1. GENERAL DESCRIPTION

The STK6006, an LCD monitor controller, is an embedded device with 8051 CPU core, which is particularly designed for application to an LCD Monitor. It consists of an 8051 CPU core, a 1024-byte SRAM, 14 built PWM DACs, a VESA DDC interface, a 4-channel A/D converter, and a 64k-byte internal program Flash ROM. STK6006 works with both 5V/3.3V power supply and I/O, and 3.3V core operating voltage.

2. FEATURES

- **14 channels of PWM DAC (max.)**
- **31 I/O pins (max.)**
- **8051 core, available for operating frequency at 12MHz with double CPU clock F/W optional**
- **1024 bytes of RAM; 64K bytes of program Flash ROM support In-System Programming function (ISP)**
- **5V/3.3V power supply and I/O; 3.3V core operating voltage**
- **Built-in self-test pattern generator with programmable free-running timing (15 –150KHz)**
- **Built-in lower power reset circuit**
- **SYNC processor for composite separation/insertion, H/V polarity/frequency check, and polarity adjustment**
- **Single master I²C interface for internal device to communicate**
- **Two slave I²C addresses; H/W auto-transfer DDC1/DDC2x data**
- **Feature corresponding to VESA DDC1/2B/2Bi/2B+**
- **4 channels of 6-bit ADC (max.)**
- **A selection to protection from the Flash ROM program code**
- **Watchdog timer featuring programmable interval**
- **Package designed with 40-pin DIP, 42-pin SDIP, or 44-pin PLCC**

4. PIN CONNECTION

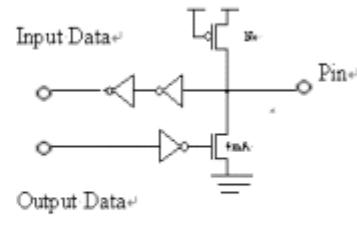

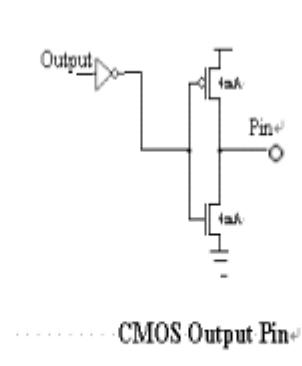

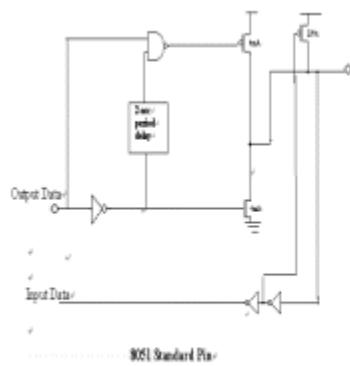

5. PINS CONFIGURATION

“Open drain pin” means the pin may sink at least 4mA current but drive only 10~20uA to V_{DD}. It may be used as input or output function and needs an external pull-up resistor.

“CMOS output” means the pin may sink at least 4mA and drive. It is not preferred to use such pin as input function.

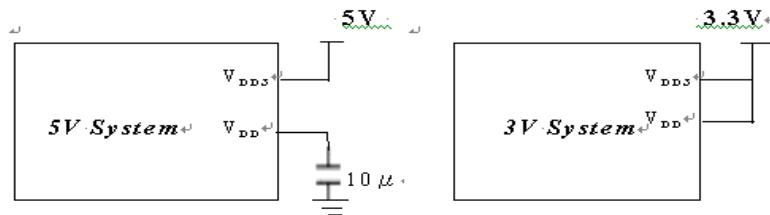

“8051 standard pin” is a pseudo-open drain pin. It may sink at least 4mA current when output stays at a low level, and drives at least 4mA current for 2 X’tal period when output changes from a low level to a high level, and then drives at 120μA for a high level. It can be used as input or output function and needs an external pull-up resistor when driving a device with heavy load.

6. POWER CONFIGURATION

The STK6006 works in a system with a 5V or 3.3V power supply. In a 5V-power system, the V_{DD} pin is connected to a 5V power supply and the V_{DD3} is connected to external capacitor; all output pins changes from 0 to 5V, and input pins can accept a voltage ranging from 0 to 5V. The voltage range of ADC conversion is 5V. However, the X1 and X2 pins operating below 3.3V.

In a 3.3V power system, V_{DD} and V_{DD3} are connected to 3.3V power, all output pins change from 0 to 3.3V, H_{SYNC}, V_{SYNC} and open drain pin may allow input ranging from 0 to 5V, and other input pins only allow input ranging from 0 to 3.3V. The voltage range of ADC conversion is 3.3V.

7. PINS DESCRIPTION

Name	Pin No.			I/O Type	Description
	40 pins	42 pins	44 pins		
DA0/P5.0	3	3	3	I/O	PWM DAC output / General purpose I/O (CMOS)
DA1/P5.1	2	2	2	I/O	PWM DAC output / General purpose I/O (CMOS)

P1.3	17	20	21	I/O	General purpose I/O (CMOS output or 8051 standard)
P1.4	18	21	22	I/O	General purpose I/O (CMOS output or 8051 standard)
P1.5	19	22	23	I/O	General purpose I/O (CMOS output or 8051 standard)
P1.6	20	23	24	I/O	General purpose I/O (CMOS output or 8051 standard)
P1.7	21	24	25	I/O	General purpose I/O (CMOS output or 8051 standard)
P6.0/AD0	23	26	27	I/O	General purpose I/O / ADC Input (CMOS)
P6.1/AD1	22	25	26	I/O	General purpose I/O / ADC Input (CMOS)
P6.2/AD2	12	15	16	I/O	General purpose I/O / ADC Input (CMOS)
P6.3/AD3	-	-	9	I/O	General purpose I/O / ADC Input (CMOS)
P6.4/DA10	26	29	30	I/O	General purpose I/O / PWM DAC output (CMOS)
P6.5/DA11	27	30	31	I/O	General purpose I/O / PWM DAC output (CMOS)
P6.6/DA12	28	31	32	I/O	General purpose I/O / PWM DAC output (CMOS)
P6.7/DA13	-	-	33	I/O	General purpose I/O / PWM DAC output (CMOS)
V _{DD3}	4	4	4	O	3.3V core power
V _{DD}	5	8	8	-	5V or 3.3V Positive Power Supply
V _{SS}	6	9	10	-	Ground
VBLANK/P4.0	32	34	36	O	Vertical blank / General purpose Output (CMOS)
HBLANK/P4.1	33	35	37	O	Horizontal blank / General purpose Output (CMOS)
X2	7	10	11	O	Oscillator output
X1	8	11	12	I	Oscillator input
RST	29	7	7	I	Active-high reset
ISDA/P3.4/T0	9	12	13	I/O	Master I ² C data / General purpose I/O / T0 (open drain)
ISCL/P3.5/T1	10	13	14	I/O	Master I ² C clock / General purpose I/O / T1 (open drain)
HSCL/P3.0/Rxd	25	28	29	I/O	Slave I ² C clock / General purpose I/O / Rxd (open drain)
HSDA/P3.1/Txd	24	27	28	I/O	Slave I ² C data / General purpose I/O / Txd (open drain)
P3.2/INT0	15	18	19	I/O	General purpose I/O / INT0 (8051 standard)
H _{SYNC}	39	41	43	I	Horizontal SYNC or Composite SYNC Input
V _{SYNC}	40	42	44	I	Vertical SYNC input
STO/P4.2	11	14	15	O	Self-test video output / General purpose Output (CMOS)

8. FUNCTIONAL DESCRIPTIONS

8.1 8051 CPU Core

The CPU core of STK6006 is compatible to 8051 industry standard, it consists of 256 bytes of RAM, special function registers (SFR), two timers, five interrupt sources, and a serial interface. The CPU core catches its program code from a 64K-byte Flash in STK6006. In addition, it uses the port0 and port2 to access an external special function register (XFR) and an external auxiliary RAM (AUXRAM).

When CPUclk is set, the CPU core can work at double rate. And then the CPU operates as if a 24-MHz crystal is applied to STK6006, but I²C, DDC, and the H/V processor still work at the original frequency.

Note: Listed in this data sheet, all registers are collected in the external RAM area of 8051. You may refer to the 8051 specifications for an internal RAM memory map in detail.

8.2 Allocation of Memory

8.2.1 Internal Special Function Registers (SFR)

The SFR are the same as the 8051 standard.

DataSheet4U.com

DataShee

8.2.2 Internal RAM

The 256 bytes of internal RAM kept in STK6006 are the same as the 8052 standard.

8.2.3 Auxiliary RAM (AUXRAM)

Total 512 bytes of auxiliary RAM is configured in the 8051 external RAM area 800h - 9FFh. Programs can use the "MOVX" instruction to access the AUXRAM.

8.2.4 Dual Port RAM (DDCRAM)

256 bytes of a Dual Port RAM is configured in the 8051 external RAM area E00h - EFFh. Programs can use the "MOVX" instruction to access the RAM. The external DDC1/2 Host can access the RAM as if a 24LC02 EEPROM is connected to the interface.

8.2.5 External Special Function Registers (XFR)

The XFR is a group of registers configured in the 8051 external RAM area F00h - FFFh for the special functions. Programs can use the "MOVX" instruction to access these registers.

FFh	Internal RAM Accessible by indirect addressing only (Using MOV A,@Ri instruction)	SFR Accessible by direct addressing	FFFh	XFR Accessible by indirect external RAM addressing (Using MOVX instruction)	DDCRAM Accessible by indirect external RAM addressing (Using MOVX instruction)	EFFh
80h			F00h		AUXRAM Accessible by indirect external RAM addressing (Using MOVX instruction)	E00h 9FFh
7Fh	Internal RAM Accessible by direct and indirect addressing					800h
00h						

8.3 Chip Configuration

The Chip Configuration registers explain the chip configuration and the pin function.

 = 0,0 → 100KHz Master I²C frequency is selected

8.4 I/O Port

8.4.1 Port 1

Port 1, a group of pseudo-open drain pins or CMOS output pins selected by corresponding P1(n)co, can be used as general purpose I/O. The performance of port 1 is the same as 8051 standard if corresponding P1(n)co bit is cleared.

8.4.2 P3.0-2, P3.4-5

If these pins are not set as I²C pins, Port 3 can be applied as general purpose I/O, interrupt, UART and Timer pins. The performance of Port 3 is the same as 8051 standard.

8.4.3 Port 4, Port 5 and, Port 6

Port 5 and Port 6 are used as general purpose I/O, other than port 4 for real output. S/W is needed to set the corresponding P5(n)oe and P6(n)oe to explain whether all these pins are input or output.

8.5 PWM DAC

Each 8 bits of PWMDA register in XFR control each output pulse width of PWM DAC converter. PWMDf selects the frequency of PWM clock as 47KHz or 94KHz, and PWMDd selects the total duty cycle step of these DAC outputs as 253 or 256. In case of PWMDd=1, writing FDH/FEH/FFH to DAC register makes output stably high. Writing 00H to DAC register makes the output stably low.

PWMDA	F2Ch(r/w)	Pulse width of PWM DAC 12
PWMDA	F2Dh(r/w)	Pulse width of PWM DAC 13

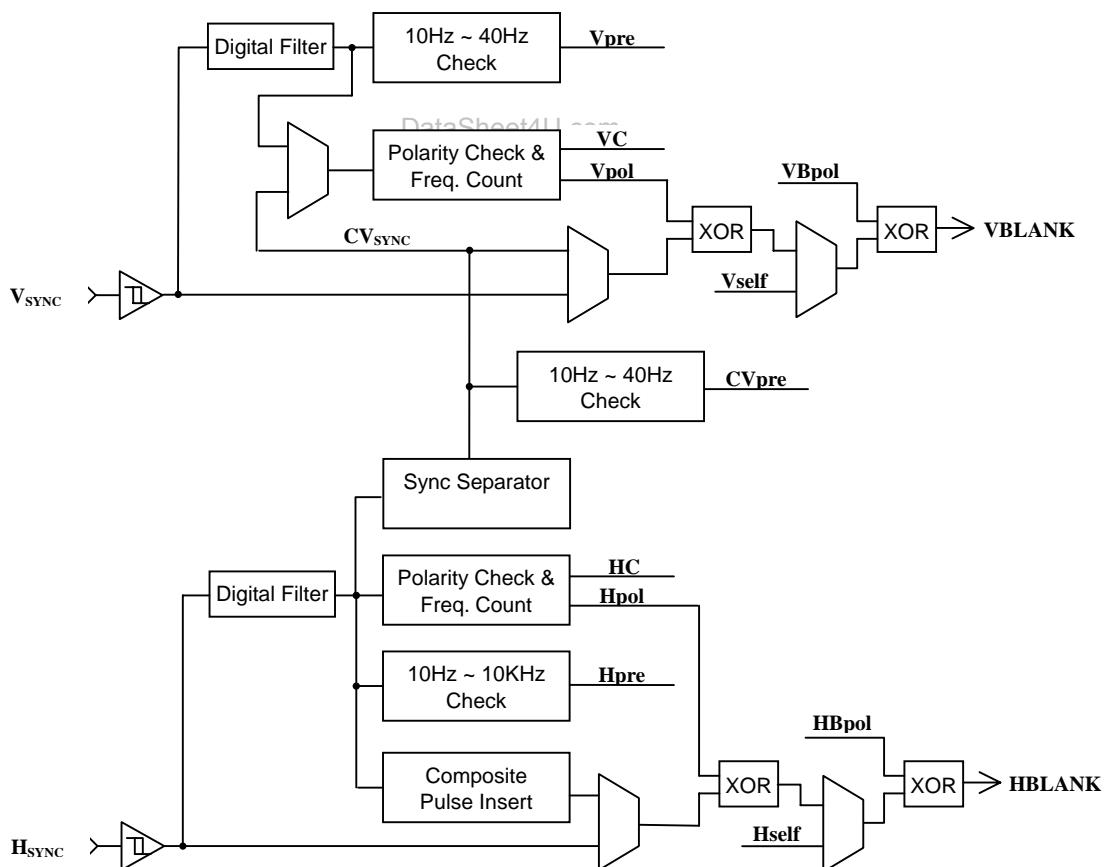

PWMDA (r/w):The mentioned-above output pulse width control is used for DA0-13.

* All of PWM DAC converters, after powered on, center on value 80h.

8.6 H_{SYNC}/V_{SYNC} Processing

H_{SYNC}/V_{SYNC} processing block functions as a composite signal separation/embedding, H/V sync inputs presence check, a frequency counting, a polarity detection and control, together with a protection of the VBLANK output while V_{SYNC} accelerates in a high clock rate of the DDC communication.

The H_{SYNC} present and frequency function block, depending on a digital filter, keep any pulse longer than the specified time period as pulse; the specified time period is under control of bits HDF1 and HDF0. However, the V_{SYNC} digital filter without control bit operates as (HDF1, HDF0) =(0,0) of H_{SYNC}.

H/V SYNC Processor Block Diagram

8.6.1 H/V Frequency Counter

It is nice that the STK6006 can tell H_{SYNC} frequency and V_{SYNC} frequency and save the information in XFRs. We are sure that 14 bits of the Hcounter counts the time of $64*H_{SYNC}$ period and then stores the result into an HCNT latch. When V_{SYNC}/CV_{SYNC} appears, the output value as $[(128000000/H-Freq.)-1]$ is renewed per V_{SYNC}/CV_{SYNC} period, or else continuously renewed when V_{SYNC}/CV_{SYNC} disappear. 12 bits of the Vcounter counts the time between the two V_{SYNC} pulses and then stores the result into a VCNT latch. Furthermore, per V_{SYNC}/CV_{SYNC} period the output value as $(62500/V-Freq.)$ is renewed. An additional overflow bit means that H/V counter overflows; the change or overflow of VCNT/HCNT value will set the IVC/IHC interrupt. For more information in detail, please see the HCNT/VCNT value under the operation at 12MHz in Table 8.6.2.1 and Table 8.6.2.2.

8.6.2 Composite SYNC Separation/Insertion

The input H_{SYNC} is continuously controlled by STK6006. Once the V_{SYNC} pulse is extracted from the H_{SYNC} input, a Cvpre flag will be set and users can select the extracted “ CV_{SYNC} ” for the sources of polarity check, frequency count, and VBLANK output. In comparison with the original signal, the CV_{SYNC} has an $8\mu s$ delay time. Also, the STK6006, during the active time of composite V_{SYNC} , can insert pulse to HBLANK output. The width of inserted pulse counts up $1/8$ H_{SYNC} period and the inserted frequency can be corresponding to the original H_{SYNC} . When “HinsB” control bit is set, the inserted pulse of HBLANK will be disabled, if “HinsB” is set to “1”, then HBLANK output will be equal to H_{SYNC} input. A polarity can surely be controlled by HBpol bit.

8.6.2.1 Horizontal Frequency table

H-Freq(KHz)	14-bit Output Value	
	12MHz-OSC (hex/dec)	
1	31.5	0FDEh / 4062
2	37.5	0D54h / 3412
3	43.3	0B8Bh / 2955
4	46.9	0AA8h / 2728
5	53.7	094Fh / 2383
6	60.0	0854h / 2132
7	68.7	0746h / 1862
8	75.0	06AAh / 1706
9	80.0	063Fh / 1599
10	85.9	05D1h / 1489

6	85	2DFh / 735

8.6.3 Output HBLANK/VBLANK Control and Polarity Adjustment

HBLANK is a mux output of the H_{SYNC}, composite Hsync and self-test horizontal pattern; VBLANK is a mux output of the V_{SYNC}, CV_{SYNC} and self-test vertical pattern. The mux selection and output polarity are S/W controllable. If the frequency of V_{SYNC} exceeds 250Hz, then the VBLANK output will be cut off. The HBLANK/VBLANK and P4.1/P4.0 share the output pin together.

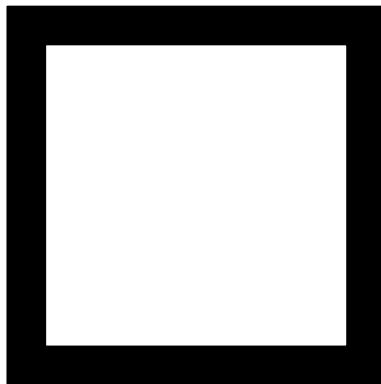

8.6.4 Detection of H/V Polarity

The polarity functions can detect a high and low pulse duty cycle of the input H_{SYNC}/V_{SYNC}. If the time width of high pulse is longer than that of low pulse, a negative polarity will be asserted; if not, a positive polarity, asserted. The change of Hpol value will set the IHpol interrupt; the change of Vpol will set the IVpol interrupt.

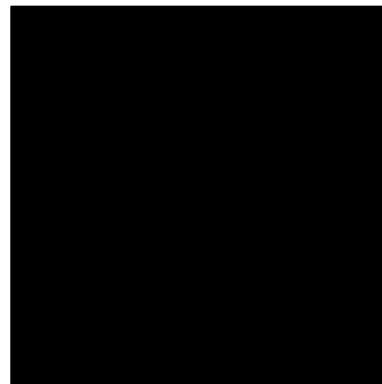

DataSheet4U.com

8.6.5 Self-Test Pattern Generator

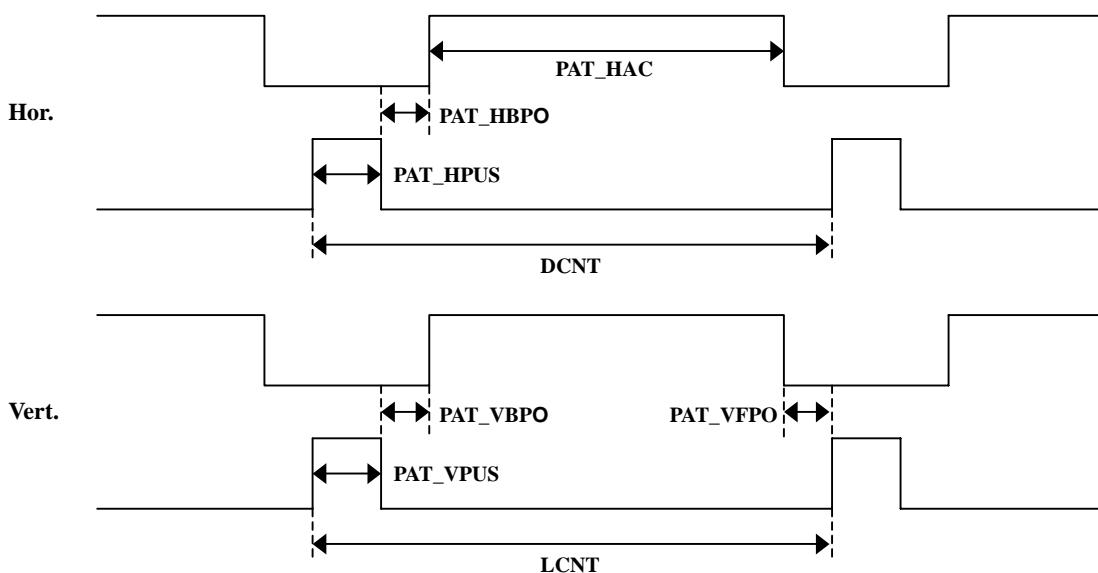

STK6006 is able to generate various free-running timings with full white and full black patterns. User can properly set the content of the dot counters, DCNT, to get the free-running HBLANK frequency, and set the content of the line counters, LCNT, to get the free-running VBLANK frequency. The HBLANK/VBLANK pulse width, video front porch, and video back porch are controlled by PAT_HPUS, PAT_HBPO, PAT_HACT, PAT_VFPO, PAT_VPUS, and PAT_VBPO registers. The self-test pattern generator supports monitor manufacturer to do burn-in test, or offers end-user a reference to check the monitor. The output STO of the generator shares the output pin with P4.2.

Full white (with black frame)

Full black

8.6.6 Real-Time Check on H/V

The Hpresent function checks the input H_{SYNC} pulse, while the H_{SYNC} rating above 10KHz will set the Hpre flag or if H_{SYNC} rating below 10Hz will clear the flag. Similarly, the Vpresent function checks the input V_{SYNC} pulse, while the V_{SYNC} rating above 40Hz will set the Vpre flag or if V_{SYNC} rating below 10Hz will clear the flag. The change of Hpre value will set the IHpre interrupt; the change of Vpre/C Vpre will set the IVpre interrupt.

8.6.7 V_{SYNC} Interrupt

The STK6006 monitors the V_{SYNC} input pulse and generates an interrupt on its leading edge. The V_{SYNC} flag is set each time when STK6006 detects a V_{SYNC} pulse. The flag will be cleared if S/W writes a “0”.

8.6.8 H_{SYNC} Clamp Pulse Output

Setting an “HCLPE” control bit enables the HCLAMP output. The leading-edge position, pulse width, and polarity of HCLAMP are regarded as S/W controllable.

8.6.9 H_{SYNC}/V_{SYNC} Processing Register

HVSTUS (r) : A status of the polarity, present, and static level in H_{SYNC} and V_{SYNC}.

Hpol = 1 → H_{SYNC} input in positive polarity DataSheet4U.com

= 0 → H_{SYNC} input negative polarity

Vpol = 1 → V_{SYNC} (CV_{SYNC}) in positive polarity

= 0 → V_{SYNC} (CV_{SYNC}) in negative polarity

Hoff = 1 → Off-level of H_{SYNC} input keeping high in case of Hpre=0 or Vpre=0

= 0 → Off-level of H_{SYNC} input keeping low in case of Hpre=0 or Vpre=0

Voff = 1 → Off-level of V_{SYNC} input keeping high

= 0 → Off-level of V_{SYNC} input keeping low

Hpre = 1 → H_{SYNC} input present

= 0 → H_{SYNC} input not present

Vpre = 1 → V_{SYNC} input present

= 0 → V_{SYNC} input not present

CVpre = 1 → An extracted CV_{SYNC} present

= 0 → An extracted CV_{SYNC} not present

HCNT (r): H-Freq counter

HCovf = 1 → H-Freq counter is overflowed; this bit is cleared by H/W when this condition is removed.

HC13 - 0: 14 bits of H-Freq counter.

VCNT (r): V-Freq counter

VCovf = 1 → V-Freq counter is overflowed; this bit is cleared by H/W when this condition is removed.

VC11 - 0: 12 high bits of V-Freq counter

HVCTR (w): H/V SYNC processor control register

C1, C0 = 1,1 → To select CV_{SYNC} as a polarity, freq, and VBLANK source.

= 1,0 → To select V_{SYNC} as a polarity, freq, and VBLANK source

= 0,0 → To disable a composite function

= 0,1 → H/W automatically switching to CV_{SYNC} in case of CVpre=1 and VSpre=0

HinsB = 1 → HBLANK without any insert pulse in composite mode

= 0 → HBLANK with an insert pulse in composite mode

HBpol = 1 → HBLANK output in negative polarity

= 0 → HBLANK output in positive polarity

VBpol = 1 → VBLANK output in negative polarity

= 0 → VBLANK output in positive polarity

HVSELF (w): Self-test pattern generator control register

Eselft = 1 → To enable the generator

= 0 → To disable the generator

RT = 1 → An output in a full white pattern

= 0 → An output in a full black pattern

INTL = 1 → Interlace mode

= 0 → Non-interlace mode

HCLAMP (w): H_{SYNC} clamp pulse control register

CLPEG = 1 → Clamp pulse corresponding to a leading edge of the H_{SYNC}

= 0 → Clamp pulse corresponding to a trailing edge of the H_{SYNC}

CLPPO = 1 → Clamp pulse output in a positive polarity

= 0 → Clamp pulse output in a negative polarity

CLPW2: CLPW0 : Pulse width of clamp pulse gained by [(CLPW2:CLPW0) + 1] x 0.167 μs for 12MHz

X'tal selection

HDF (w): H_{SYNC} digital filter control register.

HDF1, HDF0 :

= 0,0 → To make any H_{SYNC} pulse shorter than one OSC period (83.33ns) as noise, between one and two

OSC period (83.33ns to 166.67ns) as unknown region, and longer than two OSC period

(166.67ns) as pulse

= 0,1 → To treat any H_{SYNC} pulse shorter than half OSC period (41.66ns) as noise, between half and one OSC period (41.66ns to 83.33ns) as unknown region, and longer than one OSC period (83.33ns) as pulse

= 1,x → To Disable the digital filter for H_{SYNC}

INTFLG (w) : An Interrupt flag. An interrupt event will set its individual flag; a zero level will drive the INT1 source of 8051 core if the corresponding interrupt enable bit is set. Seriously, while serving the interrupt routine, software must clear this register.

IHpre = 1 → No operation.

= 0 → To clear the H_{SYNC} presence change flag.

IVpre = 1 → No operation.

= 0 → To clear the V_{SYNC} presence change flag.

IHpol = 1 → No operation.

= 0 → To clear the H_{SYNC} polarity change flag.

IVpol = 1 → No operation.

= 0 → To clear the V_{SYNC} polarity change flag.

IHC = 1 → No operation.

DataSheet4U.com

= 0 → To clear the H_{SYNC} frequency change flag.

IVC = 1 → No operation.

= 0 → To clear the V_{SYNC} frequency change flag.

IVsync = 1 → No operation.

= 0 → To clear the V_{SYNC} interrupt flag.

INTFLG (r): Interrupt flag.

IHpre = 1 → To indicate an H_{SYNC} presence change.

IVpre = 1 → To indicate a V_{SYNC} presence change.

IHpol = 1 → To indicate an H_{SYNC} polarity change.

IVpol = 1 → To indicate a V_{SYNC} polarity change.

IHC = 1 → To indicate an H_{SYNC} frequency change or counter overflow.

IVC = 1 → To indicate a V_{SYNC} frequency change or counter overflow.

IVsync = 1 → To indicate a V_{SYNC} interrupt.

INTEN (w): Interrupt enable.

EIHpre = 1 → To enable the H_{SYNC} presence change interrupt.

EIVpre = 1 → To enable the V_{SYNC} presence change interrupt.

EIHpol = 1 → To enable the H_{SYNC} polarity change interrupt.

EIVpol = 1 → To enable the V_{SYNC} polarity change interrupt.

EIHC = 1 → To enable the H_{SYNC} frequency change / counter overflow interrupt.

EIVC = 1 → To enable the V_{SYNC} frequency change / counter overflow interrupt.

EIVsync = 1 → To enable the V_{SYNC} interrupt.

DCNT (w): Dot divider in self-test pattern to get HBLANK output frequency.

DCNT9 - 0: HBLANK freq. = X'tal freq. / (DCNT9 - 0). The valid range is 15KHz to 150KHz. For example,

if 12MHz X'tal is used and 100KHz free-running HBLANK frequency is wanted, then the following dot divider content will be set

$$\text{DCNT} = 12\text{MHz} / 100\text{KHz} = 120(\text{dec}) = 78(\text{hex})$$

PAT_HACT (w): Horizontal active region dot number of self-test pattern output. Dot frequency = X'tal freq.

PAT_HPUS (w): HBLANK pulse width dot number of self-test pattern output. Dot frequency = X'tal freq.

PAT_HBPO (w): Horizontal back porch dot number of self-test pattern output. Dot frequency = X'tal freq.

LCNT (w): Line divider in self-test pattern to get VBLANK output frequency.

LCNT10 – 0: VBLANK freq. = HBLANK freq. / (LCNT10 – 0). For example, if 100Hz free-running

VBLANK frequency is wanted at HBLANK frequency = 100KHz, then the following line divider content will be set

$$\text{LCNT} = 100\text{KHz} / 100\text{Hz} = 1000(\text{dec}) = 3E8(\text{hex})$$

PAT_VFPO (w): Vertical front porch line number of self-test pattern output.

PAT_VPUS (w): VBLANK pulse width line number of self-test pattern output.

PAT_VBPO (w): Vertical back porch line number of self-test pattern output.

8.7 DDC & I²C Interface

8.7.1 SlaveB Block

Connected to HSDA and HSCL pins, the SlaveB I²C block can access the data using the I²C protocols. S/W may write the SLVBADR register to define the slave address.

The SlaveB block in a receiving mode first detects an I²C slave address matching the condition and then issues an ISlvBM interrupt. When a data byte is received, the data received from HSDA is transited into the shift register and then written to the RCBBUF register; the first data written in RCBBUF is a word address, and the slave address is dropped. Once the RCBBUF is written in every time, this block generates an IRGB

interrupt (RCBBUF full interrupt). However, if software cannot in time read out the RCBBUF, the next byte in shift register is naturally not loaded into the RCBBUF and the SlaveB block sends NACK back to the master. The WadrB flag can determine for software whether the data in RCBBUF is a word address or not.

Similarly, the block in a transmitting mode first detects an I²C slave address matching the condition, and then issues an ISlvBM interrupt, while the data loaded in the TXBBUF is written to the shift register every time, which results in an empty TXBBUF and generates a ITXB interrupt (TXBBUF empty interrupt). Before an empty shift register is formed, S/W should write a new byte to the TXBBUF for the next transfer.

Writing “0” to a corresponding bit in the INTFLG register clears the ISlvBM; reading RCBBUF out clears the IRCB; writing TXBBUF clears the ITXB.

If you want to learn more about “Slave I²C Block Timing”, please refer to the attachment.

8.7.2 DDC1/DDC2x Mode, DDCRAM, and SlaveA Block

After reset, the STK6006 exists in the DDC1 mode, and then V_{SYNC} is used as a data clock. The HSCL pin should keep at a high level. the data output to the HSDA is accessed from a shift register in the STK6006; the shift register automatically fetches an EDID data from the lower 128-byte Dual Port RAM (DDCRAM), and sends it in 9 bits of a pocket format together with a null bit (=1) as a pocket separator. By way of setting/clearing the EDDC1 control bit, software may enable/disable DDC1 function.

Detecting a high-to-low transition on the HSCL pin, the STK6006 switches to a DDC2x mode. In this mode, the SlaveA I²C block automatically transmits/receives the data to /from the I²C Master. The accessed data is taken from the DDCRAM and/or saved to the DDCRAM; namely, the STK6006 can operate as 24LC02 EEPROM. S/W writes only the EDID data to DDCRAM, so S/W can select the slave address of SlaveA block as 5-bit, 6-bit, or 7-bit one. Let's take it for example that if S/W selects a 5-bit slave address as 10100b, then the SlaveA I²C block answers to slave address 10100xxb. Setting/clearing the ESIVA bit can enable/disable the SlaveA. By means of setting/clearing the EW128/EW256 bit, the I²C Master may freely write the lower/upper DDCRAM. In addition, if the only only128 control bits are set, the SlaveA accesses only the lower 128-byte DDCRAM.

If HSCL is kept high for 128 V_{SYNC} periods, then the STK6006 goes back to the DDC1 mode. Having been detected on an HSCL/HSDA bus, a valid I²C address (1010xxxb) locks in a DDC2B mode; therefore, the DDC2 flag reflecting the present DDC status, S/W may clear it by writing a “0” to it.

8.7.3 I²C Function Block in Master Mode

The selection of a MI2CS control bit may have the I²C block in the master mode connected to the ISDA/ISCL pins, in which, its speed ranging from 50KHz to 400KHz when software sets up the MI2CF1/MI2CF0 control bit. Through this interface the S/W program can access the external I2C device.

The master I²C access process is summarized as follows:

8.7.3.1. To read the I²C Device

1. Write the Slave Address to MBUF.
2. Set S bit to Start.
3. The STK6006 transmitting this byte, an IMbuf interrupt is triggered.
4. Set or reset the MAckO flag with respect to the I²C protocol.
5. Read the useless byte out of MBUF to continue the data transfer.
6. The STK6006 receiving a new byte, the IMbuf interrupt is once more triggered.
7. Read MBUF will trigger the next receiving operation, but set P bit before read will stop I²C operation.

8.7.3.2. To write the I²C Device

1. Write the Slave Address to MBUF.
2. Set S bit to Start.
3. The STK6006 transmitting this byte, an IMbuf interrupt is triggered.
4. Programs can write MBUF to transfer a next byte or to set P bit to stop.

Reg. Name	Addr.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0							
I2CCTR	F00h (r/w)	DDC2					MAckO	P	S							
I2CSTUS	F01h (r)	WadrB		SlvRWB	SAckIn	SLVS			MackIn

INTEN	F04h (w)	EITXB	EIRCB	EISlvB M	EISTOP	EIReSta	EIWSlv A		EIMbuf							
MBUF	F05h (r/w)	Master I ² C receive/transmit data buffer														
DDCCTR	F06h (w)	EDDC 1	EW128	EW256	Only128			SlvAs1	SlvAs0							
SLVAADR	F07h (w)	ESlvA	I ² C Slave A address													
RCBBUF	F08h (r)	I ² C Slave B receiving buffer														
TXBBUF	F08h (w)	I ² C Slave B transmitting buffer														
SLVBADR	F09h (w)	ESlvB	I ² C Slave B address													

IICCTR (w): I²C interface control register.

DDC2 = 0 → Force STK6006 back to the DDC1 mode from the DDC2 mode

MackO = 1 → NACK will be returned by STK6006 in the master receiving mode

= 0 → ACK will be returned by STK6006 in the master receiving mode

S, P = ↑, 0 → Start condition in case of Master I²C being not during transfer

= X, ↑ → Stop condition in case of Master I²C being not during transfer

= 1, X → Resume transfer after a read/write MBUF operation

IICCTR (r): I²C interface status register.

DDC2 = 1 → DDC2 active

= 0 → STK6006 in the DDC1 mode

IICSTUS (r) : I²C interface status register.

WadrB = 1 → The data in RCBBUF used as word address

SlvRWB = 1 → Current transfer used as slave transmit

= 0 → Current transfer used as slave receive

SAckIn = 1 → The external I²C host responding NACK

= 0 → The external I²C host responding ACK

SLVS = 1 → The slave block having detected a START, but cleared it when STOP detected

MAckIn = 1 → NACK received from the slave I²C device in Master I²C

= 0 → ACK received from the slave I²C device in Master I²C

INTFLG (w): Interrupt flag. An interrupt event will set its individual flag, and, if the corresponding interrupt enable bit is set, a zero level will drive the 8051 INT1 source. Software is necessary to clear this register while serving the interrupt routine.

ISlvBM= 1 → No operation.

= 0 → To clear the ISlvBM flag. DataSheet4U.com

ISTOP= 1 → No operation.

= 0 → To clear the ISTOP flag.

IReSta = 1 → No operation.

= 0 → To clear the IReSta flag.

IWSlvA = 1 → No operation.

= 0 → To clear the IWSlvA flag.

IMbuf= 1 → No operation.

= 0 → To clear the Master I²C bus interrupt flag (IMbuf).

INTFLG (r): Interrupt flag.

ITXB = 1 → To indicate the TXBBUF needs a new data byte, cleared by writing TXBBUF.

IRCB = 1 → To indicate the RCBBUF has received a new data byte, cleared by reading RCBBUF.

ISlvBM = 1 → To indicate the slave I²C address B match condition.

ISTOP = 1 → To indicate the slave I²C has detected a STOP condition.

IReSta = 1 → To indicate the slave I²C has detected a repeated START condition.

IWSlvA = 1 → To indicate the slave A I²C has detected a STOP condition in write mode.

IMbuf = 1 → To indicate a byte is sent to and/or received from the master I²C bus.

INTEN (w): Interrupt enable.

EITXB= 1 → To enable the TXBBUF interrupt.

EIRCB= 1 → To enable the RCBBUF interrupt.

EISlvBM = 1 → To enable the slave address B match interrupt.

EISTOP = 1 → To enable the I²C bus STOP interrupt.

EIReSta = 1 → To enable the I²C bus repeated START interrupt.

EIWSlvA = 1 → To enable the slave A I²C bus STOP of interrupt in write mode

EIMbuf= 1 → To enable the Master I²C bus interrupt.

Mbuf (w) :

Master

I²C data shift register; after START and before STOP condition, writing this register resumes STK6006's transmission to the I²C bus.

Mbuf (r) : Master I²C data shift register; after START and before STOP condition, reading this register resumes STK6006's reception from the I²C bus

DDCCTR (w): DDC interface control register.

EDDC1 = 1 → To enable the DDC1 data transfer in DDC1 mode.

= 0 → To disable the DDC1 data transfer in DDC1 mode.

EW128 = 1 → To indicate that I2C master can write the lower 128-byte(00-7F) DDCRAM

= 0 → To indicate that I2C master can not write the lower 128-byte(00-7F) DDCRAM

EW256 = 1 → To indicate that I2C master can write the higher 128-byte(80-FF) DDCRAM

= 0 → To indicate that I2C master can not write the higher 128-byte(80-FF) DDCRAM

Only128 = 1 → To indicate that the SlaveA always accesses EDID data from the lower 128-byte of

DDCRAM

= 0 → To indicate that the SlaveA accesses EDID data from the complete 256-byte of DDCRAM

SlvAs1,SlvAs0 : Slave I²C block A's slave address length.

= 1,0 → 5 bits of the slave address.

= 0,1 → 6 bits of the slave address.

= 0,0 → 7 bits of the slave address.

SLVAADR (w): Slave I²C block A's enable and address.

ESlvA = 1 → To enable slave I²C block A.

= 0 → To disable slave I²C block A.

bit6-0: Slave I²C address A where the slave block should respond

RCBBUF (r): Slave I²C block B receiving the data buffer

TXBBUF (w): Slave I²C block B transmitting the data buffer

SLVBADR (w): Slave I²C block B's enable and address.

ESlvB = 1 → To enable slave I²C block B.

= 0 → To disable slave I²C block B.

bit6-0 : Slave I²C address B where the slave block should respond

8.8 A/D converter

Installed with four 6-bit A/D converters in V_{DD} ranges is the STK6006. Software can choose a current converting channel by setting the SAD3/SAD2/SAD1/SAD0 bits. The refresh rate of the ADC may be gained by OSC freq./1536 (128μs for 12MHz crystal).

The voltage on the input pin is compared with the voltage on the internal V_{DD} × N / 64, where N=0-63, by the ADC. The ADC output value is N when pin voltage is higher than V_{DD} × N / 64 and lower than V_{DD} × (N+1) / 64.

Reg. Name	Addr.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
ADC	F10h (r)	ADC converting result							
ADC	F10h (w)	EADC				SAD3	SAD2	SAD1	SAD0

ADC (w): ADC control.

DataSheet4U.com

DataSheet4U.com

ENADC= 1 → To enable the ADC.

SADC0= 1 → To select the ADC0 pin input.

SADC1= 1 → To select the ADC1 pin input.

SADC2= 1 → To select the ADC2 pin input.

SADC3= 1 → To select the ADC3 pin input.

ADC (r): ADC converting result

8.9 Low Power Reset (LVR) & Watchdog Timer

The Low Power Reset rise a chip reset signal when the voltage level of power supply goes below 3.8V / 2.5V in 5V / 3.3V system in a specific period of time. After the voltage level of power supply rise above 3.8V / 2.5V in 5V/3.3V system, LVR stays at a reset state for 414 crystal cycles to make sure the chip exits from reset condition with a stable crystal oscillation.

When Watchdog Timer is overflowed, it automatically ensures a device reset. The overflow interval is gained by 0.25 sec × N, in which N is a number ranging from 1 to 8, and it can be programmed by way of register WDT2-0. Since the timer function is disabled after power-on reset, users may enable this function by setting EWDT and clear the timer by setting WDTclr.

Reg. Name	Addr.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
-----------	-------	-------	-------	-------	-------	-------	-------	-------	-------

WDT	F18h (w)	EWDT	WDTclr				WDT2	WDT1	WDT0
------------	-----------------	-------------	---------------	--	--	--	-------------	-------------	-------------

WDT (w): Watchdog Timer control register.

EWDT = 1 → To enable the Watchdog Timer

WDTclr = 1 → To clear the Watchdog Timer

WDT2: WDT0 = 0 → Overflow interval = 8 x 0.25 sec.

- = 1 → Overflow interval = 1 x 0.25 sec.
- = 2 → Overflow interval = 2 x 0.25 sec.
- = 3 → Overflow interval = 3 x 0.25 sec.
- = 4 → Overflow interval = 4 x 0.25 sec.
- = 5 → Overflow interval = 5 x 0.25 sec.
- = 6 → Overflow interval = 6 x 0.25 sec.
- = 7 → Overflow interval = 7 x 0.25 sec.

8.10 In-System Programming Function (ISP)

The features of ISP are outlined as below:

1. Block Erase: 128 Byte, 10mS
2. Whole Flash erase: 100mS
3. Byte programming Cycle time: 40uS per byte
4. Whole 64K-byte Flash programming within 6 Sec.
5. CRC check.

After Power On/Reset, The STK6006 runs the original Program Code. Once the S/W detects an ISP request, S/W can accept the request following the steps below:

1. Clear watchdog and disable all interrupt.
2. Write ISP control block slave address to ISPSLV.
3. Write 93h to ISP enable register (ISPPEN) to enable ISP.
4. Enter 8051 idle mode immediately.

When ISP is enabled, the STK6006 enter into ISP mode in 15-22.5uS. In the mode, PWM DACs and I/O pins keep running at their former status.

Reg. Name	Addr.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
ISPSLV	F0Bh(w)	ISP Control Block Slave Address							
ISPPEN	F0Ch(w)	Write 93h to enable the ISP mode							

8.10.1 ISP Control Block

STK6006 built in a ISP control block, that is a I²C slave device. By this block, user can treats the 64K-byte Flash as 32 EEPROM (like as 24C16, called “EEPROM_like” in this data sheet). There are two type of I²C bus transfer in this block:

Write: S-tttttt0k-00000wwk-ddddddddk-P

Read: S-tttttt1k-CCCCCCCCCK-cccccccK-P

Where

S = start

P = stop

tttttt = ISP Control Block Slave Address

ww = word address

k = ack by slave

K = ack by host (0 or 1)

ddddddd = data

CCCCCCCC = crc_register[15:8]

ccccccc = crc_register[7:0]

Addr.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
00h(w)	SDP	SDUP	ERASE	BLANK			CRCclr	CPUclr
01h(w)				BANK4	BANK3	BANK2	BANK1	BANK0
02h(w)	EPSadr							

00h(w):

SDP = 1 → To enable the S/W data protection of Flash. User needs to set this bit in the end of ISP mode.

SDUP = 1 → To disable the S/W data protection of Flash. User needs to set this bit in the start of ISP mode.

ERASE = 1 → To erase one page (128-byte) of Flash.

BLANK = 1 → To erase whole Flash.

DataSheet4U.com

CRCclr = 1 → To clear CRC register.

CPUclr = 1 → To reset STK6006.

Above 6 bits will be clear by I²C STOP condition. And only one bit can be set to 1 at the same time.

01h(w):

BANK4 - 0 : EEPROM_like bank selection. Choice any one of EEPROM_like to access.

02h(w):

EPSadr : EEPROM_like slave address.

8.10.2 Start to ISP Data Write/Read

In STK6006, the ISP function works following the step below:

1. Define EEPROM_like slave address.
2. Set SDUP bit to disable Flash soft-ware data protection.
3. Set CRCclr bit to reset CRC_register.
4. Define the bank of EEPROM_like.
5. Set ERASE/BLANK bit to block-erase/chip-erase Flash.
6. Access EEPROM_like as standard EEPROM.
7. Check CRC_register.
8. Set SDP bit to enable Flash soft-ware data protection.
9. Set CPUclr bit to reset STK6006.

The step between 4 and 6 are re-cycled until all data are written into Flash.

There are four type of I²C bus transfer in EEPROM_like:

Byte Write: S-ttttAAA0-k-wwwwwwww-k-dddddddd-k-P

Page Write: S-ttttAAA0-k-wwwwwwww-k-dddddddd-k-dddddddd-k- ... -P

Random Read: S-ttttAAA0-k-wwwwwwww-k(-P)-S-ttttAAA1-k-dddddddd-K-P

Sequential Read: S-ttttAAA0-k-wwwwwwww-k(-P)-S-ttttAAA1-k-dddddddd-K-dddddddd-K- ... -P

Where

S = start or re-start

P = stop

tttt = EEPROM_like Slave Address

AAA = page block address

wwwwwwww = word address

k = ack by slave

K = ack by host (0 or 1)

ddddd = data

The word address automatically increases every time when data byte is transferred. The page size is 256-byte.

DataSheet4U.com

In STK6006 Flash memory, the program cycle time is 40us. If the ISP slave is not able to complete the program cycle in time, it returns non-ack to the following data byte. In the meantime, the word address does not increase and the CRC does not count the non-acked data byte.

8.10.3 Cyclic Redundancy Check (CRC)

The ISP Host is able to read the ISP Control Block directly to get the CRC value, instead of reading each byte in Flash. The CRC register counts each data byte acknowledged by the ISP slave during data program period. All bits “1” will be loaded into 16 bits of the CRC register by setting CRCclr bit. Msb is the data byte first shifted into the CRC register.

CRCin = CRC[15]^DATAin;

CRC[15:0] = {CRC[14]^CRCin, CRC[13:2], CRC[1]^CRCin, CRC[0], CRCin};

Where ^ = XOR

example:

data_byte	CRC_register_remainder
	FFFFH
F6H	FF36H
28H	34F2H
C3H	7031H
