18	V
Supply Current	I_{CC}	20	mA
Line UVLO Voltage		V_{CC}	V
FB, ILIM and COMP		-0.3 to 6	V
Output Current Source or Sink		250	mA
Storage Temperature Range	T_{STG}	-60 to +150	°C
Junction Temperature Range	T_J	-40 to +150	°C
Lead Temperature (Soldering) 10 Sec.	T_{LEAD}	260	°C
ESD Rating (Human Body Model)	ESD	2	kV

Electrical Characteristics

Unless specified: $T_A = T_J = -40^{\circ}\text{C}$ to $+125^{\circ}\text{C}$, $V_{CC} = 12\text{V}$, $R_T = 100\text{K}\Omega$, $V_{FB} = 2.4\text{V}$, $LUVLO = 1.5\text{V}$.

Parameter	Test Conditions	Min	Typ	Max	Unit
Power Supply					
Vcc Turn-On Voltage			6.0	7.0	V
Operating Current	$f_s = 200\text{kHz}$, No load		3.4	5.0	mA
Startup Current	$LUVLO = 0.6\text{V}$		45	80	μA
VCC Zener Shunt Voltage	$I_{CC} = 10\text{mA}$	15	16	17	V
Line UVLO					
Lockout Threshold		1.22	1.25	1.28	V
UVLO Hysteresis			70		mV
Bias Current	$V_{LUVLO} < 1.25\text{V}$		100		nA
Error Amplifier					
Feedback Input Voltage	$V_{CC} = 12\text{V}$	2.44	2.50	2.56	V
Feedback Input Voltage Regulation	$V_{CC} = 7\text{V}$ to 12V	2.425		2.575	V
Input Bias Current			170		nA
Amplifier Transconductance			1000		μmho
Amplifier Souce Current			500		μA
Amplifier Sink Current			600		μA
Open Loop Voltage Gain			50		dB

Block Diagram

POWER MANAGEMENT
Applications Information

The SC4911 is a voltage mode controller designed mainly for the isolated or non-isolated flyback converters. As shown in the Block Diagram, it includes start-up circuit, bandgap, error amplifier, PWM comparator, logic and output stage. Line undervoltage has dual functions of line voltage lockout and shutdown. When LUVLO is pull down to ground, the SC4911 is disabled and the quiescent current is reduced to typical 30µA. When it is connected to a resistor voltage divider between input voltage and ground, it monitors the line voltage.

Oscillator

The switching frequency of the SC4911 is set by an external resistor connected between RT and GND. Figure 1 shows the relationship between the resistance of the external resistor and the switching frequency.

Figure 1. Timing Resistor vs Oscillator Frequency

Line UVLO and VCC UVLO

The Line UVLO monitors the input line voltage and VCC UVLO monitors the supply voltage to the SC4911. If either input line or VCC is below the lockout threshold, the output is held low and the supply current to the chip is typically 30µA.

A resistor divider from the input line to GND determines the desired undervoltage lockout level. To prevent noise coupling to affect proper UVLO operation, a small capacitor, one hundred to a few hundred pF, is recommended to be used from Line UVLO pin to GND.

Start-up

As shown in Typical Applications Circuit on the front page, when input voltage is applied, C1 is trickle charged through the start-up resistor R1 until the SC4911 Vcc reaches the turn-on voltage.

The bias current consumed by the device during this period is only typical 30µA. Once Vcc exceeds the turn-on voltage, OUT starts driving the MOSFET, transferring energy to the secondary and the bias output. If the bias output voltage builds to and is above the Vcc turnoff voltage, the start-up is completed and normal operation begins.

The size of the start-up resistor not only affects power supply start-up time, but also power supply efficiency. The resistor dissipates continuous power in normal operation. Due to ultra low start-up current of the SC4911, large value resistor (several hundred Kohm to 1Mohm) could be used, particularly for off-line applications to improve efficiency considering reasonable start-up time.

Current Limit

The current sense resistor is selected by dividing the current sense threshold voltage 0.525V by the primary peak current at the desired current limit point, typically 120% of the primary peak current.

$$R_{\text{SENSE}} = \frac{0.525\text{V}}{1.2 \times I_{\text{PK}}}$$

Care must be taken to ensure proper selection of sense resistor and good layout to prevent erratic operation. The non-inductive resistor must be used as the sense resistor. Parasitic inductance in series with the sense resistor must be minimized. Additional RC filter may be necessary to eliminate the narrow spike time on the leading edge of the primary current. The RC time constant can be chosen to be equal to the time constant of the sense resistor and the parasitic inductance.

PCB Layout

Long power supply and ground traces should be avoided.

A 0.1µF ceramic capacitor closely placed between Vcc and GND is recommended. The timing resistor used to program switching frequency should be located close to pin RT and pin GND in order to have a stable switching frequency. MOSFET should be located near the device and a resistor in the range of several ohms could be used in series with the gate drive to damp the ringing if the trace between the drive output and MOSFET is not short enough. Star ground connection is recommended to avoid ground loops. The Power path for input filter, MOSFET and transformer should be separated from signal path for timing resistor and feedback resistor, and both should be brought to a single ground point.

POWER MANAGEMENT

Typical Applications

48V TO 12V FLYBACK CONVERTER AS AUXILIARY SUPPLY

Figure 2 shows a simple bias supply using the SC4911. This 36 - 72V input flyback power supply employs primary side regulation from the transformer bias winding, which eliminates the need of opto coupler and secondary reference error amplifier. This is best for low cost applications requiring isolation and narrow load variation range on the secondary.

During the start-up, the input source trickle charges the capacitor C1 through start-up resistor R1. As long as voltage across C1 reaches the Vcc turn-on threshold, the SC4911 turns on abruptly and start driving the gate of MOSFET Q1. After the SC4911 starts up the primary bias winding supplies the primary circuitry.

The output of the T1 bias winding is rectified, filtered by C1 and is fed to the FB through feedback resistor R5 and R7. The output voltage on the secondary is proportional to the bias voltage by the turns ratio of the output to the bias winding. C7 and R9 are for frequency compensation. An additional small capacitor could be used from COMP to GND if it is needed. The LUVLO pin monitors the input voltage via resistor R2 and R4 to determine turn-on and turn-off of the converter. Capacitor C5 helps filter out the noise from the input line.

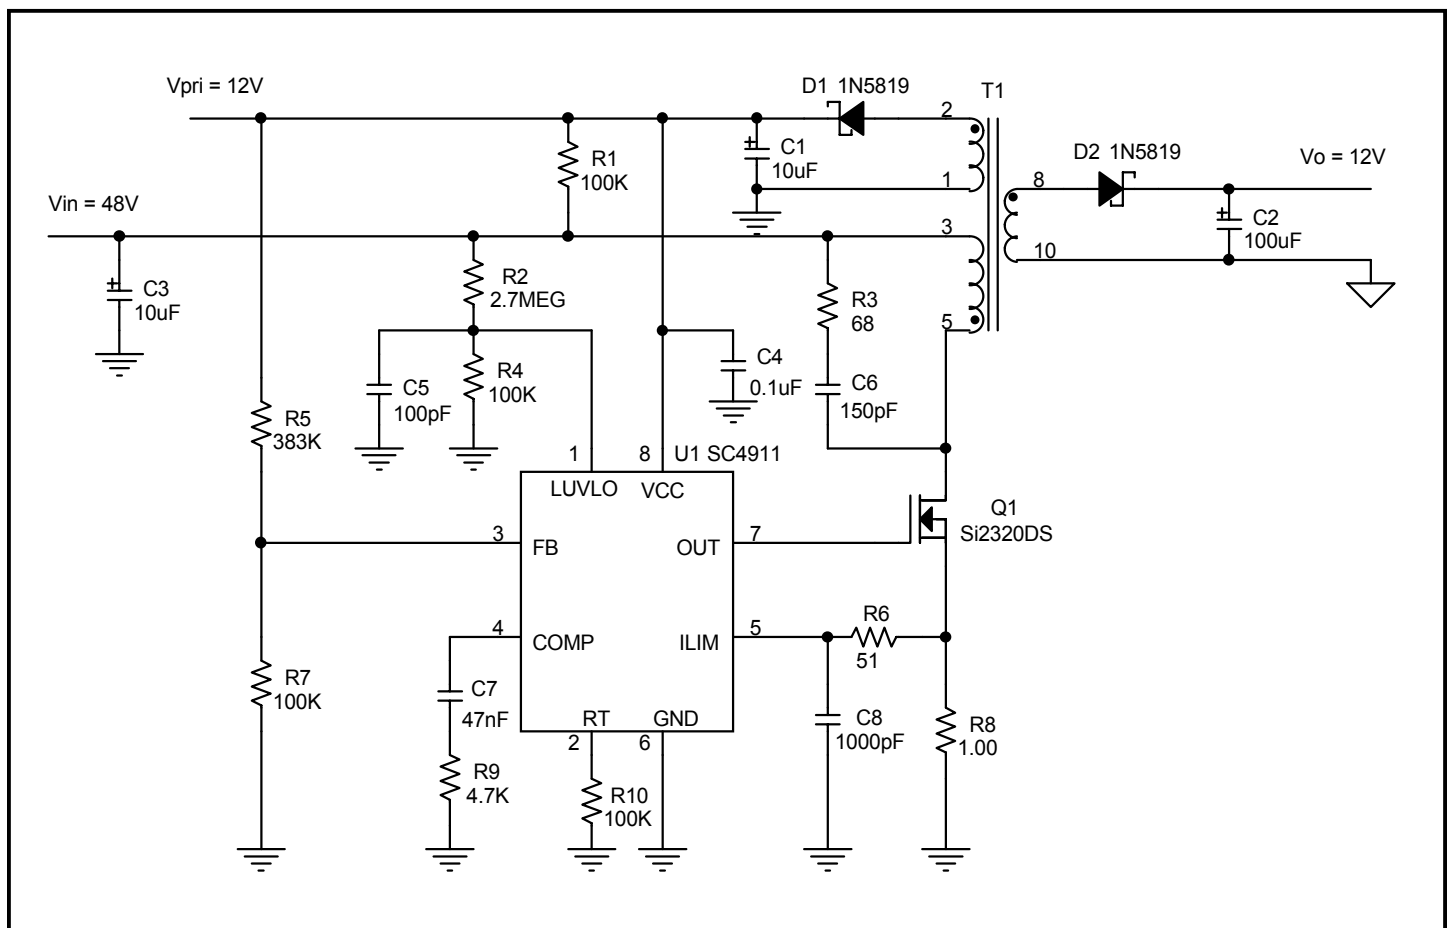

Figure 2. 48V to 12V Flyback Converter as Auxiliary Supply

POWER MANAGEMENT

Typical Applications (Cont.)

Isolated feedback 48V to 12V application

Figure 3 gives an example of isolated feedback and low power flyback application of the SC4911. T1 is a three winding transformer. The winding 1-2 is a bias winding which supplies the primary circuitry after the SC4911 starts up. During the startup, the input source trickle charges the capacitor C1 through the start-up resistor R1. As long as voltage across C1 reaches the Vcc turn-on threshold, the SC4911 turns on abruptly and start driving the gate of MOSFET Q1. As Q1 starts switching, regenerative feedback from the bias winding will provide current via D1 to capacitor C1.

In this configuration, the input voltage is in the range of 36V to 72V for telecom applications, and the LUVLO pin monitors the input voltage via resistor R2 and R5 to determine turn-on and turn-off of the converter. Capacitor C5 helps filter out the noise from the input line.

Timing resistor R13 sets switching frequency. R3 and C6 are used to suppress the voltage spikes across the switch due to leakage inductance of T1. R11 is current sense resistor to set current limit of the convertor. R10 and C9 filter spikes caused by parasitic capacitance during the turning on of Q1. The U3 SC431 is shunt regulator integrating an accurate 2.5V bandgap reference, op amp and driver into a single device. It compares sensed output voltage divided by R7 and R9 to its internal reference and drives the amplified error signal to opto-coupler U1. C7 keeps ripple and noise from over driving the device. U1 delivers the isolated feedback signal to the SC4911. C8 and R12 are for compensation. An additional small capacitor could be used from COMP to GND if needed.

Figure 3. Isolated 48V to 12V Flyback Converter

POWER MANAGEMENT

Typical Applications (Cont.)

Non-Isolated feedback 48V to 12V application

Figure 4 is an example of low cost, non-isolated feedback, low power application of the SC4911. T1 is a two winding transformer. The output voltage is directly fed to the primary circuitry.

During the start-up, the input source trickle charges the capacitor C3 through start-up resistor R1. As long as the voltage across C3 reaches the Vcc turn-on threshold, the SC4911 turns on abruptly and starts driving the gate of MOSFET Q1. After the SC4911 starts up the secondary winding supplies the primary circuitry.

In this 36V to 72V telecom application, LUVLO monitors the input voltage via resistor R2 and R4 to determine turn-on and turn-off of the converter. Capacitor C4 helps filter out the noise from the input line. Voltage feedback is directly brought from the output to the input error amplifier of SC4911 through R5 and R7. C6 and R9 are for frequency compensation. An additional small capacitor could be used from COMP to GND if needed.

Figure 4. Non-isolated 48V to 12V Flyback Converter

POWER MANAGEMENT

Typical Applications (Cont.)

48V to 12V FLYBACK CONVERTER AS BATTERY CHARGER

Figure 5 is another example of non-isolated feedback, low power and compact application of the SC4911 as a battery charger. Battery charging rate is determined by current sense resistor R8. LUVLO is used to not only turn on or turn off the charger by battery charge controller, but also monitors the input line voltage via resistor R2 and R5 to determine turn-on and turnoff of the converter. During the start-up, the input source trickle charges the capacitor C3 through start-up resistor R1. As long as voltage across C3 reaches the Vcc turn-on threshold, the SC4911 turns on abruptly and starts driving the gate of MOSFET Q1. After the SC4911 starts up the secondary winding supplies the primary circuitry.

In this application, voltage feedback is directly brought from the output to the input error amplifier of SC4911 through R4 and R7. C5 and R9 are for frequency compensation.
