

125MHz Single Supply Dual/Quad Op Amps

The EL2250/EL2450 are part of a family of the electronics industries fastest single supply op amps

available. Prior single supply op amps have generally been limited to bandwidths and slew rates to that of the EL2250/EL2450. The 125MHz bandwidth, 275V/μs slew rate, and 0.05%/0.05° differential gain/differential phase makes this part ideal for single or dual supply video speed applications. With its voltage feedback architecture, this amplifier can accept reactive feedback networks, allowing them to be used in analog filtering applications. The inputs can sense signals below the bottom supply rail and as high as 1.2V below the top rail. Connecting the load resistor to ground and operating from a single supply, the outputs swing completely to ground without saturating. The outputs can also drive to within 1.2V of the top rail. The EL2250/EL2450 will output ±100mA and will operate with single supply voltages as low as 2.7V, making them ideal for portable, low power applications.

The EL2250/EL2450 are available in PDIP and SO packages in industry standard pin outs. Both parts operate over the industrial temperature range of -40°C to +85°C, and are part of a family of single supply op amps. For single amplifier applications, see the EL2150/EL2157. For dual and triple amplifiers with power down and output voltage clamps, see the EL2257/EL2357.

NOTE: Intersil Pb-free products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which is compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J Std-020B.

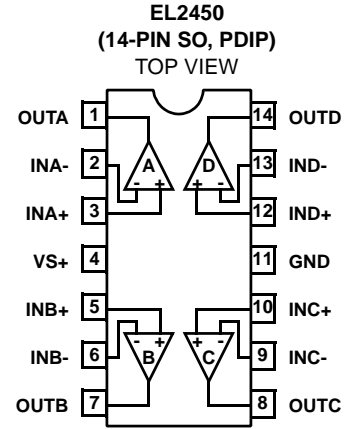

Features

- Specified for +3V, +5V, or ±5V applications
- Large input common mode range
 $0V < V_{CM} < V_S - 1.2V$
- Output swings to ground without saturating
- -3dB bandwidth = 125MHz
- ±0.1dB bandwidth = 30MHz
- Low supply current = 5mA (per amplifier)
- Slew rate = 275V/μs
- Low offset voltage = 4mV max
- Output current = ±100mA
- High open loop gain = 80dB
- Differential gain = 0.05%
- Differential phase = 0.05°
- Pb-free available

Applications

- Video amplifiers
- PCMCIA applications
- A/D drivers
- Line drivers
- Portable computers
- High speed communications
- RGB printers, FAX, scanners
- Broadcast equipment
- Active filtering

Applications Information

Product Description

The EL2250/EL2450 are part of a family of the industries fastest single supply operational amplifiers. Connected in voltage follower mode, their -3dB bandwidth is 125MHz while maintaining a 275V/ μ s slew rate. With an input and output common mode range that includes ground, these amplifiers were optimized for single supply operation, but will also accept dual supplies. They operate on a total supply voltage range as low as +2.7V or up to +12V. This makes them ideal for +3V applications, especially portable computers.

While many amplifiers claim to operate on a single supply, and some can sense ground at their inputs, most fail to truly drive their outputs to ground. If they do succeed in driving to ground, the amplifier often saturates, causing distortion and recovery delays. However, special circuitry built into the EL2250/EL2450 allows the output to follow the input signal to ground without recovery delays.

Power Supply Bypassing And Printed Circuit Board Layout

As with any high-frequency device, good printed circuit board layout is necessary for optimum performance. Ground plane construction is highly recommended. Lead lengths should be as short as possible. The power supply pins must be well bypassed to reduce the risk of oscillation. The combination of a 4.7 μ F tantalum capacitor in parallel with a 0.1 μ F ceramic capacitor has been shown to work well when placed at each supply pin. For single supply operation, where the GND pin is connected to the ground plane, a single 4.7 μ F tantalum capacitor in parallel with a 0.1 μ F ceramic capacitor across the V_{S+} and GND pins will suffice.

For good AC performance, parasitic capacitance should be kept to a minimum. Ground plane construction should be used. Carbon or Metal-Film resistors are acceptable with the

Metal-Film resistors giving slightly less peaking and bandwidth because of their additional series inductance. Use of sockets, particularly for the SO package should be avoided if possible. Sockets add parasitic inductance and capacitance which will result in some additional peaking and overshoot.

Supply Voltage Range and Single-Supply Operation

The EL2250/EL2450 have been designed to operate with supply voltages having a span of greater than 2.7V, and less than 12V. In practical terms, this means that the EL2250/EL2450 will operate on dual supplies ranging from ± 1.35 V to ± 6 V. With a single-supply, the EL2250/EL2450 will operate from +2.7V to +12V. Performance has been optimized for a single +5V supply.

Pins 8 and 4 are the power supply pins on the EL2250. The positive power supply is connected to pin 8. When used in single supply mode, pin 4 is connected to ground. When used in dual supply mode, the negative power supply is connected to pin 4.

Pins 4 and 11 are the power supply pins on the EL2450. The positive power supply is connected to pin 4. When used in single supply mode, pin 11 is connected to ground. When used in dual supply mode, the negative power supply is connected to pin 11.

As supply voltages continue to decrease, it becomes necessary to provide input and output voltage ranges that can get as close as possible to the supply voltages. The EL2250/EL2450 have an input voltage range that includes the negative supply and extends to within 1.2V of the positive supply. So, for example, on a single +5V supply, the EL2250/EL2450 have an input range which spans from 0V to 3.8V.

The output range of the EL2250/EL2450 is also quite large. It includes the negative rail, and extends to within 1V of the top supply rail with a 1k Ω load. On a +5V supply, the output is therefore capable of swinging from 0V to +4V. On split supplies, the output will swing ± 4 V. If the load resistor is tied to the negative rail and split supplies are used, the output range is extended to the negative rail.

Choice Of Feedback Resistor, R_F

The feedback resistor forms a pole with the input capacitance. As this pole becomes larger, phase margin is reduced. This increases ringing in the time domain and peaking in the frequency domain. Therefore, R_F has some maximum value which should not be exceeded for optimum performance. If a large value of R_F must be used, a small capacitor in the few picofarad range in parallel with R_F can help to reduce this ringing and peaking at the expense of reducing the bandwidth.

As far as the output stage of the amplifier is concerned, $R_F + R_G$ appear in parallel with R_L for gains other than +1. As this combination gets smaller, the bandwidth falls off. Consequently, R_F has a minimum value that should not be exceeded for optimum performance.

For $A_V = +1$, $R_F = 0\Omega$ is optimum. For $A_V = -1$ or +2 (noise gain of 2), optimum response is obtained with R_F between 500 Ω and 1k Ω . For $A_V = -4$ or +5 (noise gain of 5), keep R_F between 2k Ω and 10k Ω .

Video Performance

For good video performance, an amplifier is required to maintain the same output impedance and the same frequency response as DC levels are changed at the output. This can be difficult when driving a standard video load of 150 Ω , because of the change in output current with DC level. Differential Gain and Differential Phase for the EL2250/EL2450 are specified with the black level of the output video signal set to +1.2V. This allows ample room for the sync pulse even in a gain of +2 configuration. This results in dG and dP specifications of 0.05% and 0.05 $^\circ$ while driving 150 Ω at a gain of +2. Setting the black level to other values, although acceptable, will compromise peak performance. For example, looking at the single supply dG and dP curves for $R_L=150\Omega$, if the output black level clamp is reduced from 1.2V to 0.6V dG/dP will increase from 0.05%/0.05 $^\circ$ to 0.08%/0.25 $^\circ$. Note that in a gain of +2 configuration, this is the lowest black level allowed such that the sync tip doesn't go below 0V.

If your application requires that the output goes to ground, then the output stage of the EL2250/EL2450, like all other single supply op amps, requires an external pull down resistor tied to ground. As mentioned above, the current flowing through this resistor becomes the DC bias current for the output stage NPN transistor. As this current approaches zero, the NPN turns off, and dG and dP will increase. This becomes more critical as the load resistor is increased in

value. While driving a light load, such as 1k Ω , if the input black level is kept above 1.25V, dG and dP are a respectable 0.03% and 0.03 $^\circ$.

For other biasing conditions see the Differential Gain and Differential Phase vs. Input Voltage curves.

Output Drive Capability

In spite of their moderately low 5mA of supply current, the EL2250/EL2450 are capable of providing ± 100 mA of output current into a 10 Ω load, or ± 60 mA into 50 Ω . With this large output current capability, a 50 Ω load can be driven to ± 3 V with $V_S = \pm 5$ V, making it an excellent choice for driving isolation transformers in telecommunications applications.

Driving Cables and Capacitive Loads

When used as a cable driver, double termination is always recommended for reflection-free performance. For those applications, the back-termination series resistor will decouple the EL2250/EL2450 from the cable and allow extensive capacitive drive. However, other applications may have high capacitive loads without a back-termination resistor. In these applications, a small series resistor (usually between 5 Ω and 50 Ω) can be placed in series with the output to eliminate most peaking. The gain resistor (R_G) can then be chosen to make up for any gain loss which may be created by this additional resistor at the output.

Video Sync Pulse Remover Application

All CMOS Analog to Digital Converters (A/Ds) have a parasitic latch-up problem when subjected to negative input voltage levels. Since the sync tip contains no useful video information and it is a negative going pulse, we can chop it off.

Figure 1 shows a unity gain connected amplifier A of an EL2250. Figure 2 shows the complete input video signal applied at the input, as well as the output signal with the negative going sync pulse removed.

FIGURE 1.

FIGURE 2.

Short Circuit Current Limit

The EL2250/EL2450 have internal short circuit protection circuitry that protect it in the event of its output being shorted to either supply rail. This limit is set to around 100mA nominally and reduces with increasing junction temperature. It is intended to handle temporary shorts. If an output is shorted indefinitely, the power dissipation could easily increase such that the part will be destroyed. Maximum reliability is maintained if the output current never exceeds ±90mA. A heat sink may be required to keep the junction temperature below absolute maximum when an output is shorted indefinitely.

Power Dissipation

With the high output drive capability of the EL2250/EL2450, it is possible to exceed the 150°C Absolute Maximum junction temperature under certain load current conditions. Therefore, it is important to calculate the maximum junction temperature for the application to determine if power-supply voltages, load conditions, or package type need to be modified for the EL2250/EL2450 to remain in the safe operating area.

The maximum power dissipation allowed in a package is determined according to [1]:

$$PD_{MAX} = \frac{T_{JMAX} - T_{AMAX}}{\theta_{JA}}$$

where:

T_{JMAX} = Maximum Junction Temperature

T_{AMAX} = Maximum Ambient Temperature

θ_{JA} = Thermal Resistance of the Package

PD_{MAX} = Maximum Power Dissipation in the Package.

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the load, or [2]:

$$PD_{MAX} = N \times \left(V_S \times I_{SMAX} + (V_S - V_{OUT}) \times \frac{V_{OUT}}{R_L} \right)$$

where:

N = Number of amplifiers

V_S = Total Supply Voltage

I_{SMAX} = Maximum Supply Current per amplifier

V_{OUT} = Maximum Output Voltage of the Application

R_L = Load Resistance tied to Ground

If we set the two PD_{MAX} equations, [1] & [2], equal to each other, and solve for V_S , we can get a family of curves for various loads and output voltages according to [3]:

$$V_S = \frac{\frac{R_L \times (T_{JMAX} - T_{AMAX})}{N \times \theta_{JA}} + (V_{OUT})}{(I_S \times R_L) + V_{OUT}}$$

Figures 3 through 6 below show total single supply voltage V_S vs. R_L for various output voltage swings for the PDIP and SO packages. The curves assume WORST CASE conditions of $T_A = +85^\circ\text{C}$ and $I_S = 6.5\text{mA}$ per amplifier.
