

PWM Power Control with Interference Suppression

Description

KKA6083 is a PWM IC in bipolar technology for the control of an N-channel power MOSFET used as a high side switch. The IC is ideal for the use in the brightness control (dimming) of lamps e.g., in dashboard applications.

Features

- Pulse width modulation up to 2 kHz clock frequency
- Protection against short circuit, load dump over-voltage and reverse V_S
- Duty cycle 15 to 100% continuously
- Reduced internal pulse slope of lamp's voltage
- High side switch
- Interference and damage protection according to VDE 0839 and ISO/TR 7637/1.
- Charge pump noise suppressed
- Ground wire breakage protection
- Low interference voltage

Case: DIP 8

Block Diagram

Figure 1. Block diagram with external circuit

Pin Description

Pin	Symbol	Function
1	V _S	Supply voltage V _S
2	GND	IC ground
3	V _T	Control input (duty cycle)
4	Osc	Oscillator
5	Delay	Short circuit protection delay
6	Sense	Current sensing
7	2 V _S	Voltage doubler
8	Output	Output

Functional Description

Supply Voltage, V_S or V_{Batt}, Pin 1

GND Pin 2

Control Input, Pin 3

The pulse width is controlled by means of an external potentiometer (47 kΩ). The characteristic (angle of rotation/duty cycle) is linear. The duty cycle can be varied from 15 to 100%. It can be reduced by increasing the supply voltage as from V_{Batt} > 13 V. This produces a power reduction in the FET and increases the life time of lamps. It is possible to further restrict the duty cycle with the resistors R₁ and R₂.

Pin 3 is protected against short-circuit to V_{Batt} and ground GND (V_{Batt} ≤ 16.5 V).

Oscillator, Pin 4

The oscillator determines the frequency of the output voltage. This is defined by an external capacitor, C₂. It is charged with a constant current, I, until the upper switching threshold is reached. A second current source is then activated which taps a double current, 2 I, from the charging current. The capacitor, C₂ is thus discharged by the current, I, until the lower switching threshold is reached. The second source is then switched off again and the procedure starts once more.

Example for oscillator frequency calculation:

$$V_{T100} = V_0 \cdot \alpha_1 = (V_{Zat} - I_0 \cdot R_s) \cdot \alpha_1$$

$$V_{T<100} = V_0 \cdot \alpha_2 = (V_{Zat} - I_0 \cdot R_s) \cdot \alpha_2$$

$$V_{II} = V_0 \cdot \alpha_3 = (V_{Zat} - I_0 \cdot R_s) \cdot \alpha_3$$

whereas

V_{T100} - High switching threshold (100% duty cycle)

V_{T<100} - High switching threshold (< 100% duty cycle)

V_{II} - Low switching threshold

α₁, α₂ and α₃ are fixed constant.

The above mentioned threshold voltages are calculated for the following values given in the data sheet.

$$V_{Batt} = 12 \text{ V}, I_0 = 4 \text{ mA}, R_s = 150 \Omega,$$

$$\alpha_1 = 0.7, \alpha_2 = 0.67 \text{ and } \alpha_3 = 0.28.$$

$$V_{T100} = (12 \text{ V} - 4 \text{ mA} \cdot 150 \Omega) \cdot 0.7 \approx 8 \text{ V}$$

$$V_{T<100} = 11.4 \text{ V} \cdot 0.67 = 7.6 \text{ V}$$

$$V_{II} = 11.4 \text{ V} \cdot 0.28 = 3.2 \text{ V}$$

For a duty cycle of 100%, an oscillator frequency, f, is as follows:

$$f = \frac{I_{oss}}{2 \cdot (V_{T100} - V_{II}) \cdot C_2}, \text{ whereas } C_2 = 68 \text{ nF} \text{ and } I_{oss} = 45 \mu\text{A}$$

Therefore:

$$f = \frac{45 \mu\text{A}}{2 \cdot (8 \text{ V} - 3.2 \text{ V}) \cdot 68 \text{ nF}} = 69 \text{ Hz}$$

For a duty cycle of less than 100%, the oscillator frequency, f, is as follows:

$$f = \frac{I_{oss}}{2 \cdot (V_{T<100} - V_{II}) \cdot C_2 + 2 \cdot V_{Zat} \cdot C_4}$$

whereas C₄ = 0.1 = 45 μA and C₂ = 68 nF

$$\frac{45 \mu\text{A}}{2 \cdot (7.6 \text{ V} - 3.2 \text{ V}) \cdot 68 \text{ nF}} = 75$$

But when C₄ = 1.8 nF then

$$f = \frac{45 \mu\text{A}}{2 \times (7.6 \text{ V} - 3.2 \text{ V}) \times 68 \text{ nF} + 2 \times 12 \text{ V} \times 1.8 \text{ nF}} = 70 \text{ Hz}$$

By selecting different values of C₂ and C₄, it is possible to have a range of oscillator frequency, f, from 10 to 2000 Hz as shown in the data sheet.

Output Slope Control

The slope of the lamp voltage is internally limited to reduce radio interference, by limitation of the open loop voltage gain of the PWM comparator.

This means the voltage rise on the lamp is proportional to the oscillator voltage increase at the switch over time multiplied with the corresponding amplification.

$$\begin{aligned} dV_g/dt &= \alpha_4 \cdot dV_d/dt = \\ &= 2 \cdot \alpha_4 \cdot f \cdot (V_{TX} - V_{TL}) \cdot (V_{Batt} - I_S \cdot R_3) \\ &\text{when} \\ f &= 75 \text{ Hz, } V_{TX} = V_T < 100 \text{ and } \alpha_4 = 63 \text{ } ((63 \cdot R)/R) \\ &\text{we obtain} \\ dV_g/dt &= 2 \cdot 63 \cdot 75 \cdot (0.67 - 0.28) \cdot (12 - 4 \text{ mA} \cdot 150) \\ &= 42 \text{ V/ms} \end{aligned}$$

With an external capacitor, C_4 , the slope can be further reduced as follows:

$$\begin{aligned} dV_g/dt &= I/(C_4 + C_2/\alpha_4) \\ &\text{when} \\ I &= 45 \text{ } \mu\text{A, } C_4 = 1.8 \text{ nF, } C_2 = 68 \text{ nF and } \alpha_4 = 63 \\ &\text{then } dV_g/dt = 45 \text{ } \mu\text{A}/(1.8 \text{ nF} + 68 \text{ nF}/63) = 15.6 \text{ V/ms} \end{aligned}$$

To damp oscillation tendencies, a resistance of 100 Ω in series with capacitance, C_4 , is recommended.

Interference Suppression

"on board" radio reception according to VDE 0879 part 3/4.81

Test conditions:

Application circuit according to figure 2.

Load: nine 4 W lamps in parallel.

Duty cycle	= 18%
V_{Batt}	= 12 V
f_{Qec}	= 100 Hz

Overvoltage Detection

Stage 1:

If overvoltages $V_{Batt} > 20 \text{ V}$ (typ) occur, the external transistor is switched off and on at $V_{Batt} < 18.5 \text{ V}$ (hysteresis).

Stage 2:

If $V_{Batt} > 28.5 \text{ V}$ (typ), the voltage limitation of the IC is reduced from 26 V to 20 V. The gate of the external transistor remains at the potential of the IC ground, thus producing voltage sharing between FET and lamps in the event of overvoltage pulses occurring (e.g. load dump). The short-circuit protection is not in operation. At V_{Batt} approx. $< 23 \text{ V}$, the overvoltage detection stage 2 is switched off.

$$\begin{aligned} V_{Lamp} &= V_{Batt} - V_S - V_{GS} \\ V_S &= \text{Supply voltage of the IC at overvoltage detection} \\ &\quad \text{stage 2} \\ V_{GS} &= \text{Gate - source voltage of the FET} \end{aligned}$$

Short-Circuit Protection and Current Sensing, Pins 5 and 6

1. Short-Circuit Detection and Time Delay, t_d

The lamp current is monitored by means of an external shunt resistor. If the lamp current exceeds the threshold for the short-circuit detection circuit ($V_{T2} \approx 90 \text{ mV}$), the duty cycle is switched over to 100% and the capacitor C_5 is charged by a current source of $10 \text{ } \mu\text{A}$ ($I_{dis} - I_h$). The external FET is switched off after the cut-off threshold (V_{TL}) is reached. Renewed switching on of the FET is possible only after a power-on reset. The current source, I_{dis} , ensures that the capacitor C_5 is not charged by parasitic currents.

Time delay, t_d is as follows:

$$t_d = C_5 \times V_{TL} / (I_{dis} - I_h)$$

With $C_5 = 100 \text{ nF}$ and $V_{TL} = 10.4 \text{ V}$, $I_{dis} = 13 \text{ } \mu\text{A}$, $I_h = 3 \text{ } \mu\text{A}$, we have

$$\begin{aligned} t_d &= 100 \text{ nF} \cdot 10.4 \text{ V} / (13 \text{ } \mu\text{A} - 3 \text{ } \mu\text{A}) \\ &= 104 \text{ ms} \end{aligned}$$

2. Current limitation:

The lamp current is limited by a control amplifier to protect the external power transistor. The voltage drop across an external shunt resistor acts as the measured variable. Current limitation takes place for a voltage drop of $V_{T1} \approx 100 \text{ mV}$. Owing to the difference $V_{T1} - V_{T2} \approx 10 \text{ mV}$, it is ensured that current limitation

occurs only when the short-circuit detection circuit has responded.

After a power-on reset, the output is inactive for half an oscillator cycle. During this time the supply voltage capacitor can be charged so that current limitation is guaranteed in the event of a short-circuit when the IC is switched on for the first time.

Charge Pump and Output, Pins 7 and 8

Output, Pin 8, is suitable for controlling a power MOSFET. During the active integration phase, the supply current of the operational amplifier is mainly supplied by the capacitor C_3 (bootstrapping). In addition, a trickle charge is generated by an integrated oscillator

($f_1 \approx 400$ kHz) and a voltage doubler circuit. This permits a gate voltage supply at a duty cycle of 100%.

Undervoltage Detection

In the event of voltages of approximately $V_{Batt} < 5.0$ V, the external FET is switched off and the latch for short-circuit detection is reset.

A hysteresis ensures that the FET is switched on again at approximately $V_{Batt} > 5.4$ V.

Ground-Wire Breakage

To protect the FET in the case of ground-wire breakage, a 820 k Ω resistor between gate and source it is recommended to provide proper switch-off conditions.

Absolute Maximum Ratings

Parameters	Symbol	Value	Unit
Supply voltage	V_S	25	V
Junction temperature	T_j	150	$^{\circ}\text{C}$
Ambient temperature range	T_{amb}	-40 to +110	$^{\circ}\text{C}$
Storage temperature range	T_{str}	-55 to +125	$^{\circ}\text{C}$

Thermal Resistance

Parameters	Symbol	Value	Unit
Junction ambient	R_{thJA}	120	K/W

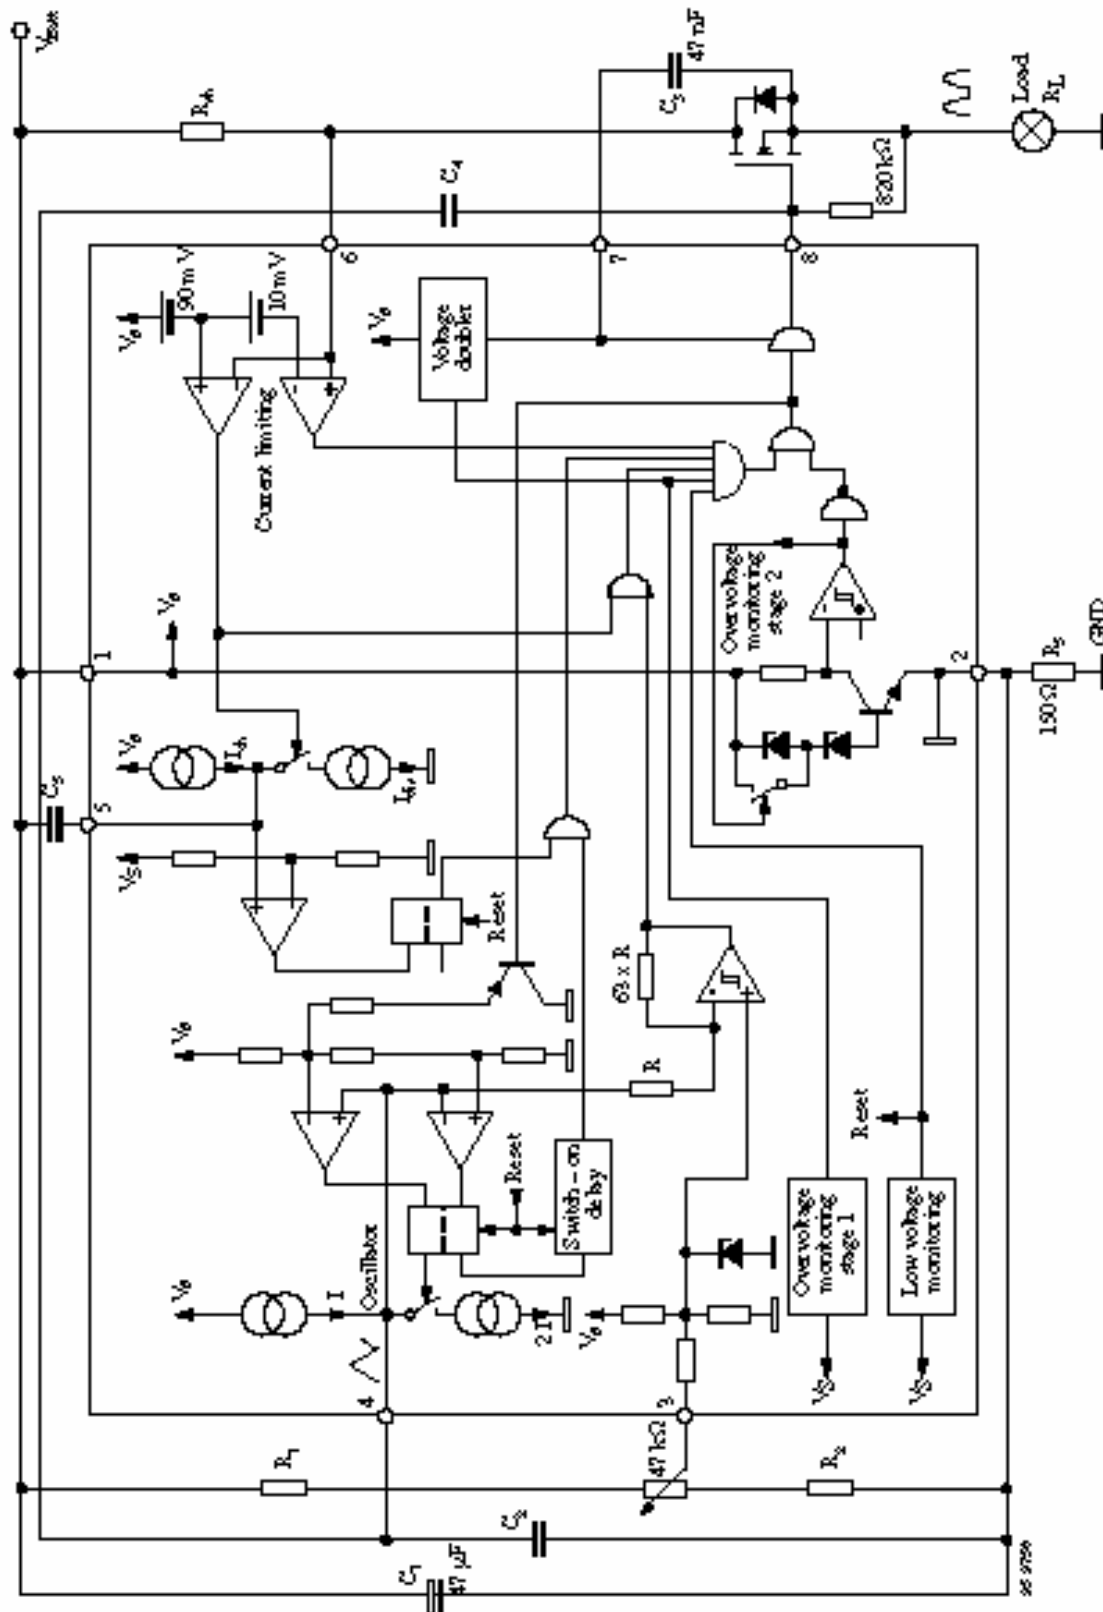

Electrical Characteristics

$T_{amb} = -40$ to $+110^{\circ}\text{C}$, $V_{Batt} = 9$ to 16.5 V, (Basic function is guaranteed between 6.0 V to 9.0 V) reference point GND, unless otherwise specified (see figure 1).
