CMOS 32-bit Micro-controller

TMP92CD54IF

1. Outline and Device Characteristics

TMP92CD54I is high-speed advanced 32-bit micro-controller developed for controlling equipment which processes mass data.

TMP92CD54I is a micro-controller which has a high-performance CPU (900/H1 CPU) and various built-in I/Os. TMP92CD54I is housed in a 100-pin mini flat package.

Device characteristics are as follows:

(1) CPU: 32-bit CPU(900/H1 CPU)

Compatible with TLCS-900,900/L,900/L1,900/H,900/H2's instruction code 16Mbytes of linear address space General-purpose register and register banks Micro DMA : 8channels (250ns / 4bytes at fc = 20MHz, best case) Minimum instruction execution time : 50ns(at 20MHz) Internal data bus : 32-bit

(2) Internal memory

Internal RAM : 32K-byte Internal ROM : 512K-byte Mask ROM

RESTRICTIONS ON PRODUCT USE

060116EBP

- The information contained herein is subject to change without notice. 021023_D
- TOSHIBA is continually working to improve the quality and reliability of its products. Nevertheless, semiconductor devices in general can malfunction or fail due to their inherent electrical sensitivity and vulnerability to physical stress. It is the responsibility of the buyer, when utilizing TOSHIBA products, to comply with the standards of safety in making a safe design for the entire system, and to avoid situations in which a malfunction or failure of such TOSHIBA products could cause loss of human life, bodily injury or damage to property.

In developing your designs, please ensure that TOSHIBA products are used within specified operating ranges as set forth in the most recent TOSHIBA products specifications. Also, please keep in mind the precautions and conditions set forth in the "Handling Guide for Semiconductor Devices," or "TOSHIBA Semiconductor Reliability Handbook" etc. 021023_A

- The TOSHIBA products listed in this document are intended for usage in general electronics applications (computer, personal equipment, office equipment, measuring equipment, industrial robotics, domestic appliances, etc.). These TOSHIBA products are neither intended nor warranted for usage in equipment that requires extraordinarily high quality and/or reliability or a malfunctionor failure of which may cause loss of human life or bodily injury ("Unintended Usage"). Unintended Usage include atomic energy control instruments, airplane or spaceship instruments, transportation instruments, traffic signal instruments, combustion control instruments, medical instruments, all types of safety devices, etc. Unintended Usage of TOSHIBA products listed in this document shall be made at the customer's own risk. 021023_B
- The products described in this document shall not be used or embedded to any downstream products of which manufacture, use and/or sale are prohibited under any applicable laws and regulations. 060106_Q
- The information contained herein is presented only as a guide for the applications of our products. No responsibility is assumed by TOSHIBA for any infringements of patents or other rights of the third parties which may result from its use. No license is granted by implication or otherwise under any patent or patent rights of TOSHIBA or others. 021023_C
- The products described in this document are subject to the foreign exchange and foreign trade laws. 021023_E
- For a discussion of how the reliability of microcontrollers can be predicted, please refer to Section 1.3 of the chapter entitled Quality and Reliability Assurance/Handling Precautions. 030619_S

(3)	External memory expansion
	16M-byte linear address space (memory mapped I/O)
	External data bus : 8bit(for external I/O expansion)
	* Can't use upper address bus when built in I/Os are selected
(4)	Memory controller (MEMC)
	Chip select output : 1 channel
(5)	8-bit timer : 8 channels
	8-bit interval timer mode (8 channels)
	16-bit interval timer mode (4 channels)
	8-bit programmable pulse generation (PPG) output mode (4 channels) 8-bit pulse width modulation (PWM) output mode (4 channels)
(6)	16-bit timer : 2 channels
	16-bit interval timer mode
	16-bit event counter mode
	16-bit programmable pulse generation (PPG) output mode
	Frequency measurement mode
	Pulse width measurement mode
(-)	Time differential measurement mode
(7)	Serial interface (SIO) : 2 channels
	I/O interface mode
(9)	Sorial asynchronous receiver transmitter (UART) mode
(6)	Devel unter 4/2/0 5Mbre et fe=20MU
(0)	Baud rate $4/2/0.5$ Mbps at IC=20MHz.
(9)	Serial bus interface (SBI) · 3 channels
	Liocked synchronous 8-oit serial interface mode
(10)	CAN controller : 1 channel
(10)	Supports CAN version 2.0B
	16 mailboxes
(11)	10-bit A/D converter (ADC) : 12 channels
	A/D conversion time 8µsec @fc=20MHz.
	Total tolerance +/- 3LSB (excluding quantization error)
	Scan mode for all 12channels
(12)	Watch dog timer (WDT)
(13)	Timer for real-time clock (RTC)
	Can operate with only low frequency oscillator.
(14)	Interrupt controller (INTC) : 60 interrupt sources
	9 interrupts from CPU
	42 internal interrupt vectors
<i>,</i> , ,	9 external interrupt vectors
(15)	I/O Port : 68pins
(16)	Standby mode
	Four modes : IDLE3, IDLE2, IDLE1 and STOP
	STOP mode can be released by 9 external inputs.

(17) Internal voltage detection flag (RAMSTB)

- Power supply voltage
 VCC5 = 4.5V to 5.25V
 VCC3 = 3.3V (VCC3 Connect to REGOUT; built-in voltage regulator.)
- (19) Operating temperature : -40 to 85 degree C
- (20) Package: P-LQFP100-1414-0.50F

SD2 SDA2	67^{th}	1	out	SBI channel 2: data input output at I2C mode	
A15			out	Address: Address bus 15.	
				Non-maskable interrupt: Interrupt request pin with programmable falling or both	
NMI	39^{th}	1	in	falling and rising edge.	
INT0	37^{th}	1	in	Interrupt request pin 0: Interrupt request pin with programmable level or rising-edge.	
AM0,1	80 th , 78 th	2	in	Address Mode selection: Connect AM0 pin to L, AM1 pins to H.	
TEST0,1	$76^{th}, 71^{st}$	2	in	Test mode pins [:] Should be set to L.	
CLK	77^{th}	1	out	Programmable clock output (with pull-up register)	
X1/X2	$74^{\text{th}}, 72^{\text{nd}}$	2	in/out	Oscillator connecting pins	
XT1/XT2	$70^{\text{th}}, 69^{\text{th}}$	2	in/out	Low frequency oscillator connecting pins. Crystal or ceramic resonator is connected. RC oscillation is also possible	
RESET	79^{th}	1	in	Reset: Initializes LSI (with pull-up register).	
VREFH	4 th	1	in	AD reference voltage high	
VREFL	3rd	1	in	AD reference voltage low	
ADVCC	2^{nd}	1	-	Power supply pin for AD converter (+5V): Connect ADVCC pin to 5V power supply.	
ADVSS	$1^{\rm st}$	1	-	GND pin for AD converter: Connect ADVSS pin to GND (0V).	
DVCC5	15 th , 40 th , 50 th ,61 st ,75 th	5	-	Power supply pins (+5V): Connect all DVCC5 pins to 5V power supply.	
DVCC3	36 th ,68 th ,86 th	3	-	Power supply pins (+3.3V): Connect all DVCC3 pins to REGOUT pin.	
DVSS	13 th ,38 th ,51 st , 63 rd ,73 rd ,88 th	6	-	GND: Connect all DVSS pins to GND (0V).	
REGOUT	49^{th}	1	out	Regulator output 3.3V: Connect capacitor to stabilize the regulator output.	
REGEN	52^{nd}	1	in	Regulator enable pin: Should be set to H or OPEN (with pull-up register).	

www.datasheatoSHIBA

3. OPERATION

This section describes the basic components, functions and operation of TMP92CD54I.

3.1 CPU

TMP92CD54I contains an advanced high-speed 32-bit CPU (900/H1 CPU)

3.1.1 CPU Outline

900/H1 CPU is high-speed and high-performance CPU based on 900/H CPU. 900/H1 CPU has expanded 32-bit internal data bus to process Instructions more quickly.

Outline of 900/H1 CPU are as follows:

	900/H1 CPU			
Width of CPU Address Bus	24-bit			
Width of CPU Data Bus	32-bit			
Internal Operating Frequency	16 to 20MHz (@fosc=8 to 10MHz)			
Minimum Bus Cycle (Internal RAM)	1-clock access (50ns@fosc=10	MHz)		
Internal RAM	32-bit 1-clock access			
Internal ROM	32-bit interleave 2-1-1-1-clock access			
Internal I/O	8/16-bit 2-clock access	PORT, INTC,		
		MEMC		
	8/16-bit 5 to 6-clock access	SEI, SIO, WDT,		
		8-bit Timer,		
		16-bit Timer,		
		RTC, 10-bit ADC,		
		SBI, CAN		
External Device	8-bit 2-clock access (can inse	ert some waits)		
Minimum Instruction	1-clock(50ns@fosc=10MHz)			
Execution Cycle				
Conditional Jump	2-clock(100ns@fosc=10MHz)			
Instruction Queue Buffer	12-byte			
Instruction Set	Compatible with TLCS-900, 900/H, 900/L,			
	900/L1 and 900/H2 (NORMAL, MIN, MAX and			
	LDX instruction is deleted)			
Micro DMA	8-channels			

3.1.2 Reset Operation

When resetting TMP92CD54I microcontroller, ensure that the power supply voltage is within the operating voltage range, and that the internal high-frequency oscillator has stabilized. Then hold the RESET input Low for at least 20 system clocks (4us). At reset the clock doubler is bypassed and system clock operates at 5MHz (f_{osc} =10MHz).

When the Reset has been accepted, the CPU performs the following:

• Sets the Program Counter (PC) as follows in accordance with the Reset Vector stored at address FFFF00H to FFFF02H:

 $\begin{array}{rll} PC{<}0 \text{ to } 7{>} & \leftarrow \text{ data in location FFFF00H} \\ PC{<}8 \text{ to } 15{>} & \leftarrow \text{ data in location FFFF01H} \\ PC{<}16 \text{ to } 23{>} & \leftarrow \text{ data in location FFFF02H} \end{array}$

- Sets the Stack Pointer (XSP) to 00000000H.
- Sets bits <IFF0 to IFF2> of the Status Register (SR) to 111 (thereby setting the Interrupt Level Mask Register to level 7).
- Clears bits <RFP0 to RFP1> of the Status Register to 00 (thereby selecting Register Bank 0).

When the Reset is released, the CPU starts executing instructions according to the Program Counter settings. CPU internal registers not mentioned above do not change when the Reset is released.

When the Reset is accepted, the CPU sets internal I/O, ports and other pins as follows.

- Initializes the internal I/O registers as table of "Special Function Register" in Section 5.
- Sets the port pins, including the pins that also act as internal I/O, to General-Purpose Input or Output Port Mode.

When external reset is released, built-in clock doubler begins operation and after the stable time (1.6384ms @ fosc=10MHz) elapse of the circuit, internal reset is released.

The operation of memory controller cannot be insured until power supply becomes stable after power-on reset. The external RAM data provided before turning on TMP92CD54I may be spoiled because the control signals are unstable until power supply becomes stable after power on reset.

TMP92CD54I can initialize all general-purpose ports and CLKOUT setting by reset, even if the device is not fed DVCC3 voltage to. When $\overline{\text{RESET}} = L$ level, CLKOUT will be initialized to High-z, but CLKOUT is pulled-up in internal logic. If the device is not fed DVCC3 voltage to, $\overline{\text{RESET}} = L$ level, CLKOUT will be High-z or pulled-up (H level output).

3.1.3 Setting of TEST0, TEST1, AM0 and AM1

Connect TEST0, TEST1 pin to "GND" to use at NORMAL mode. Set AM0 pin to "0" and set AM1 pin to "1" to use.

Operation Made	Mode Setup input pin					
Operation Mode	RESET	AM1	AM0	TEST1	TEST0	
Single-chip Mode		1	0	0	0	

Table 3.1.2 Operation Mode Setup Table

3.2 Memory Map

Figure 3.2 is a memory map of TMP92CD54I.

Figure 3.2 Memory Map

- Note1: The emulator control area is for emulator, it is mapped F00000H to F10000H address after reset.
- Note2: Don't use the last 16-byte area (FFFFF0H to FFFFFFH). This area is reserved.
- Note3: On emulator WR signal and RD signal are asserted, when emulator control area is accessed. Be careful to use external memory.
- Note4: Since there is a possibility of abnormal writing/reading of the data if Bus width put the different memories in consecutive address, do not execute an access which is placed on both memories with one command.

3.3 The Clock Function and Standby Function

*1) Clock-doubler outputs averaging 40MHz clock because it is corrected in clock unit of High Frequency OSC output (10MHz) though it has the possibility that the tolerance of 1.46ns at 40MHz (reference data) is included.

Figure 3.3.1 Block Diagram of System clock

3.3.2 Standby controller

(1) Halt Modes

When the HALT instruction is executed, the operating mode switches to Idle2, Idle1, Idle3 or Stop Mode, depending on the contents of the CLKMOD<HALTM1,HALTM0> register.

Clock Mode Register

Figure 3.3.2 Clock Mode Register

The subsequent actions performed in each mode are as follows:

① Idle2: The CPU only is halted.

In Idle2 Mode internal I/O operations can be performed by setting the following registers.

Table 3.3.1 Shows the registers of setting operation during Idle2 Mode.

Table 3.3.1 Shows the registers of setting operation during Idle2 Mode

Internal I/O	SFR
TIMER0,TIMER1	TRUN01 <i2t01></i2t01>
TIMER2,TIMER3	TRUN23 <i2t23></i2t23>
TIMER4,TIMER5	TRUN45 <i2t45></i2t45>
TIMER6,TIMER7	TRUN67 <i2t67></i2t67>
TIMER8	TRUN8 <i2t8></i2t8>
TIMERA	TRUNA <i2ta></i2ta>
SIO0	SC0MOD1 <i2s0></i2s0>
SIO1	SC1MOD1 <i2s1></i2s1>
SBI0	SBI0BR0 <i2sbi0></i2sbi0>
SBI1	SBI1BR0 <i2sbi1></i2sbi1>
SBI2	SBI2BR0 <i2sbi2></i2sbi2>
A/D converter	ADMOD1 <i2ad></i2ad>
WDT	WDMOD <i2wdt></i2wdt>

② Idle1: Only the oscillator of low and high frequency continue to operate.

③ Idle3: Only the oscillator of low frequency and RTC are operated.

④ Stop: All internal circuits stop operating.

The operation of each of the different Halt Modes is described in Table 3.3.2.

			•				
Halt Mode		Idle2	Idle1	ldle3	Stop		
CLKMOD <halt1:0></halt1:0>		11	10	00	01		
CPU			Halt				
	I/O ports	Maintain same state as when HALT instruction was executed. See tak			ble 3.3.5		
	8-bit TMR, 16-bit TMR						
×	SIO, SBI	Selectable		Stopped			
sloc	A/D converter	See table 3.3.1					
ш	WDT				_		
	RTC, XT1						
	CAN, SEI	Operational					
	Interrupt controller						

Table 3.3.2 I/O operation during Halt Modes

www.datashee

(2) How to clear a Halt mode

The Halt state can be cleared by a Reset or by an interrupt request. The combination of the value in <IFF0:IFF2> of the Interrupt Mask Register and the current Halt mode determine in which ways the Halt mode may be cleared. The details associated with each type of Halt state clearance are shown in Table 3.3.5.

• Clearance by interrupt request

Whether or not the Halt mode is cleared and subsequent operation depends on the status of the generated interrupt. If the interrupt request level set before execution of the HALT instruction is greater than or equal to the value in the Interrupt Mask Register, the following sequence takes place: the Halt mode is cleared, the interrupt is then processed, and the CPU then resumes execution starting from the instruction following the HALT instruction. If the interrupt request level set before execution of the HALT instruction is less than the value in the Interrupt Mask Register, the Halt mode is not cleared. (If a non-maskable interrupt is generated, the Halt mode is cleared and the interrupt processed, regardless of the value in the Interrupt Mask Register.)

However, for INTO only, even if the interrupt request level set before execution of the HALT instruction is less than the value in the Interrupt Mask Register, the Halt mode is cleared. In this case, the interrupt is not processed and the CPU resumes execution starting from the instruction following the HALT instruction. The interrupt request flag remains set to 1.

• Clearance by Reset

Any Halt state can be cleared by Reset.

When Stop Mode is cleared by RESET signal, sufficient time (at least 10ms@foscMHz) must be allowed after the Reset for the operation of the oscillator and clock doubler to stabilize.

When a Halt mode is cleared by resetting, the contents of the internal RAM remain the same as they were before execution of the HALT instruction. However, all other settings are re-initialized. (Clearance by an interrupt affects neither the RAM contents nor any other settings – the state which existed before the HALT instruction was executed is retained.)

Status of Received Interrupt		Interrupt Enabled (interrupt level) ≥ (interrupt mask)				Interrupt Disabled (interrupt level) < (interrupt mask)				
		Halt mode	Idle2	Idle1	Idle3	Stop	Idle2	Idle1	Idle3	Stop

Table 3.3.3 Source of Halt state clearance and Halt clearance operation

©: After clearing the Halt mode, CPU starts interrupt processing. (RESET initializes the microcont.)

- O: After clearing the Halt mode, CPU resumes executing starting from instruction following the HALT instruction.
- ×: Cannot be used to clear the Halt mode.
- -: The priority level (interrupt request level) of non-maskable interrupts is fixed to 7, the highest priority level. There is not this combination type.
- *1: The Halt mode is cleared when the warm-up time has elapsed.
- *2: Any WUINT interrupt (WUINT0 to WUINT7) generate an INT0 interrupt.
- Note 1: When the Halt mode is cleared by an INT0 interrupt of the level mode in the interrupt enabled status, hold level H until starting interrupt processing. If level L is set before holding level H, interrupt processing is not correctly started.
- Note 2: When the external interrupts INT5 to INT7 are used during Idle2 Mode, set to 1 for TRUN8<I2T8> and TRUNA<I2TA>.
 - (Example clearing Idle1 Mode)

An INT0 interrupt clears the Halt state when the device is in Idle1 Mode.

(3) Operation

① Idle2 Mode

In Idle2 Mode only specific internal I/O operations, as designated by the Idle2 Setting Register, can take place. Instruction execution by the CPU stops.

Figure 3.3.3 illustrates an example of the timing for clearance of the Idle2 Mode Halt state by an interrupt.

Figure 3.3.3 Timing chart for Idle2 Mode Halt state cleared by interrupt

② Idle1 Mode

In Idle1 Mode, only the internal oscillator continue to operate. The system clock in the MCU stops.

In the Halt state, the interrupt request is sampled asynchronously with the system clock; however, clearance of the Halt state (i.e. restart of operation) is synchronous with it.

Figure 3.3.4 illustrates the timing for clearance of the Idle1 Mode Halt state by an interrupt.

Figure 3.3.4 Timing chart for Idle1 Mode Halt state cleared by interrupt

③ Idle3 Mode

When Idle3 Mode is selected, internal circuits stop including the internal oscillator, except the oscillator of low frequency and RTC. Pin status in Stop Mode depends on the settings in the WDMOD<DRVE> register. Table 3.3.5 summarizes the state of these pins in Stop Mode and Idle3 mode.

After Idle3 Mode has been cleared system clock output starts when the warm-up time and clock doubler stable time have elapsed, in order to allow oscillation and clock doubler to stabilize. Figure 3.3.5 illustrates the timing for clearance of the Idle3 Mode Halt state by an interrupt.

Idle3 mode can only be released by an NMI pin, INTO pin or WUINTO to WUINT7 pins (generate a INT0 interrupt) interrupt, or by reset.

When Idle3 mode is released by other than reset, the system clock starts its output after the time set by the warm-up counter for the internal oscillation to stabilize. When using reset to release stop mode, input reset signals long enough for stable oscillation and clock doubler stable time.

In systems with an external oscillator, the warm-up counter also operates when Idle3 mode is released. Therefore, such systems also require a warm-up time between input of release signals and system clock output.

(Note)

Figure 3.3.5 Timing chart for Idle3 Mode Halt state cleared by interrupt

④ Stop Mode

When Stop Mode is selected, all internal circuits stop, including the internal oscillator. Pin status in Stop Mode depends on the settings in the WDMOD<DRVE> register. Table 3.3.5 summarizes the state of these pins in Stop Mode and Idle3 mode.

After Stop Mode has been cleared system clock output starts when the warm-up time and clock doubler stable time have elapsed, in order to allow oscillation and clock doubler to stabilize. Figure 3.3.6 illustrates the timing for clearance of the Stop Mode Halt state by an interrupt.

STOP mode can only be released by an NMI pin, INTO pin or WUINTO to WUINT7 pins(generate a INTO interrupt) interrupt, or by reset.

When STOP mode is released by other than reset, the system clock starts its output after the time set by the warm-up counter for the internal oscillation to stabilize. When using reset to release stop mode, input reset signals long enough for stable oscillation and clock doubler stable time.

In systems with an external oscillator, the warm-up counter also operates when STOP mode is released. Therefore, such systems also require a warm-up time between input of release signals and system clock output.

And if it released from STOP mode, RTCFC register will be initialized without a RESET input. Therefore, it is necessary to set up RTCFC register again after releasing from STOP mode.

(Note); The interrupt processing starts after it completes for Startup time (T_{sta}) of Oscillator, Warm-up time and clock doubler stable time period, after releasing HALT (T_{sta} + 1.6 ms + 1.6 ms). Please inquire about Startup time (T_{sta}) to each oscillator manufacturer.

3.4 Interrupts

Interrupts are controlled by the CPU Interrupt Mask Register <IFF2:0> (bits 12 to 14 of the Status Register) and by the built-in interrupt controller.

TMP92CD54I has a total of 60 interrupts divided into the following five types:

Interrupts generated by CPU: 9 sources

- Software interrupts: 8 sources
- Illegal Instruction interrupt: 1 source

Internal interrupts: 42 sources

- Internal I/O interrupts: 34 sources
- Micro DMA Transfer End interrupts: 8 sources

External interrupts: 9 sources

• Interrupts on external pins ($\overline{\text{NMI}}$, INT0 to INT7)

A fixed individual interrupt vector number is assigned to each interrupt source.

Any one of six levels of priority can also be assigned to each maskable interrupt. Non-maskable interrupts have a fixed priority level of 7, the highest level.

When an interrupt is generated, the interrupt controller sends the priority of that interrupt to the CPU. When more than one interrupt are generated simultaneously, the interrupt controller sends the priority value of the interrupt with the highest priority to the CPU. (The highest priority level is 7, the level used for non-maskable interrupts.)

The CPU compares the interrupt priority level which it receives with the value held in the CPU Interrupt Mask Register <IFF2:0>. If the priority level of the interrupt is greater than or equal to the value in the Interrupt Mask Register, the CPU accepts the interrupt.

However, software interrupts and Illegal Instruction interrupts generated by the CPU are processed irrespective of the value in <IFF2:0>.

The value in the Interrupt Mask Register <IFF2:0> can be changed using the EI instruction (EI num sets <IFF2:0> to num). For example, the command EI 3 enables the acceptance of all non-maskable interrupts and of maskable interrupts whose priority level, as set in the interrupt controller, is 3 or higher. The commands EI and EI 0 enable the acceptance of all non-maskable interrupts and of maskable interrupts with a priority level of 1 or above (hence both are equivalent to the command EI 1).

The DI instruction (sets $\langle IFF2:0 \rangle$ to 7) is exactly equivalent to the EI 7 instruction. The DI instruction is used to disable all maskable interrupts (since the priority level for maskable interrupts ranges from 0 to 6). The EI instruction takes effect as soon as it is executed.

In addition to the general-purpose Interrupt Processing Mode described above, there is also a Micro DMA Processing Mode.

In Micro DMA Mode the CPU automatically transfers data in one-byte, two-byte or four-byte blocks; this mode allows high-speed data transfer to and from internal and external memory and internal I/O ports.

In addition, TMP92CD54I also has a software start function in which micro DMA processing is requested in software rather than by an interrupt.

Figure 3.4.1 is a flowchart showing overall interrupt processing.

www.datasheeTOSHIBA

Figure 3.4.1 Interrupt and micro DMA processing sequence

3.4.1 General-purpose interrupt processing

When the CPU accepts an interrupt, it usually performs the following sequence of operations. However, in the case of software interrupts and Illegal Instruction interrupts generated by the CPU, the CPU skips steps (a) and (c) and executes only steps (b), (d) and (e).

- (a) The CPU reads the interrupt vector from the interrupt controller.When more than one interrupt with the same priority level have been generated simultaneously, the interrupt controller generates an interrupt vector in accordance with the default priority and clears the interrupt requests.(The default priority is determined as follows: the smaller the vector value, the higher the priority.)
- (b) The CPU pushes the Program Counter (PC) and Status Register (SR) onto the top of the stack (pointed to by XSP).
- (c) The CPU sets the value of the CPU's Interrupt Mask Register <IFF2:0> to the priority level for the accepted interrupt plus 1. However, if the priority level for the accepted interrupt is 7, the register's value is set to 7.
- (d) The CPU increments the interrupt nesting counter INTNEST by 1.
- (e) The CPU jumps to the address given by adding the contents of address FFFF00H + the interrupt vector, then starts the interrupt processing routine.

On completion of interrupt processing, the RETI instruction is used to return control to the main routine. RETI restores the contents of the Program Counter and the Status Register from the stack and decrements the Interrupt Nesting counter INTNEST by 1.

Non-maskable interrupts cannot be disabled by a user program. Maskable interrupts, however, can be enabled or disabled by a user program. A program can set the priority level for each interrupt source. (A priority level setting of 0 or 7 will disable an interrupt request.)

If an interrupt request is received for an interrupt with a priority level equal to or greater than the value set in the CPU Interrupt Mask Register <IFF2:0>, the CPU will accept the interrupt. The CPU Interrupt Mask Register <IFF2:0> is then set to the value of the priority level for the accepted interrupt plus 1.

If during interrupt processing, an interrupt is generated with a higher priority than the interrupt currently being processed, or if, during the processing of a non-maskable interrupt processing, a non-maskable interrupt request is generated from another source, the CPU will suspend the routine which it is currently executing and accept the new interrupt. When processing of the new interrupt has been completed, the CPU will resume processing of the suspended interrupt.

If the CPU receives another interrupt request while performing processing steps (a) to (e), the new interrupt will be sampled immediately after execution of the first instruction of its interrupt processing routine. Specifying DI as the start instruction disables nesting of maskable interrupts.

After a reset, initializes the Interrupt Mask Register <IFF2:0> to 111, disabling all maskable interrupts.

Table 3.4.1 shows TMP92CD54I interrupt vectors and micro DMA start vectors. FFFF00H to FFFFEFH (240 bytes) is designated as the interrupt vector area.

Default Priority	Туре	Interrupt Source and Source of Micro DMA Request	Vector Value	Address refer to Vector	Micro DMA Start Vector

Table 3.4.2 TMP92CD54I interrupt vectors and micro DMA start vectors (2/2)

Note1: Micro DMA default priority

If an interrupt request is generated by micro DMA, the interrupt has a higher priority than any other maskable interrupt (irrespective of default channel priority).

Note2: When standing-up micro DMA, set at edge detect mode.

Note3: Micro DMA processing cannot be applied.

Note4: This table mentions only the start address. Then each vector has 4 bytes.

www.datasheeTOSHIBA

3.4.2 Micro DMA processing

In addition to general-purpose interrupt processing, TMP92CD54I also includes a micro DMA function. Micro DMA processing for interrupt requests set by micro DMA is performed at the highest priority level for maskable interrupts (level 6), regardless of the priority level of the interrupt source.

Because the micro DMA function has been implemented with the cooperative operation of CPU, when CPU is a state of stand-by by HALT instruction, the requirement of micro DMA will be ignored (pending).

Micro DMA supports 8 channels and can be transferred continuously by specifying the micro DMA burst function in the following.

(1) Micro DMA operation

When an interrupt request is generated by an interrupt source specified by the Micro DMA Start Vector Register, the micro DMA triggers a micro DMA request to the CPU at interrupt priority level 6 and starts processing the request. The eight micro DMA channels allow micro DMA processing to be set for up to eight types of interrupt at once.

When micro DMA is accepted, the interrupt request flip-flop assigned to that channel is cleared. Data in one-byte or two-byte or four-byte blocks, is automatically transferred at once from the transfer source address to the transfer destination address set in the control register, and the transfer counter is decremented by 1. If the value of the counter after it has been decremented is not 0, DMA processing ends with no change in the value of the micro DMA start vector register. If the value of the decremented counter is 0, a Micro DMA Transfer End interrupt (INTTC0 to INTTC7) is sent from the CPU to the interrupt controller. In addition, the micro DMA start vector register is cleared to 0, the next micro DMA operation is disabled and micro DMA processing terminates.

If micro DMA requests are set simultaneously for more than one channel, priority is not based on the interrupt priority level but on the channel number: the lower the channel number, the higher the priority (Channel 0 thus has the highest priority and Channel 7 the lowest).

If an interrupt request is triggered on the interrupt source in use during the interval between the time at which the micro DMA start vector is cleared and the next setting, general-purpose interrupt processing is performed at the interrupt level set. Therefore, if the interrupt is only being used to initiate micro DMA (and not as a general-purpose interrupt), the interrupt level should first be set to 0 (i.e. interrupt requests should be disabled).

If micro DMA and general-purpose interrupts are being used together as described above, the level of the interrupt which is being used to initiate micro DMA processing should first be set to a lower value than all the other interrupt levels. In this case, edge-triggered interrupts are the only kinds of general interrupts which can be accepted.

Although the control registers used for setting the transfer source and transfer destination addresses are 32 bits wide, this type of register can only output 24-bit addresses. Accordingly, micro DMA can only access 16M-bytes (the upper eight bits of a 32-bit address are not valid).

Three micro DMA transfer modes are supported: one-byte transfers, two-byte (one-word) transfer and four-byte transfer. After a transfer in any mode, the transfer source and transfer destination addresses will either be incremented or decremented, or will remain unchanged. This simplifies the transfer of data from I/O to memory, from memory to I/O, from I/O to I/O, and memory to memory. For details of the various transfer modes, see Section 3.4.2 (4), Detailed description of the Transfer Mode Register.

Since a transfer counter is a 16-bit counter, up to 65536 micro DMA processing operations can be performed per interrupt source (provided that the transfer counter for the source is initially set to 0000H).

Micro DMA processing can be initiated by any one of 43 different interrupts – the 42 interrupts shown in the micro DMA start vectors in Table 3.4.1 and a micro DMA soft start. Figure 3.4.2 shows a 2-byte transfer carried out using a micro DMA cycle in Transfer Destination Address INC Mode (micro DMA transfers are the same in every mode except Counter Mode). (The conditions for this cycle are as follows: external 8-bit bus, 0 waits, and even-numbered transfer source and transfer destination addresses).

Figure 3.4.2 Timing for micro DMA cycle

- States 1, 2: Instruction fefetch cycle (pretches the next instruction code)
- State 3: Micro DMA read cycle
- State 4: Micro DMA write cycle
- State 5: (The same as in state 1, 2)

(2) Micro DMA operation

TMP92CD54I can initiate micro DMA either with an interrupt or by using the micro DMA soft start function, in which micro DMA is initiated by a Write cycle which writes to the register DMAR.

Writing 1 to any bit of the register DMAR causes micro DMA to be performed once. On completion of the transfer, the bits of DMAR which support the end channel are automatically cleared to 0.

When a burst is specified by the register DMAB, data is transferred continuously from the initiation of micro DMA until the value in the micro DMA transfer counter is 0.

Symbol	NAME	Address	7	6	5	4	3	2	1	0
DMAR DMA Request	109h (no RMW)	DREQ7	DREQ6	DREQ5	DREQ4	DREQ3	DREQ2	DREQ1	DREQ0	
		R/W								
		0	0	0	0	0	0	0	0	

(3) Transfer control registers

The transfer source address and the transfer destination address are set in the following registers. An instruction of the form LDC cr,r can be used to set these registers.

(4) Detailed description of the Transfer Mode Register

ZZ: 00 = 1-byte transfer

01 = 2-byte transfer

10 = 4-byte transfer

11 = (reserved)

Note1: The execution time is measured at 1states = 50ns (operation @internal 20 MHz)

Note2: n stands for the micro DMA channel number (0 to 7)

DMADn+/DMASn+: Post-increment (register value is incremented after transfer) DMADn-/DMASn-: Post-decrement (register value is decremented after transfer)

3.4.3 Interrupt controller operation

The block diagram in Figure 3.4.3 shows the interrupt circuits. The left-hand side of the diagram shows the interrupt controller circuit. The right-hand side shows the CPU interrupt request signal circuit and the halt release circuit.

For each of the 51 interrupt channels there is an interrupt request flag (consisting of a flip-flop), an interrupt priority setting register and a micro DMA start vector register. The interrupt request flag latches interrupt requests from the peripherals. The flag is cleared to zero in the following cases: when a Reset occurs, when the CPU reads the channel vector of an interrupt it has received, when the CPU receives a micro DMA request (when micro DMA is set), when a micro DMA burst transfer is terminated, and when an instruction that clears the interrupt for that channel is executed (by writting a micro DMA start vector to the INTCLR register).

An interrupt priority can be set independently for each interrupt source by writing the priority to the interrupt priority setting register (e.g. INTEOAD or INTE12). Six interrupt priorities levels (1 to 6) are provided. Setting an interrupt source's priority level to 0 (or 7) disables interrupt requests from that source. The priority of non-maskable interrupts (NMI pin interrupts and Watchdog Timer interrupts) is fixed at 7. If more than one interrupt request with a given priority level are generated simultaneously, the default priority (the interrupt with the lowest priority or, in other words, the interrupt with the lowest vector value) is used to determine which interrupt request is accepted first.

The 3rd and 7th bits of the interrupt priority setting register indicate the state of the interrupt request flag and thus whether an interrupt request for a given channel has occurred.

If several interrupts are generated simultaneously, the interrupt controller sends the interrupt request for the interrupt with the highest priority and the interrupt's vector address to the CPU. The CPU compares the mask value set in $\langle IFF2:0 \rangle$ of the Status Register (SR) with the priority level of the requested interrupt; if the latter is higher, the interrupt is accepted. Then the CPU sets SR $\langle IFF2:0 \rangle$ to the priority level of the accepted interrupt + 1. Hence, during processing of the accepted interrupt, new interrupt requests with a priority value equal to or higher than the value set in SR $\langle IFF2:0 \rangle$ (i.e. interrupts with a priority higher than the interrupt being processed) will be accepted.

When interrupt processing has been completed (i.e. after execution of a RETI instruction), the CPU restores to SR<IFF2:0> the priority value which was saved on the stack before the interrupt was generated.

The interrupt controller also includes eight registers which are used to store the micro DMA start vector. Writing the start vector of the interrupt source for the micro DMA processing (see Table 3.4.1), enables the corresponding interrupt to be processed by micro DMA processing. The values must be set in the micro DMA parameter registers (e.g. DMAS and DMAD) prior to micro DMA processing.

 Table 3.4.2
 Settings of External interrupt Pin Function

(3) Interrupt request flag clear register

The interrupt request flag is cleared by writing the appropriate micro DMA start vector, as given in Table 3.4.1, to the register INTCLR.

For example, to clear the interrupt flag INTO, perform the following register operation after execution of the DI instruction.

INTCLR \leftarrow 0AH ; Clears interrupt request flag INT0.

Symbol	NAME	Address	7	6	5	4	3	2	1	0
INTCLR	Interrupt Clear control		1	-	-	-	-	-	-	_
		F8H (no RMW)	W							
			0	0	0	0	0	0	0	0
			Interrupt Vector							

(4) Micro DMA start vector registers

These registers assign an interrupt source which makes a micro DMA processing start. The interrupt source whose micro DMA start vector value matches the vector set in one of these registers is designated as the micro DMA start source.

When the micro DMA transfer counter value reaches zero, the micro DMA transfer end interrupt corresponding to the channel is sent to the interrupt controller, the micro DMA start vector register is cleared, and the micro DMA start source for the channel is cleared. Therefore, in order for micro DMA processing to continue, the micro DMA start vector register must be set again during processing of the micro DMA transfer end interrupt.

If the same vector is set in the micro DMA start vector registers of more than one channel, the lowest numbered channel takes priority.

Accordingly, if the same vector is set in the micro DMA start vector registers for two different channels, the interrupt generated on the lower-numbered channel is executed until micro DMA transfer is complete. If the micro DMA start vector for this channel has not been set in the channel's micro DMA start vector register again, micro DMA transfer for the higher-numbered channel will be commenced. (This process is known as micro DMA chaining.)

(5) Specification of a micro DMA burst

Specifying the micro DMA burst function causes micro DMA transfer, once started, to continue until the value in the Transfer Counter Register reaches zero. Setting any of the bits in the register DMAB which correspond to a micro DMA channel (as shown below) to 1 specifies that any micro DMA transfer on that channel will be a burst transfer.

Symbol	NAME	Address	7	6	5	4	3	2	1	0

	DIVIA					R/	Ŵ			
	Durst		0	0	0	0	0	0	0	0

(6) Notes

The instruction execution unit and the bus interface unit in this CPU operate independently. Therefore if, immediately before an interrupt is generated, the CPU fetches an instruction which clears the corresponding interrupt request flag, the CPU may execute this instruction in between accepting the interrupt and reading the interrupt vector. In this case, the CPU will read the default vector 0004H and jump to interrupt vector address FFFF04H.

To avoid this, an instruction which clears an interrupt request flag should always be preceded by a DI instruction.

In addition, please note that the following two circuits are exceptional and demand special attention.

INT0 Level Mode	In Level Mode INT0 is not an edge-triggered interrupt. Hence, in Level Mode the interrupt request flip-flop for INT0 does not function. The peripheral interrupt request passes through the S input of the flip-flop and becomes the Q output. If the interrupt input mode is changed from Edge Mode to Level Mode, the interrupt request flag is cleared automatically. If the CPU enters the interrupt response sequence as a result of INT0 going from 0 to 1, INT0 must then be held at 1 until the interrupt response sequence has been completed. If INT0 is set to Level Mode so as to release a Halt state, INT0 must be held at 1 from the time INT0 changes from 0 to 1 until the Halt state is released. (Hence, it is necessary to ensure that input noise is not interpreted as a 0, causing INT0 to revert to 0 before the Halt state has been released.) When the mode changes from Level Mode to Edge Mode, interrupt request flags which were set in Level Mode will not be cleared. Interrupt request flags must be cleared using the following sequence. Also EI instruction should be execuse after waiting 3-cycle. DI LD (IIMC), 00H ; Switches from level to edge. LD (INTCLR), 0AH ; Clears interrupt request flag. NOP ; Wait 3-cycle
	LD (INTCLR), 0AH ; Clears interrupt request flag. NOP ; Wait 3-cycle NOP NOP EI
INTRX	The interrupt request flip-flop can only be cleared by a Reset or by reading the Serial Channel Receive Buffer. It cannot be cleared by an instruction.

- Note: The following instructions or pin input state changes are equivalent to instructions which clear the interrupt request flag.
 - INT0: Instructions which switch to Level Mode after an interrupt request has been generated in Edge Mode.

The pin input changes from High to Low after an interrupt request has been generated in Level Mode. ("H" \rightarrow "L")

INTRX: Instructions which read the Receive Buffer

3.4.4 Interrupt Mask register

TMP92CD54I has Interrupt Mask registers. Unlike Interrupt priority register, Interrupt mask register only disables or enables interrupts. An interrupt will not be generated, if the interrupt is disabled by Interrupt mask register, even if the interrupt has been enabled by setting Interrupt priority register. One, two or more interrupt factors can be prohibited synchronous by setting of Interrupt Mask register.

After reset, all bits in Interrupt mask register are initialize 1 (enabled interrupts). It is necessary to write 0 in the corresponding bit in case of making interrupt Mask register to prohibit interrupt.

Maskable bit for INTAD request

0 INTAD is disabled 1 INTAD is enabled

Note: Port D0, D1 and D4 have 2 kinds of interrupt source (PD0:INT5/WUINT0, PD1:INT6/WUINT1, PD4:INT7/WUINT4). If both interrupt requests are generated in both interrupt enabled status, both interrupt processing will be executed. When any of these interrupts is used, set Interrupt Mask register or Wake UP Mask register to enable/disable.

Example of register setting:

In the case of setting INT0 interrupt priority level to 7 from 3.

LD LD El	(INTE0AD), 03H (INTMK0), 01H	; Set INT0 level to 3 ; Enable INT0 ; Enable interrupt operation
	:	; running program
DI LD LD LD NOF NOF	(INTMK0), 00H (INTE0AD), 07H (INTCLR), 0AH	; Disable interrupt operation ; Disable INT0 ; Set INT0 level to 7 ; Clear INT0 request ; Wait 3 cycles
LD EI	(INTMK0), 01H	; Enable INT0 ; Enable interrupt operation

www.datasheeTOSHIBA

3.4.5. ON/OFF LOGIC

TMP92CD54I has 8 pins (WUINT0 to WUINT7) for wake up from standby mode. These pins are multiplexed with Port D (PD0 to PD7).

All wake up events can release standby mode and triggering edge can be independently programmable as both rising and falling edge, rising edge or falling edge. It is possible to mask all wake up events independently.

Figure 3.4.5 Block diagram of ON/OFF logic

Using ON/OFF logic, all interrupt signals of WUINT0 to 7 are sent to INT0 in internal logic. When any WUINTn requests are generated, INT0 interrupt request will be generated. Like external INT0, also INT0 from WUINTn is set disable/enable by Interrupt priority register or Interrupt mask register.

Writing 1 to any bit in WUPMASK register, INTO switches ON/OFF logic mode. In this case, WUINTn written 1 in WUPMASK register are enabled, external INTO cannot use. When external INTO is used, write 00 to WUPMASK register.

Selection edge of WUINTn signal uses WUPMOD and WUPEDGE register, rising edge, falling edge or both falling and rising edge are selectable.

Reading WUPFLAG register, request/no-request of WUINTn will be confirmed.

Wake UP Mask Register

WUPMASK (00EFH)

Wake up interrupt mask control
 WUINTn Disabled (MASK)
 WUINTn Enabled

Note1: Port D0, D1 and D4 have 2 kinds of interrupt source (PD0: INT5/WUINT0, PD1: INT6/WUINT1, PD4:INT7/WUINT4). If both interrupt requests are generated in both interrupt enabled status, both interrupt processing will be executed. When each interrupts is used, set Interrupt Mask register or Wake UP Mask register to enable/disable. Even if port D is any of Input/Output port, INTn, and WUINTn, the level of port D is inputted into these interrupts. For details, refer to the block diagram of the port.

Note2: When any WUPMASK<WMK7:0> is set to 1, external INT0 will be disabled. Using INT0, set WUPMASK<WMK7:0> to "00H".

Example of register setting:

To set WUINT0 with rising edge and set interrupt level 3, set the registers as follows:

DI		; Disable interrupt operation
LD	(INTMK0), 00H	; Disable INT0
LD	(PDFC), 00H	; Set PD0 as port mode
LD	(PDCR), 00H	; Set PD0 as input mode
LD	(WUPMOD), 01H	; Set WUINT0 as "Falling or rising edge"
LD	(WUPEDGE), 01H	; Set WUINT0 to "Rising edge"
LD	(WUPFLAG), 00H	; Clear WUINT0 flag
LD	(INTE0AD), 03H	; Set INT0 (function as WUINT0) interrupt level to 3
LD	(INTCLR), 0AH	; Clear INT0 request flag
NO	C	; Wait 3 cycles
NO	C	
NO	C	
LD	(INTMK0), 01H	; Enable WUINT0
ΕI		; Enable interrupt operation

3.5 Function of Ports

TMP92CD54I has I/O port pins that are shown in table 3.5.1. In addition to functioning as general-purpose I/O ports, these pins are also used by internal CPU and I/O functions.

Port Name	Pin Name	Number of Pins	I/O	I/O Setting	Pin Name for built-in function
Port 0	P00 to P07	8	I/O	Bit	D0 to D7
Port 4	P40 to P47	8	I/O	Bit	A0 to A7
Port 7	P70	1	I/O	Bit	RD
	P71	1	I/O	Bit	WR
	P72	1	I/O	Bit	SI2/SCL2
	P73	1	I/O	Bit	cs
	P74	1	I/O	Bit

	PN5	1	I/O	Bit	SI1/SCL1/A14
	PN6	1	I/O	Bit	SO2/SDA2/A15

Table 3.5.1 Port Functions (1/2)

3.5.1 Port 0 (P00 to P07)

Port0 is an 8-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register POCR and function register POFC.

In addition to functioning as a general-purpose I/O port, port0 can also function as a data bus (D0 to D7).

Figure 3.5.1 Port0

3.5.2 Port 4 (P40 to P47)

Port4 is an 8-bit general-purpose I/O ports. Bits can be individually set as either inputs or outputs by control register P4CR and function register P4FC.

In addition to functioning as a general-purpose I/O port, port4 can also function as an address bus (A0 to A7).

3.5.3 Port 7 (P70 to P75)

Port7 is a 6-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register P7CR and function register P7FC.

In addition to functioning as a general-purpose I/O port, P70, P71 and P73 pins can also function as read/write strobe signals and chip selection to connect with an external memory. P72 pin can also function as I/O functions of serial bus interface which employs clocked-synchronous 8-bit SIO and I²C. P75 pin can also function as wait input.

The pin is always enabled for the following input signals: SBI data input (SIO) SI2^{#1}, SBI clock I/O (I²C) SCL2^{#1}.

#1 : In IDLE3/STOP mode, input signal is valid (Input gate opened)

A reset initializes P70, P71, P73 and P74 pins to output port mode, and P72, P75 pin to input port mode.

3.5.4 Port C (PC0 to PC5)

PortC is a 6-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register PCCR and function register PCFC.

In addition to functioning as a general-purpose I/O port, PortC can also function as 8-bit timer I/O and interrupt input.

The pin is always enabled for the following input signals: timer inputs TIO#1, TI4#1.

#1 : In IDLE3/STOP mode, input signal is invalid (Input gate closed)

A reset initializes PortC to input port mode.

3.5.5 Port D (PD0 to PD7)

PortD is an 8-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register PDCR and function register PDFC.

In addition to functioning as a general-purpose I/O port, PortD can also function as 16-bit timer I/O, interrupt input and wake up interrupt input.

The pin is always enabled (excluding address bus setting) for the following input signals: 16-bit timer input TI8^{#1}, TI9^{#1}, TIA^{#1}, TIB^{#1}, external interrupt INT5^{#2} to INT7^{#2}, wake up interrupt WUINT0^{#2} to WUINT7^{#2}.

#1 : In IDLE3/STOP mode, input signal is invalid (Input gate closed)

#2 : In IDLE3/STOP mode, input signal is valid (Input gate opened)

A reset initializes Port D to input port mode.

Note: Port D0, D1 and D4 have 2 kinds of interrupt source (PD0: INT5/WUINT0, PD1: INT6/WUINT1, PD4: INT7/WUINT4). If both interrupt requests are generated in both interrupt enabled status, both interrupt processing are executed. When each interrupts is used, set Interrupt Mask register or Wake UP Mask register to enable/disable. If these ports are used as output/input ports, first, disable interrupt request, then set PDFC and PDCR (cf Timers).

3.5.6 Port F (PF0 to PF7)

PortF is an 8-bit general-purpose I/O port. Bits can be individually set as either inputs or o outputs by control register PFCR and function register PFFC.

In addition to functioning as a general-purpose I/O port, PortF can also function as serial channels I/O function and controller area network (CAN).

The pin is always enabled for the following input signals: serial receive data RXD0^{#1}, RXD1^{#1}, CAN receive data RX^{#1}, Clear-to-send CTS0^{#1}, CTS1^{#1}, and serial clock SCLK0^{#1}, SCLK1^{#1}.

#1 : In IDLE3/STOP mode, input signal is invalid (Input gate closed)

A reset initializes PortF to input port mode.

3.5.7 Port G (PG0 to PG7)
PortG is an 8-bit general-purpose input-only port.
In addition to functioning as a general-purpose input-only port, PortG can also function as input functions of AD converter.
The pin is always enabled for the following input signals: AD converter input AN0^{#1} to AN7^{#1}.

#1 : In IDLE3/STOP mode, input signal is invalid (Input gate closed)

Table 3.5.8 PortG Re	egister

3.5.9 Port M (PM0 to PM4)

PortM is a 5-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register PMCR and function register PMFC.

In addition to functioning as a general-purpose I/O port, PM0 to PM3 can also function as I/O functions of serial expansion interface. PM4 can also function as I/O function of serial bus interface which employs clocked-synchronous 8-bit SIO.

The pin is always enabled for the following input signals: slave select $\overline{SS}^{\#1}$, transmitting/ receiving serial data MOSI^{#1}, MISO^{#1}, SEI clock SECLK^{#1}.

#1 : In IDLE3/STOP mode, input signal is invalid (Input gate closed)

A reset initializes PortM to input port mode.

3.6 Memory Controller

3.6.1 Memory controller functions

TMP92CD54I has a memory controller with a variable 1-block external address area. The function is as follows.

- (1) 1-block external address area support. It specifies:
- A start address
- A block size for 1-block external address area
- (2) Connecting memory specifications. It specifies:
- SRAM
- ROM

as memories to connect with the selected address area.

(3) Data bus size

8-bit

- (4) Wait control
- Wait specification
- Wait input pin

Both control the number of waits in the external access bus cycle. Read and write cycles can specify the number of waits individually.

There are five modes all together:

0 wait, 1 wait, 2 wait, 3 wait, N wait (N is controlled with $\overline{\text{WAIT}}$ pin)

3.6.2 Control register and Operation after reset release

This section describes the registers that control the memory controller, the state after reset release and necessary settings.

(1) Control Registers

Control registers (BCSH/BCSL: Block Chip Select High / Low)	
• Sets the connecting memory type. (SRAM, ROM)	

- Sets the number of waits to be read and written.
- Memory Start Address Register (MSAR)
 Sets a start address in the selected address areas.
 - Memory Address Mask Register (MAMR)
 - Sets a block size in the selected address areas.
- (2) Operation after reset release

After reset release,

- The block address areas (specified by MSAR and MAMR) are set to address 000000H and FFFFEFH.
- Then BCSL / H is set.
- Set BCSH<BE> to 1 to enable the setting.

3.6.3 Basic functions and registers setting

In this section, Block address area specification, wait control and basic bus sizing are described.

(1) Block address area specification

If the bit BCSH<BM> is set to 0, then the block address area is set to addresses 000000H to FFFFEFH, which disables the use of both registers MSAR and MAMR.

If the bit BCSH<BM> is set to 1, then the block address area is programmable. Therefore, the start address is set using MSAR (Memory Start Address register). MAMR (Memory Address Mask Register) sets the size of the block in the selected address area. The principle is to mask or enable the comparison of each bit of the address. The combination of masked / enabled bits give the block size.

Then the memory controller compares (every bus cycle) the register value and the address in order to check whether it is an access to the external memory or not. Note that an address bit masked by MAMR (Memory Address Mask Register) is not compared. If the compared result is a match the memory controller sets the chip select signal \overline{CS} to low.

Figure 3.6.1 shows an example of connecting external memory to TMP92CD54I. In the example, RAM is connected using an 8-bit bus.

Figure 3.6.1 Example of connecting external memory (external RAM)

(i) Setting memory start address register

The MS23 to 16 bits of MSAR respectively correspond with addresses A23 to A16. The lower start address A15 to 0 is always set to address 0000H. Therefore, the start addresses of the block address area are set to addresses 00000H to FF0000H every 64KB (Because the settable LSB bit is 16^{th} ; $2^{16} = 64 \text{ KB}$)

(ii) Setting memory address mask register

MAMR sets whether an address bit is compared or not. Set the register to 0 to compare, or to 1 not to compare. The combination of masked / enabled bits give the block size and therefore the address bit to be set depends on the block address area.

Note: A23 is always compared.

Thus, the block address area is between A22 and A15.

The size to be set depending on the block address area is as follows:

Size (bytes) CS area	256	512	32 K	64 K	128 K	256 K	512 K	1 M	2 M	4 M	8 M
CS			0	0	0	0	0	0	0	0	0

Note: After reset release, BCSH<BM> (block address area specification) is set to '0', and the block address

area is set to addresses 000000H to FFFFEFH. Setting BCSH<BM> to "1" specifies the start address (using MSAR) and the address area size (using MAMR).

(iii) Example of register setting

To set the block address area 64 KB from address 110000H, set the registers as follows:

	MSB							LSE	3
	7	6	5	4	3	2	1	0	
MSAR	0	0	0	1	0	0	0	1	; set start address to 110000H
MAMR	0	0	0	0	0	0	0	1	; set block address area size to 64k-bytes

Memory Start Address Register MSAR<MS23:16> correspond with address A23 to A16. A15 to A0 are set to '0'. Therefore setting MSAR to the above mentioned value specifies the start address of the block address area to address 110000H.

Memory Address Mask Register MAMR<MV22:15> set whether address A22 to 15 are compared or not. Set the register to '0' to compare, or to '1' not to compare. Remember that A23 is always compared. Setting the above-mentioned compares A23 to A16 with the values set as the start addresses. Therefore the block size is 64 KB (since the first bit set to 0 is A16 \rightarrow 2¹⁶ = 64 KB)

To summarize, 64 KB of addresses 110000H to 11FFFFH are set as the block address area, and compared with the addresses on the bus. If the compared result is a match, the chip select signal $\overline{\text{CS}}$ is set to Low.

(iv) Case of overlapping blocks

When the set block address area overlaps with the built-in memory area, the block address area is processed according to priorities as follows:

```
Built-in I/O > Built-in memory > Block address area
```

This means that the block address is not remapped but priorities are used to disable any conflict.

Also note that any accessed areas outside the address spaces are set to 1 wait bus cycle (\overline{CS} signal is not outputted although \overline{RD} and \overline{WR} signal are outputted.). This factor depends on the speed of the external memory. It is a fixed parameter.

(2) Wait control

The external bus cycle completes a wait of two states at least (i.e. 100ns @fc = 20MHz). Setting the control register BCSL<BWW2:0> and <BWR2:0> specifies the number of waits in the read cycle and the write cycle. <BWWn> is set using the same method as for <BWRn>.

Note that this setting is only for asynchronisation purpose.

	- (- J /	-
BWW2	BWW1	BWW0	Function
BWR2	BWR1	BWR0	
0	0	1	2states (0 wait) access fixed mode
0	1	0	3states (1 wait) access fixed mode (Default)
1	0	1	4states (2 wait) access fixed mode
1	1	0	5states (3 wait) access fixed mode
0	1	1	WAIT pin input mode
	Others		(Reserved)

BWW/BWR bit (BCSL Regsiter)

(i) Waits number fixed mode

The bus cycle is completed with the set states. The number of states is selected from 2 states (0WAIT) to 5 states (3WAIT).

(ii) $\overline{\text{WAIT}}$ pin input mode

This mode continuously samples the $\overline{\text{WAIT}}$ input pins and inserts a wait if the pin is active. The bus cycle is minimum 2 states and is therefore completed at 2 states when the wait signal is non active (High level). The bus cycle extends if the wait signal is active at 2 states and more.

- (3) Basic bus timing
 - External Read / Write Bus Cycle (0 WAIT)

• External Read / Write Bus Cycle (1 WAIT)

• External Read / Write Bus Cycle (0 WAIT @ WAIT pin input mode)

• External Read / Write Bus Cycle (n WAIT @ WAIT pin input mode)

www.datasheeTOSHIBA

• Example of WAIT Input Cycle (5WAIT)

3.6.4 List of registers

The memory control registers and the settings are described as follows. For the addresses of the registers, see List of Special Function Registers in section 5.

Control registers (1)

The control register is a pair of BCSL and BCSH. BCSL has the same configuration regardless of the block address areas.

						(-)			
		7	6	5	4	3	2	1	0
BCSL	bit Symbol	-	BWW2	BWW1	BWW0	-	BWR2	BWR1	BWR0

Read/Write

Enables or masks comparison of the addresses. <MV22:15> correspond to addresses A22 to 15. If "0" is set, the comparison between the value of the address bus and the start address is enabled. If "1" is set, the comparison is masked.

3.7 8-bit Timers

TMP92CD54I features eight built-in 8-bit timers (timers 0 to 7).

These timers are paired into four modules: timers 01, timers 23, timers 45, and timers 67. Each module consists of two channels and can operate in any of the following four operating modes.

- 8-Bit Interval Timer Mode
- 16-Bit Interval Timer Mode
- 8-Bit Programmable Square Wave Pulse Generation Output Mode (PPG variable duty with variable cycle)
- 8-Bit Pulse Width Modulation Output Mode (PWM variable duty with constant cycle)

Figure 3.7.1 to Figure 3.7.4 show block diagrams for timers 01, timers 23, timers 45 and timers 67.

Each channel consists of an 8-bit up-counter, an 8-bit comparator and an 8-bit timer register. In addition, a timer flip-flop and a prescaler are provided for each pair of channels.

The operation mode and timer flip-flops are controlled by five control SFRs (special-function registers).

Each of the four modules (timers 01, timers 23, timers 45 and timers 67) can be operated independently. All modules operate in the same manner; hence only the operation of timers 01 is explained here.

Specifica	Module	timers 01	timers 23	timers 45	timers 67
External	Input pin for external clock	TI0 (shared with PC0)	-	TI4 (shared with PC3)	-
pin	Output pin for timer flip-flop	TO1 (shared with PC1)	TO3 (shared with PC2)	TO5 (shared with PC4)	TO7 (shared with PC5)
	Timer run register	TRUN01 (0080H)	TRUN23 (0088H)	TRUN45 (0090H)	TRUN67 (0098H)

3.7.2 Operation of each circuit

(1) Prescalers

A 9-bit prescaler generates the input clock to timers 01.

The clock T0 is the CPU clock fc divided by 4 and is the input to this prescaler.

The prescaler's operation can be controlled using TRUN01<T01PRUN> in the timer control register. Setting <T01PRUN> to 1 starts the count; setting <T10PRUN> to 0 clears the prescaler to zero and stops operation.

	710-2010112
Output clock	Interval
φT1 (8/fc)	400 ns
φT4 (32/fc)	1.6 μs
φT16 (128/fc)	6.4 μs
φT256 (2048/fc)	102.4 μs

Note: The following number in the parenthesis indicates the frequency when TMP92CD54I operates is the maximum frequency.

Figure 3.7.5 Prescaler

(2) Up-counters (UC0 and UC1)

These are 8-bit binary counters which count up the input clock pulses for the clock specified by TMOD01.

The input clock for UC0 is selectable and can be either the external clock input via the TI0 pin or one of the three internal clocks ϕ T1, ϕ T4 or ϕ T16. The clock setting is specified by the value set in TMOD01<T01CLK1,T01CLK0>.

The input clock for UC1 depends on the operation mode. In 16-Bit Interval Timer Mode, the overflow output from UC0 is used as the input clock. In any mode other than 16-Bit Interval Timer Mode, the input clock is selectable and can either be one of the internal clocks ϕ T1, ϕ T16 or ϕ T256, or the comparator output (the match detection signal) from timer 0.

For each interval timer the timer operation control register bits TRUN01<TORUN> and TRUN01<T1RUN> can be used to stop and clear the up-counters and to control their count. A Reset clears both up-counters, stopping the timers.

(3) Timer registers (TREG0 and TREG1)

These are 8-bit registers which can be used to set a time interval. When the value set in the timer register TREG0 or TREG1 matches the value in the corresponding up-counter, the Comparator Match Detect signal goes Active. If the value set in the timer register is 00H, the signal goes Active when the up-counter overflows.

The TREGO are double buffer structure, each of which makes a pair with register buffer.

The setting of the bit TRUN01<TORDE> determines whether TREGO's double buffer structure is enabled or disabled. It is disabled if $\langle TORDE \rangle = 0$ and enabled if $\langle TORDE \rangle = 1$.

When the double buffer is enabled, data is transferred from the register buffer to the timer register when a 2^n overflow occurs in PWM Mode, or at the start of the PPG cycle in PPG Mode. Hence the double buffer cannot be used in Interval Timer Mode.

A Reset initializes <TORDE> to 0, disabling the double buffer. To use the double buffer, write data to the timer register, set <TORDE> to 1, and write the following data to the register buffer. Figure 3.7.6 shows the configuration of TREGO.

Figure 3.7.6 Configuration of TREG0

Note: The same memory address is allocated to the timer register and the register buffer. When <T0RDE> = 0, the data is written in both registers (i.e. the Register buffer 0 and the 8-bit timer register TREG0) at the same time; when <T0RDE> = 1, only the register buffer is written to.

The address of each timer register is as follows.

TREG0: 00	0082H		TREG	1:0000	83H
TREG2: 00	008AH		TREG	3: 0000	8BH
TREG4: 00	0092H		TREG	5: 0000	93H
TREG6: 00	009AH		TREG	7:0000	9BH
• .	• .	1			1

All these registers are write-only and cannot be read.

eet4U.com

(4) Comparator (CP0)

The comparator compares the value in an up-counter with the value set in a timer register. If they match, the up-counter is cleared to zero and an interrupt signal (INTT0 or INTT1) is generated. If timer flip-flop inversion is enabled, the timer flip-flop is inverted at the same time.

(5) Timer flip-flop (TFF1)

The timer flip-flop (TFF1) is a flip-flop inverted by the match detect signal (8-bit comparator output) of each interval timer.

Whether inversion is enabled or disabled is determined by the setting of the bit TFFCR1<TFF1IE> in the Timer Flip-Flop Control Register.

A Reset clears the value of TFF1 to 0. Writing 01 or 10 to TFFCR1<TFF1C1,TFF1C0> sets TFF1 to 0 or 1. Writing 00 to these bits inverts the value of TFF1 (this is known as software inversion).

The TFF1 signal is output via the TO1 pin (which can also be used as PC1). When this pin is used as the timer output, the timer flip-flop should be set beforehand using the Port C Function Register PCFC.

TFF is inverted by	
8-bit interval timer mode	: UC0 matches TREG0. Or when UC1 matches TREG1. (Either one of the two is chosen)
16-bit interval timer mode	: UC0 matches TREG0 and UC1 matches TREG1.
8-bit PWM mode	: UC0 matches TREG0 or 2 ⁿ overflow is occurred.
8-bit PPG mode	: UC0 matches TREG0 or UC0 matches TREG1.

Note: When the double buffer is enabled for an 8-bit timer in PWM or PPG mode, caution is required as explained below.

If new data is written to the register buffer immediately before an overflow occurs by a match between the timer register value and the up-counter value, the timer flip-flop may output an unexpected value.

For this reason, make sure that in PWM mode new data is written to the register buffer by six cycles ($fc \times 6$) before the next overflow occurs by using an overflow interrupt.

In the case of using PPG mode, make sure that new data is written to the register buffer by six cycles before the next cycle compare match occurs by using a cycle compare match interrupt.

Example when using PWM mode:

Timer Register (TREG 0 to 7)

TREG is for the comparator (When UC matches TREG, occur match detect signal). Refer to setting example in Section 3.7.4, Operation in each mode.

Figure 3.7.17 Register for 8-bit Timers

3.7.4 Operation in each mode

(1) 8-Bit interval Timer Mode

Both timer 0 and timer 1 can be used independently as 8-bit interval timers.

① Generating interrupts at a fixed interval (using timer 1)

To generate interrupts at constant intervals using timer 1 (INTT1), first stop timer 1 then set the operation mode, input clock and a cycle to TMOD01 and TREG1 register, respectively. Then, enable the interrupt INTT1 and start timer 1 counting.

Example: To generate an INTT1 interrupt every 40 μ seconds at fc = 20 MHz, set each register as follows:

	MS	В						L	SB	
_		7	6	5	4	3	2	1	0	
TRUN01	←	-	Х	Х	Х	-	-	0	-	Stop timer 1 and clear it to 0.
TMOD01	←	0	0	Х	Х	0	1	-	-	Select 8-Bit Interval Timer Mode and select $_{\varphi}T1$ (0.4 $_{\mu}s$ at
										fc = 20 MHz) as the input clock.
TREG1	←	0	1	1	0	0	1	0	0	Set TREG1 to 40 μ s $\div \phi$ T1 = 100 = 64H
INTET01	←	Х	1	0	1	-	-	-	-	Set INTT1 interrupt level to 5.
TRUN01	←	-	Х	Х	Х	-	1	1	-	Start timer 1 counting.

Note: X = Don't care; "-" = No change

Select the input clock using Table 3.7.2.

Table 3.7.2 Selecting	Interrupt Interval	and the Input Clock	Using 8-Bit Timer
			••••••••••••••••••••••••••••••••••••••

Input Clock	Interrupt Interval (at fc = 20 MHz)	Resolution
φT1 (8/fc)	0.4 μs to 102.4 μs	0.4 μs
φT4 (32/fc)	1.6 μs to 409.6 μs	1.6 μs
φT16 (128/fc)	6.4 μs to 1.639 ms	6.4 μs
φT256 (2048/fc)	102.4 μs to 26.22 ms	102.4 μs

Note: The input clocks for timer 0 and timer 1 differ as follows:

timer 0: Uses timer 0 input (TI0) and can be selected from ϕ T1, ϕ T4 or ϕ T16 timer 1: Match output of timer 0 (T0TRG) and can be selected from ϕ T1, ϕ T16, ϕ T256

② Generating a 50% duty ratio square wave pulse

The state of the timer flip-flop (TFF1) is inverted at constant intervals and its status output via the timer output pin (TO1).

Example: To output a 2.4-µs square wave pulse from the TO1 pin at fc = 20 MHz, use the following procedure to make the appropriate register settings. This example uses timer 1; however, either timer 0 or timer 1 may be used.

_		7	6	5	4	3	2	1	0	
TRUN01	\leftarrow	-	Х	Х	Х	-	-	0	-	Stop timer 1 and clear it to 0.
TMOD01	\leftarrow	0	0	Х	Х	0	1	-	-	Select 8-Bit Interval Timer Mode and select ϕ T1 (0.4 μ s at
										fc = 20 MHz) as the input clock.
TREG1	\leftarrow	0	0	0	0	0	0	1	1	Set the timer register to 2.4 μ s ÷ ϕ T1 ÷ 2 = 3
TFFCR1	\leftarrow	Х	Х	Х	Х	1	0	1	1	Clear TFF1 to 0 and set it to invert on the match detect
										signal from timer 1.
PCCR	\leftarrow	Х	Х	-	-	-	-	1		Set PC1 to function on the TO1 nin
PCFC	\leftarrow	Х	Х	-	-	-	-	1		Set PCT to function as the TOT pin.
_TRUN01	←	-	Х	Х	Х	-	1	1	-	Start timer 1 counting.

Note: X = Don't care; "-" = No change

Figure 3.7.18 Square wave output timing chart (50% Duty)

③ Making timer 1 count up on the match signal from the timer 0 comparator

Select 8-Bit Interval Timer Mode and set the comparator output from timer 0 to be the input clock to timer 1.

(2) 16-Bit interval Timer Mode

A 16-bit interval timer is configured by pairing the two 8-bit timers timer 0 and timer 1.

To make a 16-bit interval timer in which timer 0 and timer 1 are cascaded together, set TMOD01 <T01M1,T01M0> to 01.

In 16-Bit Interval Timer Mode, the overflow output from timer 0 is used as the input clock for timer 1, regardless of the value set in TMOD01<T1CLK1,T1CLK0>. Table 3.7 4(1) shows the relationship between the timer (interrupt) cycle and the input clock selection.

To set the timer interrupt interval, set the lower eight bits in timer register TREG0 and the upper eight bits in TREG1. Be sure to set TREG0 first (as entering data in TREG0 temporarily disables the compare, while entering data in TREG1 starts the compare).

Figure 3.7.19 Block diagram of 16-Bit interval timer Mode

Setting example: To generate an INTT1 interrupt every 0.4 seconds at fc = 20 MHz, set the timer registers TREG0 and TREG1 as follows:

If ϕ T16 (6.4 µs at 20 MHz) is used as the input clock for counting, set the following value in the registers: 0.4 s ÷ 6.4 µs = 62500 = F424H; i.e. set TREG1 to F4H and TREG0 to 24H.

The comparator match signal is output from timer 0 each time the up-counter UC0 matches TREG0, where the up-counter UC0 is not cleared.

In the case of the timer 1 comparator, the match detect signal is output on each comparator pulse on which the values in the up-counter UC1 and TREG1 match.

When the match detect signal is output simultaneously from both the comparators timer 0 and timer 1, the up-counters UC0 and UC1 are cleared to 0 and the interrupt INTT1 is generated. Also, if inversion is enabled, the value of the timer flip-flop TFF1 is inverted.

Example: When TREG1 = 04H and TREG0 = 80H

Figure 3.7.20 Timer output by 16-Bit Interval Timer Mode

(3) 8-Bit Programmable Pulse Generation(PPG) Output Mode

Square wave pulses can be generated at any frequency and duty ratio by timer 0. The output pulses may be active-Low or active-High. In this mode timer 1 cannot be used. Timer 0 outputs pulses on the TO1 pin (which can also be used as PC1).

Figure 3.7.21 8 bit PPG output waveforms

In this mode a programmable square wave is generated by inverting the timer output each time the 8-bit up-counter (UC0) matches the value in one of the timer registers TREG0 or TREG1.

The value set in TREG0 must be smaller than the value set in TREG1.

Although the up-counter for timer 1 (UC1) is not used in this mode, TRUN01<T1RUN> should be set to 1 (To enable the comparator to compare with TREG1) so that UC1 is set for counting.

Figure 3.7.22 shows a block diagram representing this mode.

Figure 3.7.22 Block diagram of 8-Bit PPG Output Mode

If the TREG0 double buffer is enabled in this mode, the value of the register buffer will be shifted into TREG0 each time TREG1 matches UC0.

Use of the double buffer facilitates the handling of low-duty waves (when duty is varied).

Figure 3.7.23 Operation of register buffer

Example: To generate 1/4-duty 62.5 kHz pulses (at fc = 20 MHz):

Calculate the value which should be set in the timer register.

To obtain a frequency of 62.5 kHz, the pulse cycle t should be: t = 1/62.5 kHz = 16 μ s ϕ T1 = 0.4 μ s (at 20 MHz);

 $16 \ \mu s \div 0.4 \ \mu s = 40$

Therefore set TREG1 to 40 (28H)

The duty is to be set to 1/4: t × $1/4 = 16 \ \mu s \times 1/4 = 4 \ \mu s$

```
4 \ \mu s \div 0.4 \ \mu s = 10
```

Therefore, set TREG0 = 10 = 0AH.

	_		7	6	5	4	3	2	1	0		
l	TRUN01	\leftarrow	0	Х	Х	Х	-	0	0	0		Stop timer 0 and timer 1 and clear it to "0".

l	TREG0	\leftarrow	0	0	0	0	1	0	1	0		Write 0AH
l	TREG1	\leftarrow	0	0	1	0	1	0	0	0		Write 28H
	TFFCR1	←	Х	Х	Х	Х	0		1	X	>	Set TFF1 and enable inversion.
	PCCR PCFC	← ←	x x	x x	-	-	-	-	1 1	-	}	Set PC1 as the TO1 pin.
L	TRUN01	←	1	X	Х	X	-	1	1	1		Set double buffer enable, and start timer 0 and timer 1 counting.

Note: X = Don't care; "-" = No change

(4) 8-Bit Pulse with Modulation (PWM) Output Mode

This mode is only valid for timer 0. In this mode, a PWM pulse with the maximum resolution of 8 bits can be output.

When timer 0 is used the PWM pulse is output on the TO1 pin (which is also used as PC1). Timer 1 can also be used as an 8-bit timer.

The timer output is inverted when the up-counter (UC0) matches the value set in the timer register TREG0 or when 2^n counter overflow occurs (n = 6, 7 or 8 as specified by TMOD01<PWM01~PWM00>). The up-counter UC0 is cleared when 2^n counter overflow occurs.

The following conditions must be satisfied before this PWM mode can be used.

Value set in TREG0 < value set for 2^n counter overflow Value set in TREG0 $\neq 0$

Figure 3.7.24 8-bit PWM waveforms

Figure 3.7.25 shows a block diagram representing this mode.

Figure 3.7.25 Block diagram of 8-Bit PWM Mode

In this mode the value of the register buffer will be shifted into TREG0 if 2^n overflow is detected when the TREG0 double buffer is enabled.

Use of the double buffer facilitates the handling of low duty ratio waves.

Figure 3.7.26 Register buffer operation

Example: To output the following PWM waves on the TO1 pin at fc = 20 MHz:

To achieve a 51.2- μ s PWM cycle by setting ϕ T1 to 0.4 μ s (at fc = 20 MHz): 51.2 μ s \div 0.4 μ s = 128 2ⁿ = 128 Therefore n should be set to 7. Since the low-level period is 36.0 μ s when ϕ T1 = 0.4 μ s, set the following value for TREGO: 36.0 μ s \div 0.4 μ s = 90 = 5AH

3.8 16-Bit Timer/Event Counters

TMP92CD54I incorporates two multifunctional 16-bit timer/event counters (timer 8 and timer A) which have the following operation modes:

- 16-Bit Interval Timer Mode
- 16-Bit Event Counter Mode
- 16-Bit Programmable Pulse Generation (PPG) Mode

Can be used following operation modes by capture function:

- Frequency Measurement Mode
- Pulse Width Measurement Mode
- Time Differential Measurement Mode

Figure 3.8.1 to Figure 3.8.2 show block diagrams for timer 8 and timer A.

Each timer/event counter channel consists of a 16-bit up-counter, two 16-bit timer registers (one of them with a double-buffer structure), two 16-bit capture registers, two comparators, a capture input controller, a timer flip-flop and a control circuit.

Each timer/event counter is controlled by an 11-byte control SFR.

The two channels (timer 8 and timer A) can be used independently.

Both channels feature the same operations except for those described in Table 3.8.1. Thus, only the operation of timer 8 is explained below.

Specificatio	Channel	Timer 8	Timer A
	External clock /	TI8 (also used as PD0)	TIA (also used as PD4)
External	Capture trigger input pins	TI9 (also used as PD1)	TIB (also used as PD5)

3.8.1 Block diagrams

Figure 3.8.1 Block Diagram of Timer 8

Figure 3.8.2 Block diagram of Timer A

92CD54I-103

3.8.2 Operation of each block

(1) Prescaler

The 5-bit prescaler generates the source clock for timer 8. The prescaler clock (ϕ T0) is divided clock (divided by 4) from fc.

This prescaler can be started or stopped using TRUN8<T8PRUN>. Counting starts when <T8PRUN> is set to 1; the prescaler is cleared to zero and stops operation when <T8PRUN> is set to 0.

	At fc=20MHz
Output clock	Interval
φT1 (8/fc)	0.4 μs
φT4 (32/fc)	1.6 μs
φT16 (128/fc)	102.4 μs

Table 3.8.2 Prescaler clock resolution

(2) Up-counter (UC8)

UC8 is a 16-bit binary counter which counts up pulses input from the clock specified by TMOD8 <T8CLK1,T8CLK0>.

Any one of the prescaler internal clocks ϕ T1, ϕ T4 and ϕ T16 or an external clock input via the TI8 pin can be selected as the input clock. Counting or stopping & clearing of the counter is controlled by TRUN8<T8RUN>.

When clearing is enabled, the up-counter UC8 will be cleared to zero each time its value matches the value in the timer register TREG9H/L. Clearing can be enabled or disabled using TMOD8<T8CLE>.

If clearing is disabled, the counter operates as a free-running counter.

A Timer Overflow interrupt (INTTO8) is generated when UC8 overflow occurs.

(3) Timer registers (TREG8H/L and TREG9H/L)

These two 16-bit registers are used to set the interval time. When the value in the up-counter UC8 matches the value set in this timer register, the Comparator Match Detect signal will go Active.

Setting data for timer register TREG8H/L and TREG9H/L is executed using 2 byte data transfer instruction or using 1 byte date transfer instruction twice for lower 8 bits and upper 8 bits in order.

The TREG8 timer register has a double-buffer structure, which is paired with register buffer 8. The value set in TRUN8<T8RDE> determines whether the double-buffer structure is enabled or disabled: it is disabled when <T8RDE> = 0, and enabled when <T8RDE> = 1.

When the double buffer is enabled, data is transferred from the register buffer to the timer register when the values in the up-counter (UC8) and the timer register TREG9 match.

After a Reset, TREG8 and TREG9 are undefined. If the 16-bit timer is to be used after a Reset, data should be written to it beforehand.

On a Reset <T8RDE> is initialized to 0, disabling the double buffer. To use the double buffer, write data to the timer register, set <T8RDE> to 1, then write data to the register buffer as shown below.

TREG8 and the register buffer both have the same memory addresses (0000A8H & 0000A9H) allocated to them. If $\langle T8RDE \rangle = 0$, the value is written to both the timer register and the register buffer. If $\langle T8RDE \rangle = 1$, the value is written to the register buffer only.

The addresses of the Timer Registers are as follows:

The Timer Registers are write-only registers and thus cannot be read.

(4) Capture Registers (CAP8H/L and CAP9H/L)

These 16-bit registers are used to latch the values in the up-counter UC8. Data in the Capture Registers should be read using a 2-byte data load instruction or two 1-byte data load instructions. The least significant byte is read first, followed by the most significant byte.

The addresses of the Capture Registers are as follows:

The Capture Registers are read-only registers and thus cannot be written to.

(5) Capture input control and external interrupt control

This circuit controls the timing to latch the value of up-counter UC8 into CAP8, CAP8 and the generation of external interrupts. The latch timing for the capture register and selection of edge for external interrupt is determined by TMOD8<CAP89M1,CAP89M0>.

The edge of external interrupt INT6 is fixed to rise edge.

In addition, the value in the up-counter UC8 can be loaded into a capture register by software. Whenever 0 is written to TMOD8<CAP8IN>, the current value in the up-counter UC8 is loaded into capture register CAP8. It is necessary to keep the prescaler in Run Mode (i.e. TRUN8<T8PRUN> must be held at a value of 1).

(6) Comparators (CP8 and CP9)

CP8 and CP9 are 16-bit comparators which compare the value in the up-counter UC8 with the value set in TREG8 or TREG9 respectively, in order to detect a match. If a match is detected, the comparator generates an interrupt (INTTR8 or INTTR9 respectively).

(7) Timer flip-flops (TFF8 and TFF9)

These flip-flops are inverted by the match detect signals from the comparators and the latch signals to the Capture Registers. Inversion can be enabled and disabled for each element using TFFCR8<CAP9T8,CAP8T8,EQ9T8,EQ8T8>. After a reset the value of TFF8 and TFF9 are undefined. If 00 is written to TFFCR8<TFF8C1,TFF8C0> or <TFF9C1,TFF9C0>, TFF8 or TFF9 will be inverted. If 01 is written to the capture registers, the value of TFF8 or TFF9 will be set to 1.If 10 is written to the capture registers, the value of TFF8 or TFF9 will be set to 0.

The values of TFF8 and TFF9 can be output via the Timer Output pins TO8 (which is shared with PD2) and TO9 (which is shared with PD3). Timer output should be specified using the Port D SFRs.

- 3.8.4 Operation in each mode
 - (1) 16-Bit Interval Timer Mode

Generating interrupts at fixed intervals

In this example, the interrupt INTTR9 is set to be generated at fixed intervals. The interval time is set in the timer register TREG9.

_		7	6	5	4	3	2	1	0	
TRUN8	\leftarrow	0	0	Х	Х	-	0	Х	0	Stop timer 8.
INTET89	\leftarrow	Х	1	0	0	Х	0	0	0	Set INTTR9 Interrupt Level to 4. Disable INTTR8.
TFFCR8	\leftarrow	1	1	0	0	0	0	1	1	Disable the trigger.
TMOD8	\leftarrow	0	0	1	0	0	1	*	*	Select internal clock for input and
				(*	* =	01	, 1	0,	11)	disable the capture function.
TREG9	\leftarrow	*	*	*	*	*	*	*	*	Set the interval time (16 bits).
		*	*	*	*	*	*	*	*	
TRUN8	←	0	0	Х	Х	-	1	Х	1	Start timer 8.

Note: X = Don't care; "-" = No change

(2) 16-Bit Event Counter Mode

As described above, in 16-Bit Timer Mode, if the external clock (TI8 pin input) is selected as the input clock, the timer can be used as an event counter. The counter counts at the rising edge of TI8 pin input. To read the value of the counter, first perform "software capture" once, then read the captured value.

_		7	6	5	4	3	2	1	0	
TRUN8	←	0	0	Х	Х	-	0	Х	0	Stop timer 8.
PDCR	←	-	-	-	-	-	-	-	1	Set PD0 to TI8
PDFC	\leftarrow	-	-	-	-	-	-	-	1	
INTET89	←	Х	1	0	0	Х	0	0	0	Set INTTR9 Interrupt Level to 4. Disable INTTR8.
TFFCR8	\leftarrow	1	1	0	0	0	0	1	1	Disable the trigger.
TMOD8	←	0	0	1	0	0	1	0	0	Select TI8 as the input clock.
TREG9	←	*	*	*	*	*	*	*	*	Set the number of counts (16 bits).
		*	*	*	*	*	*	*	*	
TRUN8	←	0	0	Х	Х	-	1	Х	1	Start timer 8.

Note: X = Don't care; "-" = No change

When the timer is used as an event counter, set the prescaler in Run Mode (i.e. with TRUN8<T8PRUN> = 1).

(3) 16-Bit Programmable Pulse Generation (PPG) Output Mode

Square wave pulses can be generated at any frequency and duty ratio. The output pulse may be either Low-active or High-active.

The PPG mode is obtained by inversion of the timer flip-flop TFF8 that is to be enabled by the match of the up-counter UC8 with timer register TREG8 or TREG9 and to be output to TO8. In this mode the following conditions must be satisfied.

(Value set in TREG8) < (Value set in TREG9)

Figure 3.8.9 Programmable Pulse Generation (PPG) Output Waveforms

When the TREG8 double buffer is enabled in this mode, the value of Register Buffer 8 will be shifted into TREG8 at match with TREG9. This feature facilitates the handling of low-duty waves.

Figure 3.8.10 Operation of Register Buffer

The following block diagram illustrates this mode.

The following example shows how to set 16-Bit PPG Output Mode:

		7	6	5	4	3	2	1	0	
TRUN8	←	0	0	Х	Х	_	0	Х	0	Disable the TREG8 double buffer and stop timer 8.
TREG8	←	*	*	*	*	*	*	*	*	Set the duty ratio (16 bits).
		*	*	*	*	*	*	*	*	
TREG9	←	*	*	*	*	*	*	*	*	Set the frequency (16 bits).
		*	*	*	*	*	*	*	*	
TRUN8	←	1	0	Х	Х	_	0	Х	0	Enable the TREG8 double buffer.
										(The duty and frequency are changed on an INTTR9
										interrupt.)
TFFCR8	←	Х	Х	0	0	1	1	1	0	Set the mode to invert TFF8 at the match with
										TREG8/TREG9. Set TFF8 to 0.
TMOD8	←	0	0	1	0	0	1	*	*	Select the internal clock as the input clock and disable
				(*	* =	01	, 1	0,	11)	the capture function.
PDCR	←	-	-	-	-	-	1	-	-	Cat DD2 to function on TO2
PDFC	←	-	-	-	-	-	1	-	-	\int Set PD2 to function as 108.
TRUN8	←	1	0	Х	Х	-	1	Х	1	Start timer 8.

Note: X = Don't care; "-" = No change

(4) Capture function

The capture function can be used in many ways. The following are examples:

- ① As a one-shot pulse output from external trigger pulse
- ② For frequency measurement
- ③ For pulse width measurement
- ④ For time difference measurement
- ① One-shot pulse output from external trigger pulse

Set the up-counter UC8 to Free-Running Mode with the internal input clock, input an external trigger pulse via the TI8 pin, and load the value of the up-counter into the capture register CAP8 on the rising edge of the TI8 input signal.

When the interrupt INT5 is generated on the rising edge of the TI8 input, set the CAP8 value (c) plus a delay time (d) in TREG8 and set this value (c + d) plus the one-shot pulse width (p) in TREG9. (Thus TREG8 = c + d and TREG9 = c + d + p). When the interrupt INT5 occurs, TFFCR8<EQ9T8,EQ8T8> should be set to 11 and that the TFF8 inversion is enabled only when the up-counter value matches TREG8 or TREG9. When an INTTR9 interrupt occurs, a one-shot pulse will be output and inversion will be disabled.

(c), (d) and (p) correspond to c, d and p in Figure 3.8.12.

Figure 3.8.12 One-shot pulse output (with delay)

www.datashe

Setting example: To output a 2-ms one-shot pulse with a 3-ms delay to the external trigger pulse via the TI8 pin.

Main settings	6						
				Г			 Keep counting (maintain free-running counter).

-		"					
Note: $X = D$	on't car	e; "-	~ = N0	chan	ge		

If no delay time is necessary, invert the timer flip-flop TFF8 when the up-counter value is loaded into the capture register (CAP8) and set the value of TREG9 to the value of CAP8 (c) plus the one-shot pulse width (p) when the interrupt INT5 occurs. TFF8 inversion should be enabled when the up-counter (UC8) value matches TREG9, and disabled when generating the interrupt INTTR9.

Figure 3.8.13 One-shot pulse output (without delay)

② Frequency measurement

The frequency of the external clock can be measured in this mode. The clock is input via the TI8 pin and its frequency is measured using the two 8-bit timers of timers 01 and the 16-bit timer / event counter timer 8.

The TI8 pin input should be selected as the clock input to timer 8. Set TMOD8<CAP89M1,CAP89M0> to 11. The value of the up-counter is loaded into the capture register CAP8 on the rising edge of the TFF1 signal from the timer flip-flop for the two 8-bit timers (timers 01), and loaded into CAP9 on the falling edge of the TFF1 signal.

The frequency is calculated using the difference between the values loaded into CAP8 and CAP9 when the interrupt (INTT0 or INTT1) is generated by either one of the 8-bit timers.

Figure 3.8.14 Frequency Measurement

For example, if the value for the level 1 width of TFF1 of the 8-bit timer is set to 0.5 s and the difference between the values in CAP8 and CAP9 is 100, the frequency is $100 \div 0.5 \text{ s} = 200 \text{ Hz}$.

3 Pulse width measurement

This mode allows the H-level width of an external pulse to be measured. With the 16-bit timer / event counter operating as a free-running counter counting the pulses from the internal clock input, the external pulse is input via the TI8 pin. Then, the capture function is used to load values from UC8 into CAP8 and CAP9 on the rising and falling edges of the external trigger pulse respectively. The interrupt INT5 occurs on the falling edge of TI8.

The pulse width is obtained from the difference between the values in CAP8 and CAP9 and the period of the internal clock.

For example, if the period of the internal clock is 0.8 microseconds and the difference between the values in CAP8 and CAP9 is 100, the pulse width is $100 \times 0.8 \,\mu\text{s} = 80 \,\mu\text{s}$.

In addition, the pulse width which is over the UC8 maximum count time specified by the clock source can be measured by changing software.

Figure 3.8.15 Pulse width measurement

Note: In Pulse Width Measuring Mode only (i.e. when TMOD8<CAP89M1,CAP89M0> = 10), the external interrupt INT5 occurs on the falling edge of the signal input to the TI8 pin. In other modes it occurs on the rising edge.

The width of the L level is obtained by multiplying the difference between the first C9 and the second C8 at the second INT5 interrupt by the period of the internal clock.

④ Time difference measurement

This mode is used to measure the time difference between the rising edges of the external pulses input via TI8 and TI9.

With the 16-bit timer / event counter (timer 8) operating as a free-running counter counting the pulses from the internal clock input, load the UC8 value into CAP8 on the rising edge of the signal input via TI8. This generates the interrupt INT5.

Similarly, the UC8 value is loaded into CAP9 on the rising edge of the signal input via TI9, generating the interrupt INT6.

The time difference between these pulses can be obtained by multiplying the value subtracted CAP8 from CAP9 and the internal clock cycle together at which loading the up-counter value into CAP8 and CAP9 has been done.

Figure 3.8.16 Time difference measurement

www.dat**TOSHIBA**

3.9 Serial Channels

TMP92CD54I includes two serial I/O channels. For both channels either UART Mode (asynchronous transmission) or I/O Interface Mode (synchronous transmission) can be selected.

• I/O Interface Mode	—— Mode 0:	For transmitting and receiving I/O data using the synchronizing signal SCLK for extending I/O.
UART Mode	Mode 1: — Mode 2: Mode 3:	7-bit data 8-bit data 9-bit data

In Mode 1 and Mode 2, a parity bit can be added. Mode 3 has a wake-up function for making the master controller start slave controllers in a serial link (a multi-controller) system.

Figure 3.9.2 to Figure 3.9.3 are block diagrams for each channel.

Serial Channels 0 and 1 can be used independently.

Both channels operate in the same function except for the following points; thus only the operation of Channel 0 is explained below.

Table 3.9.1 Differences between Channels 0 to 1

	Channel 0	Channel 1
Pin Name	TXD0 (PF0) RXD0 (PF1) CTS0 /SCLK0 (PF2)	TXD1 (PF3) RXD1 (PF4) CTS1/SCLK1 (PF5)

• Mode 0 (I/O Interface Mode)

Figure 3.9.1 Data formats

3.9.1 Block diagrams

Figure 3.9.2 Block diagram of the Serial Channel 0

Figure 3.9.3 Block diagram of the Serial Channel 1

- 3.9.2 Operation for each circuit
 - (1) Prescaler, Prescaler clock select

There is a 6-bit prescaler for making serial clock.

The prescaler can be run by selecting the baud rate generator as the making serial clock.

Table 3.9.2 shows prescaler clock resolution into the baud rate generator.

Table 3.9.2 Prescaler Clock Resolution to Baud Rate Generator

	At fc=20MHz
Output clock	Clock resolution
φT0 (4/fc)	0.2µs
φT2 (16/fc)	0.8µs
φT8 (64/fc)	3.2µs
φT32 (256/fc)	12.8µs

The Baud Rate Generator selects between 4 clock inputs : $\phi T0,\,\phi T2,\,\phi T8,\,and\,\phi T32$ among the prescaler outputs.

(2) Baud rate generator

The baud rate generator is a circuit which generates transmission and receiving clocks which determine the transfer rate of the serial channels.

The input clock to the baud rate generator, ϕ T0, ϕ T2, ϕ T8 or ϕ T32, is generated by the 6-bit prescaler. One of these input clocks is selected using the BR0CR<BR0CK1 to BR0CK0> field in the Baud Rate Generator Control Register.

The baud rate generator includes a frequency divider, which divides the frequency by N (N=1 to 16) or by N + (16-K) / 16 (N=2 to 15 and K = 1 to 15). Note that the part (16-K)/16 can be disabled, resulting in a division of N.

A division of N+(16-K)/16 can be	[2+1/16; 3+1/16;	2+2/16; 3+2/16;	;	2+15/16; 3+15/16;	
		:;	:;	:;	:;	
		. , 15+1/16;	15+2/16;	· · · ;	15+15/16;]
A division of N can be	[1; 2;	3;;	14;	15; 16;]

so the overall division can take any value in the range [1; N+(16-K)/16; 16] with N = 2, 3, ..., 15 and K = 1, 2, ..., 15.

The transfer rate is determined by the settings of BROCR<BROADDE, BROS3 to BROS0> and BROADD<BROK3 to BROK0>:

BR0CR<BR0ADDE>: +(16-K)/16 division 0: Disabled 1: Enabled

BR0CR<BR0S3 to BR0S0>: setting of the divided frequency

0000: N=16 (Unselectable when using the division N+(16-K)/16) 0001: N= 1 0010: N= 2 :

```
1111: N=15
```

BR0ADD<BR0K3 to BR0K0>: sets the frequency divisor "K" (when using the division N+(16-K)/16)

0000: Disabled 0001: K=1 : : 1111: K=15

1111.17-

• In UART Mode

- (1) When BR0CR<BR0ADDE> = 0
 - The settings BR0ADD<BR0K3 to BR0K0> are ignored.
 - The baud rate generator divides the selected prescaler clock by N.
 - N is set in BR0CK<BR0S3 to BR0S0>. (N = 1, 2, 3, …, 16)
- (2) When BROCR < BROADDE > = 1
 - The N + (16 K) / 16 division function is enabled.
 - N is set in BR0CR<BR0S3 to BR0S0> (N = 2, 3, 4, …, 15)
 - K is set in BR0ADD<BR0K3 to BR0K0> (K = 1, 2, 3, \cdots , 15)

NOTE: At N=1 or N=16, the N+(16-K)/16 division function is disabled. Therefore set BR0CR<BR0ADDE> to "0".

- In I/O Interface Mode
 - The N + (16 K) / 16 division function is not available in I/0 Interface Mode
 - Set BR0CR<BR0ADDE> to "0"
 - Therefore the settings BR0ADD<BR0K3 to BR0K0> are ignored
 - The baud rate generator divides the selected prescaler clock by N
 - N is set in BR0CR<BR0S3 to BR0S0> (N=1, 2, 3, ..., 16)

The method for calculating the transfer rate when the baud rate generator is used is explained below.

• In UART Mode Baud Rate = $\frac{\text{Baud rate generator input clock frequency}}{\text{Frequency divider for baud rate generator}} \div 16$

• In I/O Interface Mode Baud Rate = $\frac{Baud rate generator input clock frequency}{Frequency divider for baud rate generator} \div 2$ • Integer divider (N divider)

For example, when the source clock frequency (fc) is 19.6608 MHz, the input clock is ϕ T2 (fc/16), the frequency divider N (BR0CR<BR0S3 to BR0S0>) = 8, and BR0CR<BR0ADDE> = 0, the baud rate in UART Mode is as follows:

Baud Rate =
$$\frac{\text{fc}/16}{8} \div 16$$

 $= 19.6608 \times 10^6 \div 16 \div 8 \div 16 = 9600 \text{ (bps)}$

Note: The N + (16 - K) / 16 division function is disabled and setting BR0ADD<BR0K3 to BR0K0> is invalid.

• N+(16-K)/16 divider (UART Mode only)

Accordingly, when the source clock frequency (fc) = 15.9744 MHz, the input clock is ϕ T2 (fc/16), the frequency divider N (BR0CR<BR0S3 to BR0S0>) = 6, K (BR0ADD<BR0K3 to BR0K0>) = 8, and BR0CR <BR0ADDE> = 1, the baud rate in UART Mode is as follows:

Baud Rate =
$$\frac{\text{fc/16}}{6 + (16 - 8)/16} \div 16$$

= $15.9744 \times 10^6 \div 16 \div (6 + 8/16) \div 16 = 9600 \text{ (bps)}$

Table 3.9.3 to 4 show examples of UART Mode transfer rates.

Additionally, the external clock input is available in the serial clock. (Serial Channels 0 & 1). The method for calculating the baud rate is explained below:

• In UART Mode

Baud rate = external clock input frequency ÷ 16

(External clock input frequency) must be less than or equal to $\mathrm{fc}/4$

• In I/O Interface Mode

Baud rate = external clock input frequency

(External clock input frequency) must be less than or equal to fc/16

(when baud rate generator Is used and BR0CR $\langle BR0ADDE \rangle = 0$)

					Unit (kbps)
fc [MHz]	Input Clock Frequency Divider	φΤ0 (4/fc)	φT2 (16/fc)	φT8 (64/fc)	фТ32 (256/fc)
18.432000	15	19.200	4.800	1.200	0.300
10.00000	8	38.400	9.600	2.400	0.600
19.660800	16	19.200	4.800	1.200	0.300

Note: Transfer rates in I/O Interface Mode are eight times faster than the values given above.

Table 3.9.4 Selection of Transfer Rate(2)

(When timer 0 with input Clock ϕ T1 is used)

			Unit (kbps)
fc	20	19.6608	16
TREG0	MHz	MHz	MHz
02H		76.8	62.5
04H		38.4	31.25
05H	31.25		
08H		19.2	
10H		9.6	

Method for calculating the transfer rate (when timer 0 is used):

Note: The timer 0 match detect signal cannot be used as the transfer clock in I/O Interface Mode.

www.datashee

(3) Serial clock generation circuit

This circuit generates the basic clock for transmitting and receiving data.

• In I/O Interface Mode

In SCLK Output Mode with the setting SCOCR < IOC > = 0, the basic clock is generated by dividing the output of the baud rate generator by 2, as described previously.

In SCLK Input Mode with the setting SC0CR<IOC> = 1, the rising edge or falling edge will be detected according to the setting of the SC0CR<SCLKS> register to generate the basic clock.

• In UART Mode

The SC0MOD0 <SC1, SC0> setting determines whether the baud rate generator clock, the internal clock ϕ 1 (fc/2), the match detect signal from timer 0 or the external clock (SCLK0) is used to generate the basic clock SIOCLK.

(4) Receiving counter

The receiving counter is a 4-bit binary counter used in UART Mode which counts up the pulses of the SIOCLK clock. It takes 16 SIOCLK pulses to receive 1 bit of data; each data bit is sampled three times – on the 7th, 8th and 9th clock cycles.

The value of the data bit is determined from these three samples using the majority rule.

For example, if the data bit is sampled respectively as 1, 0 and 1 on 7th, 8th and 9th clock cycles, the received data bit is taken to be 1. A data bit sampled as 0, 0 and 1 is taken to be 0.

- (5) Receiving control
 - In I/O Interface Mode

In SCLK Output Mode with the setting SCOCR<IOC> = 0, the RXD0 signal is sampled on the rising edge of the shift clock which is output on the SCLK0 pin. In SCLK Input Mode with the setting SCOCR<IOC> = 1, the RXD0 signal is sampled on the rising or falling edge of the SCLK0 input, according to the SCOCR<SCLKS> setting.

• In UART Mode

The receiving control block has a circuit which detects a start bit using the majority rule. Received bits are sampled three times; when two or more out of three samples are 0, the bit is recognized as the start bit and the receiving operation commences. The values of the data bits that are received are also determined using the majority rule.

(6) The Receiving Buffers

To prevent Overrun errors, the Receiving Buffers are arranged in a double-buffer structure.

Received data is stored one bit at a time in Receiving Buffer 1 (which is a shift register). When 7 or 8 bits of data have been stored in Receiving Buffer 1, the stored data is transferred to Receiving Buffer 2 (SC0BUF); this causes an INTRX0 interrupt to be generated. The CPU only reads Receiving Buffer 2 (SC0BUF). Even before the CPU has finished reading the contents of Receiving Buffer 2 (SC0BUF), more data can be received and stored in Receiving Buffer 1. However, if Receiving Buffer 2 (SC0BUF) has not been read completely before all the bits of the next data item are received by Receiving Buffer 1, an Overrun error occurs. If an Overrun error occurs, the contents of Receiving Buffer 1 will be lost, although the contents of Receiving Buffer 2 and SC0CR<RB8> will be preserved.

SC0CR<RB8> is used to store either the parity bit – added in 8-Bit UART Mode – or the most significant bit (MSB) – in 9-Bit UART Mode.

In 9-Bit UART Mode the wake-up function for the slave controller is enabled by setting SC0MOD0<WU> to 1; in this mode INTRX0 interrupts occur only when the value of SC0CR<RB8> is 1.

(7) Transmission counter

The transmission counter is a 4-bit binary counter which is used in UART Mode and which, like the receiving counter, counts the SIOCLK clock pulses; a TXDCLK pulse is generated every 16 SIOCLK clock pulses.

Figure 3.9.5 Generation of the transmission clock

- (8) Transmission controller
 - In I/O Interface Mode

In SCLK Output Mode with the setting SCOCR < IOC > = 0, the data in the Transmission Buffer is output one bit at a time to the TXD0 pin on the rising edge of the shift clock which is output on the SCLK0 pin.

In SCLK Input Mode with the setting SCOCR<IOC> = 1, the data in the Transmission Buffer is output one bit at a time to the TXD0 pin on the rising or falling edge of the SCLK0 input, according to the SCOCR<SCLKS> setting.

• In UART Mode

When transmission data sent from the CPU is written to the Transmission Buffer, transmission starts on the rising edge of the next TXDCLK, generating a transmission shift clock TXDSFT.

Handshake function

Serial Channels 0 & 1 each have a $\overline{\text{CTS}}$ pin. Use of this pin allows data can be sent in units of one frame; thus, Overrun errors can be avoided. The handshake functions is enabled or disabled by the SCOMODO <CTSE> setting.

When the $\overline{\text{CTS0}}$ pin foes High on completion of the current data send, data transmission is halted until the $\overline{\text{CTS0}}$ pin foes Low again. However, the INTTX0 Interrupt is generated, it requests the next data send to the CPU. The next data is written in the Transmission Buffer and data sending is halted.

Although there is no RTS pin, a handshake function can easily be configured by assigning any port to perform the RTS function. The RTS should be output High to request send data halt after data receive is completed by software in the RXD interrupt routine.

Figure 3.9.6 Handshake function

- Note 1: If the CTS signal goes High during transmission, no more data will be sent after completion of the current transmission.
- Note 2: Transmission starts on the first falling edge of the TXDCLK clock after the \overline{CTS} signal has fallen.

Figure 3.9.7 CTS (Clear to send) Timing

(9) Transmission Buffer

The Transmission Buffer (SC0BUF) shifts out and sends the transmission data written from the CPU, in order one bit at a time starting with the least significant bit (LSB) and finishing with the most significant bit (MSB). When all the bits have been shifted out, the empty Transmission Buffer generates an INTTX0 interrupt.

(10) Parity control circuit

When SCOCR<PE> in the Serial Channel Control Register is set to 1, it is possible to transmit and receive data with parity. However, parity can be added only in 7-Bit UART Mode or 8-Bit UART Mode. The SCOCR<EVEN> field in the Serial Channel Control Register allows either even or odd parity to be selected.

In the case of transmission, parity is automatically generated when data is written to the Transmission Buffer SC0BUF. The data is transmitted after the parity bit has been stored in SC0BUF<TB7> in 7-Bit UART Mode or in SC0MOD0<TB8> in 8-Bit UART Mode. SC0CR<PE> and SC0CR<EVEN> must be set before the transmission data is written to the Transmission Buffer.

In the case of receiving, data is shifted into Receiving Buffer 1, and the parity is added after the data has been transferred to Receiving Buffer 2 (SC0BUF), and then compared with SC0BUF<RB7> in 7-Bit UART Mode or with SC0CR<RB8> in 8-Bit UART Mode. If they are not equal, a Parity error is generated and the SC0CR<PERR> flag is set.

(11) Error flags

Three error flags are provided to increase the reliability of data reception.

1. Overrun error <OERR>

If all the bits of the next data item have been received in Receiving Buffer 1 while valid data still remains stored in Receiving Buffer 2 (SC0BUF), an Overrun error is generated.

The below is a processing example of when Overrun error is occurred.

(INTRX routine)

1)Read Received-Buffer

2)Read error-flag

3)if<OERR>=1

then

4)Disable receiving(write 0 to <RXE>)

5)Wait for terminating current frame

6)Read received-buffer

7)Readerror-flag

8)Enable receiving(write 1 to <RXE>)

9)Request to resend

10)Process other job

2. Parity error <PERR>

The parity generated for the data shifted into Receiving Buffer 2 (SC0BUF) is compared with the parity bit received via the RXD pin. If they are not equal, a Parity error is generated.

3. Framing error <FERR>

The stop bit for the received data is sampled three times around the center. If the majority of the samples are 0, a Framing error is generated.

(12) Timing generation

① In UART Mode

Receiving

Mode	9-Bit (Note)	8-Bit + Parity (Note)	8-Bit, 7-Bit + Parity, 7-Bit
Interrupt timing	Center of last bit (bit 8)	Center of last bit (parity bit)	Center of stop bit
Framing error timing	Center of stop bit	Center of stop bit	Center of stop bit
Parity error timing	-	Center of last bit (parity bit)	Center of last bit (parity bit)
Overrun error timing	Center of last bit (bit 8)	Center of last bit (parity bit)	Center of stop bit

Note: In 9-Bit Mode and 8-Bit + Parity Mode, interrupts coincide with the ninth bit pulse. Thus, when servicing the interrupt, it is necessary to allow a 1-bit period to elapse (so that the stop bit can be transferred) in order to allow proper framing error checking.

Transmitting

Mode	9-Bit	8-Bit + Parity	8-Bit, 7-Bit + Parity, 7-Bit
Interrupt timing	Just before stop bit is	Just before stop bit is	Just before stop bit is
Interrupt timing	transmitted	transmitted	transmitted

^② I/O interface

Transmission Interrupt timing	SCLK Output Mode	Immediately after rise of last SCLK signal. (See figure 3.9 20.)			
	SCLK Input Mode	Immediately after rise of last SCLK signal Rising Mode, or immediately after fall in Falling Mode. (See figure 3.9 21.)			
Receiving Interrupt timing	SCLK Output Mode	Timing used to transfer received data to Receive Buffer 2 (SC0BUF) (i.e. immediately after last SCLK). (See figure 3.9 22.)			
	SCLK Input Mode	Timing used to transfer received data to Receive Buffer 2 (SC0BUF) (i.e. immediately after last SCLK). (See figure 3.9 23.)

3.9.4 Operation for each mode

(1) Mode 0 (I/O Interface Mode)

This mode allows an increase in the number of I/O pins available for transmitting data to or receiving data from an external shift register.

This mode includes the SCLK output mode to output synchronous clock SCLK and SCLK input external synchronous clock SCLK.

Figure 3.9.18 Example of SCLK Output Mode Connection

Figure 3.9.19 Example of SCLK Input Mode Connection

1 Transmission

In SCLK Output Mode 8-bit data and a synchronous clock are output on the TXD0 and SCLK0 pins respectively each time the CPU writes the data to the Transmission Buffer.

When all the data has been output, INTESO <ITXOC> is set to 1, causing an INTTX0 interrupt to be generated.

In SCLK Input Mode, 8-bit data is output on the TXD0 pin when the SCLK0 input becomes active after the data has been written to the Transmission Buffer by the CPU. When all the data has been output, INTESO <ITX0C> is set to 1, causing an INTTX0 interrupt to be generated.

Figure 3.9.21 Transmitting Operation in I/O Interface Mode (SCLK0 Input Mode)

② Receiving

In SCLK Output Mode the synchronous clock is output on the SCLK0 pin and the data is shifted to Receiving Buffer 1. This is initiated when the Receive Interrupt flag INTESO<IRX0C> is cleared as the received data is read. When 8-bit data is received, the data is transferred to Receiving Buffer 2 (SC0BUF) following the timing shown below and INTESO<IRX0C> is set to 1 again, causing an INTRX0 interrupt to be generated.

Setting SC0MOD0<RXE> to 1 initiates SCLK0 output.

In SCLK Input Mode the data is shifted to Receiving Buffer 1 when the SCLK input goes active. The SCLK input goes active when the Receive Interrupt flag INTESO <IRXOC> is cleared as the received data is read. When 8-bit data is received, the data is shifted to Receiving Buffer 2 (SCOBUF) following the timing shown below and INTESO <IRXOC> is set to 1 again, causing an INTRXO interrupt to be generated.

IRX0C (INTRX0 interrupt request)				"			

Figure 3.9.23 Receiving Operation in I/O interface Mode (SCLK0 Input Mode)

Note: The system must be put in the Receive Enable state (SC0MOD0<RXE> = 1) before data can be received.

③ Transmission and Receiving (Full Duplex Mode)

When Full Duplex Mode is used, set the Receive Interrupt Level to 0 and set enable the level of transmit interrupt. Ensure that the program which transmits the interrupt reads the receiving buffer before setting the next transmit data. The following is an example of this:

Example: Channel 0, SCLK output Baud rate = 9600 bps fc = 19.6608 MHz

Main routine

	7	6	5	4	3	2	1	0	
INTES0	Х	0	0	1	Х	0	0	0	Set the INTTX0 level to 1.
									Set the INTRX0 level to 0.
PFCR	-	-	-	-	-	1	0	1	Set PF0, PF1 and PF2 to function as the TXD0, RXD0
PFFC	-	-	-	-	-	1	-	1	and SCLK0 pins respectively
SCOMODO	0	0	0	0	0	0	0	0	Select I/O Interface Mode.
SC0MOD1	1	1	0	0	0	0	0	0	Select Full Duplex Mode.
SCOCR	0	0	0	0	0	0	0	0	Sclk_out, transmit on negative edge, receive on
									positive edge
BROCR	0	0	1	1	0	1	0	0	Baud rate = 9600 bps
SC0MOD0	0	0	1	0	0	0	0	0	Enable receiving
SCOBUF	*	*	*	*	*	*	*	*	Set the transmit data and start.
INTTX0 interrupt routine									
Acc	←	SC	COBL	JF					Read the receiving buffer.
SCOBUF	*	*	*	*	*	*	*	*	Set the next transmit data.

Note: X = Don't care; "-" = No change
(2) Mode 1 (7-bit UART Mode)

7-Bit UART Mode is selected by setting the Serial Channel Mode Register SC0MOD0<SM1,SM0> field to 01.

In this mode a parity bit can be added. Use of a parity bit is enabled or disabled by the setting of the Serial Channel Control Register SCOCR<PE> bit; whether even parity or odd parity will be used is determined by the SCOCR<EVEN> setting when SCOCR<PE> is set to 1 (enabled).

Setting example: When transmitting data of the following format, the control registers should be set as described below.

Note: X = Don't care; "-" = No change

(3) Mode 2 (8-Bit UART Mode)

8-Bit UART Mode is selected by setting SC0MODO<SM1,SM0> to 10. In this mode a parity bit can be added (use of a parity bit is enabled or disabled by the setting of SC0CR<PE>); whether even parity or odd parity will be used is determined by the SC0CR<EVEN> setting when SC0CR<PE> is set to 1 (enabled).

Setting example: When receiving data of the following format, the control registers should be set as described below.

Transmission direction (transmission rate: 9600 bps at fc = 19.6608 MHz)

Main set	ttings	
	7 6 5 4 3 2 1 0	
PFCR	$\leftarrow 0 -$	Set PF1 to function as the RXD0 pin.
SC0MOD0	\leftarrow - 0 1 X 1 0 0 1	Enable receiving in 8-Bit UART Mode.
SC0CR	$\leftarrow \texttt{X 0 1 X X X 0 0}$	Add odd parity.
BROCR	\leftarrow 0 0 0 1 1 0 0 0	Set the transfer rate to 9600 bps.
INTES0	$\leftarrow x 1 0 0$	Enable the INTTX0 interrupt and set it to Interrupt Level 4.
Interrupt	processing	
Acc	← SC0CR AND 00011100	Chaoli for arrain
if Acc	\neq 0 then ERROR \int	Check for errors.
Acc	← SC0BUF	Read the received data.

Note: X = Don't care; "-" = No change

(4) Mode 3 (9-Bit UART Mode)

9-Bit UART Mode is selected by setting SC0MOD0<SM1,SM0> to 11. In this mode parity bit cannot be added.

In the case of transmission the MSB (9th bit) is written to SC0MOD0<TB8>. In the case of receiving it is stored in SC0CR<RB8>. When the buffer is written and read, the MSB is read or written first, before the rest of the SC0BUF data.

Wake-up function

In 9-Bit UART Mode, the wake-up function for slave controllers is enabled by setting SC0MOD0<WU> to 1. The interrupt INTRX0 can only be generated when<RB8> = 1.

Note: The TXD pin of each slave controller must be in Open-Drain Output Mode.

Figure 3.9.24 Serial Link using Wake-up function

Protocol

www.datasheeT4OSHIBA

① Select 9-Bit UART Mode on the master and slave controllers.

- ② Set the SC0MOD0<WU> bit on each slave controller to 1 to enable data receiving.
- ③ The master controller transmits data one frame at a time. Each frame includes an 8-bit select code which identifies a slave controller. The MSB (bit 8) of the data (<TB8>) is set to 1.

- Each slave controller receives the above frame. Each controller checks the above select code against its own select code. The controller whose code matches clears its <WU> bit to 0.
- S The master controller transmits data to the specified slave controller (the controller whose SC0MOD0<WU> bit has been cleared to 0). The MSB (bit 8) of the data (<TB8>) is cleared to 0.

⑤ The other slave controllers (whose <WU> bits remain at 1) ignore the received data because their MSBs (bit 8 or <RB8>) are set to 0, disabling INTRX0 interrupts. The slave controller whose <WU> bit = 0 can also transmit to the master controller. In this way it can signal the master controller that the data transmission from the master controller has been completed.

Setting example: To link two slave controllers serially with the master controller using the internal clock ϕ 1 as the transfer clock.

• Setting the master controller

3.10 Serial Bus Interface (SBI)

 $TMP92CD54I \ has \ 3\ channels \ serial \ bus \ interface \ which \ employs \ a \ clocked\ synchronous \ 8\ bit \ SIO \ mode \ and \ an \ I^2C \ bus \ mode. \ It \ is \ called \ SBI0, \ SBI1 \ and \ SBI2.$

	l ² C bus	Clocked-synchronous 8-bit SIO
SBI0	SCL0 (PN2), SDA0 (PN1) PNODE <oden2, oden1=""></oden2,>	SCK0 (PN0), SO0 (PN1), SI0 (PN2)
SBI1	SCL1 (PN5), SDA1 (PN4) PNODE <oden5, oden4=""></oden5,>	SCK1 (PN3), SO1 (PN4), SI1 (PN5)
SBI2	SCL2 (P72), SDA2 (PN6) PNODE <ode72, oden6=""></ode72,>	SCK2 (PM4), SO2 (PN6), SI2 (P72)

Since each channel carries out the same operation, it explains only SBI0.

The serial bus interface is connected to an external device through PN1 (SDA0) and PN2 (SCL0) in the I²C bus mode; and through PN0 (SCK0), PN1 (SO0) and PN2 (SI0) in the clocked-synchronous 8-bit SIO mode.

Each pin is specified as follows.

	PNODE <oden2, oden1=""></oden2,>	PNCR <pn2c, pn0c="" pn1c,=""></pn2c,>	PNFC <pn2f, pn0f="" pn1f,=""></pn2f,>
I ² C Bus Mode	11	11X	11X
Clocked Synchronous	XX	011	011
8-Bit SIO Mode		010	

X: Don't care

3.10.1 Configuration

Figure 3.10.1 Serial Bus Interface 0 (SBI0)

3.10.2 Serial Bus Interface (SBI) Control

The following registers are used to control the serial bus interface and monitor the operation status.

- Serial bus interface 0 control register 1 (SBI0CR1)
- Serial bus interface 0 control register 2 (SBI0CR2)
- Serial bus interface 0 data buffer register (SBI0DBR)
- I²C bus 0 address register (I2C0AR)
- Serial bus interface 0 status register (SBI0SR)
- Serial bus interface 0 baud rate register 0 (SBI0BR0)
- Serial bus interface 0 baud rate register 1 (SBI0BR1)

The above registers differ depending on a mode to be used.

Refer to Section "3.10.4 I2C bus Mode Control" and "3.10.7 Clocked-synchronous 8-bit SIO Mode Control".

3.10.3 The Data Formats in the I²C Bus Mode

The data formats in the I²C bus mode are shown below.

(a) Addressing format

(b) Addressing format (with restart)

(c) Free data format (data transferred from master device to slave device)

Note: S: Start condition

R / W: Direction bit

ACK: Acknowledge bit

P: Stop condition

3.10.4 I²C Bus Mode Control Register

The following registers are used to control and monitor the operation status when using the serial bus interface (SBI) in the I²C bus mode.

Seirial Bus Interface 0 Conrol Register 1

Note 1: Set the <BC2 to 0> to "000" before switching to a clock-synchronous 8-bit SIO mode. Note 2: For the frequency of the SCL line clock, see 3.10.5 (3) Serial clock. Note 3: Initial data of SCK0 is "0", SWRMON is "1".

Figure 3.10.3 Registers for the I²C Bus Mode

Serial Bus Interface 0 Control Register 2

Note1: Reading this register function as SBI0SR register.

Note2: Switch a mode to port mode after confirming that the bus is free. Switch a mode between I²C bus mode and clock-synchronous 8-bit SIO mode after confirming that input signals via port are high-level.

Figure 3.10.4 Registers for the I²C Bus Mode

www.datashee

Note1: Writing in this register functions as SBI0CR2.

Note2: If SBI0SR<BB> drops down from 1 to 0 (falling edge),

1 Master

INTSBS0 will be generated in both case of Master mode and Slave mode.

Figure 3.10.5 Registers for the I²C Bus Mode

1 Free data format

Addressing or free data format impact both slave and master configuration.

When addressing format is used (<ALS>=0), TRX bit is updated relying on R/W bit (=8th bit of first received byte after start condition). Moreover in slave mode, MCU spies the bus after start condition to recognize its address.

When free data format is used (<ALS>=1) all words on the bus are considered as data words, that means no address recognition is done and TRX is not updated.

Figure 3.10.6 Registers for the I²C Bus Mode

Seirial Bus Interface 1 Conrol Register 1

Note 1: Set the <BC2 to 0> to "000" before switching to a clock-synchronous 8-bit SIO mode. Note 2: For the frequency of the SCL line clock, see 3.10.5 (3) Serial clock. Note 3: Initial data of SCK0 is "0", SWRMON is "1".

Figure 3.10.14 Registers for the I²C Bus Mode

3.10.5 Control in I²C Bus Mode

(1) Specifying acknowledge mode

To operate the device in the acknowledge mode set the SBIOCR1<ACK> to "1". When operating in the master mode this device generates an additional clock pulse as an acknowledge signal; when operating in the slave mode it counts a clock pulse as an acknowledge signal. In the transmitter mode the SDA0 pin is released during the clock pulse cycle so that it can receive the acknowledge signal from the receiver. In the receiver mode the SDA0 pin is set to the low-level during the clock pulse cycle in order to generate the acknowledge signal.

To operate the device in non-acknowledge mode, clear the SBIOCR1<ACK> to "0". When operating in the master mode this device does not generate a clock pulse as an acknowledge signal; when operating in the slave mode it does not count a clock pulse as an acknowledge signal.

(2) Number of transfer bits

The SBI0CR1<BC2 to 0> setting determines the number of data bits to be transmitted or received.

Since the SBI0CR1<BC2 to 0> is cleared to "000" on start-up, a slave address and direction bit transmissions are executed in 8 bits. Other than these, the <BC2 to 0> retains a specified value.

- (3) Serial clock
 - i) Clock source

The SBI0CR1 <SCK3 to 0> is used to specify the maximum transfer frequency for output on the SCL0 pin in the master mode.

Figure 3.10.15 Clock Source

ii) Clock synchronization

In the I²C bus mode, in order to wired-AND a bus, a master device which pulls down a clock line to the low-level, in the first place, invalidate a clock pulse of another master device which generates a high-level clock pulse. The master device with a high-level clock pulse needs to detect the situation and implement the following procedure.

This device has a clock synchronization function which allows normal data transfer even when more than one master exists on the bus.

The following example explains the clock synchronization procedures used when there are two masters present on the bus.

Figure 3.10.16 Clock Synchronization

When Master A pulls the internal SCL0 output to the low-level at point "a", the SCL0 line of the bus goes to the low-level. After detecting this, Master B resets a counter of high-level width of an own clock pulse and sets the internal SCL0 output the low-level. Master A finishes counting low-level width of an own clock pulse at point "b" and sets the internal SCL0 output to the high-level. Since Master B is holding the SCL0 line of the bus at the low-level, Master A waits for counting high-level width of an own clock pulse at point "c" and Master A detects the SCL0 line of the bus at the high-level of an own clock pulse.

The clock pulse on the bus is determined by the master device with the shortest high-level width and the master device with the longest low-level width from among those master devices connected to the bus.

(4) Slave address and address recognition mode specification

When this device is to be used as an I2C slave device, set the slave address <SA6 to 0> and <ALS> in I2C0AR. Clear the <ALS> to "0" for addressing format. When this devices is to be used as an I2C master device, clear <ALS> to "0" for addressing format.

When this device is to be used in free data format system (as slave or master) set <ALS> to "1" for free data format.

(5) Master/slave selection

To operate this device as a master device set the SBI0CR2<MST> to "1". To operate it as a slave device clear the SBI0CR2<MST> to "0". The <MST> is cleared to "0" in hardware when a stop condition is detected on the bus or when arbitration is lost.

(6) Transmitter/receiver selection

To operate this device as a transmitter set the SBIOCR2<TRX> to "1". To operate it as a receiver clear the SBIOCR2<TRX> to "0". When data with an addressing format is transferred in the slave mode, when a slave address with the same value that an I2COAR or a GENERAL CALL is received (all 8-bit data are "0" after a start condition), the <TRX> is set to "1" in hardware if the direction bit (R/\overline{W}) sent from the master device is "1", and is cleared to "0" in hardware if the bit is "0". In the master mode, when an acknowledge signal is returned from the slave device, the <TRX> is cleared to "0" in hardware if the bit is "1", and is set to "1" in hardware if the value of the transmitted direction bit is "1", and is set to "1" in hardware if the value of the bit is "0". If an acknowledge signal is not returned, the current state is maintained.

The <TRX> is cleared to "0" in hardware when a stop condition is detected on the $I^{2}C$ bus or when arbitration is lost.

(7) Start/Stop condition generation

When the SBI0SR<BB> = "0", 8-bit data set in SBI0DBR is output on the bus after generating a start condition by writing "1111" to the SBI0CR2 <MST, TRX, BB, PIN>. It is necessary to set transmitted data to the data buffer register (SBI0DBR) and set "1" to the <ACK> beforehand.

Figure 3.10.17 Start Condition Generation and Slave Address Generation

When the SBI0SR<BB> = "1", the sequence for generating a stop condition can be initiated by writing "111" to the SBI0CR2<MST,TRX,PIN> and writing "0" to the SBI0CR2<BB>. Do not modify the contents of the SBI0CR2<MST, TRX, BB, PIN> until a stop condition has been generated on the bus.

Figure 3.10.18 Stop Condition Generation

The state of the bus can be ascertained by reading the contents of the SBI0SR<BB>. The SBI0SR<BB> will be set to "1" if a start condition has been detected on the bus ,and will be cleared to "0" if a stop condition has been detected.

If SBI0SR<BB> drops down from 1 to 0 (falling edge), INTSBS0 will be generated in both case of Master mode and Slave mode.

(8) Interrupt service requests and interrupt cancellation

When a serial bus interface interrupt request 0 by transfer of the slave address or the data (INTSBE0) is generated, the SBI0SR<PIN> is cleared to "0". The SCL0 line is pulled down to the low-level while the <PIN> = "0".

The <PIN> is cleared to "0" when a single word of data is transmitted or received. Either writing data to or reading data from SBI0DBR sets the <PIN> to "1".

The time from the $\langle PIN \rangle$ being set to "1" until the release of the SCL0 line is t_{LOW} .

In the address recognition mode (i.e. when <ALS> = "0"; Addressing format), the <PIN> is cleared to "0" when the slave address matches the value set in I2COAR or when a GENERAL CALL is received (all 8-bit data are "0" after a start condition). Although the SBI0CR2<PIN> can be set to "1" by a program, writing "0" to the SBI0CR2<PIN> does not clear it to "0".

(9) Serial bus interface operation mode selection

The SBI0CR2<SBIM1 to 0> is used to specify the serial bus interface operation mode. Set the SBI0CR2<SBIM1 to 0> to "10" when the device is to be used in I²C Bus Mode. Switch to port mode confirming that the bus is free.

(10) Arbitration lost detection monitor

Since more than one master device can exist simultaneously on the bus in I^2C Bus Mode, a bus arbitration procedure has been implemented in order to guarantee the integrity of transferred data.

Data on the SDA0 line is used for $\mathrm{I}^{2}\mathrm{C}$ bus arbitration.

The following example illustrates the bus arbitration procedure when there are two master devices on the bus. Master A and Master B output the same data until point "a". After Master A outputs "L" and Master B, "H", the SDA0 line of the bus is wire-AND and the SDA0 line is pulled down to the low level by Master A. When the SCL0 line of the bus is pulled up at point "b", the slave device reads the data on the SDA0 line, that is, data in Master A. Data transmitted from Master B becomes invalid. The Master B state is known as "ARBITRATION LOST". Master B device which loses arbitration releases the internal SDA0 output in order not to affect data transmitted from other masters with arbitration. When more than one master sends the same data at the first word, arbitration occurs continuously after the second word.

Figure 3.10.19 Arbitration Lost

This device compares the levels on the bus's SDA0 line with those of the internal SDA0 output on the rising edge of the SCL0 line. If the levels do not match, arbitration is lost and the SBI0SR<AL> is set to "1".

When the <AL> is set to "1", the SBI0SR<MST,TRX> are cleared to "00" and the mode is switched to a slave receiver mode. This device generates the clock pulse until data is transmitted when the <AL> is "1".

The <AL> is cleared to "0" when data is written to or read from SBI0DBR or when data is written to SBI0CR2.

Figure 3.10.20 Example of a Master Device B (D7A = D7B, D6A = D6B)

(11) Slave address match detection monitor

The SBI0SR<AAS> is set to "1" in the slave mode, in the address recognition mode (i.e. when the I2C0AR<ALS> = "0"), when a GENERAL CALL is received, or when a slave address matches the value set in I2C0AR. When the I2C0AR<ALS> = "1", the SBI0SR<AAS> is set to "1" after the first word of data has been received. The SBI0SR<AAS> is cleared to "0" when data is written to or read from the data buffer register SBI0DBR.

(12) GENERAL CALL detection monitor

The SBI0SR<AD0> is set to "1" in the slave mode, when a GENERAL CALL is received (all 8-bit received data is "0", after a start condition). The SBI0SR<AD0> is cleared to "0" when a start condition or stop condition is detected on the bus.

(13) Last received bit monitor

The value on the SDA0 line detected on the rising edge of the SCL0 line is stored in the SBI0SR<LRB>. In the acknowledge mode, immediately after an INTSBE0 interrupt request has been generated, an acknowledge signal is read by reading the contents of the SBI0SR<LRB>.

www.datashee

(14) Software Reset function

The software Reset function is used to initialize the SBI circuit, when SBI is rocked by external noises, etc.

An internal Reset signal pulse can be generated by setting SBI0CR2<SWRST1 to 0> to "10" and "01". This initializes the SBI circuit internally. All control registers and status registers excluding SBI0CR2<SBIM1 to 0> are initialized as well.

The SBI0CR2<SWRST1 to 0> is automatically cleared to "00" after the SBI circuit has been initialized.

The initialization of SBI circuit can be confirmed by monitoring SBI0CR1<SWRMON>.

(15) Serial Bus Interface Data Buffer Register (SBI0DBR)

The received data can be read and the transferred data can be writtenby reading or writing the SBI0DBR.

When the start condition has been generated in the master mode, the slave address and the direction bit are set in this register.

(16) I²C Bus Address Register (I2C0AR)

I2C0AR<SA6 to 0> is used to set the slave address when this device functions as a slave device.

ALS bit is used to select between addressing and free data format.

- For I2C bus, addressing format is used (<ALS>=0); then TRX bit is updated relying on R/W bit (=8th bit of first received byte after start condition). Moreover, in slave mode, MCU spies the bus after start condition to recognize its address
- For free data format (ALS=1) all words on the bus are considered as data words, that means no address recognition is done and TRX is not updated
- (17) Baud Rate Register (SBI0BR1)

Write "1" to the SBI0BR1<P4EN> before operation commences.

(18) Setting register for IDLE2 mode operation (SBI0BR0)

The setting of SBI0BR0<I2SBI0> determines whether the device is operating or is stopped in IDLE2 Mode. Therefore, setting <I2SBI0> is necessary before the HALT instruction is executed.

eet4U.com

3.10.6 Data Transfer in I²C Bus Mode

(1) Device Initialization

Set the SBI0BR1<P4EN> and the SBI0CR1<ACK,SCK2 to 0>. Set the SBI0BR1<P4EN> to "1" and clear bits 7 to 5 and 3 of the SBI0CR1 to "0".

Set a slave address in I2C0AR<SA6 to 0> and the I2C0AR<ALS> (<ALS> = "0" when an addressing format.)

For specifying the default setting to a slave receiver mode, clear "000" to the <MST, TRX, BB>, set "1" to the <PIN>, set "10" to the <SBIM1 to 0> and set "00" to the <SWRST1 to 0>.

- (2) Start Condition Generation and Slave Address Generation
 - i) Master mode

In the master mode the start condition and the slave address are generated as follows. Check a bus free status (when <BB>= "0").

Set the SBI0CR1<ACK> to "1" (acknowledge mode) and specify a slave address and a direction bit to be transmitted to the SBI0DBR.

When the <BB> is "0", the start condition is generated by writing "1111" to the SBI0CR2<MST,TRX,BB,PIN>. Subsequently to the start condition, nine clocks are output from the SCL0 pin. The slave address and the direction bit set to the SBI0DBR will be outputting during the 8 clocks. At the 9th clock pulse the SDA0 line is released and the acknowledge signal is received from the slave device.

An INTSBE0 interrupt request occurs on the falling edge of the ninth clock pulse. The <PIN> is cleared to "0". In the master mode the SCL0 pin is pulled down to the low-level while the <PIN> is "0". When an INTSBE0 interrupt request occurs, the value of <TRX> is changed according to the direction bit setting only if the slave device returns an acknowledge signal.

ii) Slave mode

In the slave mode the start condition and the slave address are received.

After the start condition has been received from the master device, while eight clocks are input from the SCL0 pin, the slave address and the direction bit which are output from the master device are received.

When a GENERAL CALL or an address matching the slave address set in I2C0AR is received, the SDA0 line is pulled down to the low level at the 9th clock pulse and an acknowledge signal is output.

An INTSBE0 interrupt request occurs on the falling edge of the ninth clock pulse. The <PIN> is cleared to "0". In the slave mode the SCL0 line is pulled down to the low-level while the <PIN> = "0". When an interrupt request occurs, the value of <TRX> is changed according to the direction bit setting only if the slave device returns an acknowledge signal.

(3) 1-word Data Transfer

Check the <MST> setting using an INTSBE0 interrupt process after the transfer of each word of data is completed and determine whether the device is in the master mode or the slave mode.

i) When the <MST> is "1" (Master mode)

Check the <TRX> setting and determine whether the device is in the transmitter mode or the receiver mode.

Note: TRX bit is only valid in addressing format (<ALS>=0).

When the <TRX> is "1" (Transmitter mode)

Check the <LRB> setting. When the <LRB> = "1", there is no receiver requesting data. Implement the process for generating a stop condition (see Section 3.10.6 (4)) and terminate data transfer.

When the $\langle LRB \rangle = "0"$, the receiver is requesting new data. When the next transmitted data is 8 bits, write the transmitted data to the SBI0DBR. When the next transmitted data is other than 8 bits, set the $\langle BC2 \rangle$ to $0 \rangle$, set the $\langle ACK \rangle$ to "1" and write the transmitted data to the SBI0DBR. After the data has been written, the $\langle PIN \rangle$ is set to "1", a serial clock pulse is generated to trigger transfer of the next word of data via the SCL0 pin, and the word is transmitted. After the data has been transmitted, an INTSBE0 interrupt request is generated. The $\langle PIN \rangle$ is set to "0" and the SCL0 line is pulled down to the low-level. If the length of the data to be transferred is greater than one word, repeat the latter steps of the procedure, starting from the check of the $\langle LRB \rangle$ setting.

Figure 3.10.22 Example in which <BC2 to 0> = "000" and <ACK> = "1" in Transmitter Mode

When the <TRX> is "0" (Receiver mode)

When the next transmitted data is other than 8 bits, set the <BC2 to 0> again. Set the <ACK> to "1" and read the received data from the SBI0DBR so as to release the SCL0 line (the value of data which is read immediately after a slave address is sent is undefined). After the data has been read, the <PIN> is set to "1". This device outputs a serial clock pulse on SCL0 line to transfer new 1-word of data and outputs low-level from SDA0 pin with acknowledge timing.

An INTSBE0 interrupt request is generated and the <PIN> is set to "0". Then this device pulls down the SCL0 pin to the low-level. This device outputs a clock pulse for 1-word of data transfer and the acknowledge signal each time that received data is read from SBI0DBR.

Figure 3.10.23 Example of when <BC2 to 0> = "000", <ACK> = "1" in Receiver Mode

In order to terminate the transmission of data to a transmitter, clear the $\langle ACK \rangle$ to "0" before reading data which is 1-word before the last data to be received. The last data does not generate a clock pulse for the acknowledge signal. After the data has been transmitted and an interrupt request has been generated, set the $\langle BC2 \text{ to } 0 \rangle$ to "001" and read the data. This device generates a clock pulse for a 1-bit data transfer. Since the master device is a receiver, the SDA0 line on a bus keeps the high-level. The transmitter receives the high-level signal as an ACK signal. The receiver indicates to the transmitter that data transfer is complete.

After 1-bit data is received and an interrupt request has occurred, this device generates a stop condition (see Section 3.10.6 (4)) and terminates data transfer. Because of a stop condition generation, an INTSBS0 interrupt request occurs.

Figure 3.10.24 Termination of Data Transfer in Master Receiver Mode

ii) When the <MST> is "0" (Slave mode)

In the slave mode, this device operates either in normal slave mode or in slave mode after losing arbitration.

In the slave mode, an INTSBE0 interrupt request occurs when this device receives a slave address or a GENERAL CALL from the master device, or when a GENERAL CALL is received and data transfer is complete, or after matching a received slave address. In the master mode, this device operates in a slave mode if it is losing arbitration. An INTSBE0 interrupt request occurs when word data transfer terminates after losing arbitration. When an INTSBE0 interrupt request occurs, the <PIN> is cleared to "0", and the SCL0 pin is pulled down to the low-level. Either reading data to or writing data from the SBI0DBR, or setting the <PIN> to "1" releases the SCL0 pin after taking t_{LOW} time.

If the stop condition is detected and SBI0SR<BB> drops down from 1 to 0, INTSBS0 will be generated.

Check the SBI0SR<AL>, <TRX>, <AAS> and <AD0> and implements processes according to conditions listed in the next table.

- Note: The <PIN> is set to "0" and the SCL0 pin is pulled down to the low-level, when this device as a master loses arbitration while sending slave address and is called as the slave. In the following 2 cases, the interrupt request is generated when data transfer is finished after losing arbitration, but <PIN> is not set to "0".
 - The case that this device as a master loses arbitration while sending slave address and the slave address sent from another device does not correspond to this device.
 - The case that this device as a master loses arbitration while sending the data.

<trx></trx>	<al></al>	<aas></aas>	<ad0></ad0>	Conditions	Process
1	1	1	0	This device loses arbitration when transmitting a slave address and receives a slave address of which the value of the direction bit sent from another master is "1".	Set the number of bits in 1-word to the <bc2 0="" to=""> and write the transmitted data to the SBI0DBR.</bc2>
	0	1	0	In the salve receiver Mode, this device receives a slave address of which the value of the direction bit sent from the master is "1".	
		0	0	In the salve transmitter mode, 1-word data is transmitted.	Check the <lrb>. If the <lrb> is set to "1", set the <pin> to "1" since the receiver does not request the next data. Then, clear the <trx> to "0" to release the bus. If the <lrb> is cleared to "0", set the number of bits in a word to the <bc2 0="" to=""> and write transmitted data to the SBI0DBR since the receiver requests next data.</bc2></lrb></trx></pin></lrb></lrb>
0	1	1	1/0	This device loses arbitration when transmitting a slave address and receives a GENERAL CALL or slave address of which the value of the direction bit sent from another master is "0".	Read the SBI0DBR for setting the <pin> to "1" (reading dummy data) or set the <pin> to "1".</pin></pin>
		0	0	This device loses arbitration when transmitting a slave address or data and terminates transferring word data.	Although INTSEBE0 interrupt occurs after finishing transmitting, this device is slave receiver mode. In this case the <pin> is not cleared to '0'. Execute the program again in the case of transmitting again as a master.</pin>
	0	1	1/0	In the slave receiver mode, this device receives a GENERAL CALL or slave address of which the value of the direction bit sent from the master is "0".	Read the SBI0DBR for setting the <pin> to "1" (reading dummy data) or set the <pin> to "1".</pin></pin>
		0	1/0	In the slave receiver mode, the device terminates receiving 1-word data.	Set the number of bits in a word to the <bc2 0="" to=""> and read received data from the SBI0DBR.</bc2>

Table 3.10.1	Operation in the Slave Mode

(4) Stop condition generation

When the SBI0SR<BB> is "1", the sequence of generating a stop condition is started by setting "111" to the SBI0CR2<MST,TRX,PIN> and "0" to the SBI0CR2<BB>. Do not modify the contents of the SBI0CR2<MST,TRX,PIN,BB> until a stop condition is generated on a bus. When a SCL0 line of bus is pulled down by other devices, this device generates a stop condition after they release a SCL0 line and the SDA0 becomes "1". An INTSBS0 interrupt request occurs at the timing of the SBI0SR<BB> becomes "0" in both case of master mode and slave mode..

Whenever a stop condition is detected, an INTSBS0 interrupt request will be generated in both case of master mode and slave mode, regardless of whether it means to stop data transfer or not.

Figure 3.10.25 Stop Condition Generation

(5) Restart

Restart is used during data transfer between a master device and a slave device to change the data transfer direction. The following description explains how to restart when this device is in the master mode.

Clear the SBI0CR2<MST,TRX,BB> to "000" and set the SBI0CR2<PIN> to "1" to release the bus. The SDA0 line remains the high-level and the SCL0 pin is released. Since a stop condition is not generated on the bus, other devices assume the bus to be in a busy state. Check the SBI0SR<BB> until it becomes "0" to check that the SCL0 pin of this device is released. Check the <LRB> until it becomes 1 to check that the SCL0 line on a bus is not pulled down to the low-level by other devices. After confirming that the bus stays in a free state, generate a start condition with procedure described in 3.10.6 (2).

In order to meet set-up time when restarting, take at least 4.7 us of waiting time by software from the time of restarting to confirm that the bus is free until the time to generate the start condition.

Figure 3.10.26 Timing Diagram when Restarting

3.10.7 Clocked Synchronous 8-Bit SIO Mode control

The following registers are used to control and monitor the operation status when the serial bus interface (SBI) is being operated in clocked synchronous 8-bit SIO mode.

Figure 3.10.35 Registers for the SIO Mode

- (1) Serial Clock
 - i) Clock source

SBI0CR1<SCK2 to 0> is used to select the following functions:

Internal Clock

In an internal clock mode, any of seven frequencies can be selected. The serial clock is output to the outside on the SCK0 pin. The SCK0 pin becomes a high-level when data transfer starts. When the device is writing (in the transmit mode) or reading (in the receive mode) data cannot follow the serial clock rate, an automatic wait function is executed to stop the serial clock automatically and holds the next shift operation until reading or writing is complete.

Figure 3.10.36 Automatic-wait Function

External clock (<SCK2 to 0> = "111")

An external clock input via the SCK0 pin is used as the serial clock. In order to ensure the integrity of shift operations, both the high and low-level serial clock pulse widths shown below must be maintained. The maximum data transfer frequency is 1.25 MHz (when fc = 20 MHz).

Figure 3.10.37 Maximum Data Transfer Frequency when External Clock Input

www.datashee

ii) Shift edge

Data is transmitted on the falling edge of the clock and received on the rising edge. Falling edge shift

Data is shifted on the falling edge of the serial clock (on the falling edge of the SCK0 pin input/output).

<u>Rising edge shift</u>

Data is shifted on the rising edge of the serial clock (on the rising edge of the SCK0 pin input/output).

Figure 3.10.38 Shift Edge

(2) Transfer Modes

The SBI0CR1<SIOM1 to 0> is used to select a transmit, receive or transmit/receive mode.

i) 8-bit transmit mode

Set a control register to a transmit mode and write transmission data to the SBI0DBR. After the transmit data has been written, set the SBI0CR1<SIOS> to "1" to start data transfer. The transmitted data is transferred from the SBI0DBR to the shift register and output, starting with the least significant bit (LSB), via the SO0 pin and synchronized with the serial clock. When the transmission data has been transferred to the shift register, the SBI0DBR becomes empty. The INTSBE0 (buffer empty) interrupt request is generated to request new data.

When the internal clock is used, the serial clock will stop and the automatic wait function will be initiated if new data is not loaded to the data buffer register after the specified 8-bit data is transmitted. When new transmission data is written, the automatic wait function is canceled.

When the external clock is used, data should be written to the SBI0DBR before new data is shifted. The transfer speed is determined by the maximum delay time between the time when an interrupt request is generated and the time when data is written to the SBI0DBR by the interrupt service program.

When the transmit is started, after the SBI0SR<SIOF> goes "1" output from the SO0 pin holds final bit of the last data until falling edge of the SCK0.

Data transmission ends when the <SIOS> is cleared to "0" by the INTSBE0 interrupt service program or when the <SIOINH> is set to "1". When the <SIOS> is cleared to "0", the transmitted mode ends when all data is output. In order to confirm whether data is being transmitted properly by the program, the <SIOF> (bit 3 of the SBIOSR) to be sensed. The SBIOSR<SIOF> is cleared to "0" when transmission has been completed. When the <SIOINH> is set to "1", transmitting datat stops. The <SIOF> turns "0".

When the external clock is used, it is also necessary to clear the <SIOS> to "0" before new data is shifted; otherwise, dummy data is transmitted and operation ends.

Figure 3.10.39 Transfer Mode

Example: Program to stop data transmission (when an external clock is used)

STEST1:	BIT	2, (SBI0SR)	; If $\langle SEF \rangle = 1$ then loop

STEST2:	BIT	0, (PN)	; If $SCK0 = 0$ then loop
	JR	Z, STEST2	
	LD	(SBI0CR1), 00000111B	; $<$ SIOS> $\leftarrow 0$

Figure 3.10.40 Transmitted Data Hold Time at End of Transmission

ii) 8-bit receive mode

Set the control register to receive mode and set the SBIOCR1<SIOS> to "1" for switching to receive mode. Data is received into the shift register via the SIO pin and synchronized with the serial clock, starting from the least significant bit (LSB). When the 8-bit data is received, the data is transferred from the shift register to the SBIODBR. The INTSBEO (buffer full) interrupt request is generated to request that the received data be read. The data is then read from the SBIODBR by the interrupt service program.

When the internal clock is used, the serial clock will stop and the automatic wait function will be in effect until the received data is read from the SBI0DBR.

When the external clock is used, since shift operation is synchronized with an external clock pulse, the received data should be read from the SBI0DBR before the next serial clock pulse is input. If the received data is not read, further data to be received is canceled. The maximum transfer speed when an external clock is used is determined by the delay time between the time when an interrupt request is generated and the time when the received data is read.

Receiving of data ends when the <SIOS> is cleared to "0" by the INTSBE0 interrupt service program or when the <SIOINH> is set to "1". If <SIOS> is cleared to "0", received data is transferred to the SBI0DBR in complete blocks. The received mode ends when the transfer is complete. In order to confirm whether data is being received properly by the program, the SBI0SR<SIOF> to be sensed. The <SIOF> is cleared to "0" when receiving is complete. When it is confirmed that receiving has been completed, the last data is read. When the <SIOINH> is set to "1", data receiving stops. The <SIOF> is cleared to "0" (the received data becomes invalid, therefore no need to read it).

Note: The transfer mode needs to be changed, after reading the last received data with instruction to finish data receiving by clearing the <SIOS> to "0".

www.datashee

Figure 3.10.41 Receiver Mode (example: Internal clock)

iii) 8-bit transmit/receive mode

Set a control register to a transmit/receive mode and write data to the SBI0DBR. After the data is written, set the SBI0CR<SIOS> to "1" to start transmitting/receiving. When data is transmitted, the data is output from the SO0 pin, starting from the least significant bit (LSB) and synchronized with the falling edge of the serial clock signal. When data is received, the data is input via the SI0 pin on the rising edge of the serial clock signal. 8-bit data is transferred from the shift register to the SBI0DBR and the INTSBE0 interrupt request is generated. The interrupt service program reads the received data from the data buffer register and writes the data which is to be transmitted. The SBI0DBR is used for both transmitting and receiving. Transmitted data should always be written after received data is read.

When the internal clock is used, the automatic wait function will be in effect until the received data is read and the next data is written.

When the external clock is used, since the shift operation is synchronized with the external clock, the received data is read and transmitted data is written before a new shift operation is executed. The maximum transfer speed when the external clock is used is determined by the delay time between the time when an interrupt request is generated and the time at which received data is read and transmitted data is written. When the transmit is started, after the SBI0SR<SIOF> goes "1" output from the SO0 pin holds final bit of the last data until falling edge of the SCK0.

Transmitting/receiving data ends when the <SIOS> is cleared to "0" by the INTSBE0 interrupt service program or when the SBI0CR1<SIOINH> is set to "1". When the <SIOS> is cleared to "0", received data is transferred to the SBI0DBR in complete blocks. The transmit/receive mode ends when the transfer is complete. In order to confirm whether data is being transmitted/received properly by the program, set the SBI0SR to be sensed. The <SIOF> is set to "0" when transmitting/receiving is completed. When the <SIOINH> is set to "1", data transmitting/receiving stops. The <SIOF> is then cleared to "0".

Note: When the transfer mode is changed, the contents of the SBI0DBR will be lost. If the mode must be changed, conclude data transmitting/receiving by clearing the <SIOS> to "0", read the last data, then change the transfer mode.

Figure 3.10.42 Transmit/Received Mode (Example : Internal clock)

Figure 3.10.43 Transmitted Data Hold Time at End of Transmit/Receive

3.11 Serial Expansion Interface (SEI)

3.11.1 Overview

The SEI is one of the serial interfaces built in the TMP92CD54I, which can be connected to peripheral devices, by full duplex synchronous communication protocol. TMP92CD54I incorporates 1 channel of this SEI. Also the SEI can support the micro DMA mode corresponds to the micro DMA transfer.

(1) Features

- The master outputs the shift clock only during data transfer.
- The clock polarity and phase are programmable
- The data is 8 bits long
- The MSB first or LSB first can be selected
- Micro DMA mode support for micro DMA transfers
- Transfer rate: 4Mbps, 2Mbps or 500kbps (when operating at fc = 20MHz)
- Error detection function
- ① Write collision detection: when write to the shift register during the data transfer
- 2 Overflow detection: when receive the new data with the transfer end flag is set (only slave)
- ③ Mode fault detection: when the input to the SS pin goes L in Master mode (driver output immediately turns off)

Figure 3.11.1 SEI Block Diagram

Table 3.11.1	Pin Function	of SEI Channels

SEI						
	SS MOSI MISO SECLK	(PM0) (PM1) (PM2) ((PM3)				

3.11.2 SEI operation

During a SEI transfer, data is simultaneously transmitted (shifted out serially) and received serially (shifted in serially). In order to shift or sample the information on two serial data lines (MOSI/MISO), SEI clock (SECLK) takes the synchronization. Slave selection line (\overline{ss}) individually selects the slave device. The slave device not selected cannot use the SEI bus. Because the master function is turned off in the master device when the multi master bus is connected, slave selection line (\overline{ss}) can be used.

(1) SEI clock phase and polarity controls

Software can select any four combinations of serial clock phase and polarity using two bits in the SEI control register (SECR). The clock polarity is set by < CPOL > bit, and selects the clock of active "H" or active "L". The clock phase <CPHA> control bit selects one of two fundamentally different transfer formats. The clock phase and polarity should be identical for the master SEI device and the communicating slave device.

(2) SEI data and clock timing

The programmable clock timing and data of SEI can connect almost all devices around synchronous serial. Please see "3.11.4 SEI transfer format" for a detailed description of the transfer format.

3.11.3 SEI signal lines

There are four input/output pin signals associated with the SEI transfer. Every signal depends on the mode (master/slave) of the SEI device.

(1) SECLK

The SECLK pin functions as an output pin when the SEI is set for master and functions as an input pin when the SEI is set for slave.

When the SEI is set for master, the SECLK signal is supplied by the internal SEI clock generation circuit. When the master starts transferring data, eight cycles clock are automatically output at the SECLK pin.

When the SEI is set for slave, the SECLK pin functions as an input pin, in which case the SECLK signal from the master synchronizes data transfers between the master and slave. The slave device ignores the SECLK signal if the slave select \overline{SS} pin is high.

In both master and slave SEI devices, data is shifted in or out at each rising or falling edge of the SECLK signal and is sampled at the opposite edge. Edge polarity is determined by the SEI transfer protocol.

(2) MISO/MOSI

The MISO and MOSI pins are used for transmitting and receiving serial data.

When the SEI is configured as a master, MISO is the data input line and MOSI is the data output line.

When the SEI is configured as a slave, these pins reverse roles.

In a multiple-master system, all SECLK pins are tied together, all MOSI pins are tied together and all MISO pins are tied together. Refer to Figure 3.11.5. A single SEI device is configured as a master, all other SEI devices on the SEI bus are configured as slaves. The single master drives the transfer clock and data out it's SECLK and MOSI pins to the SECLK and MOSI pins of the slaves. One selected slave device optionally drives data out it's MISO pin to the MISO master pin.

The SECLK, MISO and MOSI pins can be set to function as open-drain pins.

(3) SS

The $\overline{\mathrm{SS}}$ pin behaves differently on master and slave devices.

On a slave device, this pin is used to enable the SEI slave for transfer and receive. If the \overline{SS} pin of a slave is inactive (high), the device ignores SECLK clocks and keeps the MISO output pin in the high-impedance state.

On a master device, the \overline{SS} pin serves as an error-detection input for the SEI. If the \overline{SS} pins go low while the SEI is a master, it indicates that some other device on the SEI bus is attempting to be master. This attempt causes the master device sensing the error to immediately exit the SEI bus to avoid potentially damaging driver contentions. This error is called mode fault.

Set whether to permit the mode fault detection by < MODE > bit of the SECR register or to prohibit it. When the <MODE> bit = 0, the \overline{SS} pin is enabled for mode fault detection input. When the <MODE> bit = 1, the \overline{SS} pin is disabled from mode fault detection input.

3.11.4 SEI transfer format

The transfer format is decided the setting of the <CPHA> bit and <CPOL> bit in the SECR register. <CPHA> bit switches between two different transfer protocols.

(1) Transfer Format of <CPHA>=0

Figure 3.11.2 Transfer Format of <CPHA>=0

<CPHA>=0

	No communication (idle) SECLK level	Data shift	Data sampling
<cpol>=0</cpol>	L	Shift clock falling edge	Shift clock rising edge
<cpol>=1</cpol>	Н	Shift clock rising edge	Shift clock falling edge

In master mode, writing new data to the SEDR register starts the transfer. The new data are switched on the MOSI pin half a clock before the shift clock starts the operation. SECR<BOS> selects whether the data are shifted out from the MSB or from the LSB. After the final shift cycle, the <SEF> flag is set to 1 if Compatibility mode is selected, and the <TSRC> and <TSTC> flags are set to 1 if Micro DMA mode is selected.

In slave mode, writing to the SEDR register is prohibited while the \overline{SS} pin is L. Attempting a write during this period triggers a write collision and sets the SESR register's <WCOL> flag to 1. This terminates the transfer. At this time the software must wait until the \overline{SS} pin goes H again before writing the next data to the SEDR register, even if the <SEF> or <TSRC> flag is set to 1. When using micro DMA for transferring data to the SEDR register in slave mode, the setting of the <TSTC> flag is delayed until the \overline{SS} pin goes H.

(2) Transfer format of <CPHA>=1

Figure 3.11.3 shows the transfer format for a <CPHA>=1 transfer.

Figure 3.11.3 Transfer Format of <CPHA>=1

<CPHA>=1

	No communication (idle) SECLK level	Data shift	Data sampling
<cpol>=0</cpol>	L	Shift clock rising edge	Shift clock falling edge
<cpol>=1</cpol>	Н	Shift clock falling edge	Shift clock rising edge

In master mode, writing new data to the SEDR register starts the transfer. The new data are switched on the MOSI pin at the initial edge of the shift clock. SECR<BOS> selects whether the data are shifted out from the MSB or from the LSB.

In contrast to slave mode with $\langle CPHA \rangle = 0$, in slave mode when $\langle CPHA \rangle = 1$, the SEDR register can be written even while the \overline{SS} pin is L. In both master and slave modes, after the final shift cycle the $\langle SEF \rangle$ flag is set to 1 if compatibility mode is selected, and the $\langle TSRC \rangle$ and $\langle TSTC \rangle$ flags are set to 1 if micro DMA mode is selected.

Attempting a write to the SEDR register during a data transfer triggers a write collision. Write the data to the data to SEDR after the <SEF> is set to 1, or the <TSRC> and <TSTC> flags are set.

3.11.5 Functional description

Figure 3.11.4 shows master-to-slave connection via the SEI.

The different nodes on a SEI bus function like a distributed shift register. When data is sent from the MOSI pin of the master device to the corresponding pin of the slave device, data from the slave is sent back from the MISO pin of the slave device to the corresponding pin of the master device.

This means that data is communicated in full-duplex mode and data output and data input are synchronized by the same clock signal. After a transfer, the transmission data of eight bit shift register is replaced with receive data.

Figure 3.11.4 Connection between Master and Slave in SEI

Figure 3.11.5 shows a configuration of the SEI system.

The port used as the output of SEI, can be set for open-drain output programmable. Therefore, this port can be connected to multiple devices.

Figure 3.11.5 Configuration of SEI System (Comprised of One Master and Two Slaves)

3.11.6 Operation Modes

SEI allows the programmer the choice between 2 different operation modes, the compatibility mode and the micro DMA mode. Those operation modes differ in terms of flag clearing, interrupt generation and use propriety of micro DMA. The table below shows the differences between the two operation modes.

	compatibility mode	micro DMA mode
error flag clearing	Reading a register with the Status flag set, followed by SECR register or SEDR register access	Writing a "1" to the status register
transfer status flag clearing	Reading a register with the Status flag set, followed by an access to the data register	Writing a "1" to the status register or by reading or writing the data register
interrupt generation	INTSEM: <modf> INTSEE: <sef></sef></modf>	INTSEM: <modf> INTSEE: <wcol> or <sovf> INTSER: <tsrc> INTSET: <tstc></tstc></tsrc></sovf></wcol></modf>
micro DMA usage	No	yes

Table 3.11.2	Differences	between the	Two O	peration	Modes
	Differences		1 100 0	peration	moucs

SEI can be switched between these operation modes, if SEI is disabled (<SEE> = 0) by setting the <TMSE> bit in the SESR register.

3.11.7 SEI registers

Use SEI control register SECR, SEI status register SESR, and SEI data register SEDR to set SEI.

<SEF>: Transfer complete flag

Compatibility mode:

The <SEF> flag is automatically set to one at the end of a SEI transfer. The <SEF> flag is automatically cleared to 0 by reading the SESR register with <SEF> flag set to 1, followed by an access of the SEDR register.

Micro DMA mode:

Always reads as undefined, writes to this flag have no effect.

<WCOL>: Write collision error flag

Compatibility mode:

The <WCOL> flag is automatically set to 1, if the SEDR register is written while a transfer is in progress. The write itself has no effect on the running transmission. The <WCOL> flag is automatically cleared to 0 by reading the SESR register with <WCOL> bit set followed by an access to the SEDR register. No interrupt will be generated on the assertion of this flag.

Micro DMA mode:

The <WCOL> flag is automatically set to 1, if the SEDR register is written while a transfer is in progress. The write itself has no effect on the running transmission. The flag can only be reset by writing a "1" to it. Writing a "0" has no effect. An interrupt will be generated on INTSEE on a transition from "0" to "1", if the module is configured as a slave and the <TASM> bit is equal to "0".

www.datashee**TOSHIBA**

<SOVF>: Slave mode overflow error flag

Master mode:

Always reads as undefined, writes to this flag have no effect.

Slave mode:

Compatibility mode:

The <SOVF> flag is automatically set to 1, if a new byte has been completely received and the <SEF> flag is still set to 1. The <SOVF> flag is automatically cleared to 0 by reading the SESR register with the <SOVF> flag is set to 1 followed by an access to the SEDR register. The <SOVF> flag will also be cleared to 0 by switch to the master mode. In compatibility mode, no interrupt will be generated on the setting of <SOVF> flag.

Micro DMA mode:

The <SOVF> flag is automatically set to 1, if a new byte has been completely received and the <TSRC> flag is still set to 1. The <SOVF> flag can only be cleared to 0 by writing a "1" to it. Writing a "0" to it has no effect. INTSEE is generated with <TASM> =1, if <SOVF> flag from 0 to 1.

<MODF>: Mode-fault error flag

Master mode:

Compatibility mode:

The <MODF> flag is set to 1, if the \overline{SS} signal goes to active low while the SEI is configured as a master. In this case:

- 1. The SEI output pin drivers are disabled and the output pins are placed in high-impedance state.
- 2. The <MSTR> bit in the SECR register is cleared to 0.
- 3. The <SEE> bit is forcibly cleared to 0 to disable the SEI system.
- 4. An interrupt INTSEM is generated.

The <MODF> flag is automatically cleared to 0 by reading the SESR register with the <MODF> bit set to 1, followed by a write to SECR register.

Micro DMA mode:

It is the same as that of the compatibility mode, except the <MODF> flag's clearance.

This flag can only be cleared to 0 by writing a "1" to it. Writing a "0" to this flag has no effect.

Slave mode:

Always reads as undefined, writes to this flag have no effect.

<TSRC>: Receive completion flag

Compatibility mode:

Always reads as undefined, writes to this flag have no effect.

Micro DMA mode:

The <TSRC> flag is set to 1 when a receiving has been completed, that is when eight cycles where shifted on the SECLK signal. It is cleared to 0 by performing a read operation on the SEI data register, by switching to compatibility mode or by writing a "1" to this flag. Writing a "0" to this flag has no effect. An interrupt INTSER will be generated on the assertion of this flag.

<TSTC>: Transmit completion flag

Compatibility mode:

Always reads as undefined, writes to this flag have no effect.

Micro DMA mode:

Timing where the flag is set by transfer format and master/slave is different though < TSTC > flag is set when the transmission of the data of one byte is completed. Refer to Figure 3.11.2 and Figure 3.11.3. It is cleared to 0 by performing a write operation on the SEI data register, by switching to compatibility mode or by writing a "1" to this flag. Writing a "0" to this flag has no effect. An interrupt INTSET will be generated on the assertion on this flag.

<TASM>: Automated shift mode(master) / INTSEE interrupt mask(slave)

Compatibility mode:

Always reads as undefined, writes to this flag have no effect.

Micro DMA mode:

The function of this bit is depending on <MSTR> bit setting.

Master mode:

- 0: Disables the automated shift mode.
- 1: Enables the automated shift mode.
- In this mode a read access to the SEI data register SEDR will perform the following functions.
- The SEI data register will be cleared to 00 hex.
- A new transfer will be initiated, thus in master mode 8 low bits will be sent, 8 new bits will be received.

The automated shift mode also works when it is combined with a micro DMA. It has no effect, when SEI is in the slave mode.

Slave mode:

This bit functions as a mask for the interrupt INTSEE generation of the <SOVF> and <WCOL> flags.

- 0: An interrupt INTSEE will be generated when the <WCOL> flag is set to "1", but not effect on the <SOVF> flag.
- 1: An interrupt INTSEE will be generated when the <SOVF> flag is set to "1", but not effect on the <WCOL> flag.

<TMSE>: SEI mode select

0: Compatibility mode.

1: Micro DMA mode.

Selects the micro DMA mode, which also allows micro DMA transfers. It is necessary to disable the SEI system before switching to the micro DMA mode.

www.datashee

(3) SEI data register (SEDR)

				SEI Data	a Register				
SEDR		7	6	5	4	3	2	1	0
(Transmission)	bit Symbol	SED7	SED6	SED5	SED4	SED3	SED2	SED1	SED0
(0062H)	Read/Write				V	V			
	After reset	0	0	0	0	0	0	0	0
SEDR		7	6	5	4	3	2	1	0
(Receiving)	bit Symbol	SED7	SED6	SED5	SED4	SED3	SED2	SED1	SED0
(0062H)	Read/Write				F	2			
	After reset	0	0	0	0	0	0	0	0

Note: SEDR is not able to read, modify, write.

This register is used to transmit and receive data. When the SEI system configured as a master, transfers are started by a software write to the SEDR register.

After once starting transmission, please write after checking that the transmission end flag has surely set by interrupt or polling when master device writes to SEDR register.

Only when the <SEE> bit of the SECR register is "1", a read/write to the SEDR register is possible. When the <SEE> bit is "0", the write access is ignored and "00H" will be read whenever it read.

3.11.8 SEI system errors

Three system errors can be detected by the SEI device. The first type error arises in a multiple-master system when more than one SEI device simultaneously tries to be master. This error is called a mode fault. The second type error, a write collision, indicates that an attempt has been made to write data to the SEDR while a transfer was in progress. The third error occurs when the SEI system is configured as a slave and a new byte of data has been completely shifted in by the remote bus master before the old byte could be read.

(1) Mode-fault error

In the SEI system, if more than one device is simultaneously set as the master, competition arises among the drivers.

When an SEI device is set as the master, a mode fault error occurs when the \overline{SS} pin input goes L and the driver output goes off. This phenomenon can be used to avoid competition among masters.

When a mode fault error occurs, the following action is immediately taken.

- The SECR register's <MSTR> bit is forcibly cleared to 0 to set the SEI for slave.
- The SECR register's <SEE> bit is forcibly cleared to 0 to disable the SEI system.
- The SESR register's <MODF> flag is set to 1, and INTSEM interrupt pulse is generated.
- The SEI output pin drivers are disabled and the output pins are placed in the high-impedance state.

When the problem which has caused the mode fault is resolved in software, the <MODF> flag is cleared to 0 and the SEI system can be set up to return to normal operation. The writing is not able to the SECR register while the <MODF>flag is set. In compatibility mode the <MODF> flag is automatically cleared by reading the SESR register while the <MODF> flag is set to 1, and then writing to the SECR register. In micro DMA mode the <MODF> flag is cleared to 0 by writing a 1 to it.

Only when two or more devices are selected at the same time as the master, this product detects a mode fault error. The collision of the MISO output when two or more slave devices are selected on the SEI system cannot be detected.

The drivers can be protected from latch-up by means of an open-drain. This involves changing the SEI output driver to be of open-drain type. The SECLK pin, MOSI pin and MISO pin can be individually set as open-drain programmably. In the case, an additional external pull-up register is necessary.

(2) Write collision error

A write collision occurs is the SEDR register is written to while a transfer is in progress. Because the SEDR register is not a double buffer in the direction of the transmission, writing before transfer in the SEDR register is writing directly in the SEI shift register. Because this write corrupts any transfer in progress, a write collision error is generated. The transfer continues undisturbed and the write data which caused the error is not written to the shift register.

A write collision is normally a slave error because a slave has no control over when a master will initiate a transfer. A master knows when a transfer is in progress, thus, there is no excuse for a master generating a write collision error. Despite this, the SEI device can detect write collision in a master as well as in a slave.

In slave mode a write collision is likely to occur, since the master shifts data faster, than it can be handled by the slave. A write collision will occur, when the slave is transferring a new value to the data register after the master started the next shift cycle.

In micro DMA mode an interrupt on INTSEE will occur if the module is configured as a slave, the <TASM> bit is clear to 0 and the <WCOL> flag is set to 1.

(3) Slave mode overflow error

On an SEI bus the transmission bit rate is determined by the master. It becomes easy to cause the problem that the slave cannot follow to the master's transmission by a high-speed bit rate, i.e. that the data is shifted in faster than it can be processed by slave. The SEI device detects data overflowing with < SOVF > flag of the SESR register.

The <SOVF> flag will be set to 1 when:

- The SEI is configured as a slave.
- An old byte of data is still waiting to be read when a new byte of data has been completely received.

When <SOVF> is set to 1, it signifies that SEDR has been overwritten by new byte data.

Since this error only occurs in slave mode, the <TASM> bit can be used as an interrupt mask for this flag. If the <SOVF> flag in the status register is set to 1, an interrupt is only generated on INTSE0 if the current mode is micro DMA mode and the <TASM> bit is 1.

3.11.9 Interrupt generation

Interrupt processing differs for the two SEI operating modes, which can be selected using the <TMSE> bit in the SESR register. It generates four interrupts par one SEI that are INTSEM, INTSEE, INTSER and INTSET.

(1) Compatibility mode

In compatibility mode the INTSEM* and INTSEE are used. *The SEI generates the INTSEM interrupt, if the <MODF> flag in the SESR register shows a transition from "0" to "1". And it generates the INTSEE interrupt, if the <SEF> flag shows a transition from "0" to "1".

INTSEM	Interrupt on <modf></modf>
INTSEE	Interrupt on <sef></sef>
INTSER	Inactive
INTSET	Inactive

(2) Micro DMA mode

In micro DMA mode all four interrupts are used to allow the micro DMA transfers to and from the SEI data register. The INTSEM is generated on a transition of the <MODF> flag from "0" to "1". The INTSEE is generated if the module is in slave mode on a transition of the <WCOL> flag from "0" to "1" with <TASM> bit is "0" or on a transition of the <SOVF> flag from "0" to "1" with <TASM> bit is "1".

After a completed transfer both the <TSRC> flag and the <TSTC> flag in the SESR register are set to 1 simultaneously. However, there is an exception for <CPHA> equals "0" in slave mode. Please see "3.11.4(1) transfer format of <CPHA>=0". Both flags trigger the INTSER and INTSET interrupts.

The <TSRC> flag generates an interrupt INTSER on a transition from "0" to "1". The <TSRC> flag can be cleared by either reading the SEDR register or by writing a "1" value to this flag.

The <TSTC> flag generates an interrupt INTSET on a transition from "0" to "1". The <TSTC> flag is cleared to 0 by either writing the SEDR register or by writing a "1" value to this flag.

In order to use the micro DMA, the INTSER interrupt and the INTSET interrupt are used as a trigger of micro DMA transmission.

The INTSER interruption: The data read from the SEDR register is used as a trigger of micro DMA transfer. The INTSET interruption: A new data write to the SEDR register is used as a trigger of micro DMA transfer.

Thus initiating a new transfer.

INTSEM	Interrupt on <modf></modf>
INTSEE	Interrupt on <wcol>¹⁾ or <sovf>²⁾</sovf></wcol>
INTSER	Interrupt on <tsrc></tsrc>
INTSET	Interrupt on <tstc></tstc>

Note 1) In slave mode, it is at the time of <TASM> =0

Note 2) In slave mode, it is at the time of <TASM> =1

The Interrupts can be disabled individually at the interrupt controller.

www.datashee**TOSHIBA**

3.11.10 Usage of the micro DMA of SEI (micro DMA mode)

The usage of the micro DMA for larger SEI transfers allows speed up the communication on the SEI by

- reducing the CPU effort for interrupt processing,
- reducing the time gap between two successive transfers.

The micro DMA transfers can be used in both the master and the slave mode.

(1) Read/write micro DMA transfer

In this mode two micro DMA channels are used. One micro DMA channel is used to send the receive data from the SEDR register to the memory. The other micro DMA channel is used to send the new data from the memory to the SEDR register. The data transfer will be completely handled by the micro DMA controller.

Initiation

In this mode, set < TMSE > bit of the SESR register to 1 and set it to micro DMA mode. Two micro DMA channels have to be set up for the transfer. One micro DMA is triggered on the INTSER to transfer the value that was received from the SEDR register to the memory. The other micro DMA is triggered on the INTSET to write new data from the memory to the SEDR register. Restart transfer by this setting in the master mode.

The micro DMA with the lower channel has to be assigned to the INTSER interrupt since it takes precedence over the micro DMA with the higher channel number.

The micro DMA transfer is initiated the first time by writing the first transfer value to the SEDR register. The following transfers will be handled automatically by the micro DMA controller.

5		1	,
<see></see>	<mstr></mstr>	<tasm></tasm>	<tmse></tmse>
1	0:Slave	INTSEE interrupt mask	1
I	1:Master	0	I

Table 3.11.4 SEI setting when micro DMA transfer (read/write)

Micro DMA transfer

Once initiated the micro DMA wait to be triggered by a completed transfer. On a completed transfer both <TSRC> and <TSTC> flags are set to 1 and both SEI receive completed interrupt pulse INTSER and SEI transmit completed interrupt pulse INTSET are generated. Since the micro DMA channel with the lower channel number takes precedence, the read micro DMA transfer is performed before the write micro DMA transfer. The read micro DMA reads the value from the SEDR register and stores the value at the location specified within the micro DMA control registers. The read access also clears the <TSRC> flag to 0 in effect. After this the write micro DMA transfers a value from a specified memory address to the SEDR register. The write access to the SEDR register automatically clears the <TSTC> flag in the SESR register to 0 and starts a new transfer when the module is in master mode. After each micro DMA transfer the count registers for both micro DMA are decreased. This procedure continues until the counters reach the value of "0". A micro DMA interrupt will be generated to indicate the end of the micro DMA transfer. An interrupt service routine triggered on the end of the micro DMA transfer can be used to re-initiate the micro DMA transfers.

Figure 3.11.6 Flowchart for Micro DMA Read/Write Transfer

www.datashee

(2) Read only micro DMA transfer

This mode is used to shift in lager blocks of data, while "don't care data" is shifted out (e.g.: reads from serial EEPROM). Only a single micro DMA is used to store the data read from the SEDR register to a specified RAM area.

1 Initiation

For this mode the SEI has to be configured for micro DMA mode by setting the SESR<TMSE> to 1. When SEI is acting as master, the <TASM> bit has to be set additionally to allow the automated shifting. Just one micro DMA has to be set up to transfer the SEDR data to a memory location specified within the micro DMA destination address register. The SEI receive completion interrupt INTSER is used to trigger this micro DMA. The SEI transfer completion interrupt INTSET is disabled at the interrupt controller. If SEI is set up as a master, the first transfer has to be initiated by writing the SEDR register.

Table 5.11.5 OLT Setting when thick DMA transfer (read)			
<see></see>	<mstr></mstr>	<tasm></tasm>	<tmse></tmse>
1	0: Slave INTSEE interrupt mask		1
	1: Master	1	I

Table 3.11.5 SEI setting when micro DMA transfer (read)

2 Micro DMA transfer

After initiating the first transfer, the micro DMA waits for the transfer to be completed. With the completion of the transfer both the SESR<TSRC> and SESR<TSTC> are set to 1. On setting the <TSRC> to 1, the INTSER interrupt is generated to trigger the micro DMA. The <TSTC> flag will be set to 1 simultaneously and will remain set to 1 till the end of the block transfer.

The micro DMA moves the received value from the SEDR register to the memory location specified in its destination address register. After the micro DMA transfer, the count register of the micro DMA is decreased.

When the SEDR register is read, the SEDR register (shift register) is cleared to "00H" automatically because <TASM>bit is 1. Simultaneously a new transfer is started automatically. This procedure will repeat until the micro DMA counter reaches a value of "0". A micro DMA interrupt will be generated to indicate the end of the micro DMA transfer.

Moreover, about the <TSTC> flag, it remains set to 1 after the first transmission end, unless it is reset.

Figure 3.11.7 Flowchart for Micro DMA Read only Transfer

(3) Write only micro DMA transfer

The write only transfer mode is used to transmit larger blocks of data while the incoming data is ignored. Only a single micro DMA is used to transfer new transmit data from a memory location specified by the micro DMA source address register to the SEDR register.

① Initiation

For this mode the module has to be configured for micro DMA mode by setting the SESR<TMSE> to 1. One of the micro DMA channels has to be set up for the automated write to the SEDR register. This micro DMA is triggered by the SEI transmit completion interrupt INTSET. The SEI receive completion interrupt INTSER is disabled at the interrupt controller. If SEI is set up as a master, the first transfer is initiated by writing the first value to the SEDR register.

	0	(,
<see></see>	<mstr></mstr>	<tasm></tasm>	<tmse></tmse>
1	0: Slave	INTSEE interrupt mask	1
	1: Master	0	Ι

Table 3.11.6 SEI setting when micro DMA transfer (write)

2 Micro DMA transfer

After starting the first transfer the micro DMA waits for the transfer to be completed. On completion both the <TSRC> and <TSTC> flags in the SEI status register are set to 1. Disregard <TSRC>flag and <SOVF>flag because reception is not used.

After the first transmission end, the <TSRC> flag is set and it remains set to 1 unless it is reset. Once the <SOVF> flag is set to 1, the <SOVF> flag remains being 1, unless it is reset.

The <TSTC> flag generates the INTSET interrupt, which will trigger the micro DMA transfer.

The micro DMA reads a value from the memory address specified in its source register and transfers it to the SEDR register. After the micro DMA transfer, the count register of the micro DMA is decreased. The write access to the SEDR register clears the <TSTC> flag to 0 and starts a new transfer on the SEI bus when the module is in master mode. This procedure continues until the Micro DMA counter reaches a value of "0". A micro DMA interrupt will be generated to indicate the end of the micro DMA transfer.

Figure 3.11.8 Flowchart for Micro DMA Write only Transfer

3.12 CAN Controller

(1) Overview

- Supports CAN version 2.0B
- Supports standard format and extended format
- Supports data frames and remote frames in both format
- 16 Mailboxes (15 Receive & Transmit + 1 Receive only)
- Baud rate up to 1Mbps on the CAN bus (at fc = 20MHz)
- Programmable baud rate with bit time parameter
- Built in baud rate prescaler
- $\bullet~2$ selectable mechanism for internal arbitration of transmit messages
 - 1 mailbox number
 - 2 identifier priority
- Time stamp for receive and transmit messages
- Operation modes
 - 1 Normal operation mode
 - 2 Configuration mode
 - ③ Sleep mode (Wake up on CAN bus activity or CPU access)
 - ④ Halt mode
 - (5) Test loop back mode (Enable the stand alone operation by self acknowledge)
 - (6) Test error mode (Write enable to error counter)
- Acceptance filter
 - 1 Programmable global mask for mailboxes 0 to 14
 - 2 Programmable local mask for mailbox 15
- Acceptance mask bit for identifier extended bit
- Flexible interrupt structure (3 interrupts)
 - 1) INTCR: Receive interrupt
 - ② INTCT: Transmit interrupt
 - ③ INTCG: Global interrupt (include warning level, error passive, bus off, and so on)

(2) Nomenclature

- R/W Read and write access by the CPU
- R Read access by the CPU
- W Write access by the CPU
- R/S Read access and set (write with 1) by the CPU
- R/C Read access and clear (write with 1) by the CPU
- The bit Symbol " ```` " in the mailbox denotes blank bits. The values of these bits are indeterminate when read.
- The column of after Reset " " in the mailbox indicates that the initial value is indeterminate.
- The bit Symbol " " in the control register denotes reserved bits. They indicate that the value is indeterminate when read. Always write "0" when write.

(3) Architecture

Figure 3.12.1 Block Diagram of CAN Controller

(4) CAN bus interface

The interface to the Can bus is a simple two-wire line, consisting of an input pin RX and an output pin TX. This CAN bus interface is suitable for the operation with CAN bus transceivers based on ISO/DIS 11898.

3.12.1 Memory map

The mailboxes and control registers used by the CAN are mapped to the memory locations shown below.

Address	Register	Description
000200H *	MB0MI0

Table 3.12.1	CAN Mailboxes and	Control Registers
--------------	-------------------	-------------------

Note: * Read-modify-write prohibited.

www.datashe

3.12.2 Mailboxes

The mailbox is configured with Register to store identifiers and transmit/receive data, which can be accessed by the CAN controller and the CPU. The CPU controls the CAN controller by modifying the contents of the mailboxes and control registers. The contents of the mailboxes and control registers are used to perform the functions of the acceptance filtering, transmit message and interrupt handling.

In order to initiate a transfer, the transmission request bit has to be written to the corresponding register. The entire transmission procedure is done then without any CPU involvement. If a mailbox has been configured as receive messages the CPU easily reads its data registers using CPU read instructions. The mailbox may be configured to interrupt the CPU after every successful message transmission or reception.

The mailbox module provides 16 mailboxes, each of which has 8 bytes long data, 29-bit identifier and several control bits. Each mailbox, except the last one, can be set for either transmit or receive operation. Mailbox 15 is a receive-only mailbox with a special acceptance mask designed to allow groups of different message identifiers to be received. Each mailbox is 16 bytes in size.

Address	Mailboxes		
0200H to 020FH	MB0 (Used for transmit/receive)		
0210H to 021FH	MB1 (Used for transmit/receive)		
:	:		
:	:		
02E0H to 02EFH MB14 (Used for transmit/received)			
02F0H to 02FFH	MB15 (Used for receive-only)		

Each mailbox is configures as shown below.

(Mailbox "n")	b15		b0
MBn + 00H	MIO		(Message identifier field 0)
02H	MI1		(Message identifier field 1)
04H	M	ICF	(Message control field)
06H	D1	D0	(Data field 0,1)
08H	D3	D2	(Data field 2,3)
0AH	D5	D4	(Data field 4,5)
0CH	D7	D6	(Data field 6,7)
0EH	TSV		(Time stamp value)
Note: MBn = 0	200H + n × 10H, n =	0, 1, 2,, 15	

The components of each mailbox are explained in the next pages.
Message Identifier Field 0 (MI0)

The priority of a message ID becomes so high that 0 continues from the MSB (<ID28> bit) of ID.

Note: When ID of the received remote frame is corresponding to ID of the transmission mailbox <RFH>=1 and <GAME>=1, ID of remote frame is overwritten to this mailbox. Afterward, it responds applying overwritten ID automatically.

In the case of a receiving mailbox, there is no necessity for an initial configuration. RTR and DLC of the received message are stored in the MCF register. In the case of a transmitting mailbox, please set at the initial configuration.

www.datashe

Data field (D0 to D7)

This is a read/write register that stores up to 8 bytes of transmit/receive data. However, in the case of receive mailboxes, the write access to the data field is disabled.

For transmit, data in a length of bytes set by the mailbox's data length code is transmitted.

For receive, the data length code in the receive message is copied to the mailbox's data length code, so that the byte in a length equal to this data length code is receives as valid data.

Mailbox configuration register (MC)

Each bit corresponds to mailbox 0 through 15.

Each mailbox can be enabled or disabled.

Read/Write

After reset

Mailbox direction register (MD)

When <MCn > = 0, access to mailbox "n" is disabled.

0

0

When <MCn> = 1, access to mailbox "n" is enabled.

Set the mailbox ID at the initial configuration. Before rewriting the mailbox's MI0 or MI1 field, be sure to clear the <MC> bit to disable the corresponding mailbox. However, when <MC> bit is cleared to 0 during reception, the reception is stopped immediately. When a mailbox is transmitting (<TRS>=1), please rewrite the MI0 or MI1 field after transmission is completed (<TRS>=0).

The transmit mailbox data and control fields can be accessed for write at any time. However, in the case of transmit mailboxes with the $\langle RFH \rangle$ bit is set to 1, the write access to the message control field is enabled during the $\langle MC \rangle$ bit is cleared to 0.

	Malibox Direction Register Low

	Read/Write	R				R/W					
	After reset	1	0	0	0	0	0	0	0		

Each bit corresponds to mailbox 0 through 15.

Each mailbox except mailbox 15 can be directed for transmit or receive.

When $\langle MDn \rangle = 0$, the mailbox MBn is directed for transmit.

When <MDn> = 1, the mailbox MBn is directed for receive.

Mailbox 15 is a receive-only mailbox, so that <MD15> bit is fixed to "1". This bit can only be read; you cannot write to it.

Set the MD register at initial configuration. When changing MD register, please carry out after clearing <MCn> bit of a corresponding mailbox.

Transmission request set register (TRS)

prohibited.

Each bit corresponds to mailboxes 0 through 15. Since mailbox 15 is a receive-only mailbox, bit 15 is nonexistent.

If after writing data and identifier to mailbox "n" that has directed for transmit ($\langle MDn \rangle = 0$) the $\langle TRSn \rangle$ bit is set to 1 when the said mailbox is enabled ($\langle MCn \rangle = 1$), a message is transmitted from mailbox "n". If there are multiple transmit requests, messages are transmitted sequentially. The order in which messages are transmitted depends on the master control register MCR bit 3 </

If <MTOS> bit is clear to 0, the mailbox with the lower number has the higher priority. For example: if the mailboxes MB0, MB2 and MB5 are configured for transmission and the corresponding TRS bits are set to 1, then the messages will be transmitted in the following order: MB0, MB2 and MB5. If a new transmission request is set for MB0 during the processing of MB2 then in the next internal arbitration-run MB0 will be selected for the next transmission. This will also happen, when the CAN controller loses arbitration while transmitting MB2. In this case, MB0 will be sent at the next opportunity instead of MB2.

If <MTOS> bit is set to "1", the priority of the identifier stored in the mailbox will determine the sending order. The mailbox with the higher priority identifier will be sent first. In case of a lost arbitration on the CAN bus line a new internal arbitration run will be started and the message with the highest priority will be sent at next possible time.

The <TRSn> bit is reset when transmit has succeeded or when the transmission request concerned is cleared by setting the <TRRn> bit to 1.

If transmit has failed, transmit is retried repeatedly until it succeeds or the transmission request concerned is cleared by setting the <TRRn> bit to 1.

When the <TRSn> bit is "1", the write access to the corresponding mailbox is denied.

The <TRSn> bit cannot be set from the CPU if mailbox "n" is directed for receive.

When mailbox "n" is directed for transmit, the <TRSn> bit is set by writing a "1" from the CPU and is cleared to 0 by the internal logic. Writing a "0" from the CPU has no effect.

Transmission Request Register Low

Read	Read/Write					R/S						
modify-write	After reset		0	0	0	0	0	0	0			

Transmission Request Reset Register Low

modify-write After reset instructions prohibited.

Each bit corresponds to mailboxes 0 through 15. Since mailbox 15 is a receive-only mailbox, bit 15 is nonexistent.

If the <TRRn> bit is set to "1", the transmit request that has been asserted by setting the corresponding <TRSn> bit is canceled. This cancellation takes place in one of the following three ways:

- ① If a message has not been transmitted yet, the message transmit request is canceled. (< TRSn > = 0, < TRRn > = 0, < AAn > = 1)
- (2) If a message is currently being transmitted but a lost arbitration or an error occurs, the message transmit request is cleared and transmit operation is aborted. (< TRSn > = 0, < TRRn > = 0, < AAn > = 1)
- ③ If a message is currently being transmitted and no lost arbitration or error occurs, transmit operation is completed without ever clearing the message transmit request. $(\langle TRSn \rangle = 0, \langle TRRn \rangle = 0, \langle TAn \rangle = 1)$

When the <TRRn> bit is "1", the write access to the corresponding mailbox is denied.

The <TRRn> bit cannot be set from the CPU if mailbox "n" is directed for receive.

When mailbox "n" is directed for transmit the <TRRn> bit is set by writing a "1" from the CPU and is cleared to 0 by the internal logic in case of a successful transmission or an aborted transmission. Writing a "0" from the CPU has no effect.

0

0

0

0

If the <CDRn> bit is 1, a transmission request for mailbox "n" will be ignored. That means, that a mailbox "n" with the <TRSn> and <CDRn> bit is set to 1, it will not be considered in the internal arbitration-run: the mailbox "n" is locked for transmission. The processing of mailbox "n" in the arbitration-run will be considered again after clearing the <CDRn> bit.

The <CDR> bit is useful for dealing with remote frames. It is intended for updating the data field of a transmit mailbox, which is configured for automatic reply to remote frames (the <RFH> bit is set). By using the <CDR> bit, the user can update the data field without a need of taking additional care of the data consistency.

www.datashee

(2) Receive control registers

The identifier of each incoming message is compared with the identifiers held in the mailboxes that have been directed for receive operation. The comparison of the identifiers depends on the value of the global/local acceptance mask enable bits <GAME>/<LAME> in the mailbox and the data held in the global/local acceptance mask registers GAM/LAM.

When a matching identifier is detected, the received identifier, control bits, and data bytes are written to the mailbox that has matched. At this time, the corresponding receive message pending bit <RMPn> is set and receive successful interrupt is generated if it has been enabled. Once a matching identifier is found, no other identifiers are compared.

If not match is detected, the message is rejected.

The CPU must reset the <RMPn> bit after reading the data. If a second message is received for this mailbox when the <RMPn> bit has already been set to 1, the corresponding receive message lost bit <RMLn> is set to 1. In this case, the data stored in mailbox "n" is overwritten with the new data. In this case, a global interrupt (receive message lost) is generated if it has been enabled.

Receive-only mailbox

Only if the identifier of a received message does not match any identifiers of the mailboxes 0 through 14, the identifier is compared with the identifier of the receive-only mailbox 15. When a matching identifier is detected, the contents of the received message are written to the mailbox 15.

Receive message pending register (RMP)

			Receive	Message P	ending Reg	jister Low

Receive message lost register (RML)

prohibited.

Each bit corresponds to mailbox 0 through 15.

If a second message is received by mailbox "n" for which the <RMPn> bit has been set to 1, mailbox "n" is overwritten with the new data and the <RMLn> bit is set to 1.

The <RMLn> bit is set by the internal logic and is cleared to 0 by writing a "1" to the <RMPn> bit from the CPU. Writing a "0" to <RMPn> bit and writing a "1" or "0" to <RMLn> bit from the CPU have no effect.

ID	Before	Af	ter	Operation
	<rmp></rmp>	<rmp></rmp>	<rml></rml>	
Unmotobod	Don't	No	No	The data in receive buffer hasn't been transferred to any
Unmatcheu	care	change	change	mailbox.
Matched	0	1	No change	The data in receive buffer is transferred to a mailbox which matched the identifier of incoming message. (Old data in the mailbox was read out, and cleared <rmp> to 0. Then, the mailbox is written with new data; RECEIVE MESSAGE PENDING BIT is set.)</rmp>
Macheo	1	1	1	The data in receive buffer is transferred to a mailbox which matched the identifier of incoming message (Old data is in the mailbox. Then, the mailbox is overwritten with new data; RECEIVE MESSAGE LOST BIT and RECEIVE MESSAGE PENDING BIT are set).

Table 3.12.2 Operation when message is received

(3) Handling of remote frames

If a remote frame is received, it is compared with the identifiers of all mailboxes. The comparison of identifiers depends on the value of the global/local acceptance mask enable bits <GAME>/<LAME> in the mailbox and the data held in the global/local acceptance mask registers GAM/LAM.

If a received remote frame matches the identifier of a mailbox that is directed for transmit and the <RFH> bit for that mailbox is set to 1, the <TRSn> bit is set to 1 in order to send a message in response to the remote frame. Even when there is a matching identifier, if the <RFH> bit for that mailbox is reset (even though it may be a transmit mailbox), the remote frame is not responded to.

If there is a matching identifier and this mailbox is directed for receive, the remote frame is processed as data frame, in which case the <RMP> and <RFP> bits are set.

Once a matching identifier is found, no other identifiers are compared.

ID	Mailbox	<rfh> bit</rfh>	Handling of Remote Frame
Matched	Transmit	0	Not responded to.
		1	Responded to. (<trs> bit is set) *Note</trs>
	Receive	1/0	Not responded to. Processed as data frame. (<rmp> and <rfp> bits are set.)</rfp></rmp>
Unmatched	Transmit/Receive	1/0	Not responded to.

 Table 3.12.3
 Operation when Remote Frame is Received

Note : When <GAME> = 1 of this mail box, ID of remote frame is overwritten to this mailbox. and carries out an automatic response by new ID.

Remote frame pending register (RFP)

	Remote Frame Pending Register Low									
RFPL		7	6	5	4	3	2	1	0	
(032CH)	bit Symbol	RFP7	RFP6	RFP5	RFP4	RFP3	RFP2	RFP1	RFP0

instructions prohibited.	Remote Frame Pending Register High									
RFPH		15	14	13	12	11	10	9	8	
(032DH)	bit Symbol	RFP15	RFP14	RFP13	RFP12	RFP11	RFP10	RFP9	RFP8	
Read	Read/Write				R/	۲C				
modify-write	After reset	0	0	0	0	0	0	0	0	
instructions prohibited.										

When a remote frame is received by mailbox "n" directed for receive the corresponding <RFPn> and <RMPn> bits are set. The <RFPn> bit is cleared to 0 by writing a "1" to the <RMPn> bit. Writing a "0" has no effect. Also, the <RFPn> bit is reset automatically when the remote frame received in mailbox "n" is overwritten by a newly received data frame.

(4) Acceptance filter

The global acceptance mask registers GAM0 and GAM1 are used for filtering messages when the <GAME> bit for mailboxes 0 through 14 is set to "1". An incoming message is stored in the first mailbox with a matching identifier. Only if there is no matching identifier in the mailboxes 0 to 14, the incoming message is compared with the mailbox 15, a receive-only mailbox. The local acceptance mask registers LAM0, LAM1 are used for filtering messages when the <LAME> bit for mailbox 15 is set.

Figure 3.12.2 Acceptance Filter

	Read/Write				R/	W			
	After reset	0	0	0	0	0	0	0	0

The LAM0 and LAM1 registers are used for only filtering messages for mailbox 15. This feature allows the user to choose whether or not to locally mask any identifier bit of the incoming message for mailbox 15. Incoming messages are first checked to see if they match mailboxes 0 to 14 before being forwarded to mailbox 15.

If the <LAMn> bit is "0", messages are received only when the corresponding bit of the incoming message identifier matches that of the mailbox identifier. If the <LAMn> bit is "1", messages are received regardless of whether the corresponding bit of the incoming message identifier is "0" or "1". The GAM0 and GAM1 registers do not affect mailbox 15.

For messages in extended format, the identifier extension <IDE> bit and the whole 29bits of the identifier are compared. For messages in standard format, only the <IDE> bit and the first 11bits of the identifier (<ID28> to <ID18>) are compared.

The <LAMI> bit (local acceptance mask identifier extension bit) is used to mask the <IDE> bit of mailbox 15.

If the <LAMI> bit is "0", messages in extended or standard format are received according to the <IDE> bit of mailbox 15.

If the <LAMI> bit is "1", messages in both extended and standard formats are received regardless of whether the <IDE> bit of mailbox 15 is "0" or "1". For messages in extended format, the whole 29bits of the mailbox identifier and the whole 29 mask bits of the LAM register are used for filtering. For messages in standard format, only the first 11bits of the mailbox identifier (<ID28> to <ID18>) and the first 11 bits of the LAM register (<LAM28> to <LAM18>) are used for filtering.

Please perform the setup of LAM0 and LAM1 at initial configuration. Please do not change a setup during operation. When setting change is performed during reception, receiving message ID is compared for the receiving mask information in the middle of setting change.

GAM0L		7	6	5	4	3	2	1	0

	Read/Write				R/	W			
	After reset	0	0	0	0	0	0	0	0

The GAM0 and GAM1 registers are used for filtering messages for mailbox 0 to 14.

If the <GAME> bit for mailboxes 0 to 14 is set to 1 the GAM0 and GAM1 registers are used for incoming messages. A received message is stored in only the first mailbox with a matching identifier.

If the <GAMn> bit is "0", messages are received only when the corresponding bit of the incoming message identifier matches that of the mailbox identifier. If the <GAMn> bit is "1", messages are received regardless of whether the corresponding bit of the incoming message identifier is "0" or "1".

For messages in extended format, the identifier extension <IDE> bit and the whole 29bits of the identifier are compared. For messages in standard format, only the <IDE> bit and the first 11bits of the identifier (<ID28> to <ID18>) are compared.

The <GAMI> bit (global acceptance mask identifier extension bit) is used to mask the <IDE> bits of mailbox 0 to 14.

If the <GAMI> bit is "0", messages in extended or standard format are received according to the <IDE> bits of mailbox 0 to 14.

If the <GAMI> bit is "1", messages in both extended and standard formats are received regardless of whether the <IDE> bits of mailbox 0 to 14 are "0" or "1". For messages in extended format, the whole 29bits of the mailbox identifier and the whole 29 mask bits of the GAM register are used for filtering. For messages in standard format, only the first 11bits of the mailbox identifier (<ID28> to <ID18>) and the first 11 bits of the GAM register (<GAM28> to <GAM18>) are used for filtering.

Please perform the setup of GAM0 and GAM1 at initial configuration. Please do not change a setup during operation. When setting change is performed during reception, receiving message ID is compared for the receiving mask information in the middle of setting change.

(5) Control registers

Master control register (MCR)

			Ma	aster Contro	ol Register I	_OW			
MCRL		7	6	5	4	3	2	1	0
(0318H)	bit Symbol	CCR	SMR	HMR	WUBA	MTOS		TSCC	SRES
	Read/Write			R/W				V	V
	After reset	1	0	0	0	0		0	0

Master Control Register High

MCRH		15	14	13	12	11	10	9	8
(0319H)	bit Symbol							TSTLB	TSTERR
	Read/Write							R/	W
	After reset							0	0

TSTLB: Test Loop Back

- 0: Cancels the test loop back mode. (Normal operation)
- 1: Requests the test loop back mode.
- This mode supports stand-alone operation.

TSTERR: Test Error

- 0: Cancels the test error mode. (Normal operation)
- 1: Requests the test error mode.
 - In this mode it is possible to write the error counter register CEC.

CCR: Change Configuration Request

- 0: Cancels the configuration mode. (Normal operation)
- 1: Request the configuration mode.
 - This mode allows for writing to the bit configuration registers BCR1, BCR2.

SMR: Sleep Mode Request

- 0: The sleep mode is not requested. (Normal operation)
- 1: Requests the sleep mode.
 - When this mode is entered, the CAN controller clock stops oscillating and the error counter and transmit requests are cleared.

HMR: Halt Mode Request

- 0: Cancels the halt mode. (Normal operation)
- 1: Requests the halt mode.
 - When this mode entered, the CAN controller does no longer transmit and receive

messages. It only sends error and acknowledge flags.

WUBA: Wake Up on Bus Activity

- 0: Wakes up the module only by detecting a write access to the MCR register.
- 1: Wakes up the module when active bus state is detected or by detecting a write access to the MCR register.
- MTOS: Mailbox Transmission Order Select
 - 0: Mailbox transmission order by mailbox number. The mailbox with the lower number will be sent first.
 - 1: Mailbox transmission order by identifier priority. The mailbox with the higher priority identifier will be sent first.

TSCC: Time Stamp Counter Clear

0: No effect

1: The time stamp counter will be cleared to 0.

Note 1: This is a write-only bit; it is always "0" when read.

Note 2: The time stamp counter is also cleared to 0 by a write to the TSP register, or writing a "0" to the TSC register.

SRES: Software Reset

0: No effect

1: Resets the CAN controller in software. All internal registers are initialized.

Note: This is a write-only bit; it is always "0" when read.

							10	3×1	ISCL
							11	4×1	ISCL

The bit length is determined by parameters TSEG1, TSEG2, and BRP. All CAN controllers on the CAN bus must operate at the same baud rate. If individual CAN controllers operate with different frequencies the baud rate has to be adjusted by the mentioned parameters. In the bit timing logic, the conversion of the parameters to the required bit timing is materialized. The configuration registers BCR1 and BCR2 contains the data about the bit timing.

The length of TSCL is defined by:

 $\label{eq:tscl} \text{TSCL} = (\text{<BRP7:0>+1}) \ / \ f_{\text{IO}} \qquad (f_{\text{IO}} = \text{fc divided by 2})$

 f_{IO} is used to the CAN controller system clock frequency (input clock of the CAN controller).

The length of one bit is determined by the equation below:

1 Bit Time = SYNCSEG+TSEG1+TSEG2

1 bit time is equal or greater than $10 \div f_{IO}$.

The synchronization segment SYNCSEG has always the length of 1 × TSCL.

The length of TSEG1 should be equal or greater than the length of TSEG2.

TSEG1 \geq TSEG2.

The baud rate is defined by:

Baud rate = $f_{IO} \div [(\langle BRP7:0 \rangle + 1) \times ((\langle TSEG13:10 \rangle + 1) + (\langle TSEG22:20 \rangle + 1) + 1)]$

IPT (information processing time) is the time segment starting with the sample point reserved for processing of the sampled bit level. IPT is equal to $3 f_{IO}$ clock cycles.

The parameter SJW (2bit) indicates by how many units of TSCL is allowed to be lengthened or to be shortened when re-synchronizing. Values between 1 (SJW = 00b) and 4 (SJW = 11b) are adjustable. The bus line is re-synchronized at each falling edge. The maximum length of SJW is equal to the length of TSEG2.

SJW \leq TSEG2

With the corresponding bit timing, it is possible to reach a multiple sampling of the bus line at the sample point by setting $\langle SAM \rangle$ bit. The level determined by the CAN bus then corresponds to the result from the majority decision of the last three values. The three-time sampling is not allowed for $\langle BRP7:0 \rangle < 4$. For $\langle BRP7:0 \rangle < 4$ always a one-time sampling will be performed regardless of the value of $\langle SAM \rangle$ bit.

<brp7:0></brp7:0>	TSCL length (CAN clock cycles : f _{IO})	IPT length (CAN clock cycles : f _{IO})	TSEG2 minimum length (TSCL)
0	1	3	3
1	2	3	2
> 1	<brp7:0>+1</brp7:0>	3	2

There is a restriction as follows:

www.datashea405HIBA

Example1:

A transmission rate of 1Mbps will be adjusted, i.e. a bit has a length of 1μ s. The CAN input clock frequency f_{IO} is 10MHz. The baud rate prescaler is set to "0". That means a bit for this data transmission rate has to be programmed with a length of 10×TSCL. Since SYNCSEG is 1×TSCL, it is set as 9×TSCL by TSEG1+TSEG2.

E.g. <BRP7:0> = 00H

<TSEG13:10> = 0100B (5 × TSCL) <TSEG22:20> = 011B (4 × TSCL)

In this case, sampling point is 60%. With this setting a threefold sampling of the bus is not possible ($\langle BRP7:0 \rangle < 4$), thus SAM = 0 should be set. SJW is not allowed to be greater than TSEG2, so the maximum value could be set to $\langle SJW1:0 \rangle = 11B$ ($4 \times TSCL$)

Example2:

```
Baud rate : 500kbps (1 bit time = 2 \mu s)
Sampling point : 80%
f_{IO} : 10MHz
```

```
(a) In case of \langle BRP7:0 \rangle = 00H
```

```
\begin{split} \text{TSCL} &= (<& \text{BRP7:0>+1}) / \text{f}_{\text{IO}} = 1 / 10 \text{MHz} = 100 \text{ns} \\ 1 \text{ bit time} &= 2 \, \mu \, \text{s} / 100 \text{ns} = 20 \times \text{TSCL} \\ &<& \text{TSEG13:10>} = 1110 \text{B} (15 \times \text{TSCL}) \\ &<& \text{TSEG22:20>} = 011 \text{B} (4 \times \text{TSCL}) \end{split}
```

```
(b) In case of \langle BRP7:0 \rangle = 01H
```

$$\begin{split} \text{TSCL} &= (<& \text{BRP7:0>+1}) \ / \ \text{f}_{\text{IO}} = 2 \ / \ 10 \text{MHz} = 200 \text{ns} \\ 1 \ \text{bit time} = 2 \ \mu \ \text{s} \ / \ 200 \text{ns} = 10 \times \text{TSCL} \\ <& \text{TSEG13:10>} = 0110 \text{B} \ (7 \times \text{TSCL}) \\ <& \text{TSEG22:20>} = 001 \text{B} \ (2 \times \text{TSCL}) \end{split}$$

Example3:

```
Baud rate : 500kbps (1 bit time = 2 µ s)
Sampling point : 85%
f<sub>IO</sub> : 10MHz
```

(a) In case of $\langle BRP7:0 \rangle = 00H$

```
\begin{split} \text{TSCL} &= (<& \text{BRP7:0>+1}) \ / \ \text{f}_{\text{IO}} = 1 \ / \ 10 \text{MHz} = 100 \text{ns} \\ 1 \ \text{bit time} = 2 \ \mu \ \text{s} \ / \ 100 \text{ns} = 20 \times \text{TSCL} \\ <& \text{TSEG13:10>} = 1111 \text{B} \ (16 \times \text{TSCL}) \\ <& \text{TSEG22:20>} = 010 \text{B} \ (3 \times \text{TSCL}) \end{split}
```

(b) In case of $\langle BRP BRP7:0 \rangle = 01H$

 $TSCL = (\langle BRP7:0 \rangle + 1) / f_{IO} = 2 / 10MHz = 200ns$

1 bit time = 2 μ s / 200ns = 10 \times TSCL

In this case, 85% sampling point cannot be set up.

www.datashee

Time stamp feature

There is a free-running 16-bit time stamp counter TSC implemented in the CAN controller to get an indication of the time of reception or transmission of messages. The content of the TSC is written into the time stamp value TSV of the corresponding mailbox when a received message has been stored or a message has been transmitted.

The TSC is driven from the bit clock of the CAN bus line. When the CAN controller is in configuration mode or sleep mode, the TSC will be stopped. After a reset, the TSC can be cleared to 0 by writing a value to the time stamp counter prescaler TSP. The TSC can be written and read by CPU in configuration mode and in normal operation mode.

Time stamp counter register (TSC)	
	Time Stamp Counter Register Low

					5				
TSCL		7	6	5	4	3	2	1	0
(0332H)	bit Symbol	TSC7	TSC6	TSC5	TSC4	TSC3	TSC2	TSC1	TSC0
Read	Read/Write				R/	W			
modify-write	After reset	0	0	0	0	0	0	0	0
instructions prohibited.									
			Time	Stamp Cou	nter Registe	er High			
TSCH		15	14	13	12	11	10	9	8
(0333H)	bit Symbol	TSC15	TSC14	TSC13	TSC12	TSC11	TSC10	TSC9	TSC8
Read	Read/Write				R/	W			
modify-write	After reset	0	0	0	0	0	0	0	0
instructions prohibited.									

Overflow of the TSC can be detected by the time stamp counter overflow flag $\langle TSO \rangle$ of the global status register GSR and the time stamp counter overflow interrupt flag $\langle TSOIF \rangle$ of the global interrupt flag register GIF. Both flags are cleared to 0 by writing a "1" to the corresponding bit location in GIF. There is a 4-bit prescaler for the TSC. It is the time stamp counter prescaler register TSP that stores the value to be reloaded into this prescaler. After reset, the TSP register is cleared to "0", so a value "0" is loaded into the prescaler. The TSC counter's count-up period, TTSC, is shown below: TTSC = TBIT × ($\langle TSP3:0 \rangle +1$) (TBIT : bit cycle)

(0331H)	bit Symbol								
	Read/Write								
	After reset								

To be sure, that the value of the TSC will not change during the write cycle to the mailbox, there is a hold register implemented. The value of the TSC will be copied to this register if a message has been received or transmitted successfully. The reception is successful for the receiver, if there is no error until the last but one bit of End-of-frame. The transmission is successful for the transmitter, if there is no error until the last bit of End-of-frame. (Refer to the CAN version 2.0B)

Figure 3.10.4 Time Stamp Counter

The free running time stamp counter and the time stamp hold register will be cleared in the following cases:

- After reset (hardware reset or software reset)
- When the module enters configuration mode
- When the module enters sleep mode
- When a write access to the time stamp prescaler register is performed

- 1: The CAN controller is receiving a message. That means the CAN controller is not the transmission of the message and the bus is not idle.
- TM: Transmit Mode
 - 0: The CAN controller is not transmitting a message.
 - 1: The CAN controller is transmitting a message. That means the CAN controller stays

transmitter until the bus is idle or it loses arbitration.

- CCE: Change Configuration Enable
 - 0: The CAN controller is not in the configuration mode. (Normal operation)
 - 1: The CAN controller has entered the configuration mode.
- SMA: Sleep Mode Acknowledge
 - 0: The CAN controller is not in the sleep mode. (Normal operation)
 - 1: The CAN controller has entered the sleep mode.
- HMA: Halt Mode Acknowledge
 - 0: The CAN controller is not in the halt mode. (Normal operation)
 - 1: The CAN controller has entered the halt mode.
- TSO: Time Stamp Overflow Flag
 - 0: There was no overflow of the time stamp counter.
 - 1: There was at least one overflow of the time stamp counter since this bit has been cleared to 0. To clear this bit, clear the <TSOIF> bit to 0 in the GIF register.

www.datashe

BO: Bus Off Status

- 0: The CAN controller is in the bus on status. (Normal operation)
- 1: The CAN controller is in the bus off status.

There is an abnormal rate of occurrences of errors on the CAN bus. This condition occurs when the transmit error counter TEC has reached the limit of 256. During bus off no messages can be received or transmitted. The CAN controller will go to bus on automatically after the bus off recovery sequence. After entering bus off, the error counters are undefined.

EP: Error Passive Status

- 0: The CAN controller is in the error active mode. Both values of the error counters TEC and REC are less than 128.
- 1: The CAN controller is in the error passive mode. At least one of the error counters has reached the error passive status of 128.

EW: Warning Status

- 0: Both values of the error counters TEC and REC are less than or equal to 96.
- 1: At least one of the error counters is greater than 96 and reached the warning level.

CAN Error Counter Register Low

prohibited.

The CAN controller contains two error counters: receive error counter REC and transmit error counter TEC. The values of both counters can be read by the CPU. A write access to the error counters is only in the test error mode possible at the same time with the same value of lower 8bit. (<TSTERR> bit in MCR register is set). These error counters are incremented or decremented according to the CAN version 2.0B.

A controller takes the following three states according to the value of REC and TEC.

(1) Error active state (TEC < 128 and REC < 128)

The state where the error has hardly occurred

CAN controller is in an error active state after reset release.

When an error is detected, an active error flag is transmitted.

(2) Error passive state (TEC ≥ 128 or REC ≥ 128)

The state where many errors have occurred

When an error is detected, a passive error flag is transmitted.

(3) Bus off state (TEC ≥ 256)

CAN controller cannot perform the message transmission and reception to CAN bus.

Receive error counter REC is not incremented after exceeding the error passive limit (128). After the correct reception of a message when REC = 128, the counter is set to a value between 119 and 127. After reaching the bus off status, the counts are undefined.

www.datashe

CAN controller which changed to the bus off state will be in an error active state automatically, if the 11 continuous recessive bits on the CAN bus is detected 128 times. All internal flags are reset, and the error counters are cleared. The configuration registers keep the programmed values. The values of the error counters are undefined during bus off status.

When CAN controller enters configuration mode (see 3.12.4(1) Configuration mode) the error counters will be cleared to 0.

(7) Interrupt control registers

The CAN controller has the following interrupt sources:

- Transmit interrupt
 - When a message has been transmitted successfully
- Receive interrupt

When a message has been received successfully

- Remote frame pending interrupt
 - When a remote frame is received
- Wake-up interrupt When the CAN controller is awakened from sleep mode
- Receive message lost interrupt
 - When a receive message is lost
- Transmission abort interrupt When at least one of the bits in the AA register is set to 1
- Time stamp counter overflow interrupt

When the time stamp counter has overflowed

• Bus off interrupt

When the CAN controller enters the bus off mode

• Error passive interrupt

When the CAN controller enters the error passive mode

• Warning level interrupt When at least one of the two error counters is greater than 96 and reached the warning level

These interrupt sources are divided in three groups:

- Transmit interrupt (INTCT)
- Receive interrupt (INTCR)
- Global interrupt (INTCG)

There is one interrupt output line for each group. INTCR is dedicated for receive interrupts, INTCT is dedicated for transmit interrupts and INTCG for the global interrupts.

www.datashea40SHIBA

(0321H)	bit Symbol	/									
Read	Read/Write										
modify-write	After reset										

Global Interrupt Flag Register Low

instructions prohibited.

The interrupt flag bits will be set to 1 if the corresponding interrupt condition has occurred. If the corresponding interrupt mask bit is set to 1 in the GIM register, an interrupt pulse on the global interrupt line INTCG will be generated. As long as an interrupt flag in the GIF register is set to 1, if the corresponding interrupt source generates a new interrupt event, a new interrupt pulse on INTCG will not be generated. If an interrupt flag in the GIF register is set and another interrupt source generates an interrupt event, then a new interrupt pulse on INTCG will be generated.

If one or more interrupt flags have been cleared to 0 and one or more interrupt flags are still set to 1, a new global interrupt pulse INTCG will be generated.

The interrupt flags will be cleared to 0 by writing a "1" to the corresponding bit location.

RFPF: Remote Frame Pending Flag

- 0: No remote frame has been received.
- 1: A remote frame has been received (in a receive-mailbox).

This bit will not be set if the identifier of the remote frame matches to a transmit-mailbox with <RFH> set to 1.

- WUIF: Wake-Up Interrupt Flag
 - 0: The CAN controller is in the sleep mode or the normal operation mode.
 - 1: The CAN controller has left the sleep mode.
- RMLIF: Receive Message Lost Interrupt Flag
 - 0: No receive message has been lost.
 - 1: At least one of the receive-mailboxes, receive message lost has been occurred. At least one of the bits in the RML register is set to 1.
- TRMABF: Transmission Abort Flag
 - 0: No transmission has been aborted.
 - 1: Transmission has been aborted.
 - At least one of the bits in the AA register is set to 1.

TSOIF: Time Stamp Counter Overflow Interrupt Flag

- 0: There was no overflows of the time stamp counter since this bit has been cleared.
- 1: There was at least one overflow of the time stamp counter since this bit has been cleared.

www.datashe

BOIF: Bus Off Interrupt Flag

0: The CAN controller is still in the bus on mode.

1: The CAN controller has entered the bus off mode.

EPIF: Error Passive Interrupt Flag

0: The CAN controller is still in error active mode.

1: The CAN controller has entered the error passive mode.

WLIF: Warning Level Interrupt Flag

0: none of the error counters has reached the warning level.

1: At least one of the error counters has reached the warning level.

Global interrupt mask register (GIM)

			Globa	al Interrupt N	Mask Regist	er Low

(0323H)	bit Symbol	/								
	Read/Write									
	After reset									

Each interrupt flag bits in GIF register is masked by the corresponding mask bit in GIM register.

If a bit in GIM register is 0, the interrupt generation for the corresponding global interrupt event is disabled and if it is 1, the interrupt generation is enabled. After reset, all bits in GIM register are cleared to 0, there by disabling global interrupt.

www.DataSheet4U.com 2006-01-27

Mailbox interrupts

Separare interrupt outputs are provided for mailbox interrupts independently of global interrupts. These include mailbox transmit interrupt INTCT and mailbox receive interrupt INTCR that depend on mailbox settings. A mailbox transmit interrupt flag register MBTIF is provided for mailbox transmit interrupts, and a mailbox receive interrupt flag register MBRIF is provided for mailbox receive interrupts. In addition, there is a mailbox interrupt mask register MBIM that enables or disables each mailbox interrupt.

	Mailbox	interrupt	mask	register	(MBIM)
--	---------	-----------	------	----------	--------

	Mailbox Interrupt Mask Register Low											
MBIML		7	6	5	4	3	2	1	0

	Read/Write	Read/Write R/W										
	After reset	0	0	0	0	0	0	0	0			

	Mailbox Interrupt Mask Register High										
MBIMH		15	14	13	12	11	10	9	8		
(0329H)	9H) bit Symbol MBIM15 MBIM14 MBIM13 MBIM12 MBIM11 MBIM10 MBIM9 MBIM										
	Read/Write	e R/W									
	After reset 0 <th< td=""></th<>										

Each bit corresponds to mailboxes 0 through 15.

The MBIM register settings determine to enable or disable each mailbox interrupt.

If a bit in MBIM register is "0", the interrupt generation for the corresponding mailbox is disabled. If a bit in MBIM register is "1", the interrupt generation for the corresponding mailbox is enabled.

Mailbox Transmit Interrupt Flag Register Low

Mailbox transmit interrupt flag register (MBTIF)

modify-write After reset

This register is provided for mailbox transmit interrupts. Each bit in this register corresponds to mailboxes 0 through 15. The interrupt flag for mailbox 15, the <MBTIF15> flag, is nonexistent because mailbox 15 is the receive-only mailbox. If mailbox "n" is directed for receive, the corresponding interrupt flag in this register, the <MBTIFn> flag, will always be read as "0".

If a message in mailbox "n" has been transmitted successfully and the mask bit <MBIMn> is set to "1", the corresponding transmit interrupt flag <MBTIFn> will be set. If no other bit was set before in MBTIF register, transmit interrupt pulse INTCT will be generated.

If for a mailbox the mask bit in MBIM register is "0", the transmit interrupt flag in MBTIF register will not be set and no transmit interrupt pulse INTCT will be generated. The information about a successful transmission could be read from the TA register respectively.

If one or more transmit interrupt flags have been set in MBTIF register and another interrupt condition has been occurred no interrupt will be generated, but the corresponding flag in MBTIF register will be set.

If there is one or more transmit interrupt flags set after clearing one or more transmit interrupt flags, another mailbox transmit interrupt pulse INTCT will be generated.

The interrupt flags in MBTIF register will be cleared by writing a "1" from the CPU to MBTIF register. Writing a "0" has no effect.

Note that the interrupt flags in MBTIF register is checked to be 1 (active), before doing a clear-access.

modify-write	After reset	0	0	0	0	0	0	0	0	

Mailbox receive interrupt flag register (MBRIF)

instructions prohibited.

This register is provided for mailbox receive interrupts. Each bit in this register corresponds to mailboxes 0 through 15. If mailbox "n" is directed for transmit, the corresponding interrupt flag in this register, the <MBRIFn> flag, will always be read as "0".

If a message in mailbox "n" has been received successfully and the mask bit <MBIMn> is set to "1", the corresponding receive interrupt flag <MBRIFn> will be set. If no other bit was set before in MBRIF register, receive interrupt pulse INTCR will be generated.

If for a mailbox the mask bit in MBIM register is 0, the receive interrupt flag in MBRIF register will not be set and no receive interrupt pulse INTCR will be generated. The information about a successful reception could be read from the RMP register respectively.

If one or more receive interrupt flags have been set in MBRIF register and another interrupt condition has been occurred no interrupt will be generated, but the corresponding flag in MBRIF register will be set.

If there is one or more receive interrupt flags set after clearing one or more receive interrupt flags, another mailbox receive interrupt pulse INTCR will be generated.

The interrupt flags in MBRIF register will be cleared by writing a "1" from the CPU to MBRIF register. Writing a "0" has no effect.

Note that the interrupt flags in MBRIF register is checked to be 1 (active), before doing a clear-access.

3.12.4 Description of Mode

(1) Configuration mode

The CAN controller has to be initialized (set the bit configuration registers BCR1 and BDR2) before the activation. The BCR1 and BCR2 registers can only be modified when the module is in the configuration mode. After reset, the configuration mode is active and the <CCR> bit of MCR register and the <CCE> bit of GSR register are set to "1". The CAN controller can be set to the normal operation mode by writing a "0" to <CCR> bit. After leaving the configuration mode, the <CCE> bit will be set to "0" and the power-up sequence will start. The power-up sequence consists of detecting eleven consecutive recessive bits on the CAN bus line. After the power-up sequence, the CAN controller is bus on and ready for operation.

When the <CCR> bit is set to "1", the CAN controller will be entered to the configuration mode from the normal operation mode. After the CAN controller has entered the configuration mode, the <CCE> bit will be set to "1". See also the flowchart in Figure 3.12.5 Flowchart of CAN Initialization. When at the configuration mode, the error counter CEC, the time stamp counter TSC and the time stamp hold register will be cleared.

Figure 3.12.5 Flowchart of CAN Initialization

(2) Sleep mode

The sleep mode will be requested by writing 1 to the $\langle SMR \rangle$ bit of the MCR register. When the CAN controller enters the sleep mode, the status bit $\langle SMA \rangle$ of the GSR register will be set to 1.

During the sleep mode the clock of the CAN controller is switched off. Only the wake up logic will be active. The read value of the GSR register will be F040H, this means, there is no message in transmit buffer and the sleep mode is active (<SMA> bit is set to 1). Read accesses to all other registers will deliver the value 0000H. Write accesses to all registers but the MCR register will be denied.

The CAN controller leaves the sleep mode if a write access to the MCR register has been detected or there is any bus activity detected on the CAN bus line (with $\langle WUBA \rangle = 1$), the CAN controller begins its power up sequence. The CAN controller waits until detecting 11 consecutive recessive bits on the RX input line and goes to bus active after them. The first message that initiates the bus activity can not be received.

In sleep mode the CAN error counters and all 'transmission request set bits <TRSn>' and 'transmission request reset bits <TRRn> will be cleared to 0. After leaving the sleep mode, <SMR> bit in the MCR register and <SMA> bit in the GSR register will be cleared to 0.

If the CAN controller is transmitting a message when the <SMR> bit is set to 1, the CAN controller will not switch to the sleep mode immediately. It will continue until a successful transmission or after losing the arbitration, until a successful reception or until an error condition occurs on the CAN bus line. By this means the CAN controller will initiates no error condition on the CAN bus line.

(3) Halt mode

The halt mode will be requested by writing 1 to the <HMR> bit of the MCR register. When the CAN controller enters the halt mode, the <HMA> bit of the GSR register will be set. During the halt mode the CAN controller does not send or receive any messages. The CAN controller is still active on the CAN bus line. Error Flags and Acknowledge Flags will be sent. The CAN controller leaves the halt mode if the <HMR> bit is reset to 0.

If the CAN controller is transmitting a message when the <HMR> bit is set, the transmission will be continued until a successful transmission or detect a lost arbitration. So the CAN controller initiates no error condition on the CAN bus line.

(4) Test loop back mode

In this mode, the CAN controller can receive its own transmitted message and will generate its own acknowledge bit. No other CAN controller is necessary for the operation. The only supposition is that the RX and TX lines must be connected to a CAN bus transceiver or directly together.

In the test loop back mode, the CAN controller can transmit a message from one mailbox and receive it in another mailbox. The set-up for the mailboxes is the same as in the normal operation mode.

The test loop back mode shall only be enabled or disabled in the configuration mode. Figure 3.12(6) shows the flowchart of the test loop back mode / the test error mode set-up.

www.datashe**TOSHIBA**

(5) Test error mode

The error counters can only be written when the CAN controller is in the test error mode.

When the CAN controller is in the test error mode, both error counters will be written at the same time with the same value (lower 8 bit). The maximum value that can be written into the error counters is 255. Thus, the error counter value of 256 which forces the CAN controller into the bus off mode can not be written into the error counters.

The test error mode shall only be enabled or disabled in the configuration mode. Figure 3.12(6) shows the flowchart of the test loop back mode / the test error mode set-up.

Figure 3.12.6 Flowchart of the test loop back mode / the test error mode set-up

3.12.5 Functional description

(1) Transmit mode

Figure 3.12.7 shows one example of the flowchart of message transmit by using the transmit interrupt INTCT.

It is also possible to use polling instead of interrupt. In this case, "Transmit interrupt generated?" is replaced by "<TAn> = 1?". "Set <MBIMn> to 1" and "Clear <MBTIFn>" must be removed from the flow.

Figure 3.12.7 Flowchart of message transmission (Example)

(2) Receive mode

If the CAN controller has received a message from the CAN bus line, this message will be located in the receive buffer. The message stored in the received buffer will be compared to the identifier of mailbox. If <GAME>/<LAME> bit is set, the global/local acceptance mask register GAM/LAM will be used. If there is one of the following conditions found, no further compare will be done.

- Data fame and a matching identifier in a mailbox configured as receive
- Remote frame and a matching identifier in a mailbox configured as receive
- Remote frame and a matching identifier in a mailbox configured as transmit and <RFH> bit is set

The minimum time to save a next received message after the $\langle RMP \rangle$ bit set depends on the configured bit timing. In case of the data length code = 0, the minimal time is as follows.

- Standard format: 47 bit times 16 f_{IO}
- Extended format: 67 bit times 16 f_{IO}
① Data frames

Figure 3.12.8 shows one example of the flowchart of message reception by using the reception interrupt INTCR.

It is also possible to use polling instead of the interrupt. In this case, "Receive interrupt generated?" is replaced by "<RMPn> = 1?". "Set <MBIMn> to 1" and "Clear <MBRIFn>" must be removed from the flow.

Note1: Be sure to check <RMPn> and <MBRIFn>.

Note2: If "Clear <RMPn>" is executed and then the mailbox n receives the message before "Clear <MBRIFn>", <RMPn> will be set 1 (<MBRIFn>=0) depending on the situation.

Figure 3.12.8 Flowchart of message reception (Example)

2 Remote frame

Figure 3.12.9 shows one example of the flowchart the handling of remote frame by using the automatic reply feature. This feature is available when the <RFH> bit of a mailbox, which is configured for transmission is set. To avoid data inconsistency problems when updating the mailbox data the CDR register is used.

Figure 3.12.9 Flowchart of remote frame handling with the automatic reply feature (Example)

3.13 Analog/Digital Converter

TMP92CD54I incorporates a 10-bit successive approximation-type analog/digital converter (AD converter) with 12-channel analog input.

Figure 3.13.1 is a block diagram of the AD converter. The 12-channel analog input pins (AN0 to AN11) are shared with the input-only port Port G and Port L, so they can be used as an input port.

Note: When IDLE1, IDLE2, IDLE3 or STOP Mode is selected, as to reduce the power, with some timings the system may enter a standby mode even though the internal comparator is still enabled. Therefore be sure to check that AD converter operations are halted before a HALT instruction is executed.

Note: R: internal resistance = 7k ohm (reference data)

C: internal capacitance = 10pF+4pF (reference data)

Figure 3.13.1 Block diagram of AD converter

3.13.1 Analog/Digital converter registers

The AD converter is controlled by the two AD Mode Control Registers: ADMOD0 and ADMOD1. The twelve AD Conversion Data Result Registers (ADREG0H/L, ADREGBH/L) store the results of AD conversion.

Figure 3.13.2 shows the registers related to the AD converter.

AD Mode Control Register 0

AD Conversion Result Register A Low

Figure 3.13.9 AD Converter Related Registers

- 3.13.2 Description of operation
 - (1) Analog reference voltage

A high-level analog reference voltage is applied to the VREFH pin; a low-level analog reference voltage is applied to the VREFL pin. To perform AD conversion, the reference voltage, the difference between VREFH and VREFL, is divided by 1024 using string resistance. The result of the division is then compared with the analog input voltage.

To turn off the switch between VREFH and VREFL, write a 0 to ADMOD1<VREFON> in AD Mode Control Register 1. To start AD conversion in the OFF state, first write a 1 to ADMOD1<VREFON>, wait 3 μ s until the internal reference voltage stabilizes (this is not related to fc), then set ADMOD0<ADS> to 1.

(2) Analog input channel selection

The analog input channel selection varies depends on the operation mode of the AD converter.

- In Analog Input Channel Fixed Mode (ADMOD0<SCAN> = 0) Setting ADMOD1<ADCH3:0> selects one of the input pins AN0~AN11 as the input channel.
- In Analog Input Channel Scan Mode (ADMOD0<SCAN> = 1) Setting ADMOD1<ADCH3:0> selects one of the twelve scan modes.

Table 3.13.1 illustrates analog input channel selection in each operation mode.

On a Reset, ADMODO<SCAN> is set to 0 and ADMOD1<ADCH3~ADCH0> is initialized to 0000. Thus pin AN0 is selected as the fixed input channel. Pins not used as analog input channels can be used as standard input port pins.

<adch3:0></adch3:0>	Channel fixed <scan> = "0"</scan>	Channel scan <scan> = "1"</scan>
0000	AN0	ANO

(3) Starting AD Conversion

To start AD conversion, write a 1 to ADMODO<ADS> in AD Mode Control Register 0.When AD conversion starts, the AD Conversion Busy flag ADMODO<ADBF> will be set to 1, indicating that AD conversion is in progress.

(4) AD conversion modes and the AD Conversion End interrupt

The four AD conversion modes are:

- Channel Fixed Single Conversion Mode
- Channel Scan Single Conversion Mode
- Channel Fixed Repeat Conversion Mode
- Channel Scan Repeat Conversion Mode

The ADMOD0<REPET> and ADMOD0<SCAN> settings in AD Mode Control Register 0 determine the AD mode setting.

Completion of AD conversion triggers an INTAD AD Conversion End interrupt request. Also, ADMODO<EOCF> will be set to 1 to indicate that AD conversion has been completed.

① Channel Fixed Single Conversion Mode

Setting ADMOD0<REPET> and ADMOD0<SCAN> to 00 selects Conversion Channel Fixed Single Conversion Mode.

In this mode data on one specified channel is converted once only. When the conversion has been completed, the ADMOD0<EOCF> flag is set to 1, ADMOD0<ADBF> is cleared to 0, and an INTAD interrupt request is generated.

2 Channel Scan Single Conversion Mode

Setting ADMOD0<REPET> and ADMOD0<SCAN> to 01 selects Conversion Channel Scan Single Conversion Mode.

In this mode data on the specified scan channels is converted once only. When scan conversion has been completed, ADMOD0<EOCF> is set to 1, ADMOD0<ADBF> is cleared to 0, and an INTAD interrupt request is generated.

3 Channel Fixed Repeat Conversion Mode

Setting ADMOD0<REPET> and ADMOD0<SCAN> to 10 selects Conversion Channel Fixed Repeat Conversion Mode.

In this mode data on one specified channel is converted repeatedly. When conversion has been completed, ADMOD0<EOCF> is set to 1 and ADMOD0<ADBF> is not cleared to 0 but held at 1. INTAD interrupt request generation timing is determined by the setting of ADMOD0<ITM0>.

Setting $\langle ITM0 \rangle$ to 0 generates an interrupt request every time an AD conversion is completed.

Setting $\langle ITM0 \rangle$ to 1 generates an interrupt request on completion of every fourth conversion.

(4) Channel Scan Repeat Conversion Mode

Setting ADMOD0<REPET> and ADMOD0<SCAN> to 11 selects Conversion Channel Scan Repeat Conversion Mode.

In this mode data on the specified scan channels is converted repeatedly. When each scan conversion has been completed, ADMOD0<EOCF> is set to 1 and an INTAD interrupt request is generated. ADMOD0<ADBF> is not cleared to 0 but held at 1.

To stop conversion in a repeat conversion mode (i.e. in cases ③ and ④), write a 0 to ADMOD0<REPET>. After the current conversion has been completed, the repeat conversion mode terminates and ADMOD0<ADBF> is cleared to 0.

Switching to a halt state (IDLE2 Mode with ADMOD1<I2AD> cleared to 0, IDLE1 Mode or STOP Mode) immediately stops operation of the AD converter even when AD conversion is still in progress. In repeat conversion modes (i.e. in cases ③ and ④), when the halt is released, conversion restarts from the beginning. In single conversion modes (i.e. in cases ① and ②), conversion does not restart when the halt is released (the converter remains stopped).

Table 3.13.2 shows the relationship between the AD conversion modes and interrupt requests.

Modo	Interrupt Request	ADMOD0				
Mode	Generation	<itm0></itm0>	<repet></repet>	<scan></scan>		
Channel Fixed Single Conversion Mode	After completion of conversion	х	0	0		
Channel Scan Single Conversion Mode	After completion of scan conversion	х	0	1		
Channel Fixed Repeat	Every conversion	0	4	0		
Conversion Mode Every forth conversion		1	I	0		
Channel Scan Repeat Conversion Mode	After completion of every scan conversion	x	1	1		

Table 3.13.2 Relationship Between AD Conversion Modes and Interrupt Requests

X: Don't care

(5) AD conversion time

160/fc (8 μ s @ f_c = 20 MHz) are required for the AD conversion of one channel.

(6) Storing and reading the results of AD conversion

The AD Conversion Data Upper and Lower Registers (ADREG0H/L to ADREGBH/L) store the results of AD conversion. (ADREG0H/L to ADREGBH/L are read-only registers.)

In Channel Fixed Repeat Conversion Mode, the conversion results are stored successively in registers ADREG0H/L to ADREG3H/L. In other modes the AN0, AN1, AN2, AN3, AN4, AN5, AN6, AN7 conversion results are stored in ADREG0H/L, ADREG1H/L, ADREG2H/L, ADREG3H/L, ADREG4H/L, ADREG5H/L, ADREG6H/L, ADREG7H/L, ADREG8H/L, ADREG9H/L, ADREG9H/L, ADREG8H/L respectively. Table 3.13.3 shows the correspondence between the analog input channels and the registers which are used to hold the results of AD conversion.

Table 3.13.3 Correspondence Between Analog Input Channels and AD Conversion Result Registers

	AD Conversion Result Register						
Analog input channel (Port G/Port L)	Conversion modes other than at right	Channel fixed repeat conversion mode (every 4 th conversion)					
AN0	ADREG0H/L						
AN1	ADREG1H/L						
AN2	ADREG2H/L						
AN3	ADREG3H/L	ADREG0H/L					
AN4	ADREG4H/L	↓ ↓					
AN5	ADREG5H/L	ADREG1H/L					
AN6	ADREG6H/L						
AN7	ADREG7H/L	ADREG2H/L					
AN8	ADREG8H/L	ADREG3H/L					
AN9	ADREG9H/L						
AN10	ADREGAH/L						
AN11	ADREGBH/L						

<ADRxRF>, bit 0 of the AD conversion data lower register, is used as the AD conversion data storage flag. The storage flag indicates whether the AD conversion result register has been read or not. When a conversion result is stored in the AD conversion result register, the flag is set to 1. When either of the AD conversion result registers (ADREGxH or ADREGxL) is read, the flag is cleared to 0.

Reading the AD conversion result also clears the AD Conversion End flag ADMOD0<EOCF> to 0.

Setting example:

① Convert the analog input voltage on the AN3 pin and write the result, to memory address 0800H using the AD interrupt (INTAD) processing routine.

Main routir	ne:	
	76543210	
INTE0AD	← 1 1 0 0	Enable INTAD and set it to Interrupt Level 4.
ADMOD1	\leftarrow 1 1 0 0 0 0 1 1	Set pin AN3 to be the analog input channel.
ADMOD0	$\leftarrow \texttt{X} \texttt{X} \texttt{0} \texttt{0} \texttt{0} \texttt{0} \texttt{1}$	Start conversion in Channel Fixed Single Conversion Mode.
Interrupt ro	outine processing example:	
WA	← ADREG3	Read value of ADREG3L and ADREG3H into 16-bit
		general-purpose register WA.
WA	> > 6	Shift contents read into WA six times to right and zero-fill upper
		bits.
(0800H)	\leftarrow WA	Write contents of WA to memory address 0800H.

② This example repeatedly converts the analog input voltages on the three pins ANO, AN1 and AN2, using Channel Scan Repeat Conversion Mode.

INTE0AD	← 1 0 0 0	Disable INTAD.					
ADMOD1	\leftarrow 1 1 0 0 0 0 1 0	Set pins AN0~AN2 to be the analog input channels.					
ADMOD0	$\leftarrow \texttt{X} \texttt{X} \texttt{0} \texttt{0} \texttt{0} \texttt{1} \texttt{1} \texttt{1}$	$\label{eq:start} Start \ conversion \ in \ Channel \ Scan \ Repeat \ Conversion \ Mode.$					
Note: X = Don't care; "–" = No change							

3.14 Watchdog Timer (Runaway Detection Timer)

TMP92CD54I contains a watchdog timer of runaway detecting.

The watchdog timer (WDT) is used to return the CPU to the normal state when it detects that the CPU has started to malfunction (runaway) due to causes such as noise. When the watchdog timer detects a malfunction, it generates a non-maskable interrupt INTWD to notify the CPU of the malfunction.

Connecting the watchdog timer output to the reset pin internally forces a reset.

3.14.1 Configuration

Figure 3.14.1 is a block diagram of the watchdog timer (WDT).

Figure 3.14.1 Block Diagram of Watchdog Timer

www.datashee

The watchdog timer consists of a 22-stage binary counter which uses the clock ϕ (2/fc) as the input clock. The binary counter can output 2¹⁶/fc, 2¹⁸/fc, 2²⁰/fc and 2²²/fc. Selecting one of the outputs using WDMOD<WDTP1,WDTP0> generates a watchdog timer interrupt when an overflow occurs. In the case of using watchdog timer after INTWD request generated, the clear code (4EH) should be written to the WDCR register in other to clear the binary counter.

Figure 3.14.2 Normal Mode

The runaway detection result can also be connected to the Reset pin internally. In this case, the reset time will be between 44×4 /fc and 58×4 /fc system clocks (8.8~11.6 µs @ fc= 20 MHz) as shown in figure 3.14.3

3.14.2 Control registers

The watchdog timer WDT is controlled by three control registers WDMOD, WDCR and CLKMOD.

- (1) Watchdog Timer Mode Register (WDMOD)
 - i) Setting the detection time for the watchdog timer in <WDTP1,WDTP0>

This 2-bit register is used for setting the watchdog timer interrupt time used when detecting runaway. On a Reset this register is initialized to WDMOD<WDTP1,WDTP0> = 00.

The detection times for WDT is 2^{16} /fc [s]. (The number of system clocks is approximately 65,536.)

ii) Watchdog timer enable/disable control register <WDTE>

At reset, the WDMOD<WDTE> is initialized to 1, enabling the watchdog timer.

To disable the watchdog timer, it is necessary to set this bit to 0 and to write the disable code (B1H) to the Watchdog Timer Control Register WDCR. This makes it difficult for the watchdog timer to be disabled by runaway.

However, it is possible to return the watchdog timer from the disabled state to the enabled state merely by setting $\langle WDTE \rangle$ to 1.

iii) Watchdog timer out reset connection <RESCR>

This register is used to connect the output of the watchdog timer with the RESET terminal internally. Since WDMOD<RESCR>is initialized to 0 at reset, a reset by the watchdog timer will not be performed.

(2) Watchdog Timer Control Register (WDCR)

This register is used to disable and clear the binary counter for the watchdog timer.

• Disable control

The watchdog timer can be disabled by clearing WDMOD<WDTE> to 0 and then writing the disable code (B1H) to the WDCR register.

 WDMOD
 ←
 0
 Clear WDMOD<WDTE> to 0.

 WDCR
 ←
 1
 0
 0
 1
 Write the disable code (B1H).

• Enable control

Set WDMOD<WDTE>to 1.

• Watchdog timer clear control

To clear the binary counter and cause counting to resume, write the clear code (4EH) to the WDCR register. In the case of using watchdog timer after INTWD request generated, the clear code (4EH) should be written to the WDCR register in other to clear the binary counter.

WDCR \leftarrow 0 1 0 0 1 1 1 0 Write the clear code (4EH).

(3) Clock Mode Register (CLKMOD)

This register is used to set the warming up time after the stop mode ends. The output of CLK pin is chosen from fc and 2/5fc by the setup of CLKMOD <CLKM1,CLKM0>. Moreover, CLK pin output can be stopped by writing "0" in CLKMOD <CLKOE>. By the setup of CLKMOD <HALTM1,HALTM0>, it becomes the HALT mode of IDLE1, IDLE2, IDLE3 or STOP.

Figure 3.14.4 Watchdog Timer Mode Register

B1H	Disable code
4EH	Clear code
Others	Don't care

3.14.3 Operation

The watchdog timer generates an INTWD interrupt when the detection time set in the WDMOD<WDTP1,WDTP0> has elapsed. The watchdog timer must be zero-cleared in software before an INTWD interrupt will be generated. If the CPU malfunctions (i.e. if runaway occurs) due to causes such as noise, but does not execute the instruction used to clear the binary counter, the binary counter will overflow and an INTWD interrupt will be generated. The CPU will detect malfunction (runaway) due to the INTWD interrupt and in this case it is possible to return to the CPU to normal operation by means of an anti-mulfunction program.

The watchdog timer begins operating immediately on release of the watchdog timer reset.

The watchdog timer is reset and halted in IDLE1, IDLE3 or STOP Modes.

When the device is in IDLE2 mode, the operation of WDT depends on the WDMOD<I2WDT> setting. Ensure that WDMOD<I2WDT> is set before the device enters IDLE2 Mode. Example:

i) Clear the binary counter

1/	orcar ti	10 1	011	iai	L Y	co	u	100	· • •		
	WDCR	←	0	1	0	0	1	1	1	0	Write the clear code (4EH).
ii)	Set the	wa	tc	hd	.og	; ti	m	er	de	ete	ction time to 2^{18} / fc.
	WDMOD	←	1	0	1	-	-	-	-	-	
iii)	Disable	th	e١	va	tc	hd	og	; ti	m	er.	
	WDMOD	←	0	-	-	х	-	-	-	-	Clear <wdte> bit to 0.</wdte>
	WDCR	←	1	0	1	1	0	0	0	1	Write the disable code (B1H).

www.datashee

3.15 RAM control

RAM control register (RAMCR) has <RAMWI>bit for inhibition to write data to internal RAM and <RAMSTB> bit to detect lower voltage under VSTB level. VSTB level is the voltage level impossible to keep the data of Internal RAM.

Only data "1" can be written to RAMCR<RAMSTB>, and data "0" can't be written.

When RAMCR<RAMSTB> is set to "1" by software, in the case of voltage drop under VSTB level RAMCR<RAMSTB> is reset to "0". After power on RAMCR<RAMSTB> is reset to "0".

RAMCR<RAMSTB> is not changed by standby operation and reset operation. The detection of reset operation (Warm reset / Power-on reset) and the condition of RAM data (kept / lost) is enable, to read RAMCR<RAMSTB>.

RAM Write Inhibit<RAMWI> bit is used for inhibition to write data to internal RAM. After reset RAMCR<RAMWI> is set to "1", writing data to internal RAM is accepted. When RAMCR<RAMWI> is set to "0", writing data to internal RAM is inhibited.

RAM standby flag

0	After "1" is set by software, this bit is reset to "0" at VCC3 \leq VSTB.
	After power on reset.
1	After "1" is set by software, this data isn't changed at VCC3>VSTB.

- Note1: After power-on reset, initialized to 0. No change by warm reset. Use after setting to 1 by software. 0 cannot be written by software.
- Note2: When changed to STOP or Idle3 in HALT mode with RAMCR<RAMSTB> set to 1, current flows.

Note3: Emulator doesn't support RAM control functions.

Note4: To set to RAMCR<RAMSTB> bit to "1", need 8 state (@ fc = 20MHz; For that time, do not set Idle2, 3 or STOP mode.). After that, the power-supply detection circuit runs.

Note5: VCC3 means internal voltage.

(Note) There are restrictions at un-use of Voltage regulator (see section "4.2 DC Electrical Characteristics").

3.16 Timer for Real Time Clock (RTC)

TMP92CD54I features a timer which is used for real time count. An interrupt (INTRTC) can be generated every 0.0625 s, 0.125 s, 0.25 s, 0.50 s, 1 s or 2 s by using the low-frequency 32.768kHz clock. A clock function can be easily used.

Timer for Real Time Clock can operate in all mode in which a low frequency oscillation is operated. (except STOP mode)

In addition, INTRTC can return the device from every standby mode except STOP mode to the NORMAL mode.

3.16.1 Block diagram

Figure 3.16.1 Block diagram for timer for real-time clock

3.16.2 SFRs

RTC has 2 registers.

Timer for Real Time Clock is controlled by Timer for Real-Time Clock Control Register (RTCCR). The period of interrupt request INTRTC is selected from 6 types by setting <RTCSEL2 to 0>. To start/stop the counter is controlled by <RTCRUN>.

The low frequency oscillator is controlled by Timer for Real Time Function Register(RTCFC). If it is released from STOP mode, without RESET input, RTCFC will be initialized.

Figure 3.16.2 and 3.16.3 show these registers.

					U			
	7	6	5	4	3	2	1	0

Timer for Real Time Clock Control Register

1x1 1s

Timer for Real Time Clock Function Register

Note1: Please consider the stability-time for the oscillator.

Note2: If it released from STOP mode, RTCFC register will be initiallized without a RESET input. Therefore, it is necessary to set up RTCFC register again after releaseing from STOP mode.

Figure 3.16.2 Timer for Real Time Clock Function Register

Example of register setting:

LD	(RTCFC),01h	; L-OSC start
	:	; (Wait for the stability-time)
LD	(RTCCR),03h	; Run at 2 ¹³ /fs

www.datashee**TOSHIBA** 3.16.3 CR oscillation

RTC can also work by using CR oscillator within. And oscillation type is controlled by the RTCFC. If XTSEL bit is set, CR oscillation is available. And when CR oscillation is used in the application, it is necessary to supplement external resistor and capacitor to XT1, XT2 pins. A recommended external circuit is shown the following figure "Figure 3.16.3". And "Figure 3.16.4" shows CR oscillation frequency related to the combination of resistor and capacitor, provided that measurement environment is the typical condition described below.

Figure 3.16.3 A external circuit for CR oscillation

3.17 Voltage Regulator

3V output regulator for the internal logic power supply is installed in TMP92CD54I. The power supply is supplied to internal logic by connecting each DVCC3 terminal with regulator output terminal REGOUT.

This regulator can control use/nonuse with the terminal REGEN.

Table3.17.1 REGOUT output by REGEN setting						
REGEN input	REGOUT output					
"H"	3V output for internal logic					
"OPEN" Note)	3V output for internal logic					
"L"	0V output (Do not connect GND)					

Note) As for REGEN, use with OPEN is also possible because of an internal pull-up.

When the regulator is not used, it is necessary to supply the power supply to internal logic separately.

3.17.1 Block diagram

Diagram 3.17.1 Regulator block

3.17.2 External connecting

For the oscillation prevention of the output voltage, connect stabilization capacitor (Cs) with the place between REGOUT and DVSS as near the terminal as possible. It is necessary to add resistance (ESR) to Cs serially according to the substrate capacity as shown in Figure 3.17.2.

Because the change in internal resistance by the temperature might become the destabilizing factor of the regulator output about the selection of the capacitor, we will recommend the use of the capacitor with a good temperature characteristic.

Moreover, recommend bypass capacitor (Cb) to be connected as a noise tolerance improvement of the REGOUT output between DVCC3-DVSS.

diagram 3.17.2 Regulator connection

3.17.3 Directions

Application

This regulator is designed for TMP92CD54I. Do not connect the output from REGOUT except the terminal DVCC3 of TMP92CD54I.

• Timing of when power supply is turned on and REGEN input signal

When the power supply is turning on, keep the REGEN terminal OPEN or input the enable signal (H level) to the terminal REGEN after at least 1us passes from the power supply turning on.

• The number of wires of Cs, Cb and ESR

Depending on modular composition, its stray capacitance and parasitic capacitance might influence the regulator characteristic.

Investigating the characteristic about the static characteristic and the transient characteristic along actual use conditions, the number of wires should be decided according to the margin of Cin, Cs, Cb and ESR.

4. Electrical Characteristics

4.1 Absolute Maximum Ratings

Parameter	Symbol	Rating	Unit
Power Supply Voltage	V _{CC5}	-0.5 to 6.0	V
Input Voltage	VIN	-0.5 to VCC5+0.5	V
Output Current(total)	ΣΙΟΓ	100	mA
Output Current(total)	ΣΙΟΗ	-100	mA
Power Dissipation(Ta=85degree C)	PD	600	mW
Soldering Temperature(10s)	T _{SOLDER}	260	degree C
Storage Temperature	T _{STG}	-65 to 150	degree C
Operation Temperature	T _{OPR}	-40 to 85	degree C

Note: The absolute maximum ratings are rated values that must not be exceeded during operation, even for an instant. Any one of the ratings must not be exceeded. If any absolute maximum rating is exceeded, a device may break down or its performance may be degraded, causing it to catch fire or explode resulting in injury to the user. Thus, when designing products that include this device, ensure that no absolute maximum rating value will ever be exceeded.

d) SEI Slave (CPHA=1)

4.10 Controller Area Network (CAN)

Symbol	Parameter	Vari	able	20N	Llnit	
Symbol		Min	Max	Min	Max	Unit
t _{cclk}	CAN Clock period	2T		100		ns
t _p	Tx edge →Rx Input		2tcclk-20		180	ns

4.11 Voltage regulator

	ulator					
Voltage Regurator Vcc5 = 4.5V to 5.25V / fc = 16 to 20MHz / Ta = -40 to 85 degree C / Iload = 10u						d =10u/
Parameter	Symbol	Condition	Min.	Тур.	Max.	Unit.
Output Voltage	REGOUT		3.0	_	3.6	V
Output Current	Iro	Vin-REGOUT=1.0V	0	_	150	mA
Quiescent Current	lq	Iro≦10 uA	30	50	100	μA
	lq1	10 uA <iro<100ma (ta="25°C)</td"><td>15</td><td>250</td><td>800</td><td>μA</td></iro<100ma>	15	250	800	μA
	lop	Iro=150mA	6	8	10	mA
Standby Current	ls	REGEN=0 (Regulator Only)		0.1	0.2	μA

$0.5[Ohm] \leq ESR \leq 5.0[Ohm]$

Parameter	Symbol	Condition	Min.	Тур.	Max.	Unit.
Stabilization capactor	Cs	Cb=10uF, ESR=4.7 Ω	0.1	_	10	μF
Bypass capactor	Cb	Cs=10uF, ESR=4.7 Ω (Cs>=Cb)	0.1	_	10	μF
Input capactor	Cin (Note)	Cs=10uF, ESR=4.7Ω	4.7	—	22	μF
Equivalent Series Resistor	ESR	Cs=10uF Cb=0.1uF	0.5	_	5	Ω

$0.5[Ohm] \leq ESR \leq 50[Ohm]$

Parameter	Symbol	Condition	Min.	Тур.	Max.	Unit.
Stabilization capactor	Cs	Cb=0.6uF, ESR=47Ω	0.1	_	10	μF
Bypass capactor	Cb	Cs=10uF, ESR=47 Ω (Cs>=Cb)	0.6	_	10	μF
Input capactor	Cin (Note)	Cs=10uF, ESR=47Ω	4.7	_	22	μF
Equivalent Series Resistor	ESR	Cs=10uF Cb=0.6uF	0.5	—	50	Ω

$0.5[Ohm] \leq ESR \leq 100[Ohm]$

Parameter	Symbol	Condition	Min.	Тур.	Max.	Unit.
Stabilization capactor	Cs	Cb=1.0uF, ESR=100 Ω	0.1	-	10	μF
Bypass capactor	Cb	Cs=10uF, ESR=100 Ω (Cs>=Cb)	1.0		10	μF
Input capactor	Cin (Note)	Cs=10uF, ESR=100Ω	4.7	_	22	μF
Equivalent Series Resistor	ESR	Cs=10uF Cb=1.0uF	0.5	_	100	Ω

Note: Recommend Tantalum Capacitor.

5. Table of special function registers (SFRs) (SFR ; Special Function Register)

The special function registers (SFRs) include the I/O ports and peripheral control registers allocated to the 1024 byte addresses from 000000H to 0003FFH.

(1) I/O port

- (2) 8-bit Timer control
- (3) 16-bit Timer control
- (4) Serial Channel control
- (5) Serial Expansion Interface control
- (6) Interrupt control
- (7) DMA controller
- (8) Control register
- (9) A/D converter control
- (10)Memory controller
- (11)Serial Bus Interface control
- (12)CAN control
- (13)RTC control

Configuration of the table

Explanations of symbols

- R/W : Either read or write is possible
- R : Only read is possible
- W : Only write is possible

no RMW : Prohibit Read Modify Write

(Prohibit RES / SET / TSET / CHG / STCF / ANDCF / ORCF / XORCF etc.)

6. Port Section Equivalent Circuit Diagram.

• Reading The Circuit Diagram

Basically, the gate symbols written are the same as those used for the standard CMOS logic IC [74HCXX] series.

The dedicated signal is described below.

STOP: This signal becomes active "1" when the halt mode setting register is set to the Stop mode and the CPU executes the HALT instruction. When the drive enable bit <DRVE> is set to "1", however, Stop remains at "0".

- The input protection resistance ranges from several tens of ohms to several hundreds of ohms.
- P0 (D0 to D7), P4 (A0 to A7), P70, P71, P73 to P75, PC0 to PC5, PD0 to PD7, PF1(RXD0), PF2 (CTS0, SCLK0), PF4 (RXD1), PF5 (CTS1, SCLK1), PF6 (TX), PF7 (RX), PM0 (SS), PN0 (SCK0), PN3 (SCK1), PM4 (SCK2)

P72 (SI2/SCL2), PF0 (TXD0), PF3 (TXD1), PM1 (MOSI), PM2 (MISO), PM3 (SECLK), PN1 (SO0/SDA0), PN2 (SI0/SCL0), PN4 (SO1/SDA1), PN5 (SI1/SCL1), PN6 (SO2/SDA2)

7. Points to Note and Restrictions

7.1 Notation

- The notation for built-in I/O registers is as follows register symbol <Bit symbol> Example: TRUN01<TORUN> denotes bit TORUN of register TRUN01.
- (2) Read-modify-write instructions (RMW)

An instruction in which the CPU reads data from memory and writes the data to the same memory location in one instruction.

Example 1: SET 3, (TRUN01); Set bit3 of TRUN01.

Example 2: INC 1, (400H); Increment the data at 400H.

- Examples of read-modify-write instructions on the TLCS-900/H1
 - Exchange instruction

EX (mem), R

Arithmetic operations

ADD	(mem), R/#	ADC	(mem), R/#
SUB	(mem), R/#	SBC	(mem), R/#
INC	#3, (mem)	DEC	#3, (mem)

Logic operations

AND	(mem), R/#	OR	(mem), R/#
XOR	(mem), R/#		

Bit manipulation operations

STCF#3/A, (mem)	RES	#3, (mem)
SET #3, (mem)	CHG	#3, (mem)
TSET#3, (mem)		

Rotate and shift operations

RLC	(mem)	RRC	(mem)
RL	(mem)	RR	(mem)
SLA	(mem)	SRA	(mem)
SLL	(mem)	SRL	(mem)
RLD	(mem)	RRD	(mem)

7.2 Points to Note

(1) Watchdog timer

The watchdog timer starts operation immediately after a reset is released. When the watchdog timer is not to be used, disable it.

(2) The stable time of the internal clock

When releasing the external reset using "built-in clock doubler" until the internal reset is released, the requiring time to stabilize the circuit is automatically set. See section 3.1.2 "Reset Operation" for details. Also when releasing standby mode in STOP mode using an interrupt until the internal circuit starts the operation, the stable time of the oscillator is automatically input. See section 3.4 "Standby Function (3) STOP mode" for details.

(3) Undefined bit in the built-in I/O register

When reading the undefined bit in the built-in I/O register, the undefined value is output.

Thus, when creating program, it should not be depending on this bit condition.

(4) Reserved address areas

The 16 bytes area (FFFFF0H to FFFFFFH) cannot be used for it is reserved as internal area. If using emulator, optional 64 Kbytes of 16M bytes area are used for control emulator. Therefore, if using emulator, its area cannot be used.

(5) POP SR instruction

Execute the POP SR instruction during DI condition.

8. Package

Package Dimensions : P-LQFP100-1414-0.50F
