The previous curve gives the single pulse safe operating area for unclamped inductive loads, under the following conditions:

$$P_{D(AVE)} = 0.5 \cdot (1.3 \cdot B_{VDSS} \cdot I_{AV})$$

$$E_{AS(AR)} = P_{D(AVE)} \cdot t_{AV}$$

Where:

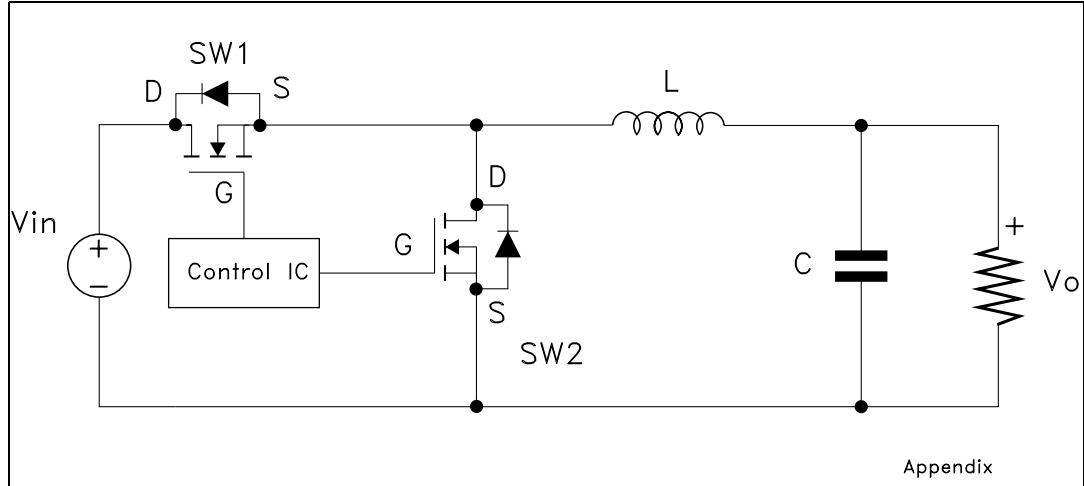

I_{AV} is the allowable current in avalanche

$P_{D(AVE)}$ is the average power dissipation in avalanche (single pulse)

t_{AV} is the time in avalanche

3 Buck converter

Figure 15. Synchronous buck converter

The power losses associated with the FETs in a Synchronous Buck converter can be estimated using the equations shown in the table below. The formulas give a good approximation, for the sake of performance comparison, of how different pairs of devices affect the converter efficiency. However a very important parameter, the working temperature, is not considered. The real device behavior is really dependent on how the heat generated inside the devices is removed to allow for a safer working junction temperature.

The low side (SW2) device requires:

Very low $R_{DS(on)}$ to reduce conduction losses

Small Q_{GLS} to reduce the gate charge losses

Small C_{OSS} to reduce losses due to output capacitance

Small Q_{rr} to reduce losses on SW1 during its turn-on

The C_{gd}/C_{gs} ratio lower than V_{th}/V_{gg} ratio especially with low drain to source voltage to avoid the cross conduction phenomenon.

The high side (SW1) device requires:

Small R_G and L_G to allow higher gate current peak and to limit the voltage feedback on the gate

Small Q_G to have a faster commutation and to reduce gate charge losses

Low $R_{DS(on)}$ to reduce the conduction losses

Table 8. Power losses

		High side switch (SW1)	Low side switch (SW2)
P _{conduction}		$R_{DS(on)} \cdot I_L^2 \cdot \delta$	$R_{DS(on)} \cdot I_L^2 \cdot (1 - \delta)$

P _{diode}	recovery	Not applicable	$V_{in} \cdot Q_{rr(SW2)} \cdot f$
