
HM62P2321 Series

32768-Word × 32-Bit Synchronous Fast Static RAM with Burst
Counter and Pipelined Data Output

HITACHI

ADE-203-413 (Z)
Preliminary
Rev. 0.1
30 Oct 1996

Features

- 3.3 V core power supply
- 2.5 V I/O power supply
- Fast clock access time: 5/5.5 ns (max)
- Clock cycle times: 7.5/8.5/10 ns (min)
- Address data pipeline capability
- Internal input registers (Address, Data, Control)
- Internal data output registers
- Internal self-timed write cycle
- $\overline{\text{ADSP}}$, $\overline{\text{ADSC}}$ and $\overline{\text{ADV}}$ burst control pins (supports interleaving)
- Asynchronous output enable controlled three-state outputs
- Individual byte write control and global write
- Common data inputs and data outputs
- High board density 100-lead LQFP package

Notes: 1. H means logic HIGH, L means logic low. x means H or L. Write = L means any one or more byte write enable signals ($\overline{BW0}$, $\overline{BW1}$, $\overline{BW2}$ or $\overline{BW3}$) and $\overline{BWE}$ are low or $\overline{GW}$ is low. Write = H means all byte write enable signals and $\overline{GW}$ are high.

2. $\overline{BW0}$ enables write to Byte0 (DQ0 to DQ7). $\overline{BW1}$ enables write to Byte1 (DQ8 to DQ15). $\overline{BW2}$ enables write to Byte2 (DQ16 to DQ23). $\overline{BW3}$ enables write to Byte3 (DQ24 to DQ31).

3. All inputs except $\overline{OE}$ must meet setup and hold times around the rising edge (low to high) of CLK.

4. Wait states are inserted by suspending burst.

5. For a write operation following a read operation, $\overline{OE}$ must be HIGH before the input data required setup time and hold high throughout the input data hold time.

6. $\overline{ADSP}$ = low always initiates an internal read at the L-H edge of CLK. A write is performed by setting one or more byte write enable signals and $\overline{BWE}$ low or $\overline{GW}$ low for the subsequent L-H edge of CLK. Refer to write timing diagram for clarification.

- Notes: 1. Transition is measured ± 200 mV from steady-state voltage with load of Figure B. This parameter is sampled.
2. A READ cycle is defined by byte write enables all high or $\overline{ADSP}$ LOW for the required setup and hold times. A write cycle is defined by at least one byte write enable low and $\overline{ADSP}$ HIGH for the required setup and hold times.
3. This is a synchronous device. All address must meet the specified setup and hold times for all rising edges of CLK when either $\overline{ADSP}$ or $\overline{ADSC}$ is LOW and chip enabled. All other synchronous inputs must meet the setup and hold times with stable logic levels for all rising edges of clock (CLK) when chip is enabled. Chip enable must be valid at each rising edge of CLK (when either $\overline{ADSP}$ or $\overline{ADSC}$ is low) to remain enabled.
4. $\overline{OE}$ is H or L when a byte write enable is sampled LOW.

Detailed Pin Description

LQFP Pin Number	Symbol	Type	Description
37, 36, 35, 34, 33, 32, 100, 99, 82, 81, 44, 45, 46, 47, 48	A0 to A14	Input	Synchronous Address Inputs: These inputs are registered and must meet setup and hold times around the rising edge of CLK.
93, 94, 95, 96	$\overline{BW0}$, $\overline{BW1}$ $\overline{BW2}$, $\overline{BW3}$	Input	Synchronous Byte Write Enables: These active LOW inputs allow individual bytes to be written and must meet the setup and hold times around the rising edge of CLK. A byte write enable is low for a write cycle and high for a read cycle. $\overline{BW0}$ controls DQ0 to DQ7. $\overline{BW1}$ controls DQ8 to DQ15. $\overline{BW2}$ controls DQ16 to DQ23. $\overline{BW3}$ controls DQ24 to DQ31. Data I/O are tri-stated if any of these four inputs are LOW.
88	$\overline{GW}$	Input	Synchronous Global Write: This active low input allows a full 32 bit Write to occur independent of the $\overline{BWE}$ and $\overline{BWi}$ lines and must meet the setup and hold times around the rising edge of CLK. System must connect pin to V_{DD} when not used.
87	$\overline{BWE}$	Input	Synchronous Byte Write Enable: This active low input permits byte write operations and must meet the setup and hold times around the rising edge of CLK. System must connect pin to V_{SS} when not used.
89	CLK	Input	Clock: This signal latches the address, data, chip enables, byte write enables and burst control inputs on its rising edge. All synchronous inputs must meet setup and hold times around the clock's rising edge.
98	$\overline{CE1}$	Input	Synchronous Chip Enables: This active low input is used to enable the device and conditions internal use of ADSP. This input is sampled only when a new external address is load.
92	$\overline{CE2}$	Input	Synchronous Chip Enable: This active low input is used to enable the device. This input is sampled only when a external address is loaded. This input can be used for memory depth expansion.
97	CE2	Input	Synchronous Chip Enable: This active high input is used to enable the device. This input sampled only when a new external address is load. This input can be used for memory depth expansion.
86	$\overline{OE}$	Input	Output Enable: This active low asynchronous input enables the data I/O output drivers.
83	ADV	Input	Synchronous Address Advance: This active low input is used to advance the internal burst counter, controlling burst access after the external address is loaded. A high on this pin effectively causes wait status to be generated (no address advance). This pin must be HIGH at the rising edge of the first clock after an ADSP cycle is initiated if a write cycle is desired (to ensure use of correct address).

HM62P2321 Series

LQFP Pin Number	Symbol	Type	Description
84	$\overline{\text{ADSP}}$	Input	Synchronous Address Status Processor: This active low input interrupts any ongoing burst, causing a new external address to be latched. A read performed using the new address, independent of the byte write enables and $\overline{\text{ADSC}}$ but dependent upon CE2 and $\overline{\text{CE2}}$. $\overline{\text{ADSP}}$ is ignored if $\overline{\text{CE1}}$ is HIGH. Power-down state is entered if $\overline{\text{CE2}}$ is HIGH or CE2 is LOW.
85	$\overline{\text{ADSC}}$	Input	Synchronous Address Status Controller: This active LOW input interrupts any ongoing burst and causes a new external address to be latched. A READ or WRITE is performed using the new address if all chip enables are active. Power-down state is entered if one or more chip enabled are inactive.
