

128 K × 8 Very Low Power CMOS SRAM Rad Tolerant

Introduction

The M65608E is a very low power CMOS static RAM organized as 131072×8 bits.

Atmel Wireless & Microcontrollers brings the solution to applications where fast computing is as mandatory as low consumption, such as aerospace electronics, portable instruments, or embarked systems.

Utilizing an array of six transistors (6T) memory cells, the M65608E combines an extremely low standby

supply current (Typical value = $0.2 \mu\text{A}$) with a fast access time at 30 ns over the full military temperature range. The high stability of the 6T cell provides excellent protection against soft errors due to noise.

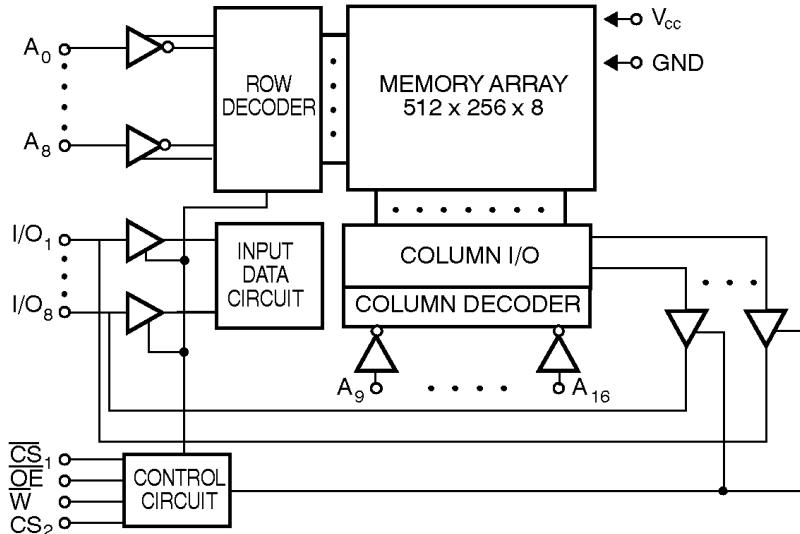

The M65608E is processed according to the methods of the latest revision of the MIL STD 883 (class B or S), ESA SCC 9000 or QML.

Data Retention Mode

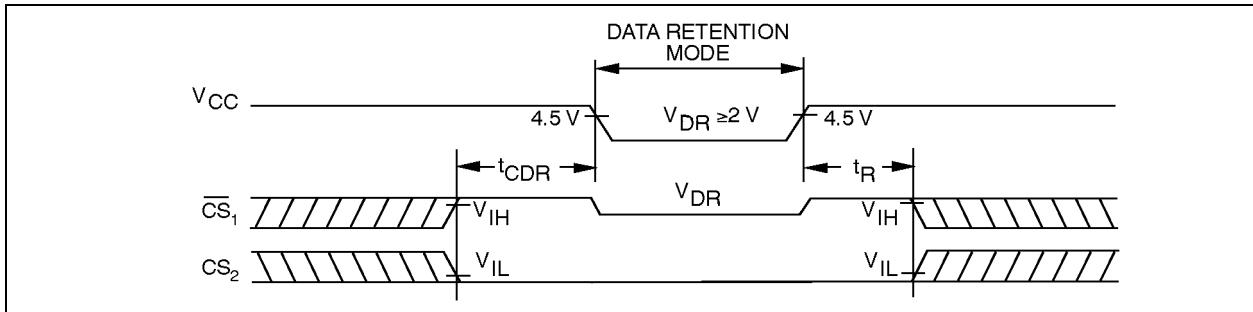

MHS CMOS RAM's are designed with battery backup in mind. Data retention voltage and supply current are guaranteed over temperature. The following rules insure data retention :

1. During data retention chip select \overline{CS}_1 must be held high within VCC to $VCC - 0.2$ V or, chip select CS_2 must be held low within GND to $GND + 0.2$ V.
2. Output Enable (\overline{OE}) should be held high to keep the

RAM outputs high impedance, minimizing power dissipation.

3. During power up and power down transitions \overline{CS}_1 and \overline{OE} must be kept between $VCC + 0.3$ V and 70 % of VCC , or with CS_2 between GND and $GND - 0.3$ V.
4. The RAM can begin operation > TR ns after Vcc reaches the minimum operation voltages (4.5 V).

Notes : 11. Parameters guaranteed, not tested, with output loading 5 pF. (see fig. 1.b.).

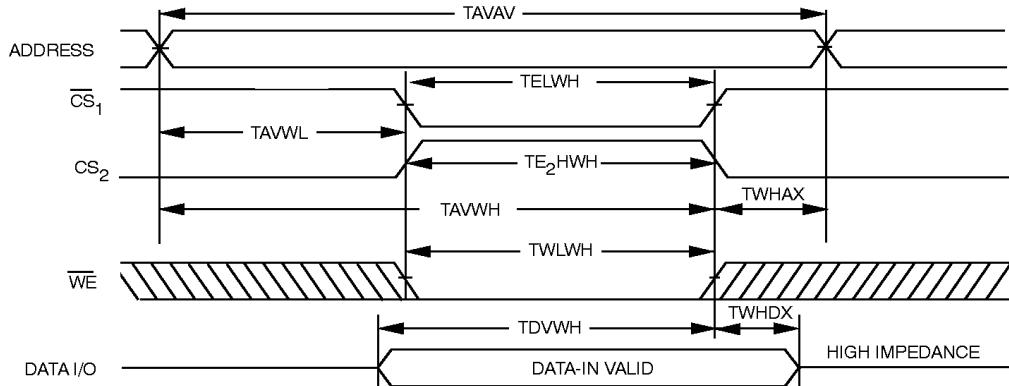

Write Cycle 1. \overline{W} Controlled. \overline{OE} High During Write

Write Cycle 2. \overline{W} Controlled. \overline{OE} Low

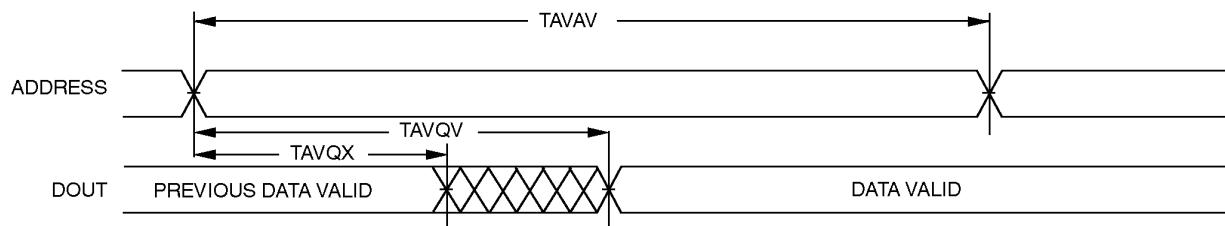

Write Cycle 3. \overline{CS}_1 or \overline{CS}_2 Controlled.

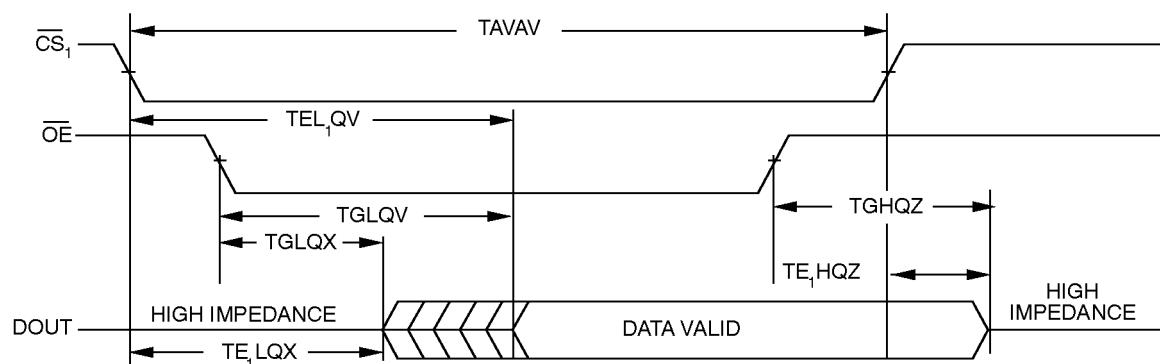

Note : 12. The internal write time of the memory is defined by the overlap of \overline{CS}_1 Low and CS_2 HIGH and \overline{W} LOW. Both signals must be activated to initiate a write and either signal can terminate a write by going in activated. The data input setup and hold timing should be referenced to the activated edge of the signal that terminates the write.
Data out is high impedance if $\overline{OE} = VIH$.
