Absolute Maximum Ratings

Parameter	Symbol	Value	Unit
Voltage on any pin relative to V_{SS}	V_{IN}, V_{OUT}	-0.5 ~ 3.6	V
Voltage on V_{DD} & V_{DDQ} supply relative to V_{SS}	V_{DD}, V_{DDQ}	-1.0 ~ 3.6	V
Storage temperature	T_{STG}	-55 ~ +150	°C
Power dissipation	P_D	1.5 * # of component	W
Short circuit current	I_{OS}	50	mA

Note : Permanent device damage may occur if ABSOLUTE MAXIMUM RATINGS are exceeded.

Functional operation should be restricted to recommend operation condition.

Exposure to higher than recommended voltage for extended periods of time could affect device reliability.

DC Operating Conditions

Recommended operating conditions(Voltage referenced to $V_{SS}=0V$, $T_A=0$ to $70^{\circ}C$)

Parameter	Symbol	Min	Max	Unit	Note
Supply voltage(for device with a nominal V_{DD} of 2.5V)	V_{DD}	2.5	2.7	V	5

Input logic high voltage	$V_{IH}(DC)$	$V_{REF}+0.15$	$V_{DDQ}+0.3$	V	
Input logic low voltage	$V_{IL}(DC)$	-0.3	$V_{REF}-0.15$	V	
Input Voltage Level, CK and \overline{CK} inputs	$V_{IN}(DC)$	-0.3	$V_{DDQ}+0.3$	V

Output leakage current	I_{OZ}	-5	5	uA	
Output High Current(Normal strength driver) ; $V_{OUT} = V_{TT} + 0.84V$	I_{OH}	-16.8		mA	
Output High Current(Normal strength driver) ; $V_{OUT} = V_{TT} - 0.84V$	I_{OL}	16.8		mA	
Output High Current(Half strength driver) ; $V_{OUT} = V_{TT} + 0.45V$	I_{OH}	-9		mA	
Output High Current(Half strength driver) ; $V_{OUT} = V_{TT} - 0.45V$	I_{OL}	9		mA	

Note : 1. V_{REF} is expected to be equal to $0.5 \cdot V_{DDQ}$ of the transmitting device, and to track variations in the dc level of same.

Peak-to-peak noise on V_{REF} may not exceed +/-2% of the dc value.

- V_{TT} is not applied directly to the device. V_{TT} is a system supply for signal termination resistors, is expected to be set equal to V_{REF} , and must track variations in the DC level of V_{REF}
- V_{ID} is the magnitude of the difference between the input level on CK and the input level on \overline{CK} .
- The ratio of the pullup current to the pulldown current is specified for the same temperature and voltage, over the entire temperature and voltage range, for device drain to source voltages from 0.25V to 1.0V. For a given output, it represents the maximum difference between pullup and pulldown drivers due to process variation. The full variation in the ratio of the maximum to minimum pullup and pulldown current will not exceed 1/7 for device drain to source voltages from 0.1 to 1.0.
- This is the DC voltage supplied at the DRAM and is inclusive of all noise up to 20MHz. Any noise above 20MHz at the DRAM generated from any source other than the DRAM itself may not exceed the DC voltage range of 2.6V +/-100mV.

AC Operating Conditions

Parameter/Condition	Symbol	Min	Max	Unit	Note
Input High (Logic 1) Voltage, DQ, DQS and DM signals	V _{IH} (AC)	V _{REF} + 0.31		V	
Input Low (Logic 0) Voltage, DQ, DQS and DM signals.	V _{IL} (AC)		V _{REF} - 0.31	V

- Note :**
1. V_{ID} is the magnitude of the difference between the input level on CK and the input on \overline{CK} .
 2. The value of V_{IX} is expected to equal 0.5*V_{DDQ} of the transmitting device and must track variations in the DC level of the same.
 3. These parameters should be tested at the pin on actual components and may be checked at either the pin or the pad in simulation. the AC and DC input specificatims are reflation to a Vref envelope that has been bandwidth limited 20MHz.

Component Notes

1. V_{id} is the magnitude of the difference between the input level on CK and the input level on \overline{CK} .
2. The value of V_{IX} is expected to equal $0.5 \cdot V_{DDQ}$ of the transmitting device and must track variations in the dc level of the same.
3. tHZ and tLZ transitions occur in the same access time windows as valid data transitions. these parameters are not referenced to a specific voltage level but specify when the device output in no longer driving (HZ), or begins driving (LZ).
4. The maximum limit for this parameter is not a device limit. The device will operate with a greater value for this parameter, but system performance (bus turnaround) will degrade accordingly.
5. The specific requirement is that DQS be valid (HIGH, LOW, or at some point on a valid transition) on or before this CK edge. A valid transition is defined as monotonic and meeting the input slew rate specifications of the device. when no writes were previously in progress on the bus, DQS will be transitioning from High- Z to logic LOW. If a previous write was in progress, DQS could be HIGH, LOW, or transitioning from HIGH to LOW at this time, depending on tDQSS.
6. A maximum of eight AUTO REFRESH commands can be posted to any given DDR SDRAM device.
7. For command/address input slew rate ≥ 0.5 V/ns
8. For CK & \overline{CK} slew rate ≥ 0.5 V/ns
9. These parameters guarantee device timing, but they are not necessarily tested on each device. They may be guaranteed by device design or tester correlation.
10. Slew Rate is measured between $V_{OH}(ac)$ and $V_{OL}(ac)$.
11. Min (tCL, tCH) refers to the smaller of the actual clock low time and the actual clock high time as provided to the device (i.e. this value can be greater than the minimum specification limits for tCL and tCH)....For example, tCL and tCH are = 50% of the period, less the half period jitter (tJIT(HP)) of the clock source, and less the half period jitter due to crosstalk (tJIT(crosstalk)) into the clock traces.
12. $t_{QH} = t_{HP} - t_{QHS}$, where:
 tHP = minimum half clock period for any given cycle and is defined by clock high or clock low (tCH, tCL). tQHS accounts for 1) The pulse duration distortion of on-chip clock circuits; and 2) The worst case push-out of DQS on one transition followed by the worst case pull-in of DQ on the next transition, both of which are, separately, due to data pin skew and output pattern effects, and p-channel to n-channel variation of the output drivers.
13. tDQSQ
 Consists of data pin skew and output pattern effects, and p-channel to n-channel variation of the output drivers for any given cycle.
14. $t_{DAL} = (t_{WR}/t_{CK}) + (t_{RP}/t_{CK})$
 For each of the terms above, if not already an integer, round to the next highest integer. Example: For DDR400(CC) at CL=3 and tCK=5ns $t_{DAL} = (15 \text{ ns} / 5 \text{ ns}) + (15 \text{ ns} / 5 \text{ ns}) = (3) + (3)$
 $t_{DAL} = 6$ clocks
15. In all circumstances, tXSNR can be satisfied using $t_{XSNR} = t_{RFCmin} + 1 \cdot t_{CK}$
16. The only time that the clock frequency is allowed to change is during self-refresh mode.

Table 7 : Output Slew Rate Matching Ratio Characteristics

AC CHARACTERISTICS		DDR400		Notes
PARAMETER	SYMBOL	MIN	MAX	
Output Slew Rate Matching Ratio (Pullup to Pulldown)		-	-	e,k

System Notes :

a. Pullup slew rate is characterized under the test conditions as shown in Figure 1.

Figure 1 : Pullup slew rate test load

b. Pulldown slew rate is measured under the test conditions shown in Figure 2.

Figure 2 : Pulldown slew rate test load

c. Pullup slew rate is measured between $(VDDQ/2 - 320 \text{ mV} \pm 250 \text{ mV})$

Pulldown slew rate is measured between $(VDDQ/2 + 320 \text{ mV} \pm 250 \text{ mV})$

Pullup and Pulldown slew rate conditions are to be met for any pattern of data, including all outputs switching and only one output switching.

Example : For typical slew rate, DQ0 is switching

For minimum slew rate, all DQ bits are switching from either high to low, or low to high.

For Maximum slew rate, only one DQ is switching from either high to low, or low to high.

The remaining DQ bits remain the same as for previous state.

d. Evaluation conditions

Typical : 25 °C (T Ambient), VDDQ = 2.6V, typical process

Minimum : 70 °C (T Ambient), VDDQ = 2.5V, slow - slow process

Maximum : 0 °C (T Ambient), VDDQ = 2.7V, fast - fast process

e. The ratio of pullup slew rate to pulldown slew rate is specified for the same temperature and voltage, over the entire temperature and voltage range. For a given output, it represents the maximum difference between pullup and pulldown drivers due to process variation.

f. Verified under typical conditions for qualification purposes.

g. TSOP11 package devices only.

h. A derating factor will be used to increase t_{IS} and t_{IH} in the case where the input slew rate is below 0.5V/ns

as shown in Table 2. The Input slew rate is based on the lesser of the slew rates determined by either $V_{IH}(AC)$ to $V_{IL}(AC)$ or $V_{IH}(DC)$ to $V_{IL}(DC)$, similarly for rising transitions.

i. A derating factor will be used to increase t_{DS} and t_{DH} in the case where DQ, DM, and DQS slew rates differ, as shown in Tables 3 & 4.

Input slew rate is based on the larger of AC-AC delta rise, fall rate and DC-DC delta rise, Input slew rate is based on the lesser of the slew rates determined by either $V_{IH}(AC)$ to $V_{IL}(AC)$ or $V_{IH}(DC)$ to $V_{IL}(DC)$, similarly for rising transitions.

The delta rise/fall rate is calculated as:

$$\{1/(\text{Slew Rate1})\} - \{1/(\text{Slew Rate2})\}$$

For example : If Slew Rate 1 is 0.5 V/ns and Slew Rate 2 is 0.4 V/ns, then the delta rise, fall rate is - 0.5ns/V . Using the table given, this would result in the need for an increase in t_{DS} and t_{DH} of 100 ps.

- j. Table 3 is used to increase t_{DS} and t_{DH} in the case where the I/O slew rate is below 0.5 V/ns. The I/O slew rate is based on the lesser of the AC - AC slew rate and the DC- DC slew rate. The input slew rate is based on the lesser of the slew rates determined by either $V_{IH}(ac)$ to $V_{IL}(ac)$ or $V_{IH}(DC)$ to $V_{IL}(DC)$, and similarly for rising transitions.
- k. DQS, DM, and DQ input slew rate is specified to prevent double clocking of data and preserve setup and hold times. Signal transitions through the DC region must be monotony.

Note : 1. OP Code : Operand Code. A0 ~ A12 & BA0 ~ BA1 : Program keys. (@EMRS/MRS)

2. EMRS/ MRS can be issued only at all banks precharge state.

A new command can be issued 2 clock cycles after EMRS or MRS.

3. Auto refresh functions are same as the CBR refresh of DRAM.

The automatical precharge without row precharge command is meant by "Auto".

Auto/self refresh can be issued only at all banks precharge state.

4. BA0 ~ BA1 : Bank select addresses.

If both BA0 and BA1 are "Low" at read, write, row active and precharge, bank A is selected.

If BA0 is "High" and BA1 is "Low" at read, write, row active and precharge, bank B is selected.

If BA0 is "Low" and BA1 is "High" at read, write, row active and precharge, bank C is selected.

If both BA0 and BA1 are "High" at read, write, row active and precharge, bank D is selected.

5. If A10/AP is "High" at row precharge, BA0 and BA1 are ignored and all banks are selected.

6. During burst write with auto precharge, new read/write command can not be issued.

Another bank read/write command can be issued after the end of burst.

New row active of the associated bank can be issued at tRP after the end of burst.

7. Burst stop command is valid at every burst length.

8. DM sampled at the rising and falling edges of the DQS and Data-in are masked at the both edges (Write DM latency is 0).

9. This combination is not defined for any function, which means "No Operation(NOP)" in DDR SDRAM.
