

PHASE-LOCKED-LOOP WITH LOCK DETECTOR

FEATURES

- Low power consumption
- Centre frequency up to 17 MHz (typ.) at $V_{CC} = 4.5$ V
- Choice of two phase comparators: EXCLUSIVE-OR; edge-triggered JK flip-flop;
- Excellent VCO frequency linearity
- VCO-inhibit control for ON/OFF keying and for low standby power consumption
- Minimal frequency drift
- Operation power supply voltage range:
VCO section 3.0 to 6.0 V
digital section 2.0 to 6.0 V
- Zero voltage offset due to op-amp buffering
- Output capability: standard
- I_{CC} category: MSI

SYMBOL	PARAMETER	CONDITIONS	TYPICAL		UNIT
			HC	HCT	
f_0	VCO centre frequency	$C_1 = 40 \text{ pF}$ $R_1 = 3 \text{ k}\Omega$ $V_{CC} = 5 \text{ V}$	19	19	MHz
C_I	input capacitance (pin 5)		3.5	3.5	pF
C_{PD}	power dissipation capacitance per package	notes 1 and 2	24	24	pF

 $GND = 0 \text{ V}; T_{amb} = 25^\circ\text{C}$

Notes

- Applies to the phase comparator section only (VCO disabled). For power dissipation of VCO and demodulator sections see Figs 20, 21 and 22.
- C_{PD} is used to determine the dynamic power dissipation (P_D in μW):

$$P_D = C_{PD} \times V_{CC}^2 \times f_i + \sum (C_L \times V_{CC}^2 \times f_o) \text{ where:}$$

 f_i = input frequency in MHz f_o = output frequency in MHz $\sum (C_L \times V_{CC}^2 \times f_o)$ = sum of outputs C_L = output load capacitance in pF V_{CC} = supply voltage in V

PACKAGE OUTLINES

16-lead DIL; plastic (SOT38CP).

16-lead mini-pack; plastic (SO16; SOT109A).

GENERAL DESCRIPTION

The 74HC/HCT7046 are high-speed Si-gate CMOS devices and are specified in compliance with JEDEC standard no. 7.

The 74HC/HCT7046 are phase-locked-loop circuits that comprise a linear voltage-controlled oscillator (VCO) and two different phase comparators (PC1 and PC2) with a common signal input amplifier and a common comparator input.

A lock detector is provided and this gives a HIGH level at pin 1 (LD) when the PLL is locked. The lock detector capacitor must be connected between pin 15 (C_{LD})

and pin 8 (GND). The value of the C_{LD} capacitor can be determined, using information supplied in Fig. 32. The input signal can be directly coupled to large voltage signals, or indirectly coupled (with a series capacitor) to small voltage signals. A self-bias input circuit keeps small voltage signals within the linear region of the input amplifiers. With a passive low-pass filter, the "7046" forms a second-order loop PLL. The excellent VCO linearity is achieved by the use of linear op-amp techniques.

(continued on next page)

APPLICATIONS

- FM modulation and demodulation
- Frequency synthesis and multiplication
- Frequency discrimination
- Tone decoding
- Data synchronization and conditioning
- Voltage-to-frequency conversion
- Motor-speed control

PIN DESCRIPTION

PIN NO.	SYMBOL	NAME AND FUNCTION
1	LD	lock detector output (active HIGH)
2	PC1OUT	phase comparator 1 output
3	COMPIN	comparator input
4	VCOOUT	VCO output
5	INH	inhibit input
6	C1A	capacitor C1 connection A
7	C1B	capacitor C1 connection B
8	GND	ground (0 V)
9	VCOIN	VCO input
10	DEMOUT	demodulator output
11	R1	resistor R1 connection
12	R2	resistor R2 connection
13	PC2OUT	phase comparator 2 output
14	SIGIN	signal input
15	CLD	lock detector capacitor input
16	VCC	positive supply voltage

GENERAL DESCRIPTION

VCO

The VCO requires one external capacitor C1 (between C1A and C1B) and one external resistor R1 (between R1 and GND) or two external resistors R1 and R2 (between R1 and GND, and R2 and GND). Resistor R1 and capacitor C1 determine the frequency range of the VCO. Resistor R2 enables the VCO to have a frequency offset if required.

The high input impedance of the VCO simplifies the design of low-pass filters by giving the designer a wide choice of

resistor/capacitor ranges. In order not to load the low-pass filter, a demodulator output of the VCO input voltage is provided at pin 10 (DEMOUT). In contrast to conventional techniques where the DEMOUT voltage is one threshold voltage lower than the VCO input voltage, here the DEMOUT voltage equals that of the VCO input. If DEMOUT is used, a load resistor (R_S) should be connected from DEMOUT to GND; if unused, DEMOUT should be left open. The VCO output (VCOOUT) can be connected directly to the comparator input (COMPIN), or connected via a frequency-divider. The

VCO output signal has a duty factor of 50% (maximum expected deviation 1%), if the VCO input is held at a constant DC level. A LOW level at the inhibit input (INH) enables the VCO and demodulator, while a HIGH level turns both off to minimize standby power consumption.

The only difference between the HC and HCT versions is the input level specification of the INH input. This input disables the VCO section. The comparators' sections are identical, so that there is no difference in the SIGIN (pin 14) or COMPIN (pin 3) inputs between the HC and HCT versions.

Phase comparators

The signal input (SIGIN) can be directly coupled to the self-biasing amplifier at pin 14, provided that the signal swing is between the standard HC family input logic levels. Capacitive coupling is required for signals with smaller swings.

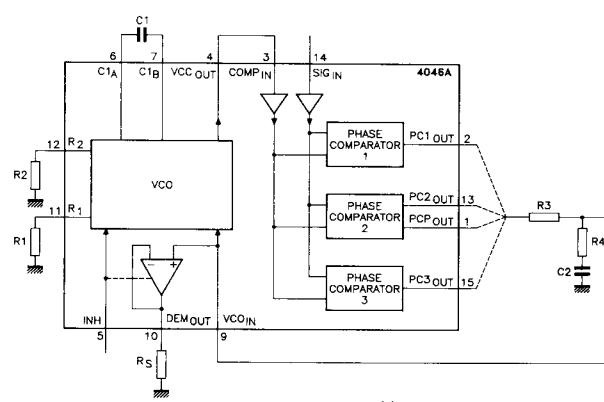

Phase comparator 1 (PC1)

This is an EXCLUSIVE-OR network. The signal and comparator input frequencies (f_1) must have a 50% duty factor to obtain the maximum locking range. The transfer characteristic of PC1, assuming ripple ($f_R = 2f_1$) is suppressed, is:

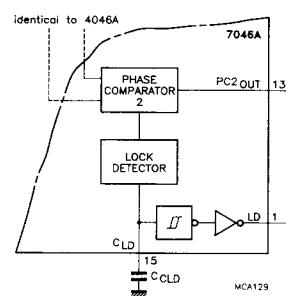

$$V_{DEMOUT} = \frac{V_{CC}}{\pi} (\phi_{SIGIN} - \phi_{COMPIN})$$

where V_{DEMOUT} is the demodulator output at pin 10;

$\phi_{DEMOUT} = V_{PC1OUT}$ (via low-pass filter).

(a)

(b)

Fig. 4 Functional diagram.

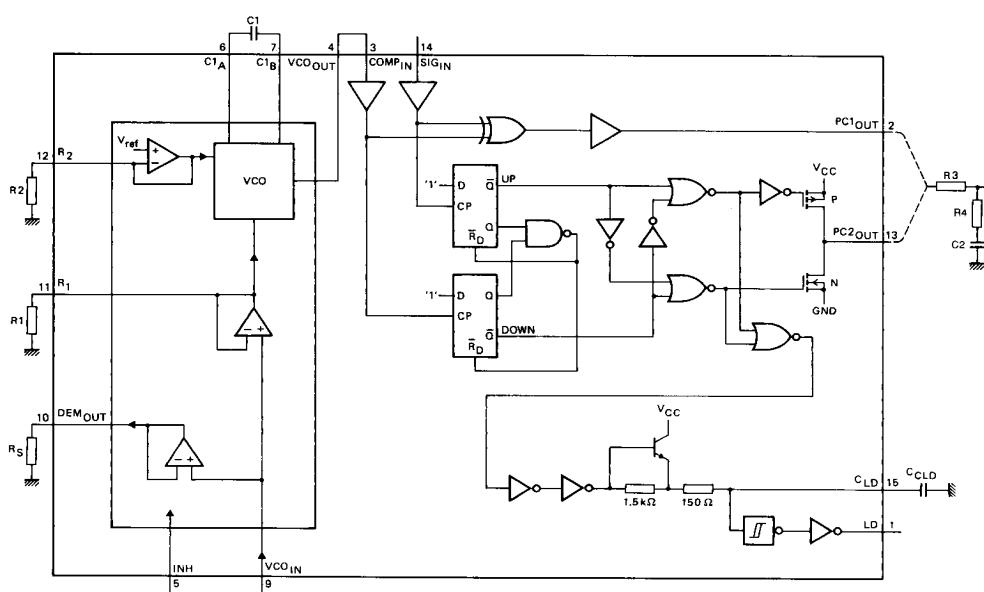

Fig. 5 Logic diagram.

The phase comparator gain is:

$$K_p = \frac{V_{CC}}{\pi} (V/r)$$

The average output voltage from PC1, fed to the VCO input via the low-pass filter and seen at the demodulator output at pin 10 ($V_{DEMOOUT}$), is the resultant of the phase differences of signals (SIG_{IN}) and the comparator input ($COMP_{IN}$) as shown in Fig. 6. The average of $V_{DEMOOUT}$ is equal to $1/2 V_{CC}$ when there is no signal or noise at SIG_{IN} and with this input the VCO oscillates at the centre frequency (f_0). Typical waveforms for the PC1 loop locked at f_0 are shown in Fig. 7.

The frequency capture range ($2f_C$) is defined as the frequency range of input signals on which the PLL will lock if it was initially out-of-lock. The frequency lock range ($2f_L$) is defined as the frequency range of input signals on which the loop will stay locked if it was initially in lock. The capture range is smaller or equal to the lock range.

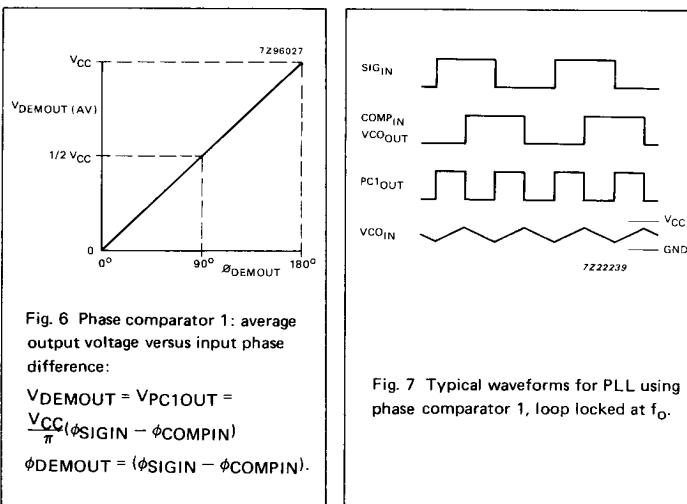

Fig. 6 Phase comparator 1: average output voltage versus input phase difference:

$$V_{DEMOOUT} = V_{CC}(\phi_{SIGIN} - \phi_{COMPIN})$$

$$\phi_{DEMOOUT} = (\phi_{SIGIN} - \phi_{COMPIN})$$

Fig. 7 Typical waveforms for PLL using phase comparator 1, loop locked at f_0 .

GENERAL DESCRIPTION

Phase comparators

With PC1, the capture range depends on the low-pass filter characteristics and can be made as large as the lock range. This configuration retains lock even with very noisy input signals. Typical behaviour of this type of phase comparator is that it can lock to input frequencies close to the harmonics of the VCO centre frequency.

Phase comparator 2 (PC2)

This is a positive edge-triggered phase and frequency detector. When the PLL is using this comparator, the loop is controlled by positive signal transitions and the duty factors of SIG_{IN} and $COMP_{IN}$ are not important. PC2 comprises two D-type flip-flops, control-gating and a 3-state output stage. The circuit functions as an up-down counter (Fig. 5) where SIG_{IN} causes an up-count and $COMP_{IN}$ a down-count. The transfer function of PC2, assuming ripple ($f_r = f_i$) is suppressed, is:

$$V_{DEMOUT} = \frac{V_{CC}}{4\pi} (\phi_{SIGIN} - \phi_{COMPIN})$$

where V_{DEMOUT} is the demodulator output at pin 10;

$V_{DEMOUT} = V_{PC2OUT}$ (via low-pass filter).

The phase comparator gain is:

$$K_p = \frac{V_{CC}}{4\pi} (V/r)$$

V_{DEMOUT} is the resultant of the initial phase differences of SIG_{IN} and $COMP_{IN}$ as shown in Fig. 8. Typical waveforms for the PC2 loop locked at f_o are shown in Fig. 9.

When the frequencies of SIG_{IN} and $COMP_{IN}$ are equal but the phase of SIG_{IN} leads that of $COMP_{IN}$, the p-type output driver at $PC2_{OUT}$ is held "ON" for a time corresponding to the phase difference (ϕ_{DEMOUT}). When the phase of SIG_{IN} lags that of $COMP_{IN}$, the n-type driver is held "ON".

When the frequency of SIG_{IN} is higher than that of $COMP_{IN}$, the p-type output driver is held "ON" for most of the input signal cycle time, and for the remainder of the cycle both n and p-type drivers are "OFF" (3-state). If the SIG_{IN} frequency is lower than the $COMP_{IN}$ frequency, then it is the n-type driver that is held "ON" for most of the cycle. Subsequently, the

voltage at the capacitor (C2) of the low-pass filter connected to $PC2_{OUT}$ varies until the signal and comparator inputs are equal in both phase and frequency. At this stable point the voltage on C2 remains constant as the PC2 output is in 3-state and the VCO input at pin 9 is a high impedance.

Thus, for PC2, no phase difference exists between SIG_{IN} and $COMP_{IN}$ over the full frequency range of the VCO. Moreover, the power dissipation due to the low-pass filter is reduced because both p and n-type drivers are "OFF" for most of the signal input cycle. It should be noted that the PLL lock range for this type of phase comparator is equal to the capture range and is independent of the low-pass filter. With no signal present at SIG_{IN} the VCO adjusts, via PC2, to its lowest frequency.

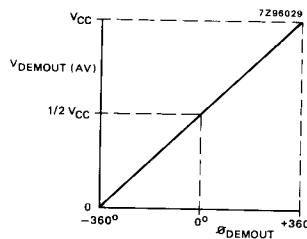

Fig. 8 Phase comparator 2: average output voltage versus input phase difference:

$$V_{DEMOUT} = V_{PC2OUT} =$$

$$\frac{V_{CC}}{4\pi} (\phi_{SIGIN} - \phi_{COMPIN})$$

$$\phi_{DEMOUT} = (\phi_{SIGIN} - \phi_{COMPIN}).$$

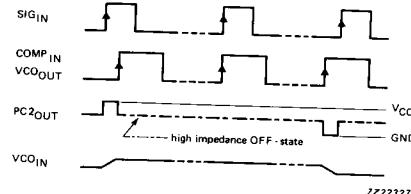

Fig. 9 Typical waveforms for PLL using phase comparator 2, loop locked at f_o .

RECOMMENDED OPERATING CONDITIONS FOR 74HC/HCT

SYMBOL	PARAMETER	74HC			74HCT			UNIT	CONDITIONS

APPLICATION INFORMATION

This information is a guide for the approximation of values of external components to be used with the 74HC/HCT7046 in a phase-lock-loop system.

References should be made to Figs 27, 28 and 29 as indicated in the table.

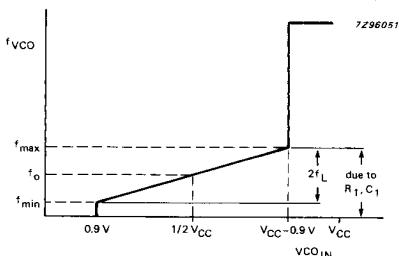

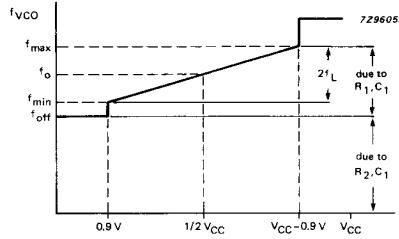

Values of the selected components should be within the following ranges:

R1 between 3 k Ω and 300 k Ω ;

R2 between 3 k Ω and 300 k Ω ;

R1 + R2 parallel value > 2.7 k Ω ;

C1 greater than 40 pF.

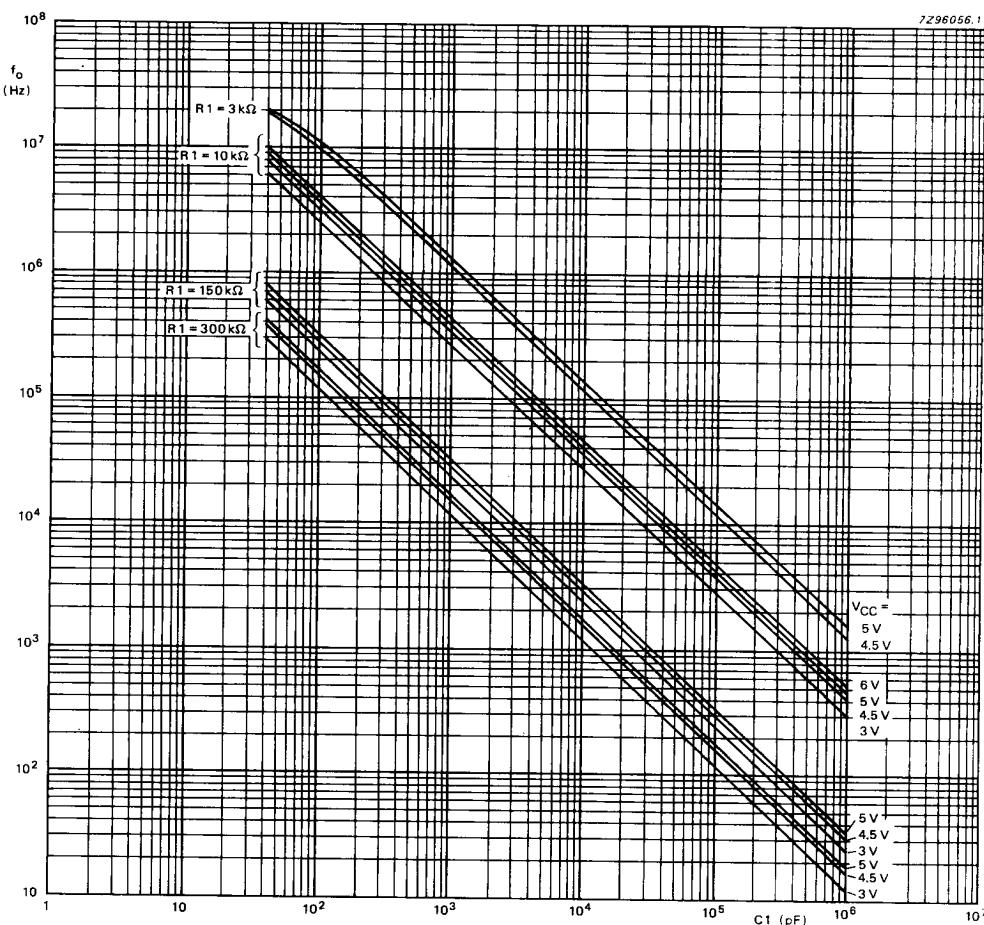

Fig. 27 Typical value of VCO centre frequency (f_0) as a function of C_1 : $R_2 = \infty$; $V_{VCOIN} = 1/2 V_{CC}$; $INH = GND$; $T_{amb} = 25^\circ\text{C}$.

Notes to Fig. 27

1. To obtain optimum VCO performance, C_1 must be as small as possible but larger than 100 pF .
2. Interpolation for various values of R_1 can be easily calculated because, a constant R_1C_1 product will produce almost the same VCO output frequency.

APPLICATION INFORMATION

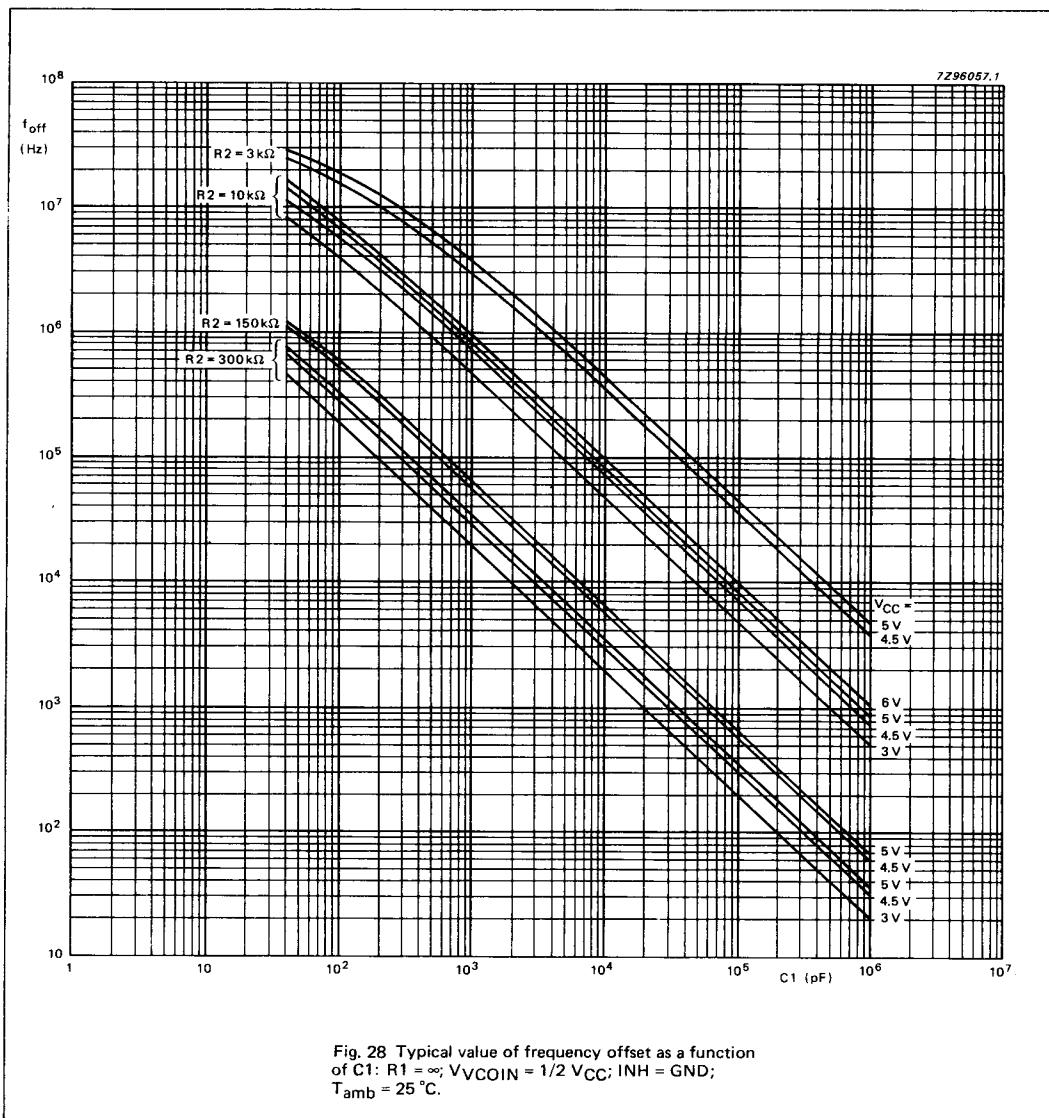

Fig. 28. Typical value of frequency offset as a function of C_1 : $R_1 = \infty$; $V_{\text{VCOIN}} = 1/2 V_{\text{CC}}$; INH = GND; $T_{\text{amb}} = 25^\circ\text{C}$.

Notes to Fig. 28

1. To obtain optimum VCO performance, C_1 must be as small as possible but larger than 100 pF.
2. Interpolation for various values of R_2 can be easily calculated because, a constant $R_2 C_2$ product will produce almost the same VCO output frequency.

$R_2 = \infty$; VCO gain:

$$K_V = \frac{2f_L}{V_{VCOIN} \text{ range}} 2\pi \text{ (r/s/V).}$$

APPLICATION INFORMATION

Lock-detection circuit

The built-in lock-detection circuit will only work when used in conjunction with the phase comparator PC2. The lock-indication is derived from the phase error between SIG_{IN} and COMP_{IN}. The PC2 has a typical phase error of zero degrees over the entire VCO operating range. However, to remain in-lock the circuit requires some small adjustments. The variation is dependent on the loop parameters and back-lash time (typically 5 ns). Depending on the application, the phase error can be defined as the limit,

a phase error of greater magnitude would be considered out-of-lock. An example of an in-lock detection circuit using the "7046A" is shown in Fig. 30.

If the PLL is in-lock, only very small pulses will come from the "up" or "down" connections of PC2. These pulses are filtered out by a RC network. A Schmitt trigger produces a steady state level, a HIGH level indicates an in-lock condition and a pulsed output indicates an out-of-lock condition as shown in Fig. 31.

Note to Fig. 30

(1) See Fig. 31 for input waveform.

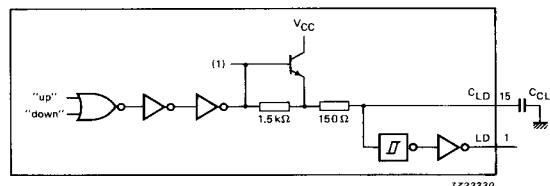

Fig. 30 An example of an in-lock detection circuit using the "7046A".

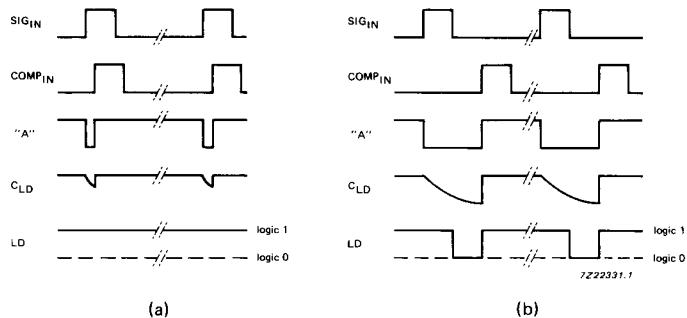

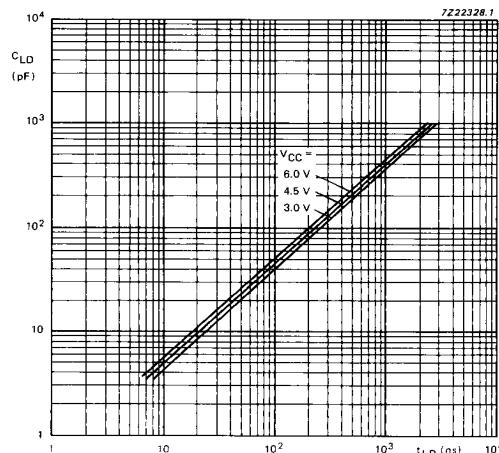

Fig. 31 Waveforms showing the lock detection process; (a) in-lock; (b) out-of-lock.

Fig. 32 C_{LD} capacitor value versus typical t_{LD} .**Where:**

C_{LD} = capacitor connected to pin 15
(includes the parasitic input capacitance of the IC, approximately 3.5 pF).

t_{LD} = phase difference between SIG_{IN} and $COMP_{IN}$ (positive-going edges).

APPLICATION INFORMATION

The maximum permitted phase error must be defined, before t_{LD} can be defined using the following formula:

$$t_{LD} = \frac{\phi_{max}}{360} \times \frac{1}{f_{IN}}$$

Using this calculated value in Fig. 32, it is possible to define the value of C_{LD} , e.g. assuming the phase error is 36° and $f_{IN} = 2 \text{ MHz}$:

$$t_{LD} = \frac{36^\circ}{360} \times \frac{1}{2 \text{ MHz}} = 50 \text{ ns},$$

and using Fig. 32, it can be seen that C_{1D} is 26 pF.

With the addition of one retriggerable monostable (e.g. "123", "423" or "4538") a steady state LOW and HIGH indication can be obtained, as shown in Fig. 33.

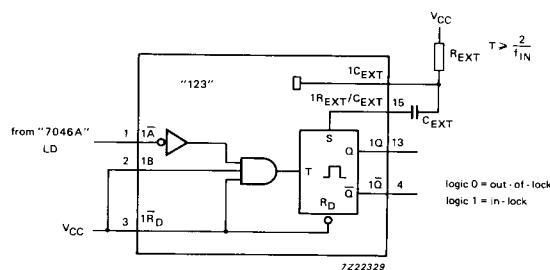

Fig. 33 Steady state signal for lock indication.

PLL design example

The frequency synthesizer, used in the design example shown in Fig. 34, has the following parameters:

Output frequency: 2 MHz to 3 MHz
frequency steps : 100 kHz
settling time : 1 ms
overshoot : < 20%

The open-loop gain is $H(s) \times G(s) = K_p \times K_f \times K_o \times K_n$.

Where:

K_p = phase comparator gain
 K_f = low-pass filter transfer gain
 K_o = K_v/s VCO gain
 K_n = $1/n$ divider ratio

The programmable counter ratio K_n can be found as follows:

$$N_{\min.} = \frac{f_{\text{out}}}{f_{\text{step}}} = \frac{2 \text{ MHz}}{100 \text{ kHz}} = 20$$

$$N_{\max.} = \frac{f_{\text{out}}}{f_{\text{step}}} = \frac{3 \text{ MHz}}{100 \text{ kHz}} = 30$$

The VCO is set by the values of R_1 , R_2 and C_1 , $R_2 = 10 \text{ k}\Omega$ (adjustable).

The values can be determined using the information in the section "DESIGN CONSIDERATIONS".

With $f_o = 2.5 \text{ MHz}$ and $f_L = 500 \text{ kHz}$ this gives the following values ($V_{CC} = 5.0 \text{ V}$):

$R_1 = 10 \text{ k}\Omega$

$R_2 = 10 \text{ k}\Omega$

$C_1 = 500 \text{ pF}$

The VCO gain is:

$$K_o = \frac{2f_L \times 2 \times \pi}{0.9 - (V_{CC} - 0.9)} = \frac{1 \text{ MHz}}{3.2} \times 2\pi \approx 2 \times 10^6 \text{ r/s/v}$$

The gain of the phase comparator is:

$$K_p = \frac{V_{CC}}{4 \times \pi} = 0.4 \text{ V/r.}$$

The transfer gain of the filter is given by:

$$K_f = \frac{1 + \tau_2 s}{1 + (\tau_1 + \tau_2)s}$$

Where:

$$\tau_1 = R_3 C_2 \text{ and } \tau_2 = R_4 C_2.$$

The characteristics equation is:

$$1 + H(s) \times G(s) = 0.$$

This results in:

$$s^2 + \frac{1 + K_p \times K_v \times K_n \times \tau_2}{(\tau_1 + \tau_2)} s +$$

$$\frac{K_p \times K_v \times K_n}{(\tau_1 + \tau_2)} = 0.$$

The natural frequency ω_n is defined as follows:

$$\omega_n = \sqrt{\frac{K_p \times K_v \times K_n}{(\tau_1 + \tau_2)}}.$$

and the damping value ξ is defined as follows:

$$\xi = \frac{1}{2\omega_n} \times \frac{1 + K_p \times K_v \times K_n \times \tau_2}{\tau_1 + \tau_2}.$$

The overshoot and settling time percentages are now used to determine ω_n . From Fig. 35 it can be seen that the damping ratio $\xi = 0.8$ will produce an overshoot of less than 20% and settle to within 5% at $\omega_n t = 4.5$. The required settling time is 1 ms. This results in:

$$\omega_n = \frac{5}{t} = \frac{5}{0.001} = 5 \times 10^3 \text{ r/s.}$$

Rewriting the equation for natural frequency results in:

$$(\tau_1 + \tau_2) = \frac{K_p \times K_v \times K_n}{\omega_n^2}.$$

The maximum overshoot occurs at $N_{\max.}$:

$$(\tau_1 + \tau_2) = \frac{0.4 \times 2 \times 10^6}{5000^2 \times 30} = 0.0011 \text{ s.}$$

When $C_2 = 470 \text{ nF}$, then

$$R_4 = \frac{(\tau_1 + \tau_2) \times 2 \times \omega_n \times \xi - 1}{K_p \times K_v \times K_n} = 790 \Omega.$$

R_3 is calculated using the damping ratio equation:

$$R_3 = \frac{\tau_1}{C_2} - R_4 = 2 \text{ k}\Omega.$$

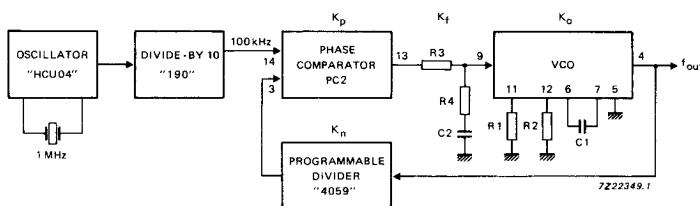

Fig. 34 Frequency synthesizer.

Note

For an extensive description and application example please refer to application note ordering number 9398 649 90011.
Also available a computer design program for PLL's ordering number 9398 961 10061.

APPLICATION INFORMATION

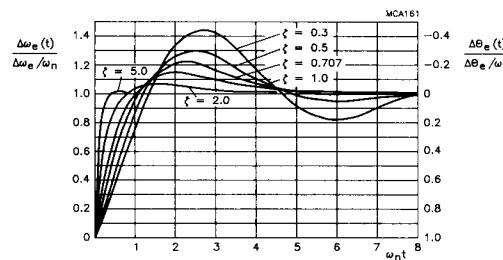

Fig. 35 Type 1, second order frequency step response.

Since the output frequency is proportional to the VCO control voltage, the PLL frequency response can be observed with an oscilloscope by monitoring pin 9 of the VCO. The average frequency response, as calculated by the Laplace method, is found experimentally by smoothing this voltage at pin 9 with a simple RC filter, whose time constant is long compared to the phase detector sampling rate but short compared to the PLL response time.

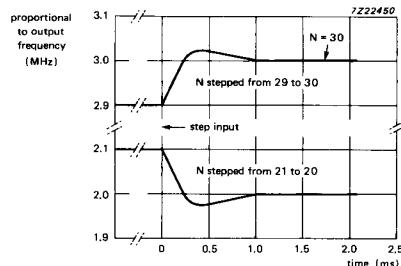

Fig. 36 Frequency compared to the time response.
