### Features

- Low-power fully static CMOS design
- Operating voltage:
  - $f_{SYS}=4\text{MHz}$ : 2.2V~5.5V
  - $f_{SYS}=8\text{MHz}$ : 3.3V~5.5V
- Program Memory:
  - 2K×15 OTP (HT46R53A)
  - 4K×15 OTP (HT46R54A)
- Data memory:
  - 192×8 RAM (HT46R53A)
  - 280×8 RAM (HT46R54A)
- A/D converter: 12bits×8Ch  
External A/D converter reference voltage input pin
- 22 bidirectional I/O lines
- 1 interrupt input shared with an I/O line
- 8-bit programmable timer/event counter with overflow interrupt and 7-stage prescaler
- On-chip crystal and RC oscillator
- 6-level subroutine nesting
- Watchdog Timer
- Low voltage reset function
- HALT function
- Up to 0.5 $\mu\text{s}$  instruction cycle with 8MHz system clock at  $V_{DD}=5\text{V}$
- 1-channel 8-bit PWM output shared with an I/O line
- PFD function
- Bit manipulation instruction
- Table read instruction
- 63 powerful instructions
- All instructions in one or two machine cycles
- 28-pin SKDIP/SOP package

### General Description

The HT46R53A/HT46R54A are 8-bit high performance, RISC architecture microcontroller devices specifically designed for A/D applications that interface directly to analog signals, such as those from sensors. The advantages of low power consumption, I/O flexibility, timer functions, oscillator options, multi-channel A/D con-

verter, Pulse Width Modulation function, HALT and wake-up functions, watchdog timer, as well as low cost, enhance the versatility of these devices to suit a wide range of A/D application possibilities such as sensor signal processing, chargers, motor driving, industrial control, consumer products, subsystem controllers, etc.

**Pin Description**

Pin Name	I/O	Options	Description
PA0~PA2 PA3/PFD PA4/TMR PA5/INT PA6~PA7	I/O	Pull-high Wake-up PA3 or PFD	Bidirectional 8-bit input/output port. Each individual bit on this port can be configured as a wake-up input by configuration option. Software instructions determine if the pin is a CMOS output or Schmitt trigger input. Configuration options determine which pin on this port have pull-high resistors. The PFD, TMR and external interrupt input are pin-shared with PA3, PA4, and PA5 respectively.
PB0/AN0~ PB7/AN7	I/O	Pull-high	Bidirectional 8-bit input/output port. Software instructions determine the CMOS output or Schmitt trigger input with or without pull-high resistor. Configuration options determine which pin on this port have pull-high resistors. PB is pin-shared with the A/D input pins. The A/D inputs are selected via software instructions. Once selected as an A/D input, the I/O function and pull-high resistor functions are disabled automatically.
PC0~PC4	I/O	Pull-high	Bidirectional 5-bit input/output port. Software instructions determine the CMOS output or Schmitt trigger input with or without pull-high resistor. Configuration options determine which pin on this port have pull-high resistors.
PD0/PWM	I/O	Pull-high PD0 or PWM	Bidirectional 1-bit input/output port. Software instructions determine the CMOS output or Schmitt trigger input with or without pull-high resistor. One configuration option determines which pin on this port has pull-high resistor. PD0 is pin-shared with the PWM output selected via configuration option.
OSC1 OSC2	I O	Crystal or RC	OSC1, OSC2 are connected to an external RC network or external crystal (determined by configuration option) for the internal system clock. For external RC system clock operation, OSC2 is an output pin for 1/4 system clock.
RES	I	—	Schmitt trigger reset input, active low.
VDD	—	—	Positive power supply
VSS	—	—	Negative power supply, ground
VREF	I	—	A/D Converter Reference Input voltage pins. Connect this pin to the desired A/D reference voltage.

**Absolute Maximum Ratings**

Supply Voltage .....	$V_{SS}-0.3V$ to $V_{SS}+6.0V$	Storage Temperature .....	$-50^{\circ}C$ to $125^{\circ}C$
Input Voltage .....	$V_{SS}-0.3V$ to $V_{DD}+0.3V$	Operating Temperature .....	$-40^{\circ}C$ to $85^{\circ}C$
$I_{OL}$ Total .....	150mA	$I_{OH}$ Total .....	-100mA
Total Power Dissipation .....	500mW		

Note: These are stress ratings only. Stresses exceeding the range specified under "Absolute Maximum Ratings" may cause substantial damage to the device. Functional operation of this device at other conditions beyond those listed in the specification is not implied and prolonged exposure to extreme conditions may affect device reliability.

## Functional Description

### Execution Flow

The system clock for the microcontroller is derived from either a crystal or an RC oscillator. The system clock is internally divided into four non-overlapping clocks. One instruction cycle consists of 4 system clock cycles.

Instruction fetching and execution are pipelined in such a way that a fetch and decoding next instruction cycle while execution takes the next instruction cycle. The pipelining scheme causes each instruction to effectively execute in a cycle. If an instruction changes the program counter, two cycles are required to complete the instruction.

### Program Counter – PC

For HT46R53A, the program counter (PC) is 11 bits wide and controls the sequence in which the instructions stored in the program ROM are executed. The contents of the PC can specify a maximum of 2048 addresses.

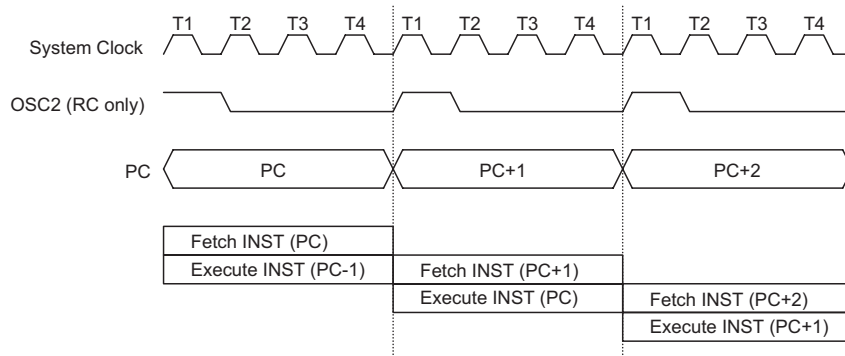

For HT46R54A, the program counter (PC) is 12 bits

wide and controls the sequence in which the instructions stored in the program ROM are executed. The contents of the PC can specify a maximum of 4096 addresses.

After accessing a program memory word to fetch an instruction code, the contents of the program counter are incremented by one. The program counter then points to the memory word containing the next instruction code.

When executing a jump instruction, conditional skip execution, loading register, subroutine call or return from subroutine, initial reset, internal interrupt, external interrupt or return from interrupts, the PC manipulates the program transfer by loading the address corresponding to each instruction.

The conditional skip is activated by instructions. Once the condition is met, the next instruction, fetched during the current instruction execution, is discarded and a dummy cycle replaces it to get the proper instruction. Otherwise proceed to the next instruction.

**Execution Flow**

Mode	Program Counter											
	*b11	*b10	*b9	*b8	*b7	*b6	*b5	*b4	*b3	*b2	*b1	*b0
Initial Reset	0	0	0	0	0	0	0	0	0	0	0	0
External Interrupt	0	0	0	0	0	0	0	0	0	1	0	0
Timer/Event Counter Overflow	0	0	0	0	0	0	0	0	1	0	0	0
A/D Converter Interrupt	0	0	0	0	0	0	0	0	1	1	0	0
Skip	Program Counter+2

Return from Subroutine	S11	S10	S9	S8	S7	S6	S5	S4	S3	S2	S1	S0

**Program Counter**

Note: \*b11~\*b0: Program counter bits

S11~S0: Stack register bits

#11~#0: Instruction code bits

@7~@0: PCL bits, PC11~PC8: Original PC counter, remain unchanged

For the HT46R53A, the program counter is 11 bits wide (b0~b10), the b11 column in the table are not applicable.

The lower byte of the PC (PCL) is a readable and writeable register (06H). Moving data into the PCL performs a short jump. The destination is within 256 locations.

When a control transfer takes place, an additional dummy cycle is required.

### Program Memory – EPROM

The program memory is used to store the program instructions which are to be executed. It also contains data, table, and interrupt entries, and is organized into 2048×15 (HT46R53A), or 4096×15 (HT46R54A) bits, addressed by the Program Counter and table pointer.

Certain locations in the ROM are reserved for special usage:

- Location 000H  
This location is reserved for program initialization. After a chip reset, the program always begins execution at location 000H.

- Location 004H  
This location is reserved for the external interrupt service program. If the INT input pin is activated, the interrupt is enabled and the stack is not full, the program begins execution at this location.
- Location 008H  
This location is reserved for the timer/event counter interrupt service program. If a timer interrupt results from a timer/event counter overflow, and the interrupt is enabled and the stack is not full, the program begins execution at location 008H.
- Location 00CH  
Location 00CH is reserved for the A/D converter interrupt service program. If an A/D converter interrupt results from an end of A/D conversion, and if the interrupt is enabled and the stack is not full, the program begins execution at location 00CH.
- Table location  
Any location in the program memory can be used as look-up tables. The instructions "TABRDC [m]" (the current page) and "TABRDL [m]" (the last page) trans-

### Program Memory

Instruction	Table Location											
	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
TABRDC [m]	P11	P10	P9	P8	@7	@6	@5	@4	@3	@2	@1	@0
TABRDL [m]	1	1	1	1	@7	@6	@5	@4	@3	@2	@1	@0

### Table Location

Note: b11~b0: Table location bits

P11~P8: Current program counter bits

@7~@0: Table pointer bits

For the HT46R53A, since the program counter is 11 bits wide (b0~b10), the b11 columns in the table are not applicable

For the HT46R54A, the TABRDC program counter is 12 bits wide. From b0~b11

fer the contents of the lower-order byte to the specified data memory, and the higher-order byte to TBLH (08H). The lower-order byte table pointer TBLP (07H) are read/write registers, which indicate the table locations. Before accessing the table, the location has to be placed in TBLP. The TBLH is read only and cannot be restored. If the main routine and the ISR (interrupt service routine) both employ the table read instruction, the contents of the TBLH in the main routine are likely to be changed by the table read instruction used in the ISR. Errors can occur. Given this, using the table read instruction in the main routine and the ISR simultaneously should be avoided. However, if the table read instruction has to be applied in both main routine and the ISR, the interrupt should be disabled prior to the table read instruction. It will not be enabled until the TBLH in the main routine has been backed-up. All table related instructions require 2 cycles to complete the operation.

### **Stack Register – STACK**

This is a special part of the memory which is used to save the contents of the program counter only. The stack is organized into 6 levels and is neither part of the data nor part of the program space, and is neither readable nor writeable. The activated level is indexed by the stack pointer (SP) and is neither readable nor writeable. At the state of a subroutine call or an interrupt acknowledgment, the contents of the program counter are pushed onto the stack. At the end of the subroutine or an interrupt routine, signaled by a return instruction (RET or RETI), the program counter is restored to its previous value from the stack. After a chip reset, the SP will point to the top of the stack.

If the stack is full and a non-masked interrupt takes place, the interrupt request flag will be recorded but the acknowledge signal will be inhibited. When the stack pointer is decremented (by RET or RETI), the interrupt is serviced. This feature prevents stack overflow, allowing the programmer to use the structure more easily. If the stack is full and a "CALL" is subsequently executed, stack overflow occurs and the first entry will be lost (only the most recent 6 return addresses are stored).

### **Data Memory – RAM**

The data memory (RAM) is designed with 217×8 bits (HT46R53A), 306×8 bits (HT46R54A), and is divided into two functional groups, namely; special function registers (25×8 bits for HT46R53A, 26×8 bits for HT46R54A) and general purpose data memory (192×8bit for HT46R53A, 280×8bit (Bank0 216×8 bits and Bank1 64×8 bits) for HT46R54A) most of which are readable/writable, although some are read only.

In case of HT46R53A, the unused space before 28H is reserved for future expanded usage and reading these locations will return the result "00H". The general purpose data memory, addressed from 28H to E7H, is used

for data and control information under instruction commands. All of the data memory areas can handle arithmetic, logic, increment, decrement and rotate operations directly. Except for some dedicated bits, each bit in the data memory can be set and reset by "SET [m].i" and "CLR [m].i". They are also indirectly accessible through memory pointer registers (MP0;01H or MP1;03H).

In case of HT46R54A, the unused space before 28H is reserved for future expanded usage and reading these locations will return the result "00H". The space before 40H is overlapping in each bank. The general purpose data memory, addressed from 28H to FFH (Bank0; BP=00H) and from 40H to 7FH (Bank1; BP=01H), are used for data and control information under instruction commands. All of the data memory areas can handle arithmetic, logic, increment, decrement and rotate operations directly. Except for some dedicated bits, each bit in the data memory can be set and reset by "SET [m].i" and "CLR [m].i". They are also indirectly accessible through memory pointer registers (MP0;01H or MP1;03H). After first setting up BP to the value of "01H" to access Bank1, this bank must then be accessed indirectly using the memory pointer MP1. With BP set to a value of "01H", using MP1 to indirectly read or write to the data memory areas with addresses at 40H will result in operations to Bank1. Directly addressing the data memory will always result in Bank0 being accessed irrespective of the value of BP.

### **Indirect Addressing Register**

Location 00H and 02H are indirect addressing registers that are not physically implemented. Any read/write operation of [00H] ([02H]) will access the data memory pointed to by MP0 (MP1). Reading location 00H (02H) itself indirectly will return the result "00H". Writing indirectly results in no operation. The memory pointer registers (MP0 and MP1) are 8-bit registers.

### **Accumulator – ACC**

The accumulator closely relates to ALU operations. It is also mapped to location "05H" of the data memory which can operate with immediate data. The data movement between two data memories has to pass through the accumulator.

### **Arithmetic and Logic Unit – ALU**

This circuit performs 8-bit arithmetic and logic operations. The ALU provides the following functions:

- Arithmetic operations (ADD, ADC, SUB, SBC, DAA)
- Logic operations (AND, OR, XOR, CPL)
- Rotation (RL, RR, RLC, RRC)
- Increment and Decrement (INC, DEC)
- Branch decision (SZ, SNZ, SIZ, SDZ ....)

### RAM Mapping

The ALU not only saves the results of a data operation but also changes the status register.

#### Status Register – STATUS

This 8-bit register (0AH) contains the zero flag (Z), carry flag (C), auxiliary carry flag (AC), overflow flag (OV), power down flag (PDF), and watchdog time-out flag (TO). It also records the status information and controls the operation sequence.

With the exception of the TO and PDF flags, bits in the status register can be altered by instructions like most other registers. Any data written into the status register will not change the TO and PDF flags. Addition opera-

tions related to the status register may give different results from those intended. The TO flag can be affected only by system power-up, a WDT time-out or executing the "HALT" or "CLR WDT" instruction. The PDF flag can be affected only by executing the "HALT" or "CLR WDT" instruction or a system power-up.

The Z, OV, AC, and C flags reflect the status of the latest operations. On entering the interrupt sequence or executing the subroutine call, the status register will not be automatically pushed onto the stack. If the contents of the status is important, and if the subroutine is likely to corrupt the status register, the programmer should take precautions and save it properly.

Bit No.	Label	Function
0	C	C is set if an operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation; otherwise C is cleared. C is also affected by a rotate through carry instruction.
1	AC	AC is set if an operation results in a carry out of the low nibbles in addition or no borrow from the high nibble into the low nibble in subtraction; otherwise AC is cleared.
2	Z	Z is set if the result of an arithmetic or logic operation is zero; otherwise Z is cleared.
3	OV	OV is set if an operation results in a carry into the highest-order bit but not a carry out of the highest-order bit, or vice versa; otherwise OV is cleared.
4	PDF	PDF is cleared by system power-up or executing the "CLR WDT" instruction. PDF is set by executing the "HALT" instruction.
5	TO	TO is cleared by system power-up or executing the "CLR WDT" or "HALT" instruction. TO is set by a WDT time-out.
6~7	—	Unused bit, read as "0"

#### Status (0AH) Register

#### Interrupts

The device provides an external interrupt, an internal timer/event counter interrupt, and an A/D converter interrupt. The interrupt control register (INTC;0BH) contains the interrupt control bits to set the enable/disable and the interrupt request flags.

Once an interrupt subroutine is serviced, all the other interrupts will be blocked (by clearing the EMI bit). This scheme may prevent any further interrupt nesting. Other interrupt requests may occur during this interval but only the interrupt request flag is recorded. If a certain interrupt requires servicing within the service routine, the EMI bit and the corresponding bit of the INTC may be set to allow interrupt nesting. If the stack is full, the interrupt request will not be acknowledged, even if the related interrupt is enabled, until the SP is decremented. If immediate service is desired, the stack must be prevented from becoming full.

All these kinds of interrupts have a wake-up capability. As an interrupt is serviced, a control transfer occurs by pushing the program counter onto the stack, followed by

a branch to a subroutine at specified location in the program memory. Only the program counter is pushed onto the stack. If the contents of the register or status register (STATUS) are altered by the interrupt service program which corrupts the desired control sequence, the contents should be saved in advance.

External interrupts are triggered by a high to low transition of  $\overline{INT}$  and the related interrupt request flag (EIF; bit 4 of the INTC) will be set. When the interrupt is enabled, the stack is not full and the external interrupt is active, a subroutine call to location "04H" will occur. The interrupt request flag (EIF) and EMI bits will be cleared to disable other interrupts.

The internal Timer/Event Counter interrupt is initialized by setting the Timer/Event Counter interrupt request flag (TF; bit 5 of the INTC), which is normally caused by a timer overflow. After the interrupt is enabled, and the stack is not full, and the TF bit is set, a subroutine call to location "08H" occurs. The related interrupt request flag (TF) is reset, and the EMI bit is cleared to disable further maskable interrupts.

Bit No.	Label	Function
0	EMI	Controls the master (global) interrupt (1= enable; 0= disable)
1	EEI	Controls the external interrupt (1= enable; 0= disable)
2	ETI	Controls the Timer/Event Counter interrupt (1= enable; 0= disable)
3	EADI	Control the A/D converter interrupt (1= enable; 0= disable)
4	EIF	External interrupt request flag (1= active; 0= inactive)
5	TF	Internal Timer/Event Counter request flag (1= active; 0= inactive)
6	ADF	A/D converter request flag (1= active; 0= inactive)
7	—	For test mode used only. Must be written as "0"; otherwise may result in unpredictable operation.

#### INTC (0BH) Register

The A/D converter interrupt is initialized by setting the A/D converter request flag (ADF; bit 6 of the INTC), caused by an end of A/D conversion. When the interrupt is enabled, the stack is not full and the ADF is set, a sub-routine call to location "0CH" will occur. The related interrupt request flag (ADF) will be reset and the EMI bit cleared to disable further interrupts.

During the execution of an interrupt subroutine, other interrupt acknowledgments are held until the "RETI" instruction is executed or the EMI bit and the related interrupt control bit are set to 1 (if the stack is not full). To return from the interrupt subroutine, "RET" or "RETI" may be invoked. RETI will set the EMI bit to enable an interrupt service, but RET will not.

Interrupts, occurring in the interval between the rising edges of two consecutive T2 pulses, will be serviced on the latter of the two T2 pulses, if the corresponding interrupts are enabled. In the case of simultaneous requests the following table shows the priority that is applied. These can be masked by resetting the EMI bit.

Interrupt Source	Priority	Vector
External Interrupt	1	04H
Timer/Event Counter Overflow	2	08H
A/D Converter Interrupt	3	0CH

EMI, EEI, ETI, and EADI are used to control the enabling/disabling of interrupts. These bits prevent the requested interrupt from being serviced. Once the interrupt request flags (TF, EIF, and ADF) are set, they will remain in the INTC register until the interrupts are serviced or cleared by a software instruction.

It is recommended that a program does not use the "CALL subroutine" within the interrupt subroutine. Interrupts often occur in an unpredictable manner or need to be serviced immediately in some applications. If only one stack is left and enabling the interrupt is not well controlled, the original control sequence will be damaged once the "CALL" operates in the interrupt subroutine.

**Oscillator Configuration**

There are two oscillator circuits in the microcontroller.

Both of them are designed for system clocks, namely the external RC oscillator and the external Crystal oscillator, which are determined by options. No matter what oscillator type is selected, the signal provides the system clock. The HALT mode stops the system oscillator and ignores an external signal to conserve power.

If an RC oscillator is used, an external resistor between OSC1 and VSS is required and the resistance must range from 30kΩ to 750kΩ. The system clock, divided by 4, is available on OSC2 with pull-high resistor, which can be used to synchronize external logic. The RC oscillator provides the most cost effective solution. However, the frequency of oscillation may vary with VDD, temperatures and the chip itself due to process variations. It is therefore not suitable for timing sensitive operations where an accurate oscillator frequency is desired.

If the Crystal oscillator is used, a crystal across OSC1 and OSC2 is needed to provide the feedback and phase shift required for the oscillator, and no other external components are required. Instead of a crystal, a resonator can also be connected between OSC1 and OSC2 to get a frequency reference, but two external capacitors in OSC1 and OSC2 are required (If the oscillator can be disabled by options to conserve power).

The WDT oscillator is a free running on-chip RC oscillator, and no external components are required. Even if the system enters the power down mode, the system clock is stopped, but the WDT oscillator still works with a period of approximately 65μs at 5V. The WDT oscillator can be disabled by option to conserve power.

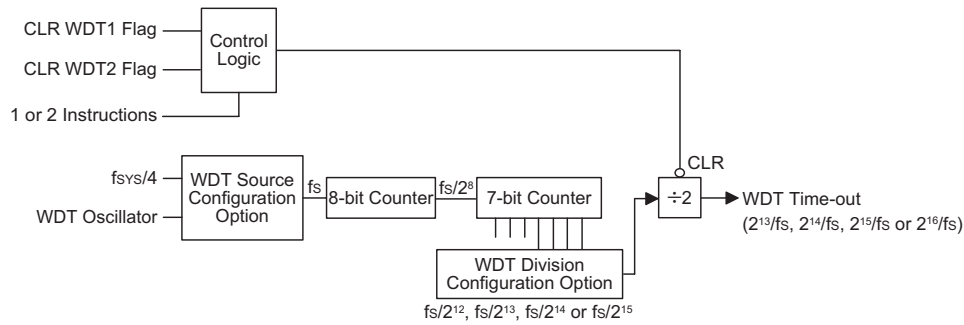

**Watchdog Timer – WDT**

The clock source of the WDT is implemented by a dedicated RC oscillator (WDT oscillator) or instruction clock (system clock divided by 4) decided by options. This timer is designed to prevent a software mal-function or sequence jumping to an unknown location with unpredictable results. The watchdog timer can be disabled by an option. If the watchdog timer is disabled, all the executions related to the WDT result in no operation.

The WDT clock ( $f_s$ ) is further divided by an internal counter to give longer watchdog time-outs. In the case of HT46R53A/HT46R54A devices, the division ratio can be varied by selecting different configuration options to give  $2^{12}$  to  $2^{15}$  division ratio range.

Once an internal WDT oscillator (RC oscillator with period of 65μs normally) is selected, it is divided by  $2^{16}$  to get the time-out period of approximately 4.3s. This time-out period may vary with temperature, VDD and process variations.

If the WDT oscillator is disabled, the WDT clock may still come from the instruction clock and operate in the same manner except that in the HALT state the WDT may stop counting and lose its protecting purpose. In this situation

**Watchdog Timer**

the logic can only be restarted by external logic. If the device operates in a noisy environment, using the on-chip RC oscillator (WDT OSC) is strongly recommended, since the HALT will stop the system clock.

The WDT overflow under normal operation will initialize a "chip reset" and set the status bit TO. Whereas in the HALT mode, the overflow will initialize a "warm reset" wherein only the Program Counter and SP are reset to zero. To clear the contents of the WDT, three methods are adopted; external reset (a low level to  $\overline{\text{RES}}$ ), software instructions, or a HALT instruction. The software instructions include "CLR WDT" and the other set CLR WDT1 and CLR WDT2. Of these two types of instruction, only one can be active depending on the option – "CLR WDT times selection option". If the "CLR WDT" is selected (i.e. CLRWDT times equal one), any execution of the CLR WDT instruction will clear the WDT. In case "CLR WDT1" and "CLR WDT2" are chosen (i.e. CLRWDT times equal two), these two instructions must be executed to clear the WDT; otherwise, the WDT may reset the chip because of time-out.

If the WDT division option is selected to  $f_s/2^{16}$ , the WDT time-out period is fixed to  $f_s/2^{16}$ , because the "CLR WDT" or "CLR WDT1" and "CLR WDT2" instructions will clear the whole counter of the WDT.

#### Power Down Operation – HALT

The HALT mode is initialized by the "HALT" instruction and results in the following...

- The system oscillator is turned off but the WDT oscillator keeps running (if the WDT oscillator or the real time clock is selected).
- The contents of the on-chip RAM and registers remain unchanged
- The WDT and WDT prescaler will be cleared to zero. If the WDT clock source is from the RTC/WDT oscillator, the WDT will remain active, and if the WDT clock source is  $f_{\text{SYS}}/4$ , the WDT will stop running.
- All of the I/O ports maintain their original status
- The PDF flag is set and the TO flag is cleared

The system quits the HALT mode by way of an external reset, an interrupt, an external falling edge signal on port A or a WDT overflow. An external reset causes a device initialization and the WDT overflow performs a "warm reset". After examining the TO and PDF flags, the cause for a chip reset can be determined. The PDF flag is cleared by system power-up or by executing the "CLR WDT" instruction and is set when executing the "HALT" instruction. On the other hand, the TO flag is set if the WDT time-out occurs, and causes a wake-up that only resets the Program Counter and SP, and leaves the others in their original status.

The port A wake-up and interrupt methods can be considered as a continuation of normal execution. Each bit in port A can be independently selected to wake up the device by options. Awakening from an I/O port stimulus, the program resumes execution of the next instruction. On the other hand, awakening from an interrupt, two sequence may occur. If the related interrupt is disabled or the interrupt is enabled but the stack is full, the program resumes execution at the next instruction. But if the interrupt is enabled, and the stack is not full, the regular interrupt response takes place. When an interrupt request flag is set before entering the "HALT" status, the system cannot be awakened using that interrupt. If wake-up events occur, it takes  $1024 t_{\text{SYS}}$  (system clock period) to resume normal operation. In other words, a dummy period is inserted after the wake-up. If the wake-up results from an interrupt acknowledgment, the actual interrupt subroutine execution is delayed by more than one cycle. However, if the Wake-up results in the next instruction execution, the execution will be performed immediately after the dummy period is finished.

To minimize power consumption, all the I/O pins should be carefully managed before entering the HALT status.

#### Reset

There are three ways in which a reset may occur:

- $\overline{\text{RES}}$  reset during normal operation
- $\overline{\text{RES}}$  reset during HALT
- WDT time-out reset during normal operation

The WDT time-out during HALT differs from other chip reset conditions, for it can perform a "warm reset" that resets only the Program Counter and SP, leaving the other circuits at their original state. Some registers remain unaffected during any other reset conditions. Most registers are reset to the "initial condition" when the reset conditions are met. Examining the PDF and TO flags, the program can distinguish between different "chip resets".

TO	PDF	RESET Conditions
0	0	$\overline{\text{RES}}$ reset during power-up
u	u	$\overline{\text{RES}}$ reset during normal operation
0	1	$\overline{\text{RES}}$ wake-up HALT
1	u	WDT time-out during normal operation
1	1	WDT wake-up HALT

Note: "u" stands for "unchanged"

To guarantee that the system oscillator is started and stabilized, the SST (System Start-up Timer) provides an extra-delay of 1024 system clock pulses when the system reset (power-up, WDT time-out or  $\overline{\text{RES}}$  reset) or the system awakes from the HALT state. When a system reset occurs, the SST delay is added during the reset period. Any wake-up from the HALT will enable the SST delay. An extra option load time delay is added during system reset (Power-up, WDT time-out at normal mode or  $\overline{\text{RES}}$  reset).

The functional unit chip reset status are shown below.

Program Counter	000H
Interrupt	Disable
Prescaler, Divider	Cleared
WDT	Clear. After master reset, WDT begins counting
Timer/Event Counter	Off
Input/Output Ports	Input mode
Stack Pointer	Points to the top of the stack

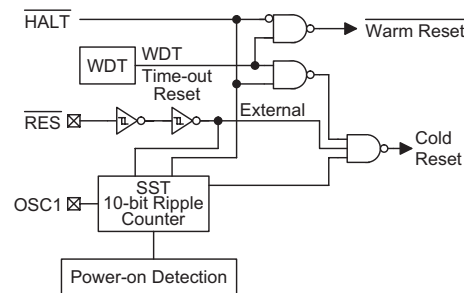

**Reset Circuit**

Note: "\*" Make the length of the wiring, which is connected to the RES pin as short as possible, to avoid noise interference.

**Reset Timing Chart**

**Reset Configuration**

Note: "\*" stands for "warm reset"  
 "u" stands for "unchanged"  
 "x" stands for "unknown"

**Timer/Event Counter**

Only one timer/event counter (TMR) are implemented in the microcontroller. The timer/event counter contains an 8-bit programmable count-up counter and the clock may come from an external source or an internal clock source. An internal clock source comes from  $f_{SYS}$ . The external clock input allows the user to count external events, measure time intervals or pulse widths, or to generate an accurate time base.

There are two registers related to the Timer/event counter; TMR (0DH), TMRC (0EH). Writing TMR will transfer the specified data to timer/event counter registers. Reading the TMR will read the contents of the timer/event counter. The TMRC is a control register, which defines the operating mode, counting enable or disable and an active edge.

The TM0 and TM1 bits define the operation mode. The event count mode is used to count external events, which means that the clock source is from an external (TMR) pin. The timer mode functions as a normal timer with the clock source coming from the internal selected clock source. Finally, the pulse width measurement mode can be used to count the high or low level duration of the external signal (TMR), and the counting is based on the internal selected clock source.

In the event count or timer mode, the timer/event counter starts counting at the current contents in the timer/event counter and ends at FFH. Once an overflow occurs, the counter is reloaded from the timer/event counter preload register, and generates an interrupt request flag (TF; bit 5 of the INTC ). In the pulse width measurement mode with the values of the TON and TE bits equal to 1, after the TMR has received a transient from low to high (or high to low if the TE bit is "0"), it will start counting until the TMR returns to the original level and resets the TON. The measured result remains in the timer/event counter even if the activated transient occurs again. In other words, only 1-cycle measurement can be made until the TON is set. The cycle measurement will re-operate as long as it receives further transient pulse. In this operation mode, the timer/event counter begins counting not according to the logic level but to the transient edges. In the case of counter overflows, the counter is reloaded from the timer/event coun-

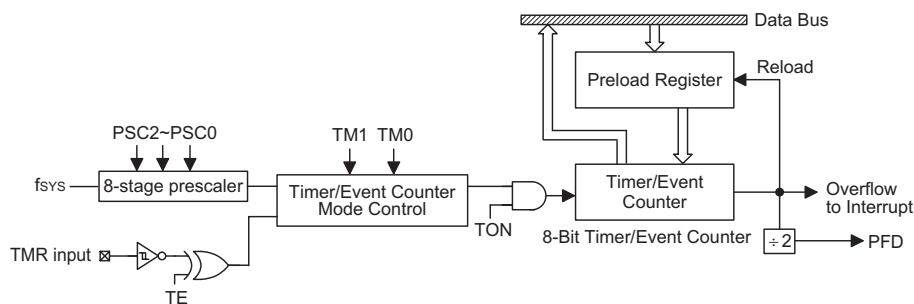

ter register and issues an interrupt request, as in the other two modes, i.e., event and timer modes.

To enable the counting operation, the Timer ON bit (TON; bit 4 of the TMRC) should be set to "1". In the pulse width measurement mode, the TON is automatically cleared after the measurement cycle is completed. But in the other two modes, the TON can only be reset by instructions. The overflow of the timer/event counter is one of the wake-up sources and can also be applied to a PFD (Programmable Frequency Divider) output at PA3 by options. No matter what the operation mode is, writing a "0" to ETI (bit2 of the INTC) disables the related interrupt service. When the PFD function is selected, executing "SET [PA].3" instruction to enable the PFD output and executing "CLR [PA].3" instruction to disable the PFD output.

In the case of timer/event counter OFF condition, writing data to the timer/event counter preload register also reloads that data to the timer/event counter. But if the timer/event counter is turn on, data written to the timer/event counter is kept only in the timer/event counter preload register. The timer/event counter still continues its operation until an overflow occurs.

When the timer/event counter (TMR) is read, the clock is blocked to avoid errors, as this may results in a counting error. Blocking of the clock issue should be taken into account by the programmer. It is strongly recommended to load a desired value into the TMR register first, before turning on the related timer/event counter, for proper operation since the initial value of TMR is unknown. Due to the timer/event scheme, the programmer should pay special attention on the instruction to enable then disable the timer for the first time, whenever there is a need to use the timer/event function, to avoid unpredictable result. After this procedure, the timer/event function can be operated normally.

The bit0~bit2 of the TMRC can be used to define the pre-scaling stages of the internal clock sources of the timer/event counter. The definitions are as shown. The overflow signal of the timer/event counter can be used to generate the PFD signal. The timer prescaler is also used as the PWM counter.

**8-Bit Timer/Event Counter Structure**

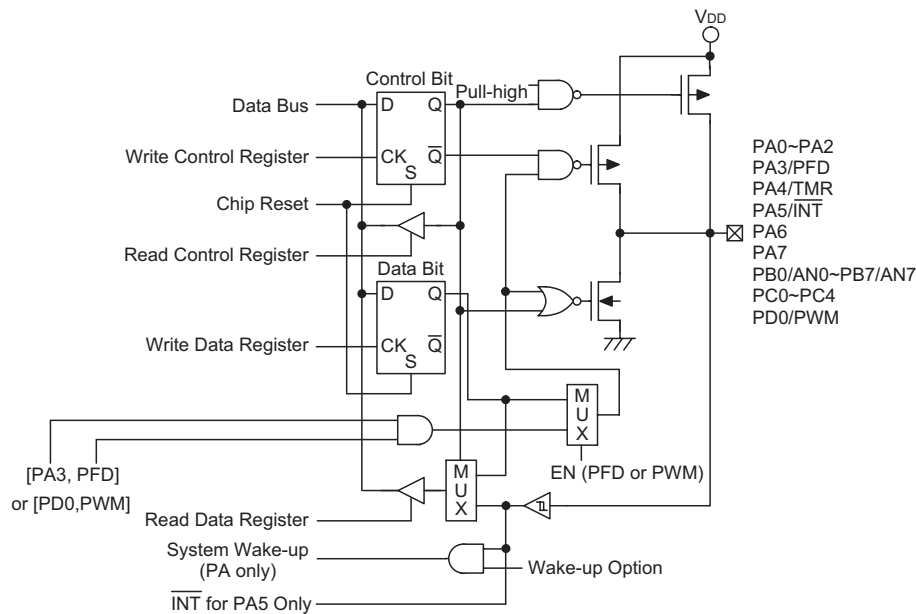

Bit No.	Label	Function
0 1 2	PSC0 PSC1 PSC2	Defines the prescaler stages, PSC2, PSC1, PSC0= 000: $f_{INT}=f_{SYS}$ 001: $f_{INT}=f_{SYS}/2$ 010: $f_{INT}=f_{SYS}/4$ 011: $f_{INT}=f_{SYS}/8$ 100: $f_{INT}=f_{SYS}/16$ 101: $f_{INT}=f_{SYS}/32$ 110: $f_{INT}=f_{SYS}/64$ 111: $f_{INT}=f_{SYS}/128$
3	TE	Defines the TMR active edge of the timer/event counter: In Event Counter Mode (TM1, TM0)=(0,1): 1:count on falling edge; 0:count on rising edge In Pulse Width measurement mode (TM1, TM0)=(1,1): 1: start counting on the rising edge, stop on the falling edge; 0: start counting on the falling edge, stop on the rising edge
4	TON	Enable/disable timer counting (0=disable; 1=enable)
5	—	Unused bit, read as "0"
6 7	TM0 TM1	Defines the operating mode, TM1, TM0: 01=Event count mode (external clock) 10=Timer mode (internal clock) 11=Pulse width measurement mode 00=Unused

TMRC (0EH) Register

**Input/Output Ports**

There are 22 bidirectional input/output lines in the microcontroller, labeled as PA, PB, PC and PD, which are mapped to the data memory of [12H], [14H], [16H] and [18H] respectively. All of these I/O ports can be used for input and output operations. For input opera-

tion, these ports are non-latching, that is, the inputs must be ready at the T2 rising edge of instruction "MOV A,[m]" (m=12H, 14H, 16H or 18H). For output operation, all the data is latched and remains unchanged until the output latch is rewritten.

Input/Output Ports

Each I/O line has its own control register (PAC, PBC, PCC, PDC) to control the input/output configuration. With this control register, CMOS output or Schmitt trigger input with or without pull-high resistor structures can be reconfigured dynamically under software control. To function as an input, the corresponding latch of the control register must write "1". The input source also depends on the control register. If the control register bit is "1", the input will read the pad state. If the control register bit is "0", the contents of the latches will move to the internal bus. The latter is possible in the "read-modify-write" instruction.

For output function, CMOS is the only configuration. These control registers are mapped to locations 13H, 15H, 17H and 19H.

After a chip reset, these input/output lines remain at high levels or floating state (dependent on pull-high options). Each bit of these input/output latches can be set or cleared by "SET [m].i" and "CLR [m].i" (m=12H, 14H, 16H or 18H) instructions.

Some instructions first input data and then follow the output operations. For example, "SET [m].i", "CLR [m].i", "CPL [m].i", "CPLA [m].i" read the entire port states into the CPU, execute the defined operations (bit-operation), and then write the results back to the latches or the accumulator.

Each line of port A has the capability of waking-up the device. Each I/O port has a pull-high option. Once the pull-high option is selected, the I/O port has a pull-high resistor, otherwise, there's none. Take note that a non-pull-high I/O port operating in input mode will cause a floating state.

The PA3, PA4 and PA5 are pin-shared with PFD, TMR and INT pins respectively.

If the PFD option is selected, the output signal in output mode of PA3 will be the PFD signal generated by the timer/event counter overflow signal. The input mode always remain in its original functions. Once the PFD option is selected, the PFD output signal is controlled by the PA3 data register only. The I/O functions of PA3 are shown below.

I/O Mode	I/P (Normal)	O/P (Normal)	I/P (PFD)	O/P (PFD)
PA3	Logical Input	Logical Output	Logical Input	PFD (Timer on)

Note: The PFD frequency is the timer/event counter overflow frequency divided by 2.

The definitions of the PFD control signal and PFD output frequency are listed in the following table.

Timer	Timer Preload Value	PA3 Data Register	PA3 Pad State	Frequency
OFF	X	0	0	X
OFF	X	1	U	X
ON	N	0	0	X
ON	N	1	PFD	$f_{INT}/(2 \times (256-N))$

Note: "X" stands for "unused"  
 "U" stands for "unknown"  
 "N" is the preload value for the timer/event counter  
 "f<sub>TMR</sub>" is the input clock frequency for the timer/event counter

The PB can also be used as A/D converter inputs. The A/D function will be described later. There is a PWM function shared with PD0. If the PWM function is enabled, the PWM signal will appear on PD0 (if PD0 is operating in output mode). The I/O functions of PD0 are as shown.

I/O Mode	I/P (Normal)	O/P (Normal)	I/P (PWM)	O/P (PWM)
PD0	Logical Input	Logical Output	Logical Input	PWM

It is recommended that unused or not bonded out I/O lines should be set as output pins by software instruction to avoid consuming power under input floating state.

#### PWM

The microcontroller provides one channel PWM output shared with PD0. The PWM supports (7+1) or (6+2) modes which are selected by configuration option. The PWM channel has their data register denoted as PWM(1AH). The frequency source of the PWM counter comes from f<sub>SYS</sub>. The PWM register is an 8-bit register. The waveforms of the PWM outputs are as shown. Once the PD0 are selected as the PWM outputs and the output function of the PD0 are enabled (PDC.0= "0"), writing "1" to PD0 data register will enable the PWM output function and writing "0" will force the PD0 to stay at "0".

A (6+2) bits mode PWM cycle is divided into four modulation cycles (modulation cycle 0~modulation cycle 3). Each modulation cycle has 64 PWM input clock period. In a (6+2) bit PWM function, the contents of the PWM

register is divided into two groups. Group 1 of the PWM register is denoted by DC which is the value of PWM.7~PWM.2. The group 2 is denoted by AC which is the value of PWM.1~PWM.0. In a (6+2) bits mode PWM cycle, the duty cycle of each modulation cycle is shown in the table.

Parameter	AC (0~3)	Duty Cycle
Modulation cycle i (i=0~3)	$i < AC$	$\frac{DC+1}{64}$
	$i \geq AC$	$\frac{DC}{64}$

A (7+1) bits mode PWM cycle is divided into two modulation cycles (modulation cycle0~modulation cycle 1). Each modulation cycle has 128 PWM input clock period. In a (7+1) bits PWM function, the contents of the PWM register is divided into two groups. Group 1 of the PWM register is denoted by DC which is the value of

PWM.7~PWM.1. The group 2 is denoted by AC which is the value of PWM.0. In a (7+1) bits mode PWM cycle, the duty cycle of each modulation cycle is shown in the table.

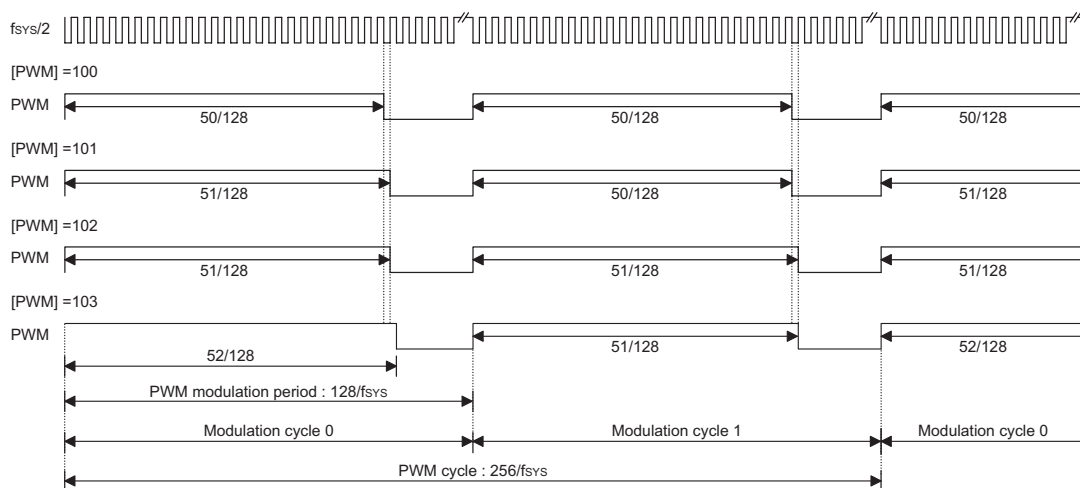

Parameter	AC (0~1)	Duty Cycle
Modulation cycle i (i=0~1)	$i < AC$	$\frac{DC+1}{128}$
	$i \geq AC$	$\frac{DC}{128}$

The modulation frequency, cycle frequency and cycle duty of the PWM output signal are summarized in the following table.

PWM Modulation Frequency	PWM Cycle Frequency	PWM Cycle Duty
$f_{SYS}/64$ for (6+2) bits mode $f_{SYS}/128$ for (7+1) bits mode	$f_{SYS}/256$	$[PWM]/256$

**(6+2) PWM Mode**

**(7+1) PWM Mode**

**A/D Converter**

The 8 channels 12-bit resolution A/D converter are implemented in this microcontroller.

The A/D converter contains 4 special registers which are; ADRL (20H), ADRH (21H), ADCR (22H) and ACSR (23H). The ADRH and ADRL are A/D result register higher-order byte and lower-order byte and are read-only. After the A/D conversion is completed, the ADRH and ADRL should be read to get the conversion result data. The ADCR is an A/D converter control register, which defines the A/D channel number, analog channel select, start A/D conversion control bit and the end of A/D conversion flag. If the users want to start an A/D conversion, define PB configuration, select the converted analog channel, and give START bit a raising edge and falling edge (0→1→0). At the end of A/D conversion, the EOCB bit is cleared and an A/D converter interrupt occurs (if the A/D converter interrupt is enabled). The ACSR is A/D clock setting register, which is used to select the A/D clock source.

The A/D converter control register is used to control the A/D converter. The bit2~bit0 of the are used to select an analog input channel. There are a total of eight channels to select. The bit5~bit3 of the ADCR are used to set PB configurations. PB can be an analog input or as digital I/O line determined by these 3 bits. Once a PB line is selected as an analog input, the I/O functions and pull-high resistor of this I/O line are disabled and the A/D converter circuit is powered on. The EOCB bit (bit6 of the ADCR) is end of A/D conversion flag. Check this bit to know when the A/D conversion is completed.

The START bit of the ADCR is used to begin the conversion of the A/D converter. Giving START bit a rising edge and falling edge means that the A/D conversion has started. In order to ensure that the A/D conversion is completed, the START should remain at "0" until the EOCB is cleared to "0" (end of A/D conversion). Bit 7 of the ACSR register is used for test purposes only and must not be used for other purposes by the application program. Bit1 and bit0 of the ACSR register are used to select the A/D clock source.

When the A/D conversion has completed, the A/D interrupt request flag will be set. The EOCB bit is set to "1" when the START bit is set from "0" to "1".

**Important Note for A/D initialisation:**

Special care must be taken to initialise the A/D converter each time the Port B A/D channel selection bits are modified, otherwise the EOCB flag may be in an undefined condition. An A/D initialisation is implemented by setting the START bit high and then clearing it to zero within 10 instruction cycles of the Port B channel selection bits being modified. Note that if the Port B channel selection bits are all cleared to zero then an A/D initialisation is not required.

Bit No.	Label	Function
0 1	ADCS0 ADCS1	Selects the A/D converter clock source 00= system clock/2 01= system clock/8 10= system clock/32 11= undefined
2~6	—	Unused bit, read as "0"
7	TEST	For test mode used only

**ACSR (23H) Register**

Bit No.	Label	Function
0 1 2	ACS0 ACS1 ACS2	Defines the analog channel select
3 4 5	PCR0 PCR1 PCR2	Defines the port B configuration select. If PCR0, PCR1 and PCR2 are all zero, the ADC circuit is powered off to reduce power consumption
6	EOCB	Indicates end of A/D conversion. (0= end of A/D conversion) Each time bits 3~5 change state the A/D should be initialised by issuing a START signal, otherwise the EOCB flag may have an undefined condition. See "Important note for A/D initialisation".
7	START	Starts the A/D conversion. 0→1→0= Start 0→1= Reset A/D converter and set EOCB to "1".

**ADCR (22H) Register**

### Port B Configuration

### A/D Conversion Timing

The following two programming examples illustrate how to setup and implement an A/D conversion. In the first example, the method of polling the EOCB bit in the ADCR register is used to detect when the conversion cycle is complete, whereas in the second example, the A/D interrupt is used to determine when the conversion is complete.

Example: using EOCB Polling Method to detect end of conversion

```

clr    EADI                ; disable ADC interrupt
mov    a,00000001B
mov    ACSR,a              ; setup the ACSR register to select  $f_{sys}/8$  as the A/D clock
mov    a,00100000B        ; setup ADCR register to configure Port PB0~PB3 as A/D inputs
mov    ADCR,a             ; and select AN0 to be connected to the A/D converter
:
:
:                          ; As the Port B channel bits have changed the following START
:                          ; signal (0-1-0) must be issued within 10 instruction cycles
:
:
Start_conversion:
clr    START
set    START              ; reset A/D
clr    START              ; start A/D
Polling_EOC:
sz     EOCB               ; poll the ADCR register EOCB bit to detect end of A/D conversion
jmp    polling_EOC        ; continue polling
mov    a,ADRH             ; read conversion result high byte value from the ADRH register
mov    adr_buffer,a       ; save result to user defined memory
mov    a,ADRL             ; read conversion result low byte value from the ADRL register
mov    adrl_buffer,a      ; save result to user defined memory
:
:
:
jmp    start_conversion    ; start next A/D conversion

```

Example: using Interrupt Method to detect end of conversion

```

clr    EADI                ; disable ADC interrupt
mov    a,00000001B
mov    ACSR,a              ; setup the ACSR register to select fsys/8 as the A/D clock

mov    a,00100000B        ; setup ADCR register to configure Port PB0~PB3 as A/D inputs
mov    ADCR,a              ; and select AN0 to be connected to the A/D converter
:
:                          ; As the Port B channel bits have changed the following START
:                          ; signal (0-1-0) must be issued within 10 instruction cycles
:
:
Start_conversion:
clr    START                ; reset A/D
set    START                ; start A/D
clr    ADF                  ; clear ADC interrupt request flag
set    EADI                ; enable ADC interrupt
set    EMI                  ; enable global interrupt
:
:
:
; ADC interrupt service routine
ADC_ISR:
mov    acc_stack,a         ; save ACC to user defined memory
mov    a,STATUS
mov    status_stack,a     ; save STATUS to user defined memory

### Low Voltage Reset – LVR

There is a low voltage reset circuit (LVR) implemented in the microcontrollers. The function can be enabled/disabled by options.

If the supply voltage of the device is within the range  $0.9V \sim V_{LVR}$  such as changing a battery, the LVR will automatically reset the device internally.

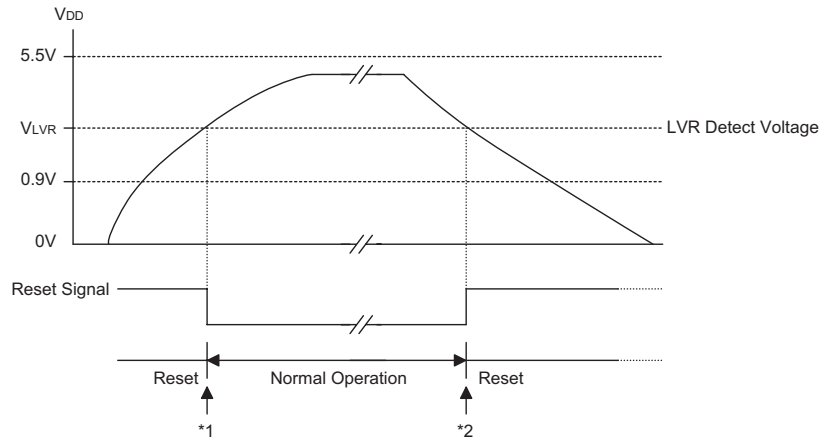

The LVR includes the following specifications:

- The low voltage ( $0.9V \sim V_{LVR}$ ) has to remain in their original state to exceed 1ms. If the low voltage state does not exceed 1ms, the LVR will ignore it and do not perform a reset function.
- The LVR uses the "OR" function with the external  $\overline{RES}$  signal to perform chip reset.

The relationship between  $V_{DD}$  and  $V_{LVR}$  is shown below.

Note:  $V_{OPR}$  is the voltage range for proper chip operation at 4MHz system clock.

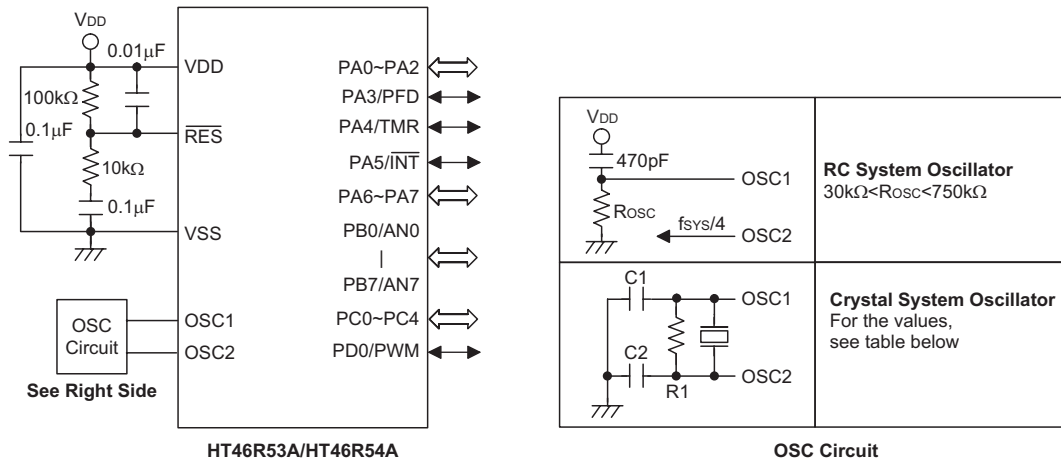

**Low Voltage Reset**

- Note: \*1: To make sure that the system oscillator has stabilized, the SST provides an extra delay of 1024 system clock pulses before entering the normal operation.
- \*2: Since low voltage state has to be maintained in its original state for over 1ms, therefore after 1ms delay, the device enters the reset mode.

**Options**

The following shows kinds of options in the device. ALL the options must be defined to ensure having a proper functioning system.

Options
<p>OSC type selection. This option is to decide if an RC or crystal oscillator is chosen as system clock.</p>
<p>WDT source selection. There are three types of selection: on-chip RC oscillator, instruction clock or disable the WDT.</p>
<p>CLRWDWT times selection. This option defines how to clear the WDT by instruction. "One time" means that the "CLR WDT" instruction can clear the WDT. "Two times" means only if both of the "CLR WDT1" and "CLR WDT2" instructions have been executed, then WDT can be cleared.</p>
<p>Wake-up selection. This option defines the wake-up function activity. External I/O pins (PA only) all have the capability to wake-up the chip from a HALT by a falling edge. (Bit option)</p>
<p>Pull-high selection. This option is to decide whether a pull-high resistance is visible or not in the input mode of the I/O ports. PA is bit option; PB, PC and PD are port option.</p>
<p>PFD selection. PA3: Level output or PFD output.</p>
<p>PWM selection: (7+1) or (6+2) mode PD0: level output or PWM output</p>
<p>WDT time-out period selection. There are four types of selection: WDT clock source divided by <math>2^{12}</math>, <math>2^{13}</math>, <math>2^{14}</math> and <math>2^{15}</math></p>
<p>LVR selection. Enable or disable LVR function.</p>

**Application Circuits**

The following table shows the C1, C2 and R1 values corresponding to the different crystal values. (For reference only)

Crystal or Resonator	C1, C2	R1
4MHz Crystal	0pF	10kΩ
4MHz Resonator	10pF	12kΩ
3.58MHz Crystal	0pF	10kΩ
3.58MHz Resonator	25pF	10kΩ
2MHz Crystal & Resonator	25pF	10kΩ
1MHz Crystal	35pF	27kΩ
480kHz Resonator	300pF	9.1kΩ
455kHz Resonator	300pF	10kΩ
429kHz Resonator	300pF	10kΩ

The function of the resistor R1 is to ensure that the oscillator will switch off should low voltage conditions occur. Such a low voltage, as mentioned here, is one which is less than the lowest value of the MCU operating voltage. Note however that if the LVR is enabled then R1 can be removed.

Note: The resistance and capacitance for reset circuit should be designed in such a way as to ensure that the VDD is stable and remains within a valid operating voltage range before bringing RES high.

\*\*\* Make the length of the wiring, which is connected to the RES pin as short as possible, to avoid noise interference.

**Instruction Set Summary**

Mnemonic	Description	Instruction Cycle	Flag Affected
<b>Arithmetic</b>			
ADD A,[m]	Add data memory to ACC	1	Z,C,AC,OV
ADDM A,[m]	Add ACC to data memory	1 <sup>(1)</sup>	Z,C,AC,OV
ADD A,x	Add immediate data to ACC	1	Z,C,AC,OV
ADC A,[m]	Add data memory to ACC with carry	1	Z,C,AC,OV
ADCM A,[m]	Add ACC to data memory with carry	1 <sup>(1)</sup>	Z,C,AC,OV
SUB A,x	Subtract immediate data from ACC	1	Z,C,AC,OV
SUB A,[m]	Subtract data memory from ACC	1	Z,C,AC,OV
SUBM A,[m]	Subtract data memory from ACC with result in data memory	1 <sup>(1)</sup>	Z,C,AC,OV
SBC A,[m]	Subtract data memory from ACC with carry	1	Z,C,AC,OV
SBCM A,[m]	Subtract data memory from ACC with carry and result in data memory	1 <sup>(1)</sup>	Z,C,AC,OV
DAA [m]	Decimal adjust ACC for addition with result in data memory	1 <sup>(1)</sup>	C
<b>Logic Operation</b>			
AND A,[m]	AND data memory to ACC	1	Z
OR A,[m]	OR data memory to ACC	1	Z
XOR A,[m]	Exclusive-OR data memory to ACC	1	Z
ANDM A,[m]	AND ACC to data memory	1 <sup>(1)</sup>	Z
ORM A,[m]	OR ACC to data memory	1 <sup>(1)</sup>	Z
XORM A,[m]	Exclusive-OR ACC to data memory	1 <sup>(1)</sup>	Z
AND A,x	AND immediate data to ACC	1	Z
OR A,x	OR immediate data to ACC	1	Z
XOR A,x	Exclusive-OR immediate data to ACC	1	Z
CPL [m]	Complement data memory	1 <sup>(1)</sup>	Z
CPLA [m]	Complement data memory with result in ACC	1	Z
<b>Increment &amp; Decrement</b>			
INCA [m]	Increment data memory with result in ACC	1	Z
INC [m]	Increment data memory	1 <sup>(1)</sup>	Z
DECA [m]	Decrement data memory with result in ACC	1	Z
DEC [m]	Decrement data memory	1 <sup>(1)</sup>	Z
<b>Rotate</b>			
RRA [m]	Rotate data memory right with result in ACC	1	None
RR [m]	Rotate data memory right	1 <sup>(1)</sup>	None
RRCA [m]	Rotate data memory right through carry with result in ACC	1	C
RRC [m]	Rotate data memory right through carry	1 <sup>(1)</sup>	C
RLA [m]	Rotate data memory left with result in ACC	1	None
RL [m]	Rotate data memory left	1 <sup>(1)</sup>	None
RLCA [m]	Rotate data memory left through carry with result in ACC	1	C
RLC [m]	Rotate data memory left through carry	1 <sup>(1)</sup>	C
<b>Data Move</b>			
MOV A,[m]	Move data memory to ACC	1	None
MOV [m],A	Move ACC to data memory	1 <sup>(1)</sup>	None
MOV A,x	Move immediate data to ACC	1	None
<b>Bit Operation</b>			
CLR [m].i	Clear bit of data memory	1 <sup>(1)</sup>	None
SET [m].i	Set bit of data memory	1 <sup>(1)</sup>	None

Mnemonic	Description	Instruction Cycle	Flag Affected
<b>Branch</b>			
JMP addr	Jump unconditionally	2	None
SZ [m]	Skip if data memory is zero	1 <sup>(2)</sup>	None
SZA [m]	Skip if data memory is zero with data movement to ACC	1 <sup>(2)</sup>	None
SZ [m].i	Skip if bit i of data memory is zero	1 <sup>(2)</sup>	None
SNZ [m].i	Skip if bit i of data memory is not zero	1 <sup>(2)</sup>	None
SIZ [m]	Skip if increment data memory is zero	1 <sup>(3)</sup>	None
SDZ [m]	Skip if decrement data memory is zero	1 <sup>(3)</sup>	None
SIZA [m]	Skip if increment data memory is zero with result in ACC	1 <sup>(2)</sup>	None
SDZA [m]	Skip if decrement data memory is zero with result in ACC	1 <sup>(2)</sup>	None
CALL addr	Subroutine call	2	None
RET	Return from subroutine	2	None
RET A,x	Return from subroutine and load immediate data to ACC	2	None
RETI	Return from interrupt	2	None
<b>Table Read</b>			
TABRDC [m]	Read ROM code (current page) to data memory and TBLH	2 <sup>(1)</sup>	None
TABRDL [m]	Read ROM code (last page) to data memory and TBLH	2 <sup>(1)</sup>	None
<b>Miscellaneous</b>			
NOP	No operation	1	None
CLR [m]	Clear data memory	1 <sup>(1)</sup>	None
SET [m]	Set data memory	1 <sup>(1)</sup>	None
CLR WDT	Clear Watchdog Timer	1	TO,PDF
CLR WDT1	Pre-clear Watchdog Timer	1	TO <sup>(4)</sup> ,PDF <sup>(4)</sup>
CLR WDT2	Pre-clear Watchdog Timer	1	TO <sup>(4)</sup> ,PDF <sup>(4)</sup>
SWAP [m]	Swap nibbles of data memory	1 <sup>(1)</sup>	None
SWAPA [m]	Swap nibbles of data memory with result in ACC	1	None
HALT	Enter power down mode	1	TO,PDF

Note: x: Immediate data

m: Data memory address

A: Accumulator

i: 0~7 number of bits

addr: Program memory address

√: Flag is affected

–: Flag is not affected

<sup>(1)</sup>: If a loading to the PCL register occurs, the execution cycle of instructions will be delayed for one more cycle (four system clocks).

<sup>(2)</sup>: If a skipping to the next instruction occurs, the execution cycle of instructions will be delayed for one more cycle (four system clocks). Otherwise the original instruction cycle is unchanged.

<sup>(3)</sup>: <sup>(1)</sup> and <sup>(2)</sup>

<sup>(4)</sup>: The flags may be affected by the execution status. If the Watchdog Timer is cleared by executing the "CLR WDT1" or "CLR WDT2" instruction, the TO and PDF are cleared. Otherwise the TO and PDF flags remain unchanged.

**Instruction Definition**
**ADC A,[m]**

Add data memory and carry to the accumulator

Description

The contents of the specified data memory, accumulator and the carry flag are added simultaneously, leaving the result in the accumulator.

Operation

 $ACC \leftarrow ACC+[m]+C$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	√	√	√	√

**ADCM A,[m]**

Add the accumulator and carry to data memory

Description

The contents of the specified data memory, accumulator and the carry flag are added simultaneously, leaving the result in the specified data memory.

Operation

 $[m] \leftarrow ACC+[m]+C$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	√	√	√	√

**ADD A,[m]**

Add data memory to the accumulator

Description

The contents of the specified data memory and the accumulator are added. The result is stored in the accumulator.

Operation

 $ACC \leftarrow ACC+[m]$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	√	√	√	√

**ADD A,x**

Add immediate data to the accumulator

Description

The contents of the accumulator and the specified data are added, leaving the result in the accumulator.

Operation

 $ACC \leftarrow ACC+x$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	√	√	√	√

**ADDM A,[m]**

Add the accumulator to the data memory

Description

The contents of the specified data memory and the accumulator are added. The result is stored in the data memory.

Operation

 $[m] \leftarrow ACC+[m]$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	√	√	√	√

**AND A,[m]** Logical AND accumulator with data memory  
 Description Data in the accumulator and the specified data memory perform a bitwise logical\_AND operation. The result is stored in the accumulator.

Operation  $ACC \leftarrow ACC \text{ "AND" } [m]$

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**AND A,x** Logical AND immediate data to the accumulator  
 Description Data in the accumulator and the specified data perform a bitwise logical\_AND operation. The result is stored in the accumulator.

Operation  $ACC \leftarrow ACC \text{ "AND" } x$

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**ANDM A,[m]** Logical AND data memory with the accumulator  
 Description Data in the specified data memory and the accumulator perform a bitwise logical\_AND operation. The result is stored in the data memory.

Operation  $[m] \leftarrow ACC \text{ "AND" } [m]$

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**CALL addr** Subroutine call  
 Description The instruction unconditionally calls a subroutine located at the indicated address. The program counter increments once to obtain the address of the next instruction, and pushes this onto the stack. The indicated address is then loaded. Program execution continues with the instruction at this address.

Operation  $Stack \leftarrow Program\ Counter + 1$   
 $Program\ Counter \leftarrow addr$

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**CLR [m]** Clear data memory  
 Description The contents of the specified data memory are cleared to 0.

Operation  $[m] \leftarrow 00H$

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**CLR [m].i** Clear bit of data memory  
 Description The bit i of the specified data memory is cleared to 0.  
 Operation  $[m].i \leftarrow 0$   
 Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**CLR WDT** Clear Watchdog Timer  
 Description The WDT is cleared (clears the WDT). The power down bit (PDF) and time-out bit (TO) are cleared.  
 Operation  $WDT \leftarrow 00H$   
 $PDF \text{ and } TO \leftarrow 0$   
 Affected flag(s)

TO	PDF	OV	Z	AC	C
0	0	—	—	—	—

**CLR WDT1** Preclear Watchdog Timer  
 Description Together with CLR WDT2, clears the WDT. PDF and TO are also cleared. Only execution of this instruction without the other preclear instruction just sets the indicated flag which implies this instruction has been executed and the TO and PDF flags remain unchanged.  
 Operation  $WDT \leftarrow 00H^*$   
 $PDF \text{ and } TO \leftarrow 0^*$   
 Affected flag(s)

TO	PDF	OV	Z	AC	C
0*	0*	—	—	—	—

**CLR WDT2** Preclear Watchdog Timer  
 Description Together with CLR WDT1, clears the WDT. PDF and TO are also cleared. Only execution of this instruction without the other preclear instruction, sets the indicated flag which implies this instruction has been executed and the TO and PDF flags remain unchanged.  
 Operation  $WDT \leftarrow 00H^*$   
 $PDF \text{ and } TO \leftarrow 0^*$   
 Affected flag(s)

TO	PDF	OV	Z	AC	C
0*	0*	—	—	—	—

**CPL [m]** Complement data memory  
 Description Each bit of the specified data memory is logically complemented (1's complement). Bits which previously contained a 1 are changed to 0 and vice-versa.  
 Operation  $[m] \leftarrow \overline{[m]}$   
 Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**CPLA [m]** Complement data memory and place result in the accumulator  
 Description Each bit of the specified data memory is logically complemented (1's complement). Bits which previously contained a 1 are changed to 0 and vice-versa. The complemented result is stored in the accumulator and the contents of the data memory remain unchanged.

Operation  $ACC \leftarrow \overline{[m]}$

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**DAA [m]** Decimal-Adjust accumulator for addition  
 Description The accumulator value is adjusted to the BCD (Binary Coded Decimal) code. The accumulator is divided into two nibbles. Each nibble is adjusted to the BCD code and an internal carry (AC1) will be done if the low nibble of the accumulator is greater than 9. The BCD adjustment is done by adding 6 to the original value if the original value is greater than 9 or a carry (AC or C) is set; otherwise the original value remains unchanged. The result is stored in the data memory and only the carry flag (C) may be affected.

Operation If  $ACC.3 \sim ACC.0 > 9$  or  $AC=1$   
 then  $[m].3 \sim [m].0 \leftarrow (ACC.3 \sim ACC.0) + 6$ ,  $AC1 = \overline{AC}$   
 else  $[m].3 \sim [m].0 \leftarrow (ACC.3 \sim ACC.0)$ ,  $AC1 = 0$   
 and  
 If  $ACC.7 \sim ACC.4 + AC1 > 9$  or  $C=1$   
 then  $[m].7 \sim [m].4 \leftarrow ACC.7 \sim ACC.4 + 6 + AC1$ ,  $C=1$   
 else  $[m].7 \sim [m].4 \leftarrow ACC.7 \sim ACC.4 + AC1$ ,  $C=C$

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	√

**DEC [m]** Decrement data memory  
 Description Data in the specified data memory is decremented by 1.

Operation  $[m] \leftarrow [m] - 1$

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**DECA [m]** Decrement data memory and place result in the accumulator  
 Description Data in the specified data memory is decremented by 1, leaving the result in the accumulator. The contents of the data memory remain unchanged.

Operation  $ACC \leftarrow [m] - 1$

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**HALT** Enter power down mode

Description This instruction stops program execution and turns off the system clock. The contents of the RAM and registers are retained. The WDT and prescaler are cleared. The power down bit (PDF) is set and the WDT time-out bit (TO) is cleared.

Operation Program Counter  $\leftarrow$  Program Counter+1  
 PDF  $\leftarrow$  1  
 TO  $\leftarrow$  0

Affected flag(s)

TO	PDF	OV	Z	AC	C
0	1	—	—	—	—

**INC [m]** Increment data memory

Description Data in the specified data memory is incremented by 1

Operation [m]  $\leftarrow$  [m]+1

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**INCA [m]** Increment data memory and place result in the accumulator

Description Data in the specified data memory is incremented by 1, leaving the result in the accumulator. The contents of the data memory remain unchanged.

Operation ACC  $\leftarrow$  [m]+1

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**JMP addr** Directly jump

Description The program counter are replaced with the directly-specified address unconditionally, and control is passed to this destination.

Operation Program Counter  $\leftarrow$  addr

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**MOV A,[m]** Move data memory to the accumulator

Description The contents of the specified data memory are copied to the accumulator.

Operation ACC  $\leftarrow$  [m]

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**MOV A,x**

Move immediate data to the accumulator

Description

The 8-bit data specified by the code is loaded into the accumulator.

Operation

 $ACC \leftarrow x$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**MOV [m],A**

Move the accumulator to data memory

Description

The contents of the accumulator are copied to the specified data memory (one of the data memories).

Operation

 $[m] \leftarrow ACC$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**NOP**

No operation

Description

No operation is performed. Execution continues with the next instruction.

Operation

 $Program\ Counter \leftarrow Program\ Counter + 1$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**OR A,[m]**

Logical OR accumulator with data memory

Description

Data in the accumulator and the specified data memory (one of the data memories) perform a bitwise logical\_OR operation. The result is stored in the accumulator.

Operation

 $ACC \leftarrow ACC \text{ "OR" } [m]$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**OR A,x**

Logical OR immediate data to the accumulator

Description

Data in the accumulator and the specified data perform a bitwise logical\_OR operation. The result is stored in the accumulator.

Operation

 $ACC \leftarrow ACC \text{ "OR" } x$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**ORM A,[m]**

Logical OR data memory with the accumulator

Description

Data in the data memory (one of the data memories) and the accumulator perform a bitwise logical\_OR operation. The result is stored in the data memory.

Operation

 $[m] \leftarrow ACC \text{ "OR" } [m]$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	√	—	—

**RET**

Return from subroutine

Description

The program counter is restored from the stack. This is a 2-cycle instruction.

Operation

 Program Counter  $\leftarrow$  Stack

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**RET A,x**

Return and place immediate data in the accumulator

Description

The program counter is restored from the stack and the accumulator loaded with the specified 8-bit immediate data.

Operation

 Program Counter  $\leftarrow$  Stack

 ACC  $\leftarrow$  x

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**RETI**

Return from interrupt

Description

The program counter is restored from the stack, and interrupts are enabled by setting the EMI bit. EMI is the enable master (global) interrupt bit.

Operation

 Program Counter  $\leftarrow$  Stack

 EMI  $\leftarrow$  1

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**RL [m]**

Rotate data memory left

Description

The contents of the specified data memory are rotated 1 bit left with bit 7 rotated into bit 0.

Operation

 $[m].(i+1) \leftarrow [m].i$ ;  $[m].i$ : bit i of the data memory (i=0~6)

 $[m].0 \leftarrow [m].7$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

**RLA [m]**

Rotate data memory left and place result in the accumulator

Description

Data in the specified data memory is rotated 1 bit left with bit 7 rotated into bit 0, leaving the rotated result in the accumulator. The contents of the data memory remain unchanged.

Operation

 $ACC.(i+1) \leftarrow [m].i$ ;  $[m].i$ : bit i of the data memory (i=0~6)

 $ACC.0 \leftarrow [m].7$ 

Affected flag(s)

TO	PDF	OV	Z	AC	C
—	—	—	—	—	—

<b>RLC [m]</b>	Rotate data memory left through carry												
Description	The contents of the specified data memory and the carry flag are rotated 1 bit left. Bit 7 replaces the carry bit; the original carry flag is rotated into the bit 0 position.												
Operation	$[m].(i+1) \leftarrow [m].i$ ; $[m].i$ :bit $i$ of the data memory ( $i=0\sim 6$ ) $[m].0 \leftarrow C$ $C \leftarrow [m].7$
