DESCRIPTIONS

The FUJITSU MB90420G/5G (A) Series is a 16-bit general purpose high-capacity microcontroller designed for vehicle meter control applications etc.

The instruction set retains the same AT architecture as the FUJITSU original F²MC-8L and F²MC-16L series, with further refinements including high-level language instructions, expanded addressing mode, enhanced (signed) multipler-divider computation and bit processing.

In addition, A 32-bit accumulator is built in to enable long word processing.

■ FEATURES

• 16-bit input capture (4 channels)

Detects rising, falling, or both edges.

16-bit capture register \times 4

Pin input edge detection latches the 16-bit free-run timer counter value, and generates an interrupt request.

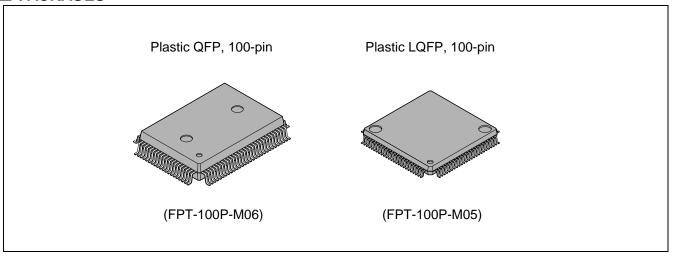

• 16-bit reload timer (2 channels)

16-bit reload timer operation (select toggle output or one-shot output)

Event count function selection provided

(Continued)

■ PACKAGES

Clock timer (main clock)

Operates directly from oscillator clock.

Compensates for oscillator deviation

Read/write enabled second/minute/hour register

Signal interrupt

• 16-bit PPG (3 channels)

Output pins (3), external trigger input pin (1)

Output clock frequencies: fcp, fcp/22, fcp/24, fcp/26

Delay interrupt

Generates interrupt for task switching.

Interruptions to CPU can be generated/deleted by software setting.

• External interrupts (8 channels)

8-channel independent operation

Interrupt source setting available: "L" to "H" edge/ "H" to "L" edge/ "L" level/ "H" level.

A/D converter

10-bit or 8-bit resolution × 8 channels (input multiplexed)

Conversion time : $6.13 \,\mu s$ or less (at fcp = $16 \,MHz$)

External trigger startup available (P50/INT0/ADTG)

Internal timer startup available (16-bit reload timer 1)

• UART (2 channels)

Full duplex double buffer type

Supports asynchronous/synchronous transfer (with start/stop bits)

Internal timer can be selected as clock (16-bit reload timer 0)

Asynchronous : 4808 bps, 5208 bps, 9615 bps, 10417 bps, 19230 bps, 38460 bps, 62500 bps, 500000 bps Synchronous : 500 Kbps, 1Mbps, 2Mbps (at $f_{CP} = 16$ MHz)

• CAN interface *1

Conforms to CAN specifications version 2.0 Part A and B.

Automatic resend in case of error.

Automatic transfer in response to remote frame.

16 prioritized message buffers for data and messages for data and ID

Multiple message support

Receiving filter has flexible configuration: All bit compare/all bit mask/two partial bit masks

Supports up to 1 Mbps

CAN WAKEUP function (connects RX internally to INT0)

• LCD controller/driver (1 channel)

Segment driver and command driver with direct LCD panel (display) drive capability

Low voltage/Program Looping detect reset *2

Automatic reset when low voltage is detected

Program Looping detection function

• Stepping motor controller (4 channels)

High current output for all channels × 4

Synchronized 8/10-bit PWM for all channels × 2

· Sound generator

8-bit PWM signal mixed with tone frequency from 8-bit reload counter.

PWM frequencies: 62.5 kHz, 31.2 kHz, 15.6 kHz, 7.8 kHz (at fcp = 16MHz)

Tone frequencies: 1/2 PWM frequency, divided by (reload frequency +1)

(Continued)

Input/output ports

Push-pull output and Schmitt trigger input

Programmable in bit units for input/output or peripheral signals.

Flash memory

Supports automatic programming, Embedde Algorithm™, write/erase/erase pause/erase resume instructions Flag indicates algorithm completion

Minato Electronics flash writer

Boot block configuration

Erasable by blocks

Block protection by external programming voltage

- *1 : MB90420G (A) series has 2 channels built-in, MB90425G (A) series has 1 channel built-in
- *2 : Built-in to MB90420GA/5GA series only. Not built-in to MB90420G/5G series.

Embeded Algorithm is a registered trademark of Advanced Micro Devices Inc.

В		 Pull-up resistance attached : approx. 50 kΩ, hysteresis input
С		Hysteresis input
D	Hyteresis input	 Pull-down resistance attached : approx. 50 kΩ, hysteresis input No pull-down resistance on flash models.
E	LCDC output Hysteresis input	CMOS output LCDC output Hysteresis input

HANDLING DEVICES

When handling semiconductor devices, care must be taken with regard to the following ten matters.

- Strictly observe maximum rated voltages (prevent latchup)
- Stable supply voltage
- Power-on procedures
- · Treatment of unused input pins
- Treatment of A/D converter power supply pins
- · Use of external clock signals
- · Power supply pins
- Proper sequence of A/D converter power supply analog input
- Handling the power supply for high-current output buffer pins (DVcc, DVss)
- Pull-up/pull-down resistance
- Precautions when not using a sub clock signal.

Precautions for Handling Semiconductor Devices

• Strictly observe maximum rated voltages (prevent latchup)

When CMOS integrated circuit devices are subjected to applied voltages higher than Vcc at input and output pins other than medium- and high-withstand voltage pins, or to voltages lower than Vss, or when voltages in excess of rated levels are applied between Vcc and Vss, a phenomenon known as latchup can occur. In a latchup condition, supply current can increase dramatically and may destroy semiconductor elements. In using semi-conductor devices, always take sufficient care to avoid exceeding maximum ratings.

Also care must be taken when power to analog systems is switched on or off, to ensure that the analog power supply (AVcc, AVRH, DVcc) and analog input do not exceed the digital power supply (Vcc).

Once the digital power supply (Vcc) is switched on, the analog power (AVcc,AVRH,DVcc) may be turned on in any sequence.

· Stable supply voltage

Even within the warranted operating range of Vcc supply voltage, sudden fluctuations in supply voltage can cause abnormal operation. The recommended stability for ripple fluctuations (P-P values) at commercial frequencies (50 to 60 Hz) should be within 10% of the standard Vcc value, and voltage fluctuations that occur during switching of power supplies etc. should be limited to transient fluctuation rates of 0.1 V/ms or less.

• Power-on procedures

In order to prevent abnormal operation of the internal built-in step-down circuits, voltage rise time during power-on should be attained within 50 μ s (0.2 V to 2.7 V) .

· Treatment of unused input pins

If unused input pins are left open, they may cause abnormal operation or latchup which may lead to permanent damage to the semiconductor. Any such pins should be pulled up or pulled down through resistance of at least $2 \text{ k}\Omega$.

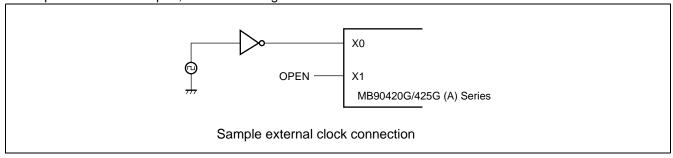

Also any unused input/output pins should be left open in output status, or if found set to input status, they should be treated in the same way as input pins.

• Treatment of A/D converter power supply pins

Even if the A/D converter is not used, pins should be connected so that AVcc = Vcc, and AVss = AVRH = Vss.

· Use of external clock signals

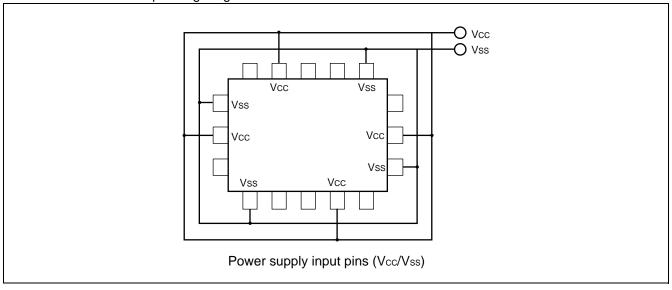

Even when an external clock is used, a stabilization period is required following a power-on reset or release from sub clock mode or stop mode. Also, when an external clock is used it should drive only the X0 pin and the X1 pin should be left open, as shown in Figure 3.

Power supply pins

Devices are designed to prevent problems such as latchup when multiple Vcc and Vss supply pins are used, by providing internal connections between pins having the same potential. However, in order to reduce unwanted radiation, and to prevent abnormal operation of strobe signals due to rise in ground level, and to maintain total output current ratings, all such pins should always be connected externally to power supplies and ground.

As shown in Figure 4, all Vcc power supply pins must have the same potential. All Vss power supply pins should be handled in the same way. If there are multiple Vcc or Vss systems, the device will not operate properly even within the warranted operating range.

In addition, care must be given to connecting the V_{CC} and V_{SS} pins of this device to a current source with as little impedance as possible. It is recommended that a bypass capacitor of 1.0 μF be connected between V_{CC} and V_{SS} as close to the pins as possible.

Proper sequence of A/D converter power supply analog input

A/D converter power (AVcc, AVRH) and analog input (AN0-AN7) must be applied after the digital power supply (Vcc) is switched on. When power is shut off, the A/D converter power supply and analog input must be cut off before the digital power supply is switched on (Vcc) . In both power-on and shut-off, care should be taken that AVRH does not exceed AVcc. Even when pins which double as analog input pins are used as input ports, be sure that the input voltage does not exceed AVcc. (There is no problem if analog power supplies and digital power supplies are turned off and on at the same time.)

• Handling the power supply for high-current output buffer pins (DVcc, DVss)

Always apply power to high-current output buffer pins (DVcc, DVss) after the digital power supply (Vcc) is turned on. Also when switching power off, always shut off the power supply to the high-current output buffer pins (DVcc, DVss) before switching off the digital power supply (Vcc) . (There will be no problem if high-current output buffer pins and digital power supplies are turned off and on at the same time.)

Even when high-current output buffer pins are used as general purpose ports, the power for high current output buffer pins (DVcc, DVss) should be applied to these pins.

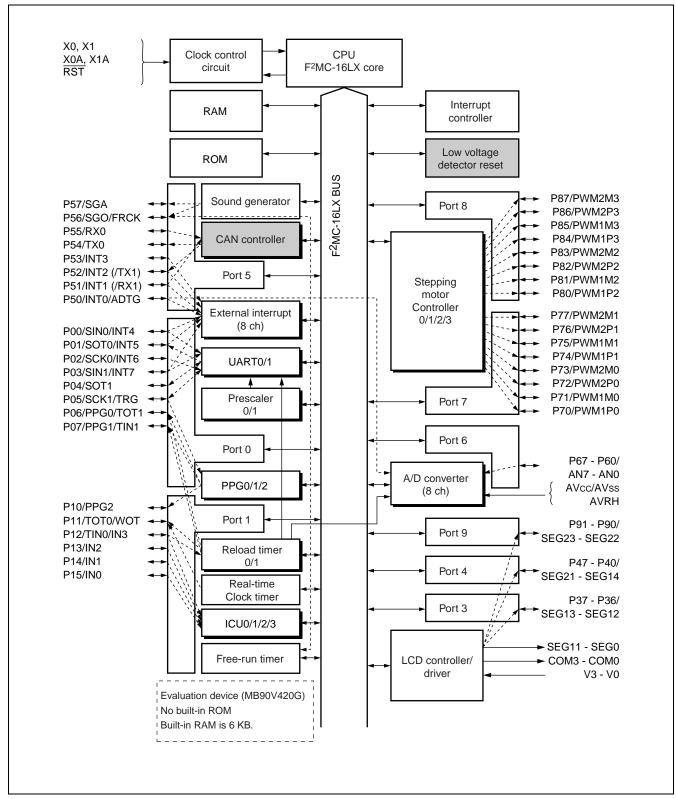

• Pull-up/pull-down resistance

The MB90420G/5G series does not support internal pull-up/pull-down resistance. If necessary, use external components.

• Precautions for when not using a sub clock signal.

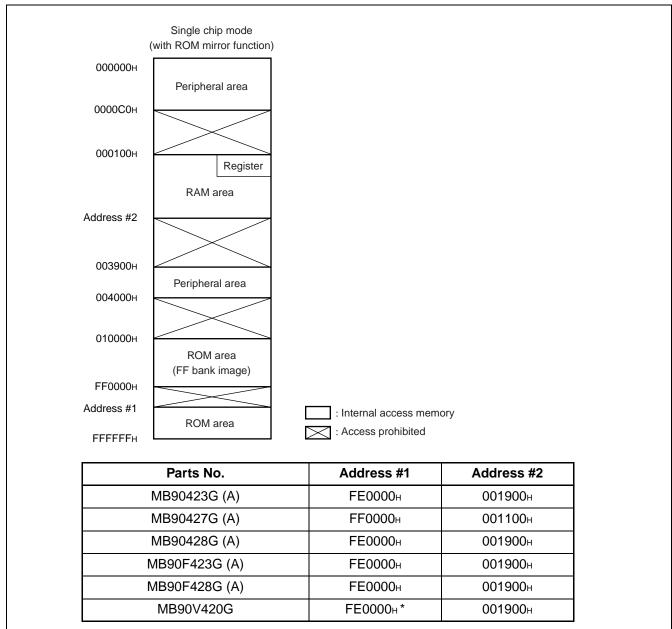

If the X0A and X1A pins are not connected to an oscillator, apply pull-down treatment to the X0A pin and leave the X1A pin open.

■ BLOCK DIAGRAM

■ MEMORY MAP

decoder.

Note: To select models without the ROM mirror function, see the "ROM Mirror Function Selection Module." The image of the ROM data in the FF bank appears at the top of the 00 bank, in order to enable efficient use of small C compiler models. The lower 16-bit address for the FF bank will be assigned to the same address, so that tables in ROM can be referenced without declaring a "far" indication with the pointer. For example when accessing the address 00C000H, the actual access is to address FFC000H in ROM. Here the FF bank ROM area exceeds 48 KB, so that it is not possible to see the entire area in the 00 bank image. Therefore because the ROM data from FF4000H to FFFFFFH will appear in the image from 004000H to 00FFFFH, it is recommended that the ROM data table be stored in the area from FF4000H to FFFFFFH.

*: MB90V420G has no built-in ROM. On the tool side this area may be considered a ROM

- Initial value symbols :
 - "0" initial value 0.
 - "1" initial value 1.
 - "X" initial value undetermined
 - "-" initial value undetermined (none)
- Write/read symbols :
 - "R/W" read/write enabled
 - "R" read only
 - "W" write only
- Addresses in the area 0000_H to 00FF_H are reserved for the principal functions of the MCU. Read access attempts to reserved areas will result in an "X" value. Also, write access to reserved areas is prohibited.

- : Compatible, with El²OS stop function
- : Compatible
- $\triangle\,$: Compatible when interrupt sources sharing ICR are not in use
- × : Not compatible
- *1 : Peripheral functions sharing the ICR register have the same interrupt level.
 - If peripheral functions sharing the ICR register are using expanded intelligent I/O services, one or the other cannot be used.
 - When peripheral functions are sharing the ICR register and one specifies expanded intelligent I/O services, the interrupt from the other function cannot be used.
- *2 : Priority applies when interrupts of the same level are generated.

■ PERIPHERAL FUNCTIONS

1. I/O Ports

The I/O ports function is to send data from the CPU to be output from I/O pins and load input signals at the I/O pins into the CPU, according to the port data register (PDR). Port input/output at I/O pins can be controlled in bit units by the port direction register (DDR) as required. The following list shows each of the functions as well as the shared peripheral function for each port.

- Port 0 : General purpose I/O port, shared with peripheral functions (external interrupt/UART/PPG)
- Port 1 : General purpose I/O port, shared with peripheral functions (PPG/reload timer/clock timer/ICU)
- Port 3 : General purpose I/O port, shared with peripheral functions (LCD)
- Port 4 : General purpose I/O port, shared with peripheral functions (LCD)
- Port 5: General purpose I/O port, shared with peripheral functions (External interrupt/CAN/SG)
- Port 6: General purpose I/O port, shared with peripheral functions (A/D converter)
- Port 7: General purpose I/O port, shared with peripheral functions (Stepping motor controller)
- Port 8: General purpose I/O port, shared with peripheral functions (Stepping motor controller)
- Port 9: General purpose I/O port, shared with peripheral functions (LCD)

Note: Port 6 also functions as an analog input pin. When using this port as a general purpose port, always write "0" to the corresponding analog input enable register (ADER) bit. The ADER bit is initialized to "1" at reset.

(2) Block Diagrams

2. Watchdog Timer/Time Base Timer/Clock Timer

The watchdog timer, timer base timer, and clock timer have the following circuit configuration.

· Watchdog timer : Watchdog counter, control register, watchdog reset circuit

Time base timer: 18-bit timer, interval interrupt control circuit
Clock timer: 15-bit timer, interval interrupt control circuit

(1) Watchdog timer function

The watchdog timer is composed of a 2-bit watchdog counter that uses the carry signal from the 18-bit time base timer or 15-bit clock timer as a clock source, plus a control register and watchdog reset control circuit.

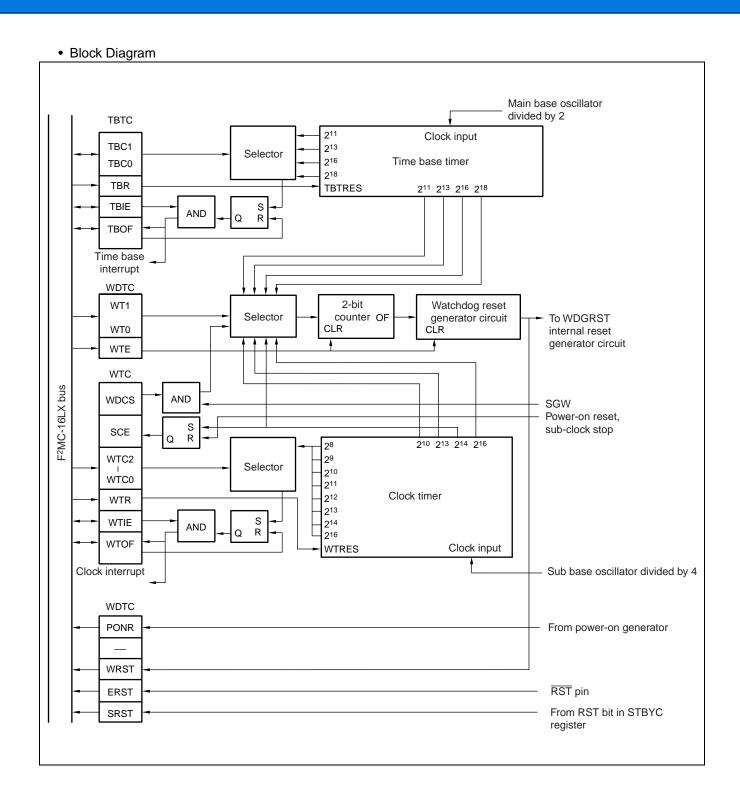

After startup, this function will reset the CPU if not cleared within a given time.

(2) Time base timer function

The time base timer is an 18-bit free-run counter (time base counter) synchronized with the internal count clock (base oscillator divided by 2), with an interval timer function providing a selection of four interval times. Other functions include a timer output for an oscillator stabilization wait time and clock feed to the watchdog timer or other operating clocks. Note that the time base timer uses the main clock regardless of the setting of the MCS bit or SCS bit in the CKSCR register.

(3) Clock timer function

The clock timer provides functions including a clock source for the watchdog timer, a sub clock base oscillator stabilization wait timer, and an interval timer to generate an interrupt at fixed intervals. Note that the clock timer uses the sub clock regardless of the setting of the MCS bit or SCS bit in the CKSCR register.

3. Input Capture

This circuit is composed of a 16-bit free-run timer and four 16-bit input capture circuits.

(1) Input capture (\times 4)

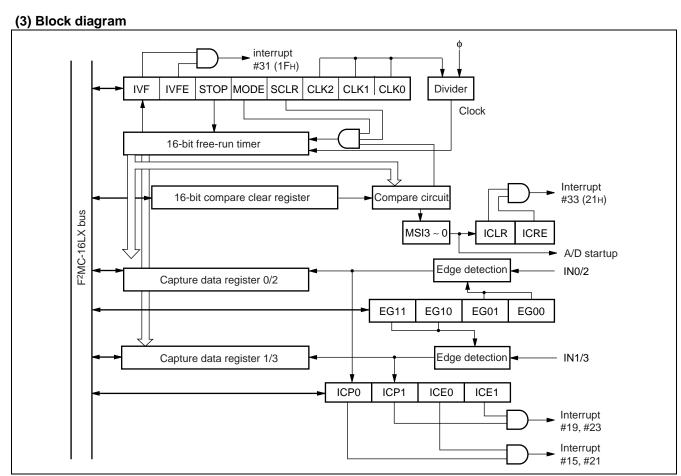

The input capture circuits consist of four independent external input pins and corresponding capture registers and control registers. When the specified edge of the external signal input (at the input pin) is detected, the value of the 16-bit free-run timer is saved in the capture register, and at the same time an interrupt can also be generated.

- The valid edge (rising edge, falling edge, both edges) of the external signal can be selected.
- The four input capture circuits can operate independently.
- The interrupt can be generated from the valid edge of the external input signal.

(2) 16-bit free-run timer (\times 1)

The 16-bit free-run timer is composed of a 16-bit up-counter, control register, 16-bit compare register, and prescaler. The output values from this counter are used as the base time for the input capture circuits.

- The counter clock operation can be selected from 8 options. The eight internal clock settings are φ, φ/2, φ/4, φ/8, φ/16, φ/32, φ/64, φ/128 where φ represents the machine clock cycle.
- Interrupts can be generated from overflow events, or from compare match events with the compare register. (Compare match operation requires a mode setting.)
- The counter value can be initialized to "0000н" by a reset, soft clear, or a compare match with the compare register.

4. 16-bit Reload Timer

The 16-bit reload timer can either count down in synchronization with three types of internal clock signals in internal clock mode, or count down at the detection of the designated edge of an external signal. The user may select either function. This timer defines a transition from $0000_{\rm H}$ to FFFF_H as an underflow event. Thus an underflow occurs when counting from the value [Reload register setting + 1].

A selection of two counter operating modes are available. In reload mode, the counter is reset to the count value and continues counting after an underflow, and in one-shot mode the count stops after an underflow. The counter can generate an interrupt when an underflow occurs, and is compatible with the expanded intelligent I/O services (EI²OS).

(1) 16-bit Reload timer operating modes

Clock mode	Counter mode	16-bit reload timer operation
	Reload mode	Soft trigger operation
Internal clock mode	One-shot mode	External trigger operation External gate input operation
Event count mode	Reload mode	Soft trigger operation
(external clock mode)	One-shot mode	Soft trigger operation

(2) Internal clock mode

One of three input clocks is selected as the count clock, and can be used in one of the following operations.

- Soft trigger operation
 - When "1" is written to the TRG bit in the timer control status register (TMCSR0/1), the count operation starts. Trigger input at the TRG bit is normally valid with an external trigger input, as well as an external gate input.
- External trigger operation
 - Count operation starts when a selected edge (rising, falling, both edges) is input at the TIN0/1 pin.
- External gate input operation
 - Counting continues as long as the selected signal level ("L" or "H") is input at the TINO/1 pin.

(3) Event count mode (External clock mode)

In this mode a down count event occurs when a selected valid edge (rising, falling, both edges) is input at the TINO/1 pin. This function can also be used as an interval timer when an external clock with a fixed period is used.

(4) Counter operation

Reload mode

In down count operation, when an underflow event (transition from "0000H" to "FFFFH") occurs, the set count value is reloaded and count operation continues. The function can be used as an interval timer by generating an interrupt request at each underflow event. Also, a toggle waveform that inverts at each underflow can be output from the TOT0/1 pin.

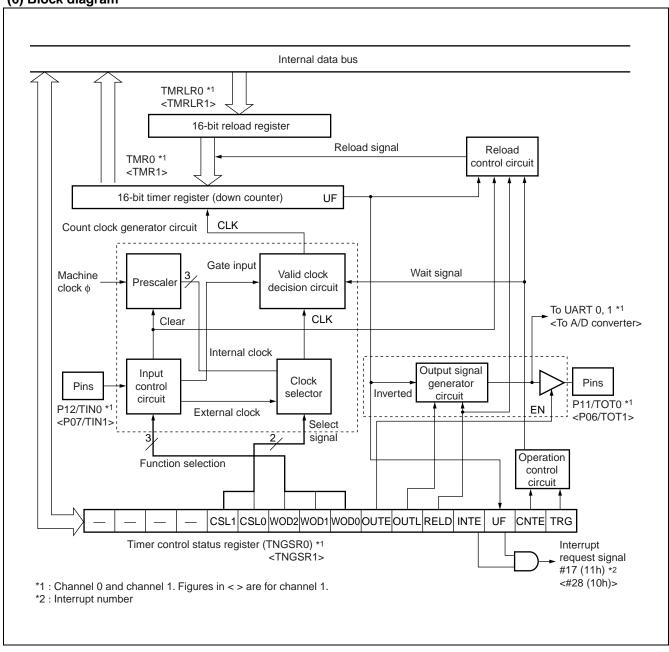

Counter clock	Counter clock period	Interval time		
	2¹/φ (0.125 μs)	0.125 μs to 8.192 ms		
Internal clock	2³/φ (0.5 μs)	0.5 μs to 32.768 ms		
	25/φ (2.0 μs)	2.0 μs to 131.1 ms		
External clock	2 ³ /φ or greater (0.5 μs)	0.5 μs or greater		

φ: Machine clock cycle. Figures in () are values at machine clock frequency 16 MHz.

(5) One-shot mode

In down count operation, the count stops when an underflow event (transition from "0000H" to "FFFFH") occurs. This function can generate an interrupt at each underflow. While the counter is operating, a rectangular wave form indicating that the count is in progress can be output form the TOT0 and TOT1 pins.

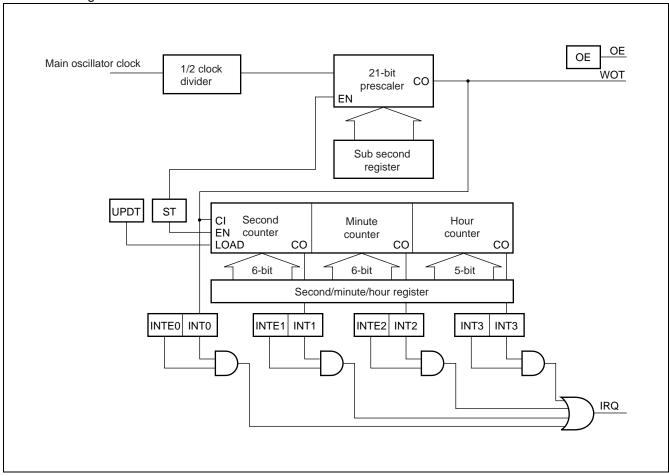

(6) Block diagram

5. Real Time Clock Timer

The real time clock timer is composed of a real time clock timer control register, sub second data register, second/minute/hour data registers, 1/2 clock divider, 21-bit prescaler and second/minute/hour counters. Because the MCU oscillation frequency operates on a given real time clock timer operation, a 4 MHz frequency is assumed. The real time clock timer operates as a real world timer and provides real world time information.

· Block diagram

6. PPG Timer

The PPG timer consists of a prescaler, one 16-bit down-counter, 16-bit data register with buffer for period setting, and 16-bit compare register with buffer for duty setting, plus pin control circuits.

The timer can output pulses synchronized with an externally input soft trigger. The period and duty of the output pulse can be adjusted by rewriting the values in the two 16-bit registers.

(1) PWM function

Programmable to output a pulse, synchronized with a trigger.

Can also be used as a D/A converter with an external circuit.

(2) One-shot function

Detects the edge of a trigger input, and outputs a single pulse.

(3) Pin control

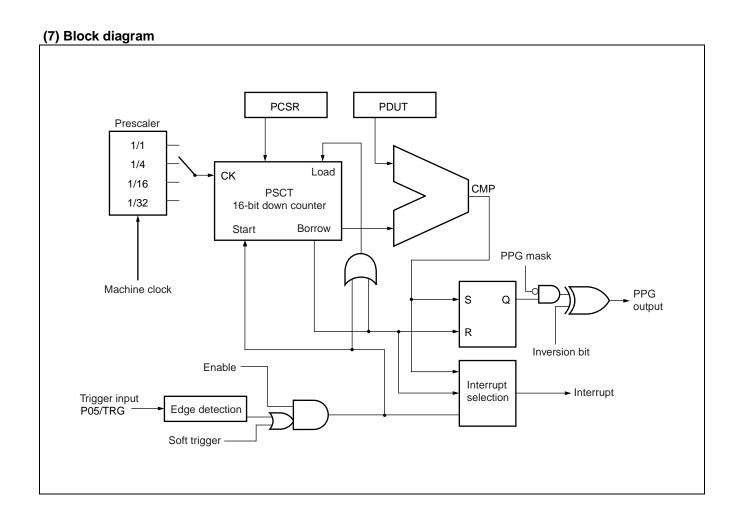

- Set to "1" at a duty match (priority) .
- Reset to "0" at a counter borrow event
- Has a fixed output mode to output a simple all "L" (or "H") signal.
- · Polarity can be specified

(4) 16-bit down counter

- Select from four types of counter operation clocks. Four internal clocks (φ, φ/4, φ/16, φ/64)
 φ: Machine clock cycles.
- The counter value can be initialized to "FFFFH" at a reset or counter borrow event.

(5) Interrupt requests

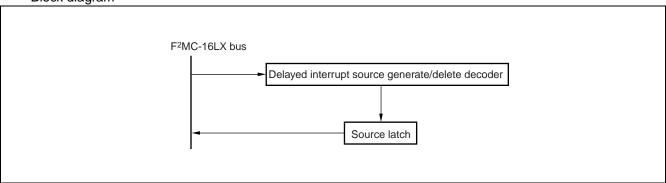

- Timer startup
- Counter borrow event (period match)
- · Duty match event
- Counter borrow event (period match) or duty match event
- (6) Multiple channels can be set to start up at an external trigger, or to restart during operation.

7. Delayed Interrupt Generator Module

The delayed interrupt generator module is a module that generates interrupts for task switching. This module makes it possible to use software to generate/cancel interrupt requests to the F²MC-16LX CPU.

• Block diagram

8. DTP/External Interrupt Circuit

The DTP (Data transfer peripheral) /external interrupt circuit is located between an externally connected peripheral device and the F²MC-16LX CPU and sends interrupt requests or data transfer requests generated from the peripheral device to the CPU, thereby generating external interrupt requests or starting the expanded intelligent I/O services (EI²OS).

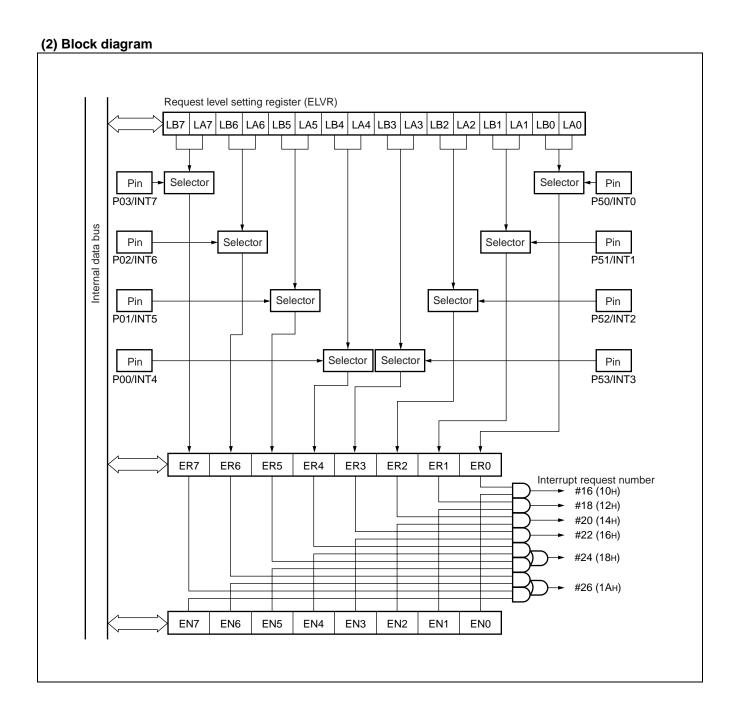

(1) DTP/external interrupt function

The DTP/external interrupt function uses a signal input from the DTP/external interrupt pin as a startup source. And it is accepted by the CPU by the same procedure as a normal hardware interrupt, and can generate an external interrupt or start the expanded intelligent I/O service (EI²OS).

When the interrupt is accepted by the CPU, if the corresponding expanded intelligent I/O service (El²OS) is prohibited the interrupt operates as an external interrupt function and branches to an interrupt routine. If the El²OS is permitted the interrupt functions as a DTP function, using El²OS for automatic data transfer, then branching to an interrupt routine after the completion of the specified number of data transfers.

	External interrupt	DTP function			
Input pins	8 pins (P50/INT0 to P53/INT3, P00/INT4	to P03 INT7)			
Interrupt courses	Request level setting register (ELVR) sets the detection level, or selected edge for each pin				
Interrupt sources	"H" level/ "L" level/ rising edge/falling edge input	"H" level/ "L" level input			
Interrupt numbers	#16 (10н) , #18 (12н) , #20 (14н) , #22 (16	бн) , #24 (18н) , #26 (1Aн)			
Interrupt control	DTP/interrupt enable register (ENIR) perr	mits/prohibits interrupt request output			
Interrupt flags	DTP/interrupt enable register (EIRR) stor	es interrupt sources			
Process selection	When El ² OS prohibited (ICR : ISE = 0) When El ² OS is enabled (ICR : ISE =				
Processing	Branch to external interrupt processing routine	El ² OS performs automatic data transfer then after a specified number of cycles, branches to an interrupt routine			

ICR: Interrupt control register

9. 8/10-bit A/D Converter

The 8/10-bit A/D converter has functions for using RC sequential comparator conversion format to convert analog input voltage into 10-bit or 8-bit digital values. The input signal is selected from 8-channel analog input pins, and the conversion start can be selected from three types: by software, 16-bit reload timer 1 or a trigger input from an external signal pin.

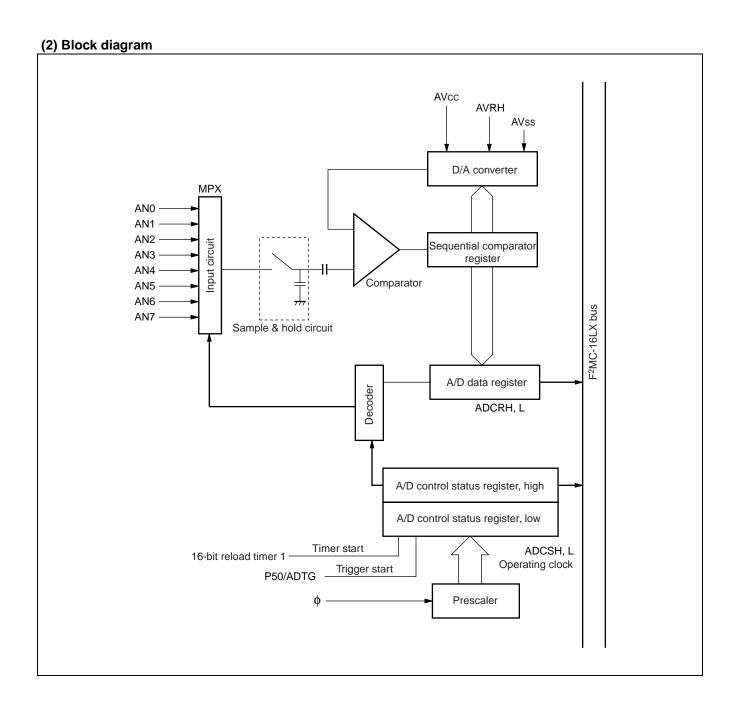

(1) 8/10-bit A/D converter functions

The A/D converter takes analog voltage signals (input voltage) input at analog input pins, and converts these to digital values, providing the following features.

- Minimum conversion time is $6.13~\mu s$ (at machine clock frequency of 16~MHz, including sampling time) .
- Minimum sampling time is 3.75 μs (at machine clock 16 MHz)
- The conversion method is an RC sequential conversion in comparison with a sample hold circuit.
- Either 10-bit or 8-bit resolution can be selected.
- The analog input pin can select from 8 channels by a program setting.
- At completion of A/D conversion, an interrupt request can be generated, or El²OS can be started.
- Because the conversion data protection function operates in an interrupt enabled state, no data is lost even in continuous conversion.
- The conversion start source may be selected from : software, 16-bit reload timer 1 (rising edge) , or external trigger input (falling edge) .

Three conversion modes are available

Conversion mode	Single conversion operation	Scan conversion operation
Single conversion mode	Converts the specified channel (1 channel only) one time, then stops.	Converts multiple consecutive channels (up to 8 channels may be specified) one time, then stops.
Continuous conversion mode	Converts the specified channel (1 channel only) repeatedly.	Converts multiple consecutive channels (up to 8 channels may be specified) repeatedly.
Stop conversion mode	Converts the specified channel (1 channel only) one time, then pauses, waits until the next start is applied.	Converts multiple consecutive channels (up to 8 channels may be specified), however pauses after conversion of each channel, waits until the next start is applied.

10. UART

The UART is a general purpose serial data communication interface for synchronous communication, or asynchronous (start-stop synchronized) communication with external devices. Functions include normal bi-directional functions, as well as master/slave type communication functions (multi-processor mode: master side only supported).

(1) UART Functions

The UART is a general purpose serial data communication interface for sending and receiving of serial data with other CPU's or peripheral devices, and provides the following functions.

	Functions
Data buffer	Full duplex double buffer
Transfer modes	Clock synchronous (no start/stop bits)Clock asynchronous (start-stop synchronized)
Baud rate	 Exclusive baud rate generator provides a selection of 8 rates External clock input enabled Internal clock (can use internal clock feed from 16-bit reload timer)
Data length	7-bit (asynchronous normal mode only)8-bit
Signal type	NRZ (Non return to zero)
Receiving error detection	 Framing errors Overrun errors Parity errors (not enabled in multiprocessor mode)
Interrupt request	 Receiving interrupt (receiving completed, receiving error detection) Sending interrupt (sending completed) Sending/receiving both compatible with expanded intelligent I/O services (EI²OS)
Master/slave type communication function (multi-processor mode)	1 (master) -to-n (slave) communication enabled (only master side supported) .

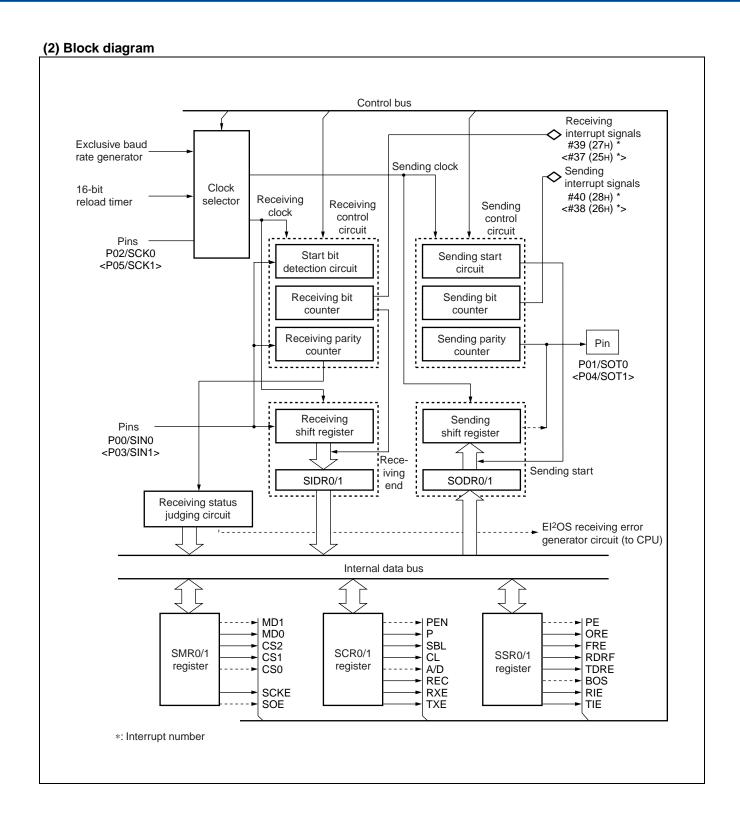

Note: The UART in clock synchronous transfer does not add start bits or stop bits, but transfers data only.

	Operating mode	Data I	ength	Synchronization	Stop bit length	
	No par		Parity	Sylicinomization	Stop bit length	
0	Normal mode	7-bit or 8-bit		Asynchronous	1-bit or 2-bit *2	
1	Multi-processor mode	8 + 1 *1	_	Asynchronous	1-011 01 2-011 -	
2	Normal mode	8 —		Synchronous	None	

^{—:} Setting not available

^{*1: &}quot;+" indicates an address/data selection bit (A/D) for communication control.

^{*2 :} In receiving only one stop bit is detected.

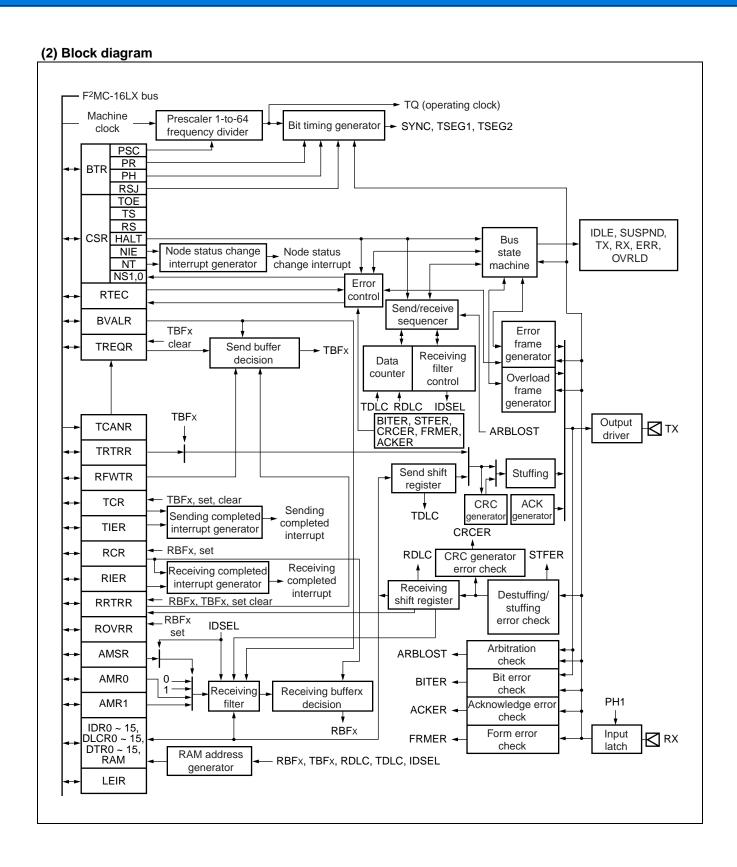

11. CAN Controller

The CAN controller is a self-contained module within a 16-bit microcomputer (F²MC-16LX). The CAN (controller area network) controller is the standard protocol for serial transmissions among automotive controllers and is widely used in the industry.

(1) CAN controller features

The CAN controller has the following features.

- Conforms to CAN specifications version 2.0 A and B.
 Supports sending and receiving in standard frame and expanded frame format.
- Supports data frame sending by means of remote frame receiving.
- 16 sending/receiving message buffers 29-bit ID and 8-byte data
 - Multi-level message buffer configuration
- Supports full bit compare, full bit mask as well as partial bet mask filtering.
 Provides two receiving mask registers for either standard frame or expanded frame format.
- Bit speed programmable from 10 KB/s to 1 MB/s (at machine clock 16 MHz)
- CAN WAKE UP function
- The MB90420G (A) series has a two-channel built-in CAN controller. The MB90425G (A) series has a 1-channel built-in CAN controller.

12. LCD Controller/Driver

The LCD controller/driver has a built-in 16×8 -bit display data memory, and controls the LCD display by means of four common outputs and 24 segment outputs. A selection of three duty outputs are available. This block can drive an LCD (liquid crystal display) panel directly.

(1) LCD controller/driver functions

The LCD controller/driver provides functions for directly displaying the contents of display data memory (display RAM) on the LCD panel by means of segment output and common output.

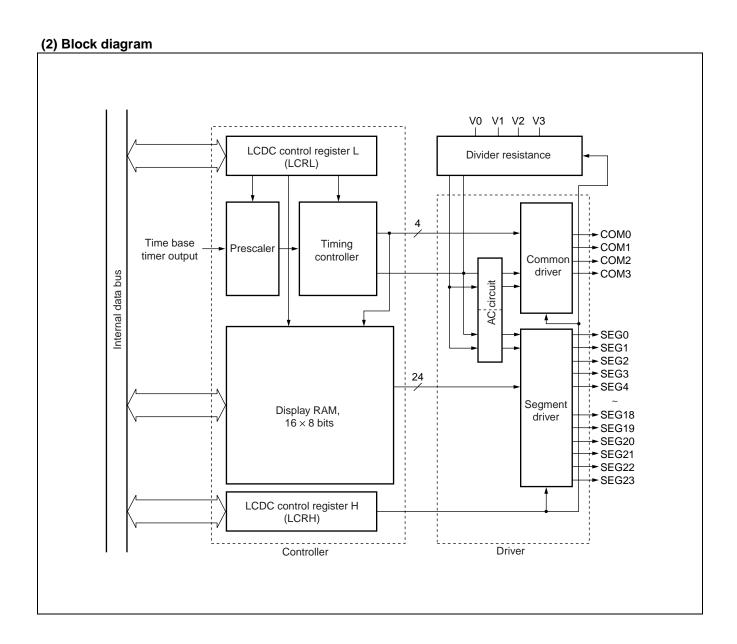

- LCD drive voltage divider resistance is built-in. External divider resistance can also be connected.
- Up to 4 common outputs (COM0 to COM3) and 24 segment outputs (SEG0 to SEG23) can be used.
- 16-byte display data memory (display RAM) is built-in.
- The duty can be selected at 1/2, 1/3, 1/4 (limited by bias setting) .
- Drives the LCD directly.

Bias	1/2 duty	1/3 duty	1/4 duty	
1/2 bias	0	×	×	
1/3 bias	×	0	0	

: Recommended mode

× : Use prohibited

Note: When the SEG12 to SEG23 pins have been selected as general purpose ports by the LCRH setting, they cannot be used for segment output.

13. Low voltage/Program Looping Detection Reset Circuit

The Low voltage detection reset circuit is a function that monitors power supply voltage in order to detect when a voltage drops below a given voltage level. When a low voltage condition is detected, an internal reset signal is generated.

The Program Looping detection reset circuit is a count clock with a 20-bit counter that generates an internal reset signal if not cleared within a given time after startup.

(1) Low voltage detection reset circuit

Detection voltage
$4.0 \text{ V} \pm 0.3 \text{ V}$

When a low voltage condition is detected, the low voltage detection flag (LVRC : LVRF) is set to "1" and an internal reset signal is output.

Because the low voltage detection circuit continues to operate even in stop mode, detection of a low voltage condition generates an internal reset and releases stop mode.

During an internal RAM write cycle, an internal reset is generated after the completion of writing. During the output of this internal reset, the reset output from the low voltage detection circuit is suppressed.

(2) Program Looping detection reset circuit

The Program Looping detection reset circuit is a counter that prevents program looping. The counter starts automatically after a power-on reset, and must be continually cleared within a given time. If the given time interval elapses and the counter has not been cleared, a cause such as infinite program looping is assumed and an internal reset signal is generated. The internal reset generated form the Program Looping detection circuit has a width of 5 machine cycles.

Interval duration	Number of oscillation clock cycles		
Approx. 262 ms *	2 ²⁰ cycles		

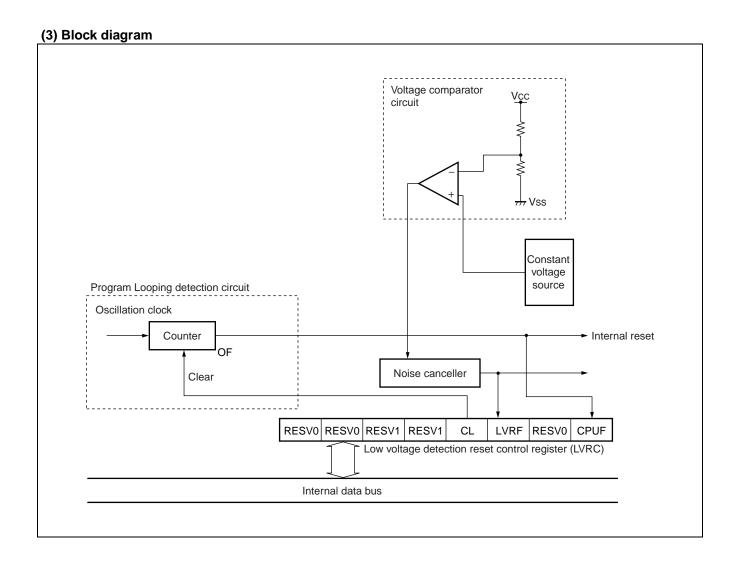

^{*:} This value assumes an oscillation clock speed of 4 MHz.

During recovery from standby mode the detection period is the maximum interval plus 20 µs.

This circuit does not operate in modes where CPU operation is stopped.

The Program Looping detection reset circuit counter is cleared under any of the following conditions.

- 1. Writing "0" to the LVRC register CL bit
- 2. Internal reset
- 3. Main oscillation clock stop
- 4. Transition to sleep mode
- 5. Transition to time base timer mode or clock mode
- 6. Start of hold

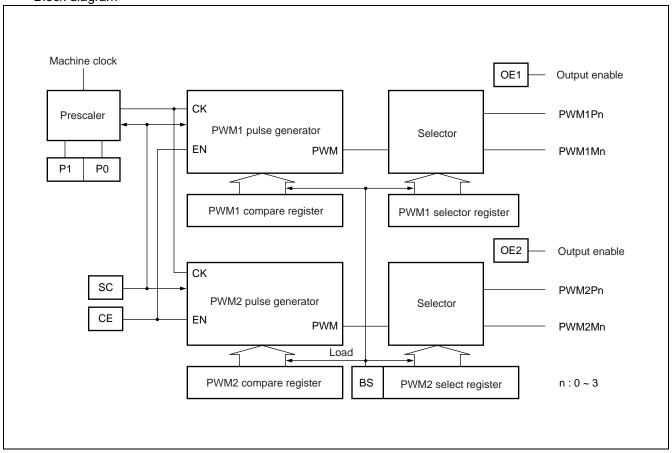

14. Stepping Motor Controller

The stepping motor controller is composed of two PWM pulse generators, four motor drivers and selector logic circuits.

The four motor drivers have a high output drive capacity and can be directly connected to the four ends of two motor coils. They are designed to operate together with the PWM pulse generators and selector logic circuits to control motor rotation. A synchronization mechanism assures synchronization of the two PWM pulse generators.

15. Sound Generator

The sound generator is composed of a sound control register, frequency data register, amplitude data register, decrement grade register, tone count register, PWM pulse generator, frequency counter, decrement counter, and tone pulse counter.

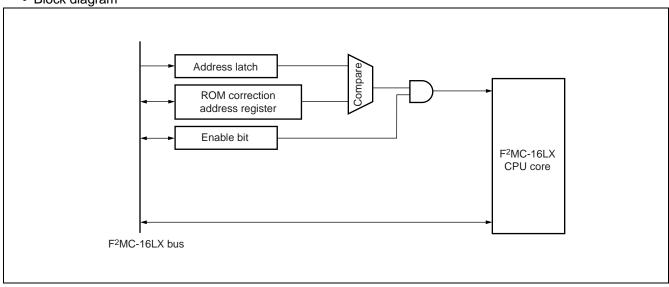

• Block diagram Clock input Prescaler Frequency 8-bit PWM Toggle СО counter CI pulse generator flip-flop ΕN CO D **PWM** ΕN ΕN S1 S0 Reload Reload 1/d Frequency data Amplitude data register register DEC DEC Decrement CI counter CO ΕN SGA OE1 Decrement grade register Blend SGO OE2 Tone pulse TONE OE2 counter CI CO ΕN INTE INT ST Tone count register IRQ

16. Address Match Detect Function

If the address setting is the same as the ROM correction address register, an INT9 instruction is executed. The ROM correction function can be implemented by processing the INT9 interrupt service routine.

Two address registers are used, each with its own compare enable bit. When there is a match between the address register and program counter, and the compare enable bit is set to "1", the INT9 instruction is forcibly executed by the CPU.

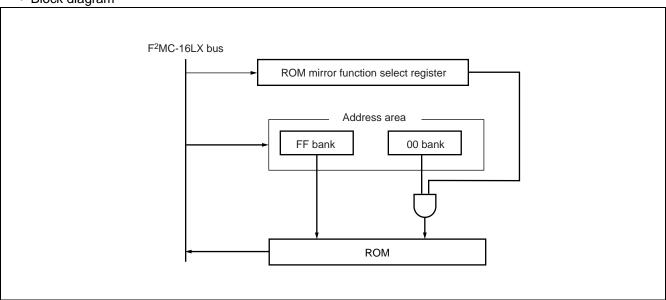

• Block diagram

17. ROM Mirror Function Select Module

The ROM mirror function select module uses a select register setting to enable the contents of ROM allocated to the FF bank to be viewed in the 00 bank.

• Block diagram

^{*1 :} Care must be taken to ensure that AVcc and DVcc do not exceed Vcc at power-on etc.

WARNING: Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of absolute maximum ratings. Do not exceed these ratings.

^{*2 :} Maximum output current is defined as the peak value of the current of any one of the corresponding pins.

^{*3 :} Average output current is defined as the value of the average current flowing over 100 ms at any one of the corresponding pins. The "average value" can be calculated from the formula of "operating current" times "operating factor".

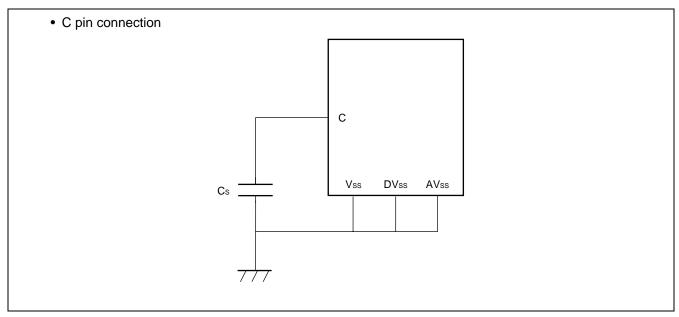

^{*4 :} Average total output current is defined as the value of the average current flowing over 100 ms at all of the corresponding pins. The "average value" can be calculated from the formula of "operating current" times "operating factor".

2. Recommended Operating Conditions

(Vss = DVss = AVss = 0.0 V)

Parameter	Symbol	Value		Unit	Remarks	
rarameter	Syllibol	Min.	Max.	Oilit	Kelliaiks	
	Vcc	4.5	5.5	V	In normal operation: (MB90F428G/F428GA, MB90428G/428GA, MB90427G/427GA)

		4.5	5.5	V	Holding stop operation status (MB90F428GA, MB90428GA, MB90427GA)	
Smoothing capacitor*	Cs	0.1	1.0	μF	Use a ceramic capacitor or other capacitor of equivalent frequency characteristics. A smoothing capacitor on the Vcc pin should have a capacitance greater than Cs.	
Operating temperature	Та	-40	+105	°C		

^{*:} For smoothing capacitor Cs connections, see the illustration below.

WARNING: The recommended operating conditions are required in order to ensure the normal operation of the semiconductor device. All of the device's electrical characteristics are warranted when the device is operated within these ranges.

Always use semiconductor devices within their recommended operating condition ranges. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their FUJITSU representatives beforehand.

^{*1 :} At FcP = 16 MHz, $t_{SMP} = 32 \times t_{CP} = 2.000 (\mu s)$.

Notes: •The relative error increases as AVRH is reduced.

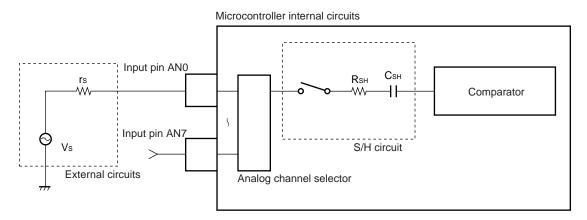

- •The output impedance (rs) on the external analog input circuit should be used as follows. External circuit output impedance $rs = 5 \text{ k}\Omega$ max.
- •If the output impedance on the external circuit is too great, the analog voltage sampling time may be insufficient.
- •If DC inhibitor capacitance is placed between the external circuit and input pin, then a capacitance value several thousand times the value of the chip internal sampling capacitance (CSH) should be selected in order to suppress the effects of voltage division with CSH.

^{*2 :} At Fcp = 16 MHz, $t_{CMP} = 66 \times t_{CP} = 4.125 \, (\mu s)$.

^{*3 :} Equivalent to conversion time per channel at $F_{CP} = 16$ MHz, and selection of $t_{SMP} = 32 \times t_{CP}$ and $t_{CMP} = 32 \times t_{CP}$

^{*4 :} Defined as supply current (when Vcc = AVcc = AVRH = 5.0 V) with A/D converter not operating, and CPU in stop mode.

· Analog input equivalent circuit

<Recommended and guide values for element parameters>

 $rs=5~k\Omega~or~less$

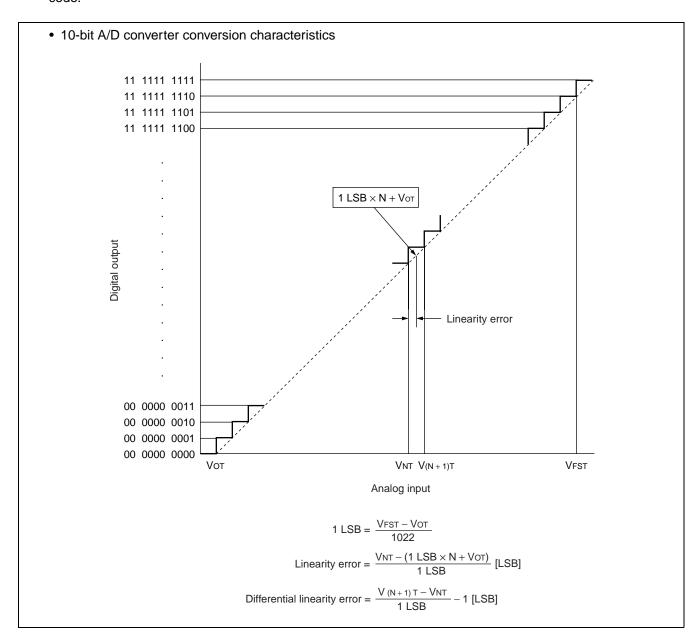

R_{SH} = approx. 3 k Ω

Сsн = approx. 25 pF

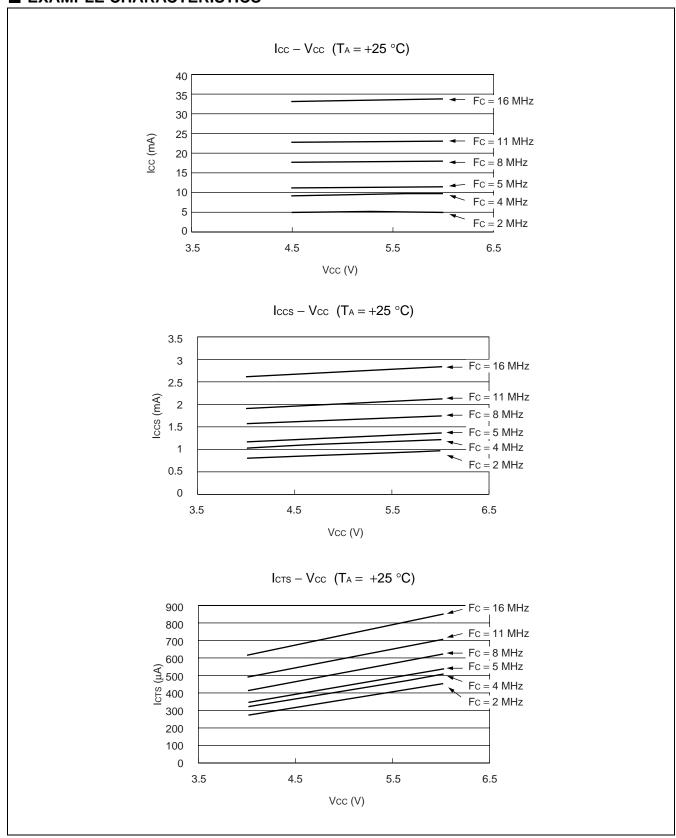

Note: These element parameters are intended as guidelines for reference, and are not warranted for actual use.

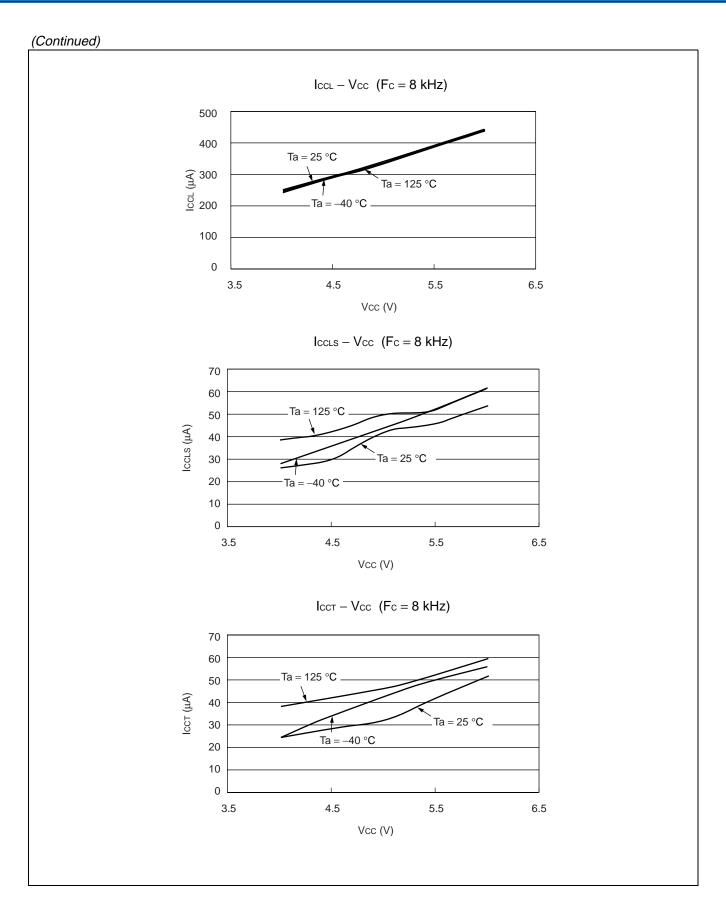

(2) Definition of terms

- Resolution
 - Indicates the ability of the A/D converter to discriminate in analog conversion.
 - 10-bit resolution indicates that analog voltage can be resolved into $2^{10} = 1024$ levels.
- · Total error
 - Expresses the difference between actual and logical values. It is the total value of errors that can come from offset error, gain error, non-linearity error and noise.
- · Linearity error
 - Expresses the deviation between actual conversion characteristics and a straight line connecting the device's zero transition point (00 0000 0000 \longleftrightarrow 00 0000 0001) and full scale transition point (11 1111 1110 \longleftrightarrow 11 1111 1111).
- Differential linearity error
 Expresses the deviation of the logical value of input voltage required to create a variation of 1 SLB in output code.

■ EXAMPLE CHARACTERISTICS

■ INSTRUCTIONS (351 INSTRUCTIONS)

Table 1 Explanation of Items in Tables of Instructions

Item	Meaning
Mnemonic	Upper-case letters and symbols: Represented as they appear in assembler. Lower-case letters: Replaced when described in assembler. Numbers after lower-case letters: Indicate the bit width within the instruction code.
#	Indicates the number of bytes.
~	Indicates the number of cycles. m: When branching n: When not branching See Table 4 for details about meanings of other letters in items.
RG	Indicates the number of accesses to the register during execution of the instruction. It is used calculate a correction value for intermittent operation of CPU.
В	Indicates the correction value for calculating the number of actual cycles during execution of the instruction. (Table 5) The number of actual cycles during execution of the instruction is the correction value summed with the value in the "~" column.
Operation	Indicates the operation of instruction.
LH	Indicates special operations involving the upper 8 bits of the lower 16 bits of the accumulator. Z: Transfers "0". X: Extends with a sign before transferring. -: Transfers nothing.
АН	Indicates special operations involving the upper 16 bits in the accumulator. * : Transfers from AL to AH. - : No transfer. Z : Transfers 00H to AH. X : Transfers 00H or FFH to AH by signing and extending AL.
I	Indicates the status of each of the following flags: I (interrupt enable), S (stack), T (sticky bit),
S	N (negative), Z (zero), V (overflow), and C (carry). * : Changes due to execution of instruction.
Т	- : No change.
N	S: Set by execution of instruction.
Z	R: Reset by execution of instruction.
V	
RMW	Indicates whether the instruction is a read-modify-write instruction. (a single instruction that reads data from memory, etc., processes the data, and then writes the result to memory.) * : Instruction is a read-modify-write instruction. - : Instruction is not a read-modify-write instruction. Note: A read-modify-write instruction cannot be used on addresses that have different meanings depending on whether they are read or written.

• Number of execution cycles

The number of cycles required for instruction execution is acquired by adding the number of cycles for each instruction, a corrective value depending on the condition, and the number of cycles required for program fetch. Whenever the instruction being executed exceeds the two-byte (word) boundary, a program on an internal ROM connected to a 16-bit bus is fetched. If data access is interfered with, therefore, the number of execution cycles is increased.

For each byte of the instruction being executed, a program on a memory connected to an 8-bit external data bus is fetched. If data access in interfered with, therefore, the number of execution cycles is increased. When a general-purpose register, an internal ROM, an internal RAM, an internal I/O device, or an external bus is accessed during intermittent CPU operation, the CPU clock is suspended by the number of cycles specified by the CG1/0 bit of the low-power consumption mode control register. When determining the number of cycles required for instruction execution during intermittent CPU operation, therefore, add the value of the number of times access is done \times the number of cycles suspended as the corrective value to the number of ordinary execution cycles.

Table 2 Explanation of Symbols in Tables of Instructions

Symbol	Meaning
A	32-bit accumulator The bit length varies according to the instruction. Byte: Lower 8 bits of AL Word: 16 bits of AL Long: 32 bits of AL and AH
AH AL	Upper 16 bits of A Lower 16 bits of A
SP	Stack pointer (USP or SSP)
PC	Program counter
PCB	Program bank register
DTB	Data bank register
ADB	Additional data bank register
SSB	System stack bank register
USB	User stack bank register
SPB	Current stack bank register (SSB or USB)
DPR	Direct page register
brg1	DTB, ADB, SSB, USB, DPR, PCB, SPB
brg2	DTB, ADB, SSB, USB, DPR, SPB
Ri	R0, R1, R2, R3, R4, R5, R6, R7
RWi	RW0, RW1, RW2, RW3, RW4, RW5, RW6, RW7
RWj	RW0, RW1, RW2, RW3
RLi	RL0, RL1, RL2, RL3
dir	Compact direct addressing
addr16 addr24 ad24 0 to 15 ad24 16 to 23	Direct addressing Physical direct addressing Bit 0 to bit 15 of addr24 Bit 16 to bit 23 of addr24
io	I/O area (000000н to 0000FFн)
imm4 imm8 imm16 imm32 ext (imm8)	4-bit immediate data 8-bit immediate data 16-bit immediate data 32-bit immediate data 16-bit data signed and extended from 8-bit immediate data
disp8 disp16	8-bit displacement 16-bit displacement
bp	Bit offset
vct4 vct8	Vector number (0 to 15) Vector number (0 to 255)
()b	Bit address
rel	PC relative addressing
ear eam	Effective addressing (codes 00 to 07) Effective addressing (codes 08 to 1F)
rlst	Register list

Table 3 Effective Address Fields

Code	ı	Notation	1	Address format	Number of bytes in address extension *
00 01 02 03 04 05 06 07	R0 R1 R2 R3 R4 R5 R6 R7	RW0 RW1 RW2 RW3 RW4 RW5 RW6 RW7	RL0 (RL0) RL1 (RL1) RL2 (RL2) RL3 (RL3)	Register direct "ea" corresponds to byte, word, and long-word types, starting from the left	
08 09 0A 0B	@R\ @R\ @R\ @R\	N1 N2		Register indirect	0
0C 0D 0E 0F	@R\ @R\	N0 + N1 + N2 + N3 +		Register indirect with post-increment	0
10 11 12 13 14 15 16 17	@R\ @R\ @R\ @R\ @R\	N0 + dis N1 + dis N2 + dis N3 + dis N4 + dis N5 + dis N6 + dis N7 + dis	p8 p8 p8 p8 p8 p8	Register indirect with 8-bit displacement	1
18 19 1A 1B	@R\ @R\	N0 + dis N1 + dis N2 + dis N3 + dis	p16 p16	Register indirect with 16-bit displacement	2
1C 1D 1E 1F	@R\	W0 + RW W1 + RW C + disp1 16	<i>l</i> 7	Register indirect with index Register indirect with index PC indirect with 16-bit displacement Direct address	0 0 2 2

Note: The number of bytes in the address extension is indicated by the "+" symbol in the "#" (number of bytes) column in the tables of instructions.

Table 4 Number of Execution Cycles for Each Type of Addressing

		(a)	Number of register accesses					
Code	Operand	Number of execution cycles for each type of addressing	Number of register accesses for each type of addressing					
00 to 07	Ri RWi RLi	Listed in tables of instructions	Listed in tables of instructions					
08 to 0B	@RWj	2	1					
0C to 0F	@RWj +	4	2					
10 to 17	@RWi + disp8	2	1					
18 to 1B	@RWj + disp16	2	1					
1C 1D 1E 1F	@RW0 + RW7 @RW1 + RW7 @PC + disp16 addr16	4 4 2 1	2 2 0 0					

Note: "(a)" is used in the "~" (number of states) column and column B (correction value) in the tables of instructions.

Table 5 Compensation Values for Number of Cycles Used to Calculate Number of Actual Cycles

Operand	(b)	byte	(c) v	vord	(d) I	ong
Operand	Cycles	Access	Cycles	Access	Cycles	Access
Internal register	+0	1	+0	1	+0	2
Internal memory even address Internal memory odd address	+0 +0	1 1	+0 +2	1 2	+0 +4	2 4
Even address on external data bus (16 bits) Odd address on external data bus (16 bits)	+1 +1	1 1	+1 +4	1 2	+2 +8	2 4
External data bus (8 bits)	+1	1	+4	2	+8	4

Notes: • "(b)", "(c)", and "(d)" are used in the "~" (number of states) column and column B (correction value) in the tables of instructions.

• When the external data bus is used, it is necessary to add in the number of wait cycles used for ready input and automatic ready.

Table 6 Correction Values for Number of Cycles Used to Calculate Number of Program Fetch Cycles

Instruction	Byte boundary	Word boundary
Internal memory	_	+2
External data bus (16 bits)	_	+3
External data bus (8 bits)	+3	_

Notes: • When the external data bus is used, it is necessary to add in the number of wait cycles used for ready input and automatic ready.

• Because instruction execution is not slowed down by all program fetches in actuality, these correction values should be used for "worst case" calculations.

- *1: Set to 3 when the division-by-0, 8 or 18 for an overflow, and 18 for normal operation.
- *2: Set to 3 when the division-by-0, 10 or 21 for an overflow, and 22 for normal operation.
- *3: Set to 4 + (a) when the division-by-0, 11 + (a) or 22 + (a) for an overflow, and 23 + (a) for normal operation.
- *4: Positive dividend: Set to 4 when the division-by-0, 10 or 29 for an overflow, and 30 for normal operation. Negative dividend: Set to 4 when the division-by-0, 11 or 30 for an overflow and 31 for normal operation.
- *5: Positive dividend: Set to 4 + (a) when the division-by-0, 11 + (a) or 30 + (a) for an overflow, and 31 + (a) for normal operation.

Negative dividend: Set to 4 + (a) when the division-by-0, 12 + (a) or 31 + (a) for an overflow, and 32 + (a) for normal operation.

- *6: When the division-by-0, (b) for an overflow, and $2 \times$ (b) for normal operation.
- *7: When the division-by-0, (c) for an overflow, and $2 \times (c)$ for normal operation.
- *8: Set to 3 when byte (AH) is zero, 12 when the result is positive, and 13 when the result is negative.
- *9: Set to 3 when byte (ear) is zero, 12 when the result is positive, and 13 when the result is negative.
- *10: Set to 4 + (a) when byte (eam) is zero, 13 + (a) when the result is positive, and 14 + (a) when the result is negative.
- *11: Set to 3 when word (AH) is zero, 12 when the result is positive, and 13 when the result is negative.
- *12: Set to 3 when word (ear) is zero, 16 when the result is positive, and 19 when the result is negative.
- *13: Set to 4 + (a) when word (eam) is zero, 17 + (a) when the result is positive, and 20 + (a) when the result is negative.
- Notes: When overflow occurs during DIV or DIVW instruction execution, the number of execution cycles takes two values because of detection before and after an operation.
 - When overflow occurs during DIV or DIVW instruction execution, the contents of AL are destroyed.
 - For (a) to (d), refer to "Table 4 Number of Execution Cycles for Effective Address in Addressing Modes" and "Table 5 Correction Values for Number of Cycles for Calculating Actual Number of Cycles."

All Rights Reserved.

The contents of this document are subject to change without notice. Customers are advised to consult with FUJITSU sales representatives before ordering.

The information and circuit diagrams in this document are presented as examples of semiconductor device applications, and are not intended to be incorporated in devices for actual use. Also, FUJITSU is unable to assume responsibility for infringement of any patent rights or other rights of third parties arising from the use of this information or circuit diagrams.

The contents of this document may not be reproduced or copied without the permission of FUJITSU LIMITED.

FUJITSU semiconductor devices are intended for use in standard applications (computers, office automation and other office equipments, industrial, communications, and measurement equipments, personal or household devices, etc.).

CAUTION:

Customers considering the use of our products in special applications where failure or abnormal operation may directly affect human lives or cause physical injury or property damage, or where extremely high levels of reliability are demanded (such as aerospace systems, atomic energy controls, sea floor repeaters, vehicle operating controls, medical devices for life support, etc.) are requested to consult with FUJITSU sales representatives before such use. The company will not be responsible for damages arising from such use without prior approval.

Any semiconductor devices have inherently a certain rate of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions.

If any products described in this document represent goods or technologies subject to certain restrictions on export under the Foreign Exchange and Foreign Trade Control Law of Japan, the prior authorization by Japanese government should be required for export of those products from Japan.
