Control of input signal clamp condition

0V Sync tip clamp condition

5V Center bias condition

Center biased to approx. 2.1V by means of the IC internal resistance (approx. 10k Ω).

In this mode, the input signal is limited to APL 50% and the maximum input signal amplitude is 200mVp-p.

Notes

(1) This is the IC supply current value during clock and signal input.

(2) GL is the output gain of OUT pin when a 500mVp-p, 200kHz sine wave is fed to IN pin.

$$GL = 20 \log \frac{\text{OUT pin output voltage [mVp-p]}}{500 [\text{mVp-p}]} \quad [\text{dB}]$$

(3) Indicates the dissipation at 4.43MHz in relation to 200kHz.

From the output voltage at OUT pin when a 150mVp-p, 200kHz sine wave is fed to IN pin, and from the output voltage at OUT pin when a 150mVp-p, 4.43MHz sine wave is fed to same, calculation is made according to the following formula.

$$fR = 20 \log \frac{\text{OUT pin output voltage (4.43MHz) [mVp-p]}}{\text{OUT pin output voltage (200kHz) [mVp-p]}} \quad [\text{dB}]$$

- (4) In figure below, differential gain (DG) and differential phase (DP) are tested with a vector scope when the 5-staircase wave is fed.

- (5) The internal clock component to the output signal during no-signal input and the leakage of that high harmonic component are tested.

- (6) S/N ratio during a 50% white video signal input shown in figure below is tested at a video noise meter, in BPF 100kHz to 5MHz, Sub Carrier Trap mode.
