TEMIC

U6433B-FP

Hazard Warning and Car Direction Indicator

Description

It's design is mainly based on the good results of U6043B in terms of EMC (Electro Magnetic Capability) and protection features. U6433B contains an additional 8-mV comparator and a logical connection with the frequency doubling stage. This combination can be used for a hazard switch which bypasses the external shunt resistor to disable the frequency doubling. This feature is a request of the US automotive industry. During direction mode U6433B works like other flashers, i.e., frequency doubling in the case of lamp outage.

Features

- Temperature and voltage compensated frequency
- Warning indication of lamp failure by means of frequency doubling can be disabled
- Voltage dependence of the car indicator lamps compensated for lamp failure
- Relay output with high current carrying capacity and low saturation voltage
- Lamp load $\geq$ 1 W

- Load-dump protection
- RF protected
- Damage and interference protection with a minimum of external components

Benefits

U6433B gives an easy access to more flasher applications in the US automotive market

Circuit Description

The application circuit shows the operation of the U6433B-FP as a car direction indicator signal generator. The flashing frequency is determined by the components R_t snd C_t, and the frequency can be calculated from

$$f_1 \sim \frac{1}{R_t \cdot C_t \cdot 1.5} \text{ (Hz)}$$

where f_1 is the frequency in normal flashing operation (basic frequency). The control frequency, f_2, is typically 2.2 times the value of f_1 and is the frequency in the case of lamp failure. The bright periods for f_1 and f_2 are internally set in the IC and are 50% for f_1 and 40% for f_2.

The resistors R_1 and R_2 are needed to protect the circuit against possible damage. An integrated protection circuit, together with these external resistors, limits the impulse current in the integrated circuit.

Protection in the case of battery reversal: The resistors R_1, R_2 and the relay coil limit the currents so the integrated circuit will not be damaged. To achieve a protection for continuous battery reversal, resistor R_1 should be capable of 30 mA (0.5 W type).

A short circuit between indicator lamp (49a) and ground (31) can give rise to a voltage drop of about 4 V across the measuring resistance R_3. In this case, the integrated circuit would not be damaged.

The use of the application circuit (figure 1) ensures damage and interference protection consistent with ISO/TR 7637/1 and load dump.

Control Signal Threshold 1 (49-mV Comparator)

The detection point for lamp failure can be calculated from the control signal threshold, typically 49 mV with $V_S = 12$ V. With a measuring resistance of $R_3 = 18$ mΩ, the frequency changeover is reached at a lamp load of 21 W + 11.4 W. The variation of the control signal threshold supply voltage takes into account the PTC characteristic of filament lamps.

## Control Signal Threshold 2 (8-mV Comparator)

A voltage drop at R_3 between 49 mV and 8 mV shunt resistor let the flasher work in frequency doubling mode.

If the voltage drop of $V_{R3MAX} = 8$ mV falls the frequency doubling is disabled. This can be achieved either with a switch which by passes the shunt resistor (e.g., a special hazard warning switch) or with a small lamp load.

The arrangement of the supply connections to Pins 2 and 6 must ensure that, on the connection, PCB, the layer resistance from V_S to Pin 6 is lower than the one to Pin 2.

Flasher operation starts with a lamp load of $P_L \geqq 1$ W.

Preliminary Information

Pin Description
