Features

- **Clock Controller**
  - 80C51 core with 6 clocks per instruction
  - 8 MHz On-Chip Oscillator
  - PLL for generating clock to supply CPU core, USB and Smart Card Interfaces
  - Programmable CPU clock from 500 KHz / X1 to 48 MHz / X1
- **Reset Controller**
  - Power On Reset (POR) feature avoiding an external reset capacitor
  - Power Fail Detector (PFD)
  - Watch-Dog Timer
- **Power Management**
  - Two power saving modes : Idle and Power Down
  - Four Power Down Wake-up Sources : Smart Card Detection, Keyboard Interrupt, USB Resume, External Interrupt
  - Input Voltage Range : 3.6V - 5.5V
  - Core's Power Consumption (Without Smart Card and USB) :
    - 30 mA Maximum Operating Current @ 48 MHz / X1
    - 200 μA Maximum Power-down Current @ 5.5V
- **Interrupt Controller**
  - up to 9 interrupt sources
  - up to 4 Level Priority
- **Memory Controller**
  - Internal Program memory :
    - up to 32KB of Flash or CRAM or ROM for AT8xC5122
    - up to 30KB of ROM for AT83C5123
  - Internal Data Memory : 768 bytes including 256 bytes of data and 512 bytes of XRAM
  - Optional : internal data E2PROM 512 bytes
- **Two 16-bit Timer/Counters**
- **USB 2.0 Full Speed Interface**
  - 48 MHz DPLL
  - On-Chip 3.3V USB voltage regulator and transceivers
  - Software detach feature
  - 7 endpoints programmable with In or out directions and ISO, Bulk or Interrupt Transfers :
    - Endpoint 0: 32 Bytes Bidirectionnal FIFO for Control transfers
    - Endpoints 1,2,3: 8 bytes FIFO
    - Endpoints 4,5: 64 Bytes FIFO
    - Endpoint 6: 2*64 bytes FIFO with Pin-Pong feature
- **ISO 7816 UART Interface Fully Compliant with EMV, GIE-CB and WHQL Standards**
  - Programmable ISO clock from 1 MHz to 4.8 MHz
  - Card insertion/removal detection with automatic deactivation sequence
  - Programmable Baud Rate Generator from 372 to 11.625 clock pulses
  - Synchronous/Asynchronous Protocols T=0 and T=1 with Direct or Inverse Convention
  - Automatic character repetition on parity errors
  - 32 Bit Waiting Time Counter
  - 16 Bit Guard Time Counter
  - Internal Step Up/Down Converter with Programmable Voltage Output :
    - 1.8V-30 mA, 3V-60 mA and 5V-60 mA
  - Current overload protection
  - 6 kV ESD (MIL/STD 833 Class 3) protection on whole Smart Card Interface
- **Alternate Smart Card Interface with CLK, IO and RST**
- **UART Interface with Integrated Baud Rate Generator (BRG)**
- **Keyboard interface with up to 20x8 matrix management capability**
- **Master/Slave SPI Interface**
- **Four 8 bit Ports, one 6 bit port, one 3-bit port**
  - Up to Seven LED outputs with 3 level programmable current source : 2, 4 and 10 mA
  - Two General Purpose I/O programmable as external interrupts
  - Up to 8 input lines programmable as interrupts
  - Up to 30 output lines

Reference Documents   The user must get the following additionnal documents which are not included but which complete this product datasheet

- Product Errata Sheet
- Bootloader Datasheet

Product Description

AT8xC5122/23 products are high-performance CMOS derivatives of the 80C51 8-bit microcontrollers designed for USB smart card reader applications.

The AT8xC5122 is proposed in four versions :

- ROM version with or without internal data E2PROM. The ROM device is only factory programmable.

- CRAM version without internal data E2PROM. The CRAM device implements a volatile program memory which is programmed by means of an embedded ROMed bootloader which transfers the code from a remote software programming tool called FLIP through UART or USB interfaces.

- Flash version without internal data E2PROM. At power-up, the program located in the flash memory is transferred into the CRAM then executed.

The AT83C5123 is a low pin count of the AT8xC5122 and is proposed in ROM version with or without internal data E2PROM. The ROM device is only factory programmable.
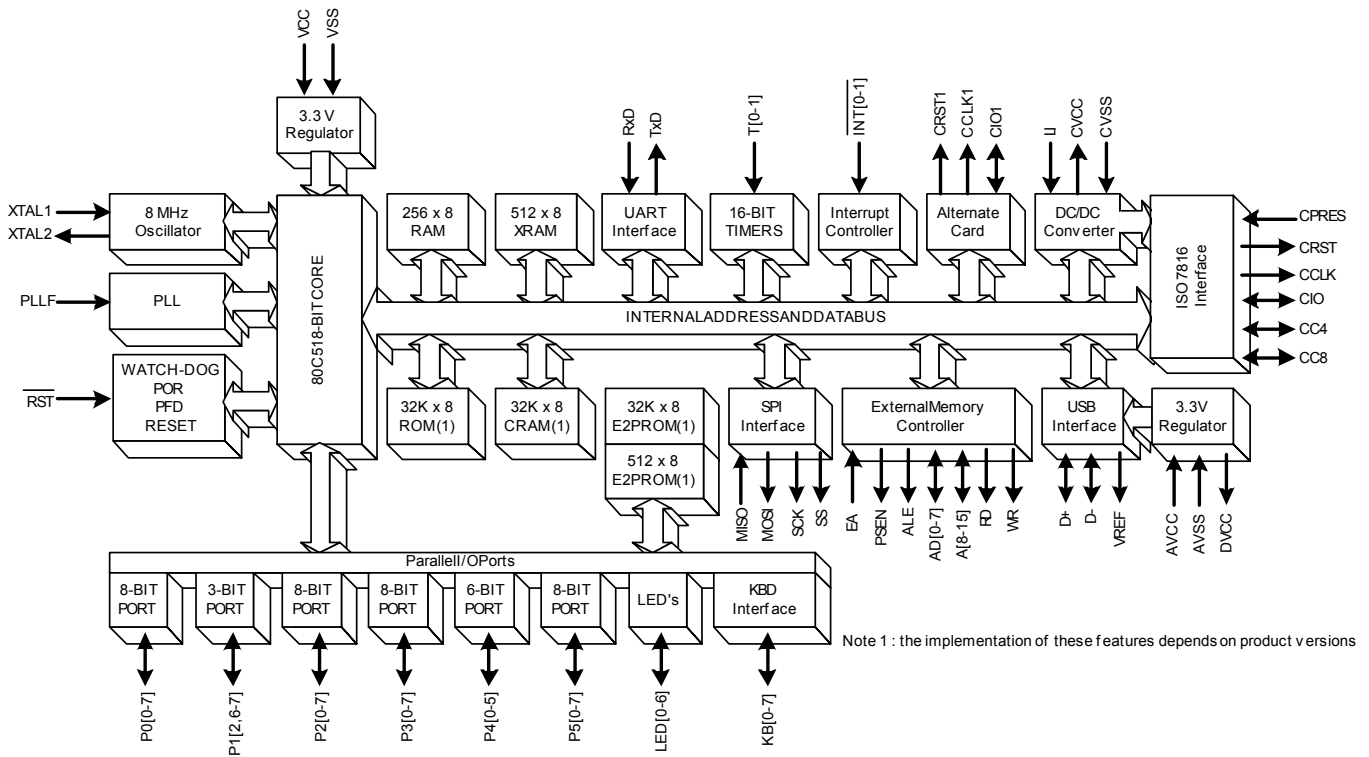

The AT8xC5122DS is a secure version of the AT8xC5122 on which the external program memory access mode is disabled.
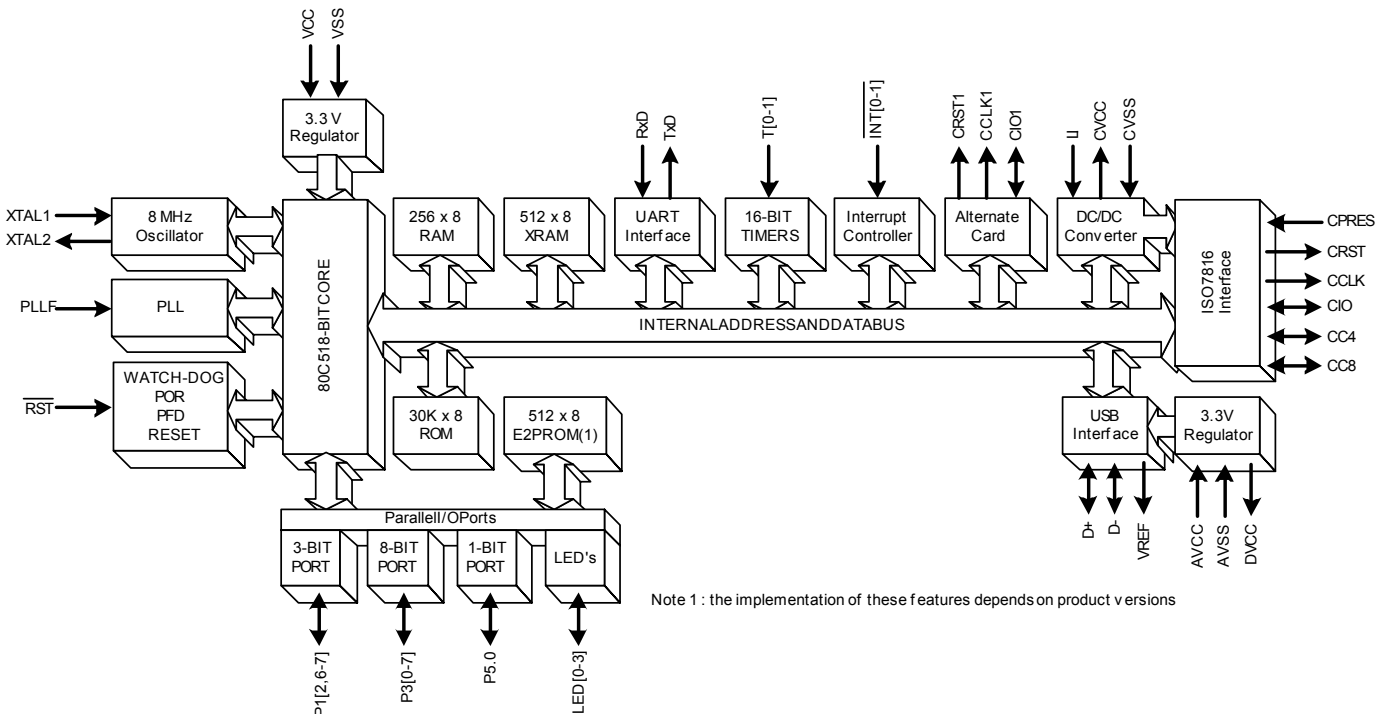

Table 1. Product versions

Features		AT83C5122	AT83EC5122	AT85C5122	AT89C5122	AT89C5122DS	AT83C5123	AT83EC5123

P5.6	5	-	14	-	5	-	VCC	2KV	I/O	1	KB6	Port51	Push-pull	Input WPD	Input WPU	
P5.7	4	-	13	-	4	-	VCC	2KV	I/O	1	KB7	Port51	Push-pull	Input WPD	Input WPU	
$\overline{\text{RST}}$	34	16	45	19	34	16	VCC		I/0		**Reset Input** The Port pins are driven to their reset conditions when a voltage lower than V_{IL} is applied, whether or not the oscillator is running. This pin has an internal 10K pull-up resistor which allows the device to be reset by connecting a capacitor between this pin and VSS. Asserting $\overline{\text{RST}}$ when the chip is in Idle mode or Power-Down mode returns the chip to normal operation. The output is active for at least 12 oscillator periods when an internal reset occurs.					
D+	60	29	5	2	60	29	DVCC		I/O		**USB Positive Data Upstream Port** This pin requires an external serial resistor of 27Ω (AT8xC122) or 33Ω (AT83C5123) and a 1.5 KΩ pull-up to V_{REF} for full speed configuration.					
D-	59	28	4	1	59	28	DVCC		I/O		**USB Negative Data Upstream Port** This pin requires an external serial resistor of 27Ω (AT8xC122) or 33Ω (AT83C5123)					
V_{REF}	61	30	6	3	61	30	AVCC		O		**USB Voltage Reference**: $3.0 < V_{REF} < 3.6$ V V_{REF} can be connected to D+ through a 1.5 KΩ resistor. The V_{REF} voltage is controlled by software.					
XTAL 1	31	14	42	17	31	14	VCC		I		**Input to the on-chip inverting oscillator amplifier** To use the internal oscillator, a crystal or an external oscillator must be connected to this pin.					
XTAL 2	32	15	43	18	32	15	VCC		O		**Output of the on-chip inverting oscillator amplifier** To use the internal oscillator, a crystal circuit must be connected to this pin. If an external oscillator is used, leave XTAL2 unconnected.					
$\overline{\text{EA}}$/ VCC	63	-	8	-	63	-	VCC		I		**External Access Enable (Only AT8xC5122)** $\overline{\text{EA}}$ must be strapped to ground in order to enable the device to fetch code from external memory locations 0000h to FFFFh. If security level 1 is programmed, $\overline{\text{EA}}$ will be latched on reset. **Warning** : EA pin cannot be left floating. If the External Access Enable mode is not used, EA pin must be strapped to VCC. If this last condition is not met,the MCU may have an unpredictable behaviour. VCC (Only AT89C5122DS)					
ALE	21	-	32	-	21	-	VCC		O		**Address Latch Enable/Program Pulse:** Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 (1/3 in X2 mode) the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. ALE can be disabled by setting SFR's AUXR.0 bit. With this bit set, ALE will be inactive during internal fetches					

Table 2. Pin Description (Continued)

Port	VQFP64	VQFP32	PLCC68	PLCC28	QFN64	QFN32	Internal Power Supply	ESD	I/O	Reset Level	Alt	Reset Config	Conf 1	Conf 2	Conf 3	Led
$\overline{\text{PSEN}}$	15	-	24	-	15	-	VCC		O		**Program Strobe Enable:** The read strobe to external program memory. When executing code from the external program memory, $\overline{\text{PSEN}}$ is activated twice each machine cycle, except that two $\overline{\text{PSEN}}$ activations are skipped during each access to external data memory. $\overline{\text{PSEN}}$ is not activated during fetches from internal program memory.					
PLLF	54	26	67	27	54	26	AVCC		O		**PLL Low Pass Filter input** Receives the RC network of the PLL low pass filter.					
AVCC	55	27	68	28	55	27			PWR		**Analog Supply Voltage** AVCC is used to supply the internal 3.3V analog regulator which supplies the internal USB driver					
VCC	20	12	31	15	20	12			PWR		**Supply Voltage** VCC is used to supply the internal 3.3V digital regulator which supplies the PLL, CPU core and internal I/O's					
LI	18	10	29	13	18	10			PWR		**DC/DC Input** LI supplies the current for the charge pump of the DC/DC converter. - LI tied directly to VCC : the DC/DC converter must be configured in regulator mode. - LI tied to VCC through an external 10µH coil : the DC/DC converter can be configured either in regulator or in pump mode.					
CVCC	17	9	28	12	17	9			PWR		**Card Supply Voltage** CVCC is the ouput of internal DC/DC converter which supplies the Smart Card Interface. It must be connected to an external decoupling capacitor of 10 µF with the lowest ESR as this parameter influences on the CVCC noise					
DVCC	1	1	10	5	1	1			PWR		**Digital Supply Voltage** DVCC is the output of the internal analog 3.3V regulator which supplies the USB driver. This pin must be connected to an external 680nF decoupling capacitor if the USB interface is used. This output can be used by the application with a maximum of 10 mA.					
CVSS	19	11	30	14	19	11			GND		**DC/DC Ground** CVSS is used to sink high shunt currents from the external coil					
VSS	16	8	25	11	16	8			GND		**Digital Ground** VSS is used to supply the PLL, buffer ring and the digital core					
AVSS	53	25	66	26	53	25			GND		**Analog Ground** AVSS is used to supply the USB driver.					

Typical Applications

Recommended External components

All the external components described in the figure and table below must be implemented as close as possible from the microcontroller package.

Table 3. External Components Bill Of Materials

Reference	Description	Value	Comments
R1	USB Full Speed Pull-up	1.5 KΩ +/-10%	All product versions
R2	USB pad serial resistor	27 Ω +/-10%	For AT8xC5122 versions
		33 Ω +/-10%	For AT83C5123 versions
R3	USB pad serial resistor	27 Ω +/-10%	For AT8xC5122 versions
		33 Ω +/-10%	For AT83C5123 versions
R4	PLL filter resistor	1.8 KΩ +/-10%	All product versions
R5	CIO Pull-up resistor	10 KΩ +/10%	All product versions
C1	Power Supply filter capacitor	100 nF +80/-20%	All product versions
C2	PLL filter capacitor	33 pF +/-10%	All product versions
C3	PLL filter capacitor	150 pF +/-10%	All product versions
C4	USB pad decoupling capacitor	680 nF +/-30%	All product versions. If USB interface is not used, this capacitor is optional
C5	Smart Card clock filter capacitor	27 pF +/-10%	All product versions.
C6	DC/DC Converter decoupling capacitor	10 µF +/-10% Low ESR	All product versions. This capacitor does not impact the USB Inrush Current
C7	DC/DC Converter filter capacitor	100 nF +80/-20%	All product versions
C8	Power Supply decoupling capacitor	4.7 µF +/-10%	All products versions This capacitor impacts the USB Inrush Current. Maximum application capacitance allowed by the USB standard is 10 µF.
C9	Power Supply filter capacitor	100 nF +80/-20C	All product versions
C10	Reset capacitor	10 µF +/-10%	Optional capacitor for all product versions
L1	DC/DC converter input inductance	10 µH +/- 10% Min rated current : 200 mA Min rated freq. : 4 MHz	All product versions. Qualified component : Murata LQH32CN100K21L If DC/DC converter is not used at 5V, this inductance is optional.
Q1	Crystal	8.0000 Mhz +/- 2500 ppm max ESR max : 100 Ω	All product versions

USB Keyboard with Smart Card Reader Using the AT8xC5122 and AT89C5122DS Versions
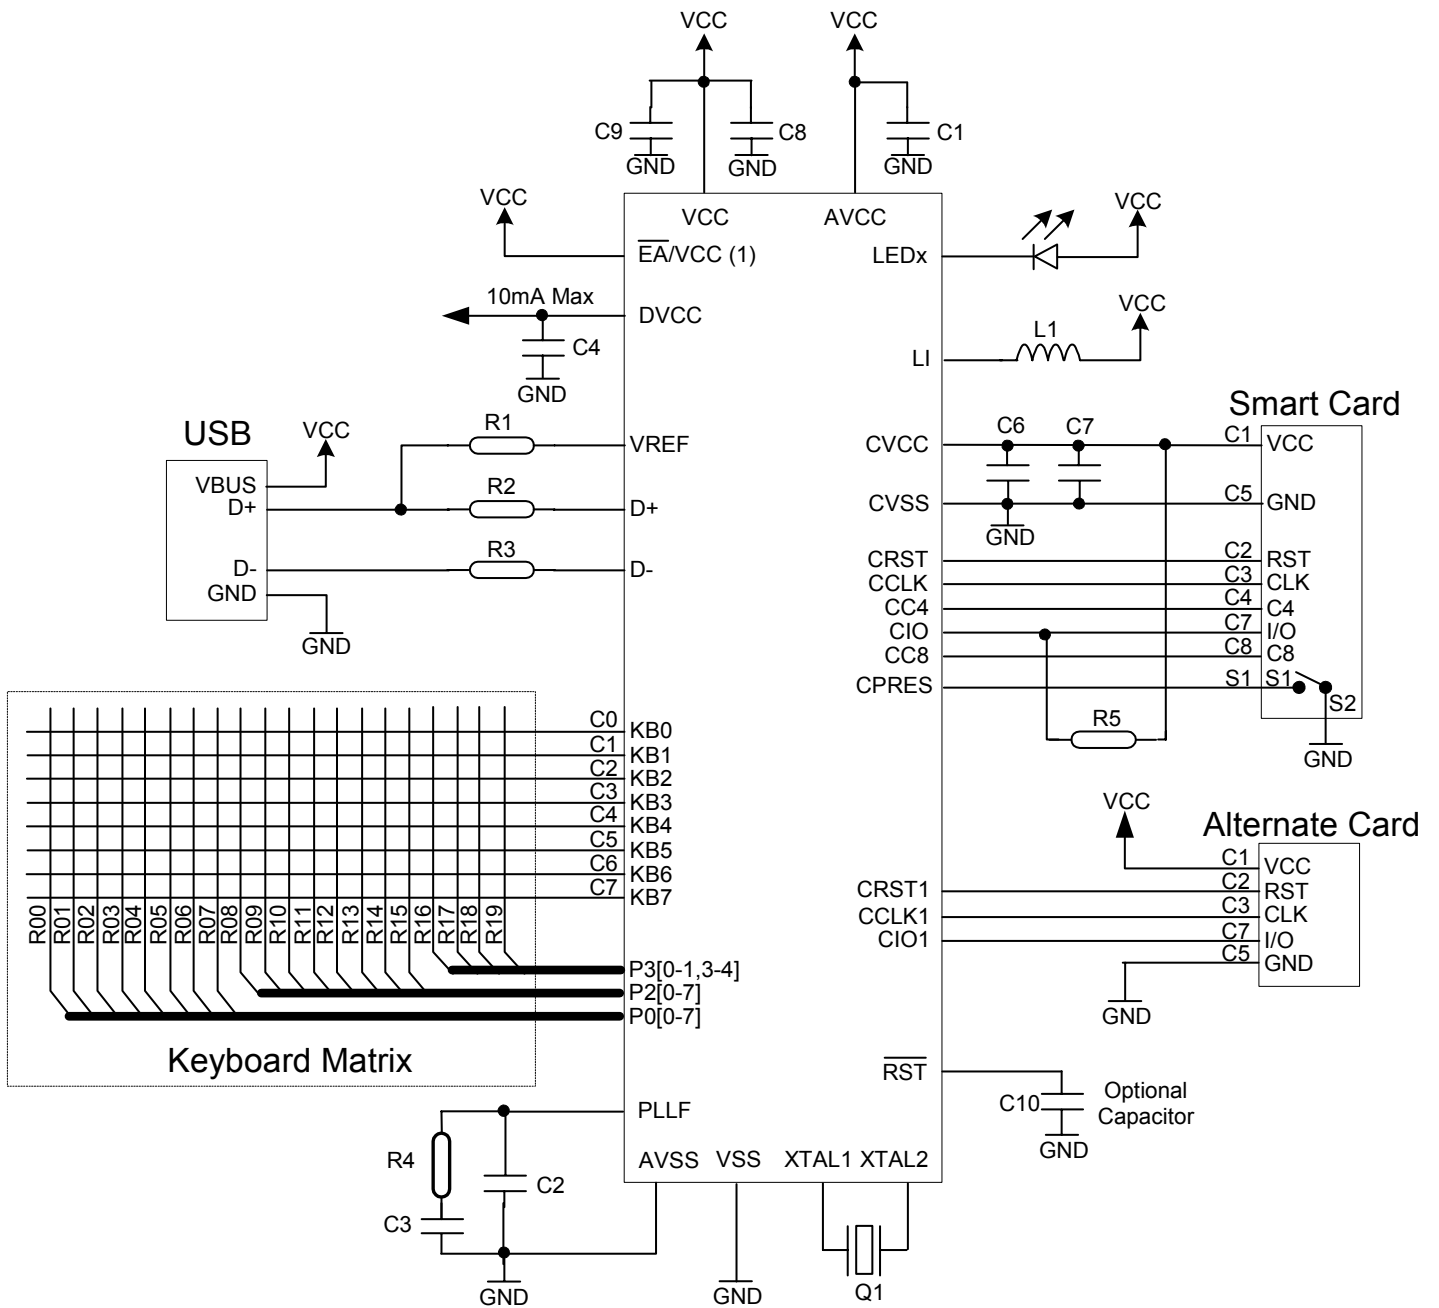

Notes :

1 - Pin configuration depends on product versions

USB Smart Card Reader Using the AT83C5123 Version
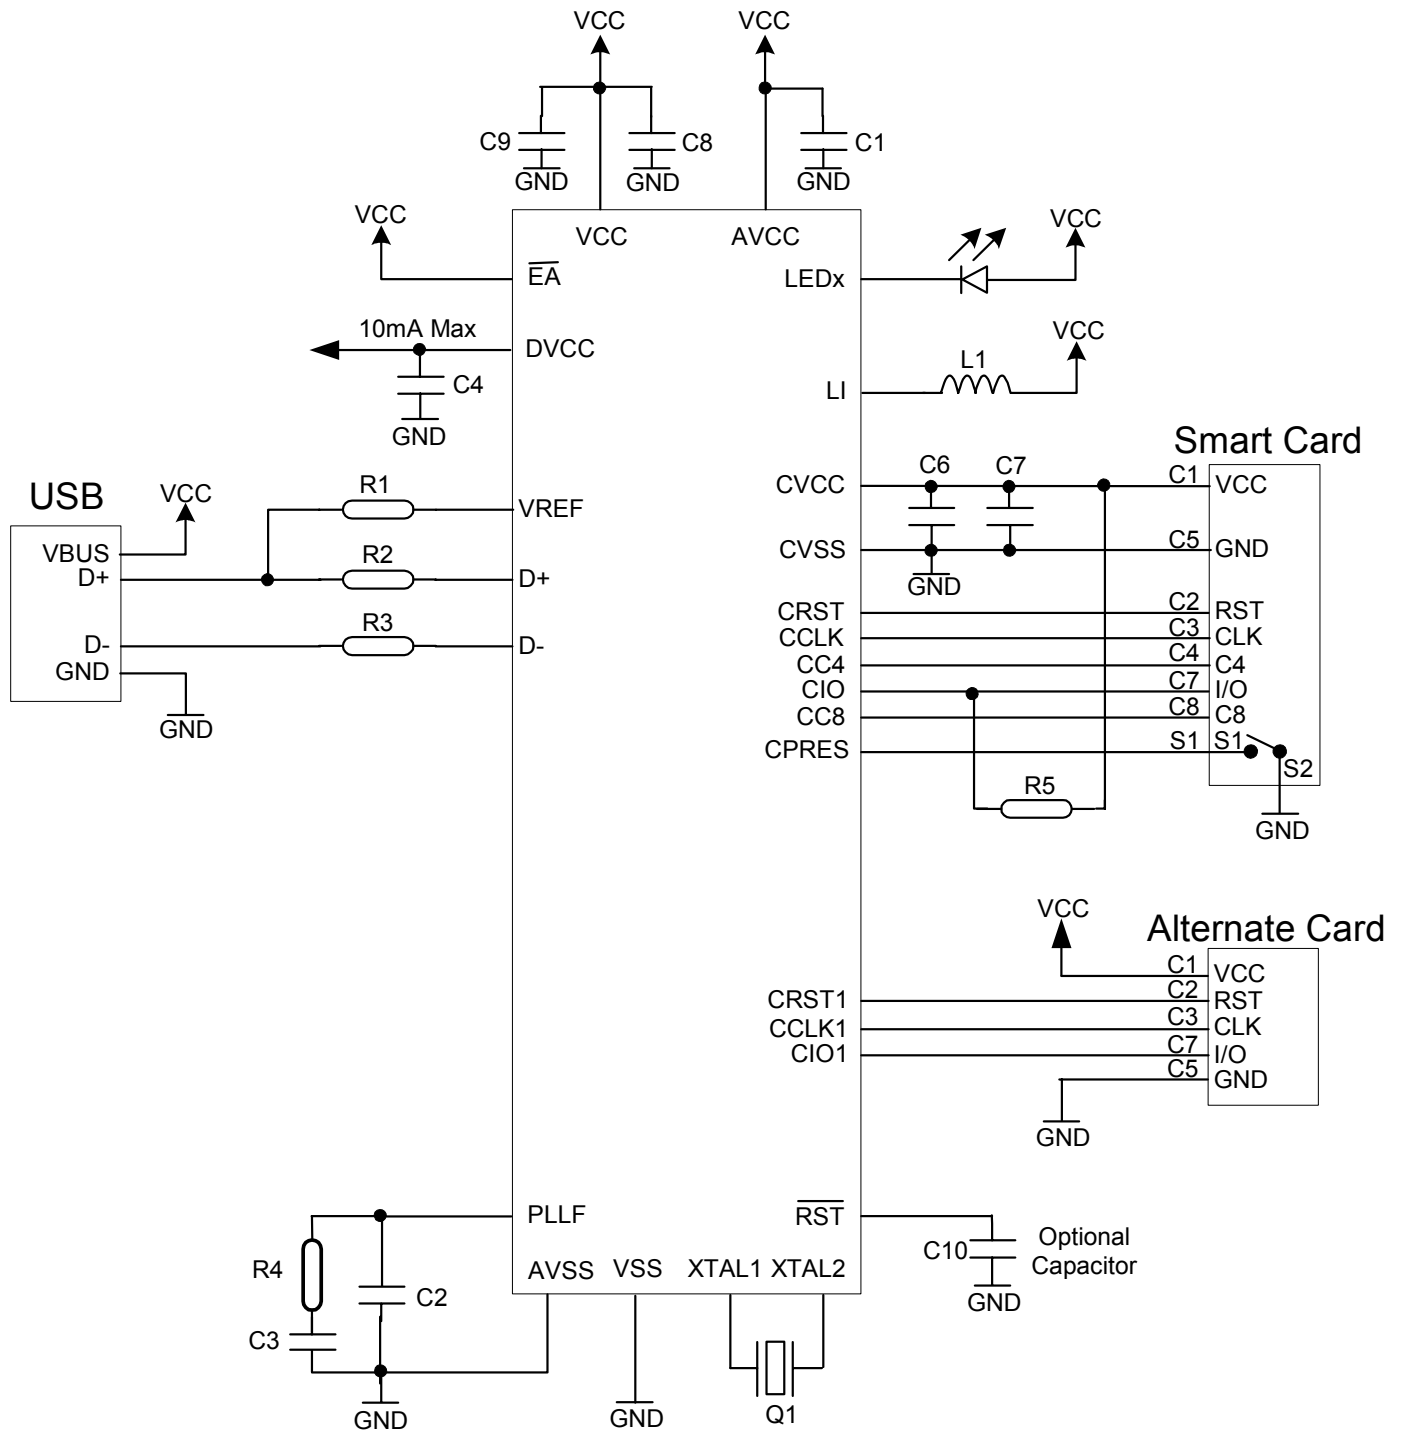

Memory Organization The AT8xC5122/23 devices have separated address spaces for Program and Data Memory, as shown in Figure 13 on page 29, Figure 14 on page 31 and Figure 15 on page 32. The logical separation of Program and Data memory allows the Data Memory to be accessed by 8-bit addresses, which can be more quickly stored and manipulated by an-bit CPU. Nevertheless, 16-bit Data Memory addresses can also be generated through the DPTR register.

Program Memory Managament

Depending on the state of EA pin, the MCU fetches the code from internal or external program memory (ROMless mode)

Warning : the EA pin can not be left floating, otherwise MCU may have an unpredictable behaviour.

If EA is strapped to VCC, the MCU fetches the code from the internal program memory. The way the MCU works in this mode depends on the device version. See next paragraphs for further details.

If the EA is strapped to GND, the MCU fetches the code from external program memory. This mode is common for all device versions wich supports it. After reset, the CPU begins the execution from location 0000h. There can be up to 64 KBytes of program memory. In this mode, the internal program memories are disabled.

The hardware configuration for external program execution is shown in Figure 9.

Figure 9. Executing from External Program Memory
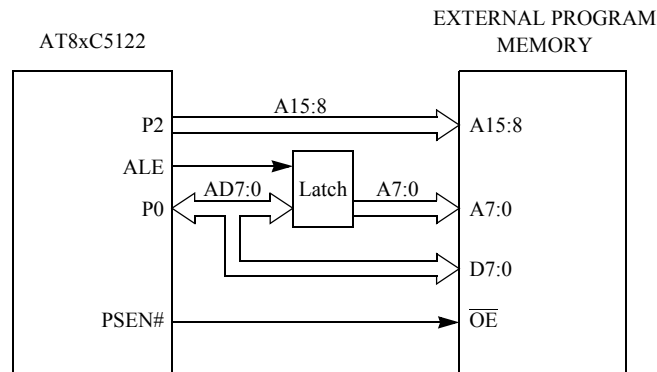

Note that the 16 I/O lines (Ports 0 and 2) are dedicated to bus functions during external Program Memory fetches. Port 0 serves as a multiplexed address/dat bus. It emits the low byte of the Program Counter (PCL) as an address, and then goes into a float state awaiting the arrival of the code byte from the Program Memory. During the time that the low byte of the Program Counter is valid on P0, the signal ALE (Address Latch Enable) clocks the byte into an address latch. Meanwhile, Port 2 emits the high byte of the Program Counter (PCH). Then PSEN strobes the External Program Memory and the code byte is read into the MCU.

PSEN is not activated and Ports P0 and P2 are not affected during internal program fetches.

Data Memory Managment

All device versions implements :

- 256 Bytes of RAM to increase data parameter handling and high level language usage

- 512 bytes of XRAM (Extended RAM) to store program data.

RAM Achitecture

The internal RAM is mapped into three separate segments :

- The Lower 128 bytes (addresses 00h to 7Fh) are directly and indirectly addressable.

- The Upper 128 bytes (addresses 80h to FFh) are indirectly addressable only.

- The Special Function Registers (SFRs) (addresses 80h to FFh) are directly addressable only.

The Upper 128 bytes and SFR's have the same address space but are physically separated.

When an instruction accesses an internal location above address 7Fh, the CPU knows whether the access is in the upper 128 bytes of data RAM or to SFR space by the addressing mode used in the instruction.

- Instructions that use direct addressing access SFR space. For example: MOV 0A0H, # data, accesses the SFR at location 0A0h (which is P2).

- Instructions that use indirect addressing access the Upper 128 bytes of data RAM. For example: MOV @R0, # data where R0 contains 0A0h, accesses the data byte at address 0A0h, rather than P2 (whose address is 0A0h).

The stack pointer (SP) may be located anywhere in the 256 bytes RAM (lower and upper RAM) internal data memory. The stack may not be located in the XRAM.

The M0 bit allows to stretch the XRAM timings. If M0 is set, the read and write pulses are extended from 6 to 30 clock periods. This is useful to access external slow peripherals.

XRAM Achitecture

Depending on the state of EXTRAM bit in AUXR register (See Table 5 on page 24), the MCU fetches data from internal or external XRAM.

If EXTRAM=0 (reset condition), the MCU fetches the data from internal XRAM. The size of internal XRAM is configured by the bit XRS0 in AUXR register (See Table 5 on page 24).

Table 4. XRAM Size Configuration

XRS0	XRAM size	Address	
		Start	End
0	256 Bytes (Reset condition)	000h	0FFh
1	512 bytes	000h	1FFh

The XRAM logically occupies the first bytes of external data memory. The bit XRS0 can be used to hide a part of the available XRAM . This can be useful if external peripherals are mapped at addresses already used by the internal XRAM.

The XRAM is indirectly addressed, using the MOVX instruction in combination with any of the registers R0, R1 of the selected bank or DPTR.

For example, MOVX @R0, # data where R0 contains 0A0H, accesses the XRAM at address 0A0H rather than external memory.

An access to external XRAM memory locations higher than the accessible size of the memory (roll-over feature) will be performed with the MOVX DPTR instructions, with P0 and P2 as data/address busses, WR and RD as respectively write and read signals. Accesses above XRAM size can only be done by the use of DPTR.

If EXTRAM=1 the MCU fetches the data from external XRAM Memory. There can be up to 64 KBytes of external XRAM Memory.

The hardware configuration for external Data Memory Access is shown in Figure 10

Figure 10. Accessing to External XRAM Memory
MOVX @Ri and MOVX @DPTR will be similar to the standard 80C51. MOVX @ Ri will provide an eight-bit address multiplexed with data on Port 0 and any output port pins can be used to output higher order address bits. This is to provide the external paging capability. MOVX @DPTR will generate a sixteen-bit address. Port 2 outputs the high-order eight address bits (DPH) while Port0 multiplexes the low-order eight address bits (DPL) with data. MOVX @ Ri and MOVX @DPTR will generate either read or write signals on WR and RD.

Ports P0, P2 are not affected and RD, WR signals are not activated during access to internal XRAM.

Note that external XRAM Memory access is only available on High Pin Count Packages.

External Program Memory and external XRAM Memory may be combined if desired by applying the RD and PSEN signals to the inputs of an AND gate and using the ouput of the gate as the read strobe to the external program/data memory.
Dual Data Pointer Register (DDPTR)

The additional data pointer can be used to speed up code execution and reduce code size.

The dual DPTR structure is a way by which the chip will specify the address of an external data memory location. There are two 16-bit DPTR registers that address the external memory, and a single bit called DPS = AUXR1.0 (see Table 7) that allow the program code to switch between them (Figure 11).

Figure 11. Use of Dual Pointer
a. Bit 2 stuck at 0; this allows to use INC AUXR1 to toggle DPS without changing GF3.

Assembly Language

```
; Block move using dual data pointers
; Modifies DPTR0, DPTR1, A and PSW
; note: DPS exits opposite of entry state
; unless an extra INC AUXR1 is added
;
00A2  AUXR1 QU 0A2H
;
0000 909000MOV DPTR,#SOURCE ; address of SOURCE
0003 05A2 INC AUXR1 ; switch data pointers
0005 90A000 MOV DPTR,#DEST ; address of DEST
0008  LOOP:
0008 05A2 INC AUXR1 ; switch data pointers
000A E0 MOVX A,@DPTR ; get a byte from SOURCE
000B A3 INC DPTR ;increment SOURCE address
000C 05A2 INC AUXR1 ; switch data pointers
000E F0 MOVX @DPTR,A ; write the byte to DEST
000F A3 INC DPTR ; increment DEST address
0010 70F6JNZ LOOP ; check for 0 terminator
0012 05A2 INC AUXR1 ; (optional) restore DPS
```

INC is a short (2 bytes) and fast (12 clocks) way to manipulate the DPS bit in the AUXR1 SFR. However, note that the INC instruction does not directly force the DPS bit to a particular state, but simply toggles it. In simple routines, such as the block move example, only the fact that DPS is toggled in the proper sequence matters, not its actual value. For example, the block move routine works the same whether DPS is '0' or '1' on entry. Observe that without the last instruction (INC AUXR1), the routine will exit with DPS in the opposite state.

Registers

Table 5. Auxiliary Register - AUXR (8Eh)

7	6	5	4	3	2	1	0
DPU	-	-	-		XRS0	EXTRAM	AO

Bit Number	Bit Mnemonic	Description
7	DPU	**Disable weak Pull-up** 0 weak pull-up is enabled 1 weak pull-up is disabled
6-3	-	**Reserved** The value read from this bit is indeterminate. Do not change these bits.
2	XRS0	**XRAM Size** 0 256 bytes (default) 1 512 bytes
1	EXTRAM	**EXTRAM bit** Cleared to access internal XRAM using MOVX @ Ri/ @ DPTR. Set to access external memory. Programmed by hardware after Power-up regarding Hardware Security Byte (HSB), default setting , XRAM selected.
0	AO	**ALE Output bit** Cleared , ALE is emitted at a constant rate of 1/6 the oscillator frequency (or 1/3 if X2 mode is used)(default). Set , ALE is active only when a MOVX or MOVC instruction is used.

Reset Value = 0XXX X000b

Table 6. Auxiliary Register 1 AUXR1- (0A2h) for AT8xC5122

7	6	5	4	3	2	1	0
-	-	ENBOOT	-	GF3	0	-	DPS

Bit Number	Bit Mnemonic	Description
7 - 6	-	**Reserved** The value read from this bit is indeterminate. Do not change these bits.
5	ENBOOT	**Enable Boot ROM (CRAM / E2PROM version only)** Set this bit to map the Boot ROM from 8000h to FFFFh. If the PC increments beyond 7FFFh address, the code is fetch from internal ROM Clear this bit to disable Boot ROM. If the PC increments beyond 7FFFh address, the code is fetch from external code memory (C51 standard roll over function) This bit is forced to 1 at reset
4	-	**Reserved** The value read from this bit is indeterminate. Do not change this bit.
3	GF3	This bit is a general-purpose user flag.
2	0	Always cleared.
1	-	**Reserved** The value read from this bit is indeterminate. Do not change this bit.
0	DPS	**Data Pointer Selection** Cleared to select DPTR0. Set to select DPTR1.

Reset Value = XX1X XX0X0b (Not bit addressable)

Table 7. Auxiliary Register 1 AUXR1- (0A2h) for AT83C5123

7	6	5	4	3	2	1	0
-	-	-	-	GF3	0	-	DPS

Bit Number	Bit Mnemonic	Description
7 - 6	-	**Reserved** The value read from this bit is indeterminate. Do not change these bits.
5		**Reserved** The value read from this bit is indeterminate. Do not change these bits.
4	-	**Reserved** The value read from this bit is indeterminate. Do not change this bit.
3	GF3	This bit is a general-purpose user flag.
2	0	Always cleared.
1	-	**Reserved** The value read from this bit is indeterminate. Do not change this bit.
0	DPS	**Data Pointer Selection** Cleared to select DPTR0. Set to select DPTR1.

Reset Value = XXXX XX0X0b (Not bit addressable)

Table 8. CRAM Configuration Register - RCON (D1h)

7	6	5	4	3	2	1	0
-	-	-	-	RPS	-	-	-

Bit Number	Bit Mnemonic	Description
7 - 4	-	**Reserved** The value read from this bit is indeterminate. Do not change these bits.
3	RPS	**CRAM Memory Mapping Bit** Set to map the CRAM memory during MOVX instructions Clear to map the XRAM memory during MOVX. This bit has priority over the EXTRAM bit.
2-0	-	**Reserved** The value read from this bit is indeterminate. Do not change these bits.

Reset Value = XXXX 0XXXb

AT8xC5122's CRAM and E2PROM Versions

The AT8xC5122's CRAM and E2PROM versions implements :

- 32 KB of ROM mapped from 8000 to FFFF in which is embedded a bootloader for In-System Programming feature

- 32 KB of CRAM (Code RAM) , a volatile program memory mapped from 0000 to 7FFF

In CRAM versions only :

- 512 bytes of E2PROM can be optionally implemented to store permanent data

In E2PROM version :

- 32KB of E2PROM are implemented to store permanent code

Warnings :

– some bytes of user program memory space are reserved for bootloader configuration. Depending on the configuration, up to 256 bytes of code may be not available for the user code from 7F00h location. Refer to bootloader datasheet for further details.

– Port P3.7 may be used by the bootloader as a hardware condition at reset to select the In-System Programming mode. Once the bootloader has started, the P3.7 Port is no more used.

AT8xC5122 Microcontroller
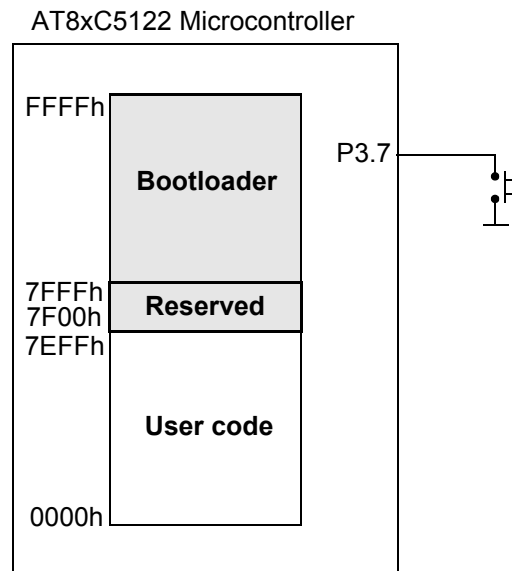

When pin EA =1 and after the reset, the MCU begins the execution of the embedded bootloader from location F800h of the ROM. The bootloader implements an In-System Programming (ISP) mode which manages the transfer of the code in the volatile Program Memory (CRAM).

For CRAM version, the code is supplied by the ATMEL's FLexible In-system Programming software (FLIP) through USB or UART interface

For E2PROM version, the code is supplied from the internal code E2PROM or by FLIP. The state of pin P3.7 at reset determines the code source. If P3.7=1 (reset condition) the source is the internal E2PROM and the transfer takes about 1.5 seconds. If P3.7=0 the source is FLIP and the transfer time depends mainly on external conditions not related to bootloader.

Once the code is running in CRAM, the roll-over condition (code fetched beyond address 7FFFh) depends on the state of ENBOOT bit of AUXR1 register (Table 6 on page 25).

If ENBOOT=1 (reset condition) the MCU fetches the code from bootloader ROM. If ENBOOT=0, the MCU fetches the code from the external Program Memory. In this last case, PSEN is activated and Ports P0 and P2 are used to emit data and address signals.

Warning : external Program Memory access is not allowed on Low Pin Count Packages.

Using CRAM Memory

The CRAM is a read / write volatile memory that is mapped in the program memory space. Then when the power is switched off the code is lost and needs to be reload at each power up. In return, the CRAM enables a lot of flexibility in the code development as it can be programmed indefinitely. The user code running in the CRAM can perform read operations in CRAM itself by means of MOVC instructions like any C51 microcontroller does. Although the writing operations in CRAM are usually handled by the bootloader, it is possible for the user code to handle its own writing operations in CRAM as well. The user code must call API functions provided by the bootloader in the ROM memory. Refer to bootloader datasheet for further details about the use of these API functions. These API functions use a mechanism provided by the AT8xC5122 microcontroller. When the bit RPS is set in RCON register (Table 8 on page 26), the MOVX intructions are configured to write in CRAM instead of XRAM memory. However, due to C51 architecture, it is not possible for the user code to write directly in CRAM when it is itself running in CRAM. This is why the API functions must be called in order to have the code executing in ROM while the CRAM is written.

AT8xC5122's ROM Version

The AT8xC5122's ROM version implements :

- 32 K of ROM mapped from 0000h to 7FFFh in which is embedded the user code. The ROM device is only factory programmable.

- 512 bytes of E2PROM can be optionally implemented to store permanent data. With this option, the size of ROM is reduced to 30K.

After the reset, the MCU begins the execution of the user code from location 0000h of the ROM.

Access to external Program Memory is not allowed.

Security Level

There are two security levels (applicable to High Pin Count packages only) :

Table 9. Security Levels Description

Security Level	Protection description
1	No protection lock enabled
2	MOVC instruction executed from external Program Memory is disabled when fetching code bytes from internal Program Memory $\overline{EA}$ is sampled and latched on reset. External code execution is enabled.

The security level 2 can be used to protect the user code from piracy. This option is configured at factory and must be requested by the customer at order time.

Figure 14. AT8xC5122's ROM Version
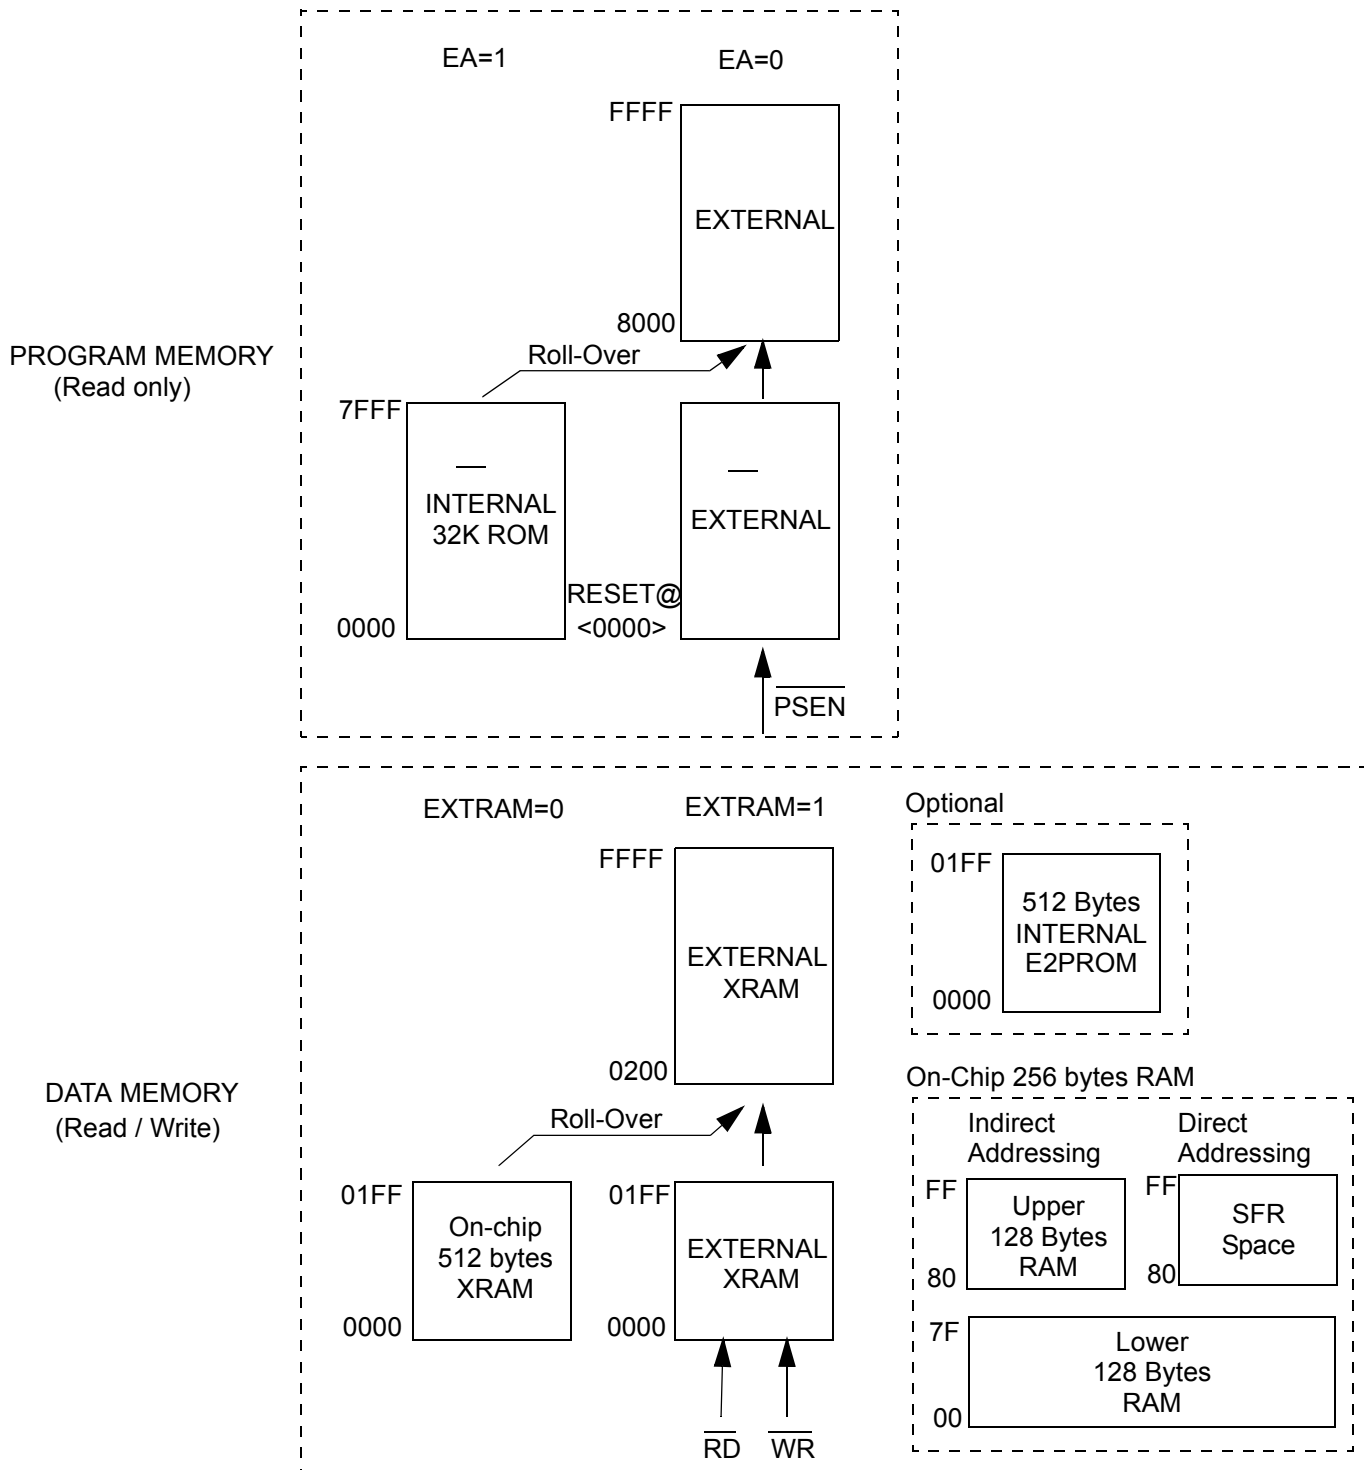

AT83C5123 Version

The AT83C5123 device is a low pin count version of the AT8xC5122.

The ROM version implements :

- 30 KB of ROM mapped from 0000 to 77FF in which is embedded the user code. The ROM device is only factory programmable.

- 512 bytes of E2PROM can be optionally implemented to store permanent data

Figure 15. AT83C5123's Device
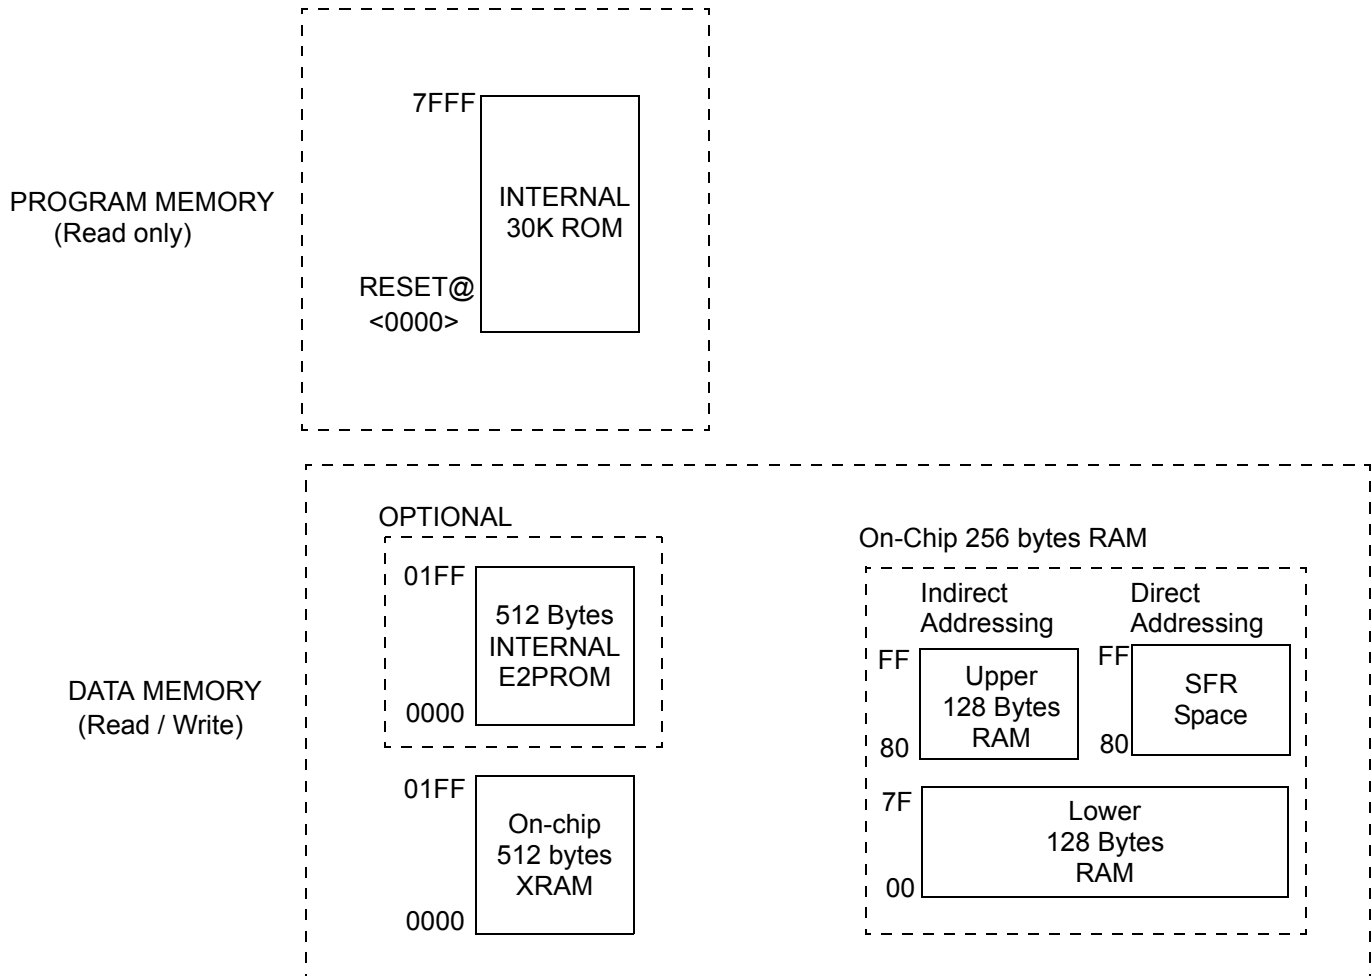

Special Function Registers (SFR's)

Introduction

The Special Function Registers (SFRs) of the AT8xC5122/23 can be ranked into the following categories:

- C51 Core Registers: ACC, B, DPH, DPL, PSW, SP
- System Configuration Registers: PCON, CKRL, CKCON0, CKCON1, CKSEL, PLLCON, PLLDIV, AUXR, AUXR1, RCON
- I/O Port Registers: P0, P1, P2, P3, P4, P5, PMOD1, PMOD2
- Timer Registers: TCON, TH0, TH1, TMOD, TL0, TL1
- Watchdog (WD) Registers: WDTRST, WDTPRG
- Serial I/O Port Registers: SADDR, SADEN, SBUF, SCON
- Baud Rate Generator (BRG) Registers: BRL, BDRCON
- System Interrupt Registers: IE0, IPL0, IPH0, IE1, IPL1, IPH1
- Smart Card Interface (SCI) Registers: SCSR, SCCON/SCETU0, SCISR/SCETU1, SCIER/SCIIR, SCIBUF, SCGT0/SCWT0, SCGT1/SCWT1, SCICR/SCWT2, SCICLK
- DC/DC Converter Registers: DCCKPS
- Keyboard Interface Registers: KBE, KBF, KBLS
- Serial Port Interface (SPI) Registers: SPCON, SPSTA, SPDAT
- Universal Serial Bus (USB) Registers:USBCON, USBADDR, USBINT, USBIEN, UEPNUM, UEPCONX, UEPSTAX, UEPRST, UEPINT, UEPIEN, UEPDATX, UBYCTX, UFNUML, UFNUMH
- LED Controller Registers: LEDCON0, LEDCON1

Clock Controller

The clock controller is based on an on-chip oscillator feeding an on-chip Phase Lock Loop (PLL). All the internal clocks to the CPU core and peripherals are generated by this controller.

On-Chip Oscillator

The on-chip oscillator is composed of a single-stage inverter and a parallel feedback resistor. The XTAL1 and XTAL2 pins are respectively the input and the output of the inverter, which can be configured with off-chip components as a Pierce oscillator (see Figure 16).

The on-chip oscillator has been designed and optimized to work with an external 8 MHz crystal and very few load capacitance. Then external load capacitors are not needed given that :

– the internal capacitance of the microcontroller and the stray capacitance of circuit board are enough to ensure a stable oscillation

– a very high accuracy on the oscillation frequency is not needed

The circuit works on its fundamental frequency at 8 MHz.

Figure 16. Oscillator Schematic
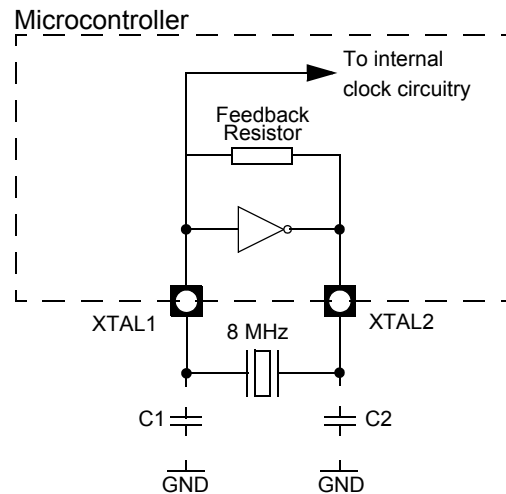

C1 and C2 represents the internal capacitance of the microcontroller and the stray capacitance of the circuit board. It is recommended to implement the crystal as close as possible from the microcontroller package.

Quartz Specification

The equivalent circuit of a crystal is represented on the figure below :
The Equivalent Serial Resistance R1 must be lower than 100 Ohm.

Phase Lock Loop (PLL)

PLL Description

The AT8xC5122/23's PLL is used to generate internal high frequency clock synchronized with an external low-frequency. Figure 17 shows the internal structure of the PLL.

The PFLD block is the Phase Frequency Comparator and Lock Detector. This block makes the comparison between the reference clock coming from the N divider and the reverse clock coming from the R divider and generates some pulses on the Up or Down signal depending on the edge position of the reverse clock. The PLLEN bit in PLLCON register is used to enable the clock generation. When the PLL is locked, the bit PLOCK in PLLCON register is set.

The CHP block is the Charge Pump that generates the voltage reference for the VCO by injecting or extracting charges from the external filter connected on PLLF pin (see Figure 18). Value of the filter components are detailed in the Section "DC Characteristics".

The VCO block is the Voltage Controlled Oscillator controlled by the voltage V_{REF} produced by the charge pump. It generates a square wave signal: the PLL clock. The CK_PLL frequency is defined by the follwing formula:

$$F_{CK\_PLL} = F_{CK\_XTAL1} * (R+1) / (N+1)$$

Figure 17. PLL Block Diagram and Symbol
Figure 18. PLL Filter Value
PLL Programming

The PLL must be programmed to work at 96 MHz frequency by means of PLLCON and PLLDIV registers. As soon as the PLL is enabled, the firmware must wait for the lock bit status to ensure that the PLL is ready.

Figure 19. PLL Programming Flow
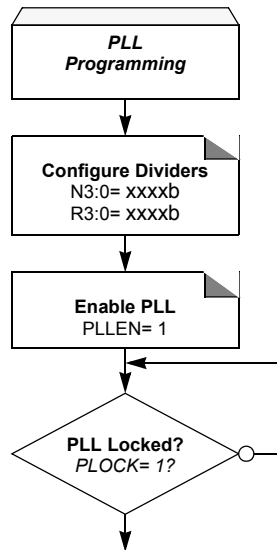

Clock Tree Architecture

The clock controller outputs several different clocks as shown in Figure 20:

- a clock for the CPU core
- a clock for the peripherals which is used to generate the timers, watchdog, SPI, UART, and ports sampling clocks. This divided clock will be used to generate the alternate card clock.
- a clock for the USB
- a clock for the SCIB controller
- a clock for the DC/DC converter

These clocks are enabled or not depending on the power reduction mode as detailed in Section "Power Management", page 180.

These clocks are generated using four presacalers defined in the table below:

Prescaler	Register	Reload Factor	Function
PR1	CKRL	CKRL[0:3]	CPU & Peripheral clocks
PR2	SCICLK	SCICLK[0:5]	Smart card
PR3	SCSR	ALTKPS[0:1]	Alternate card
PR4	DCCKPS	DCCKPS[3:0]	DC/DC

Figure 20. Clock Tree Diagram
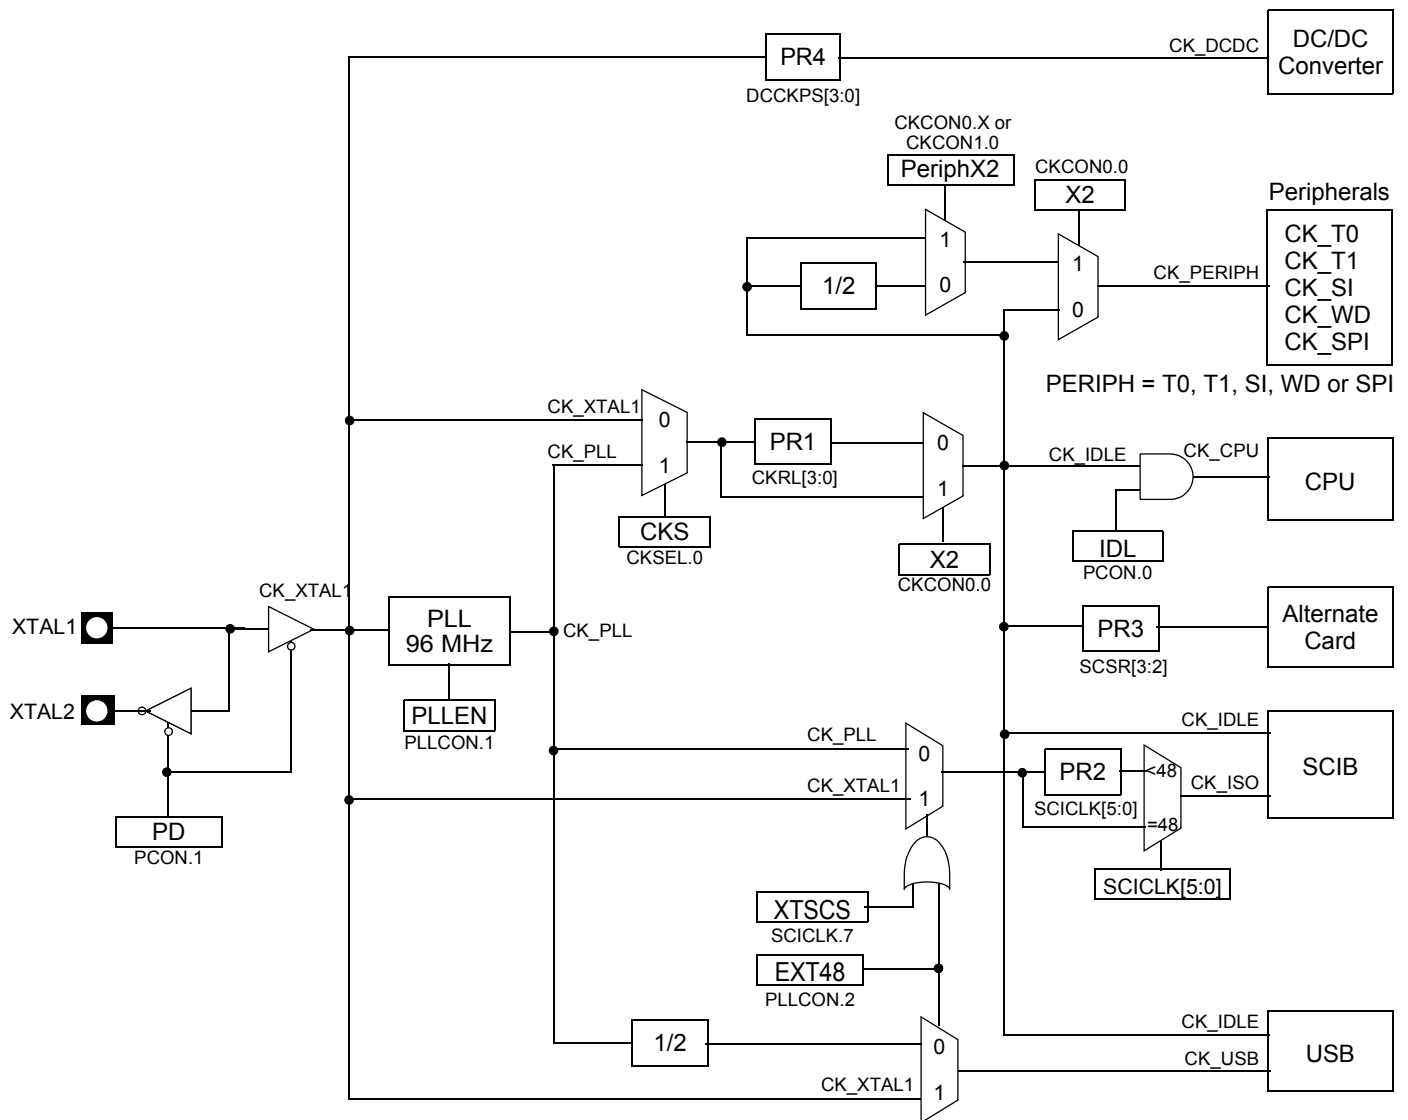

CPU and Peripheral Clocks

Two clocks sources are available for CPU and peripherals:

– on-chip oscillator
– a derivative of the PLL clock.

These clock sources are configured by the PR1 prescaler to generate the CPU core CK_CPU and the peripheral clocks:

– CK_IDLE for alternate card and peripherals registers access
– CK_T0 for Timer 0
– CK_T1 for Timer 1
– CK_SI for the UART
– CK_WD for the Watchdog Timer
– CK_SPI for SPI

The CPU and peripherals clocks frequencies are defined in the table below.

CKS	X2	F_{CK_IDLE}
0	0	$F_{CK\_XTAL1}/(2*(16-CKRL))$
0	1	F_{CK_XTAL1}
1	0	$F_{CK\_PLL}/(2*(16-CKRL))$
1	1	Not allowed

X1 and X2 Modes

Use of on-chip oscillator

When the CPU and Peripherals clocks are fed by the on-chip oscillator, the CPU and Peripherals can be configured independently in X1 or X2 mode depending on the frequencies wanted by the user. There is however one exception : the periperals can be configured in X2 mode while the CPU remains in X1 mode. This exception is handled by the hardware and the user does not need to take care of.

Table 1. X1 and X2 Mode Selection

CPU	Peripherals	Status	Frequenci
X1 mode	X1 mode	Allowed (default configuration at reset)	$F_{CK\_IDLE} = F_{CK\_PERIPH}$
X1 mode	X2 mode	Not Allowed by the hardware	
X2 mode	X1 mode	Allowed Once the CPU is switched to X2 mode, the user is free to switch any of the peripherals to X1 mode	$F_{CK\_IDLE} = 2*F_{CK\_PERIPH}$
X2 mode	X2 mode	Allowed Default configuration when CPU is switched to X2 mode	$F_{CK\_IDLE} = F_{CK\_PERIPH}$

The X1 or X2 modes can be individually selected for the CPU and each peripheral by means of CKCON0 and CKCON1 registers. At reset, the CPU and Peripherals are set all by default to X1 mode. In this mode, changing any peripheral to X2 mode has no effect. When X2 bit is set in CKCON0 register, CPU and All peripherals are automatically switched to X2 mode. It is then possible for the user to individually switch any peripheral back to X1 mode.

In X1 mode (X2 bit cleared in CKCON0 regsiter), the PR1 prescaler is active while it is bypassed in X2 mode (X2 bit set in CKCON0 register).

The X1 mode is true only when the prescaler PR1 is set to 1/2 (default condition at reset).

Figure 21. X1 mode

```
Crystal          PR1 prescaler      CPU frequency
8 MHz            1/2                4 MHz

                                    Peripheral frequency
                                    4 MHz
```
When the X1 mode is selected, the CPU and Peripherals work at 8Mhz / X1

Figure 22. X2 mode

```
Crystal                            CPU frequency (X2 Mode)
8 MHz                              8 MHz

                                   Peripheral frequency (X2 mode)
                                   8 MHz

                 Internal Prescaler   Peripheral frequency (X1 mode)
                 1/2                  4 MHz
```
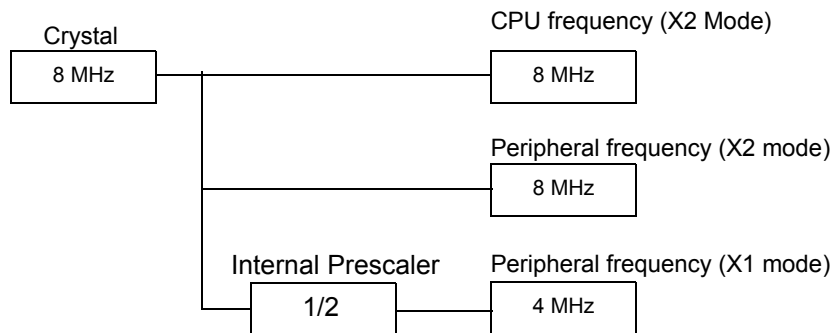

When the X2 mode is selected, the CPU works at 8 MHz / X2. The Peripherals can work at 8 MHz / X2 or 8 MHz / X1.

When the PR1 prescaler is different from 1/2, the usual X1 mode can not be defined. In this case, it is necessary to define a X1 or X2 equivalent mode from equivalent clock circuits.

Example : PR1=1/8, X2=0.

In this configuration, the CPU works at 1 MHz. This frequency could also be obtained by an equivalent clock circuit where the on-chip oscillator would run at 2 MHz in X1 mode or at 1 MHz in X2 mode. So we can say that the CPU works at 2 MHz / X1 or 1MHz / X2.

As the X2 bit is cleared in CKCON0 register, we have $F_{CK\_IDLE} = F_{CK\_PERIPH}$.

```
Use of PLL Clock

When the CPU clock is fed by the PLL, the X2 mode is forbidden. The bit X2 must always remain cleared in CKCON0 register. As the PR1 prescaler is always different from 1/2, the usual X1 mode can not be defined. So it is necessary to define an equivalent X1 or X2 mode from equivalent clock circuits, as in previous section.

Example: PR1=1/4, PLL feeds the CPU. The CPU works in this case at 24 MHz. This frequency could also be obtained by an equivalent clock circuit where the on-chip oscillator would run at 48 MHz in X1 mode or at 24 Mhz in X2 mode. So we can say that in this configuration, the CPU works at 48 MHz / X1 or 24 MHz / X2 (See figures below).

As the X2 bit is cleared in CKCON0 register, we have always $F_{CK\_IDLE} = F_{CK\_PERIPH}$.

PLL 96 MHz → Prescaler 1/4 → CPU frequency 24 MHz, PERIPH frequency 24 MHz

(Equivalent to)

External Clock 48 MHz → X1 mode selected 1/2 → CPU frequency 24 MHz, PERIPH frequency 24 MHz

(Equivalent to)

External Clock 24 MHz → X2 mode selected → CPU frequency 24 MHz, PERIPH frequency 24 MHz
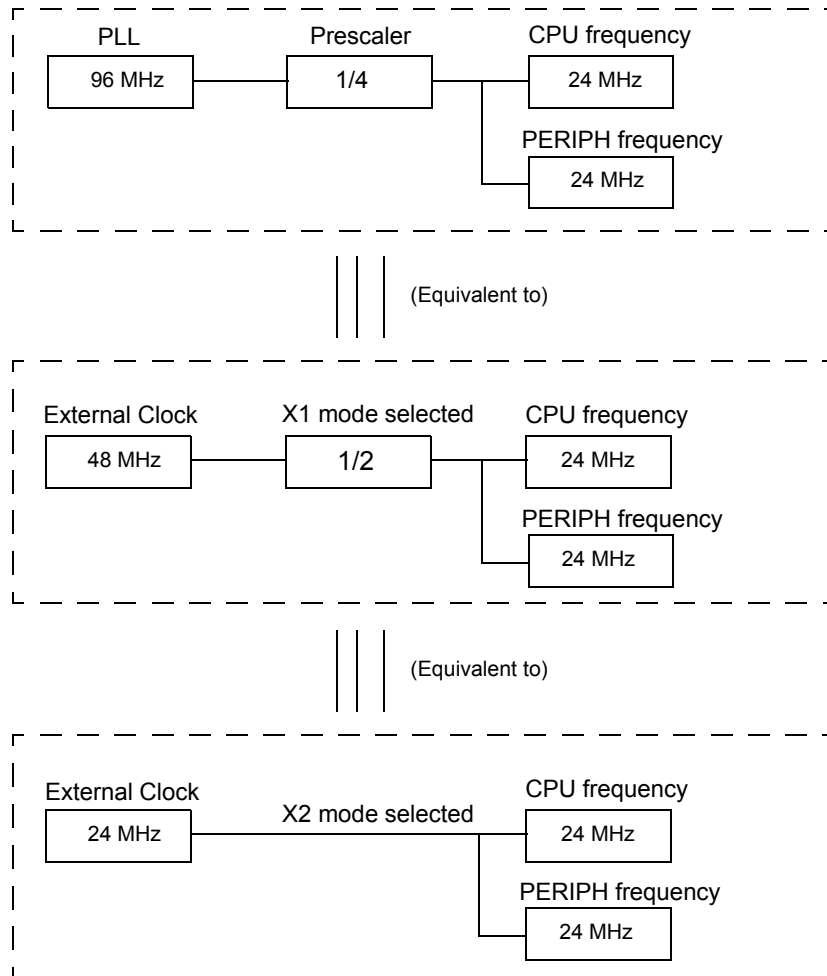

SCIB Clock

The Smart Card Interface Block (SCIB) uses two clocks :

– The first one, CK_IDLE, is the peripheral clock used for the interface with the microcontroller.

– The second one, CK_ISO, is independant from the CPU clock and is generated from the PLL or XTAL1 output.
PR2, a 6-bit prescaler, will be used to generate:
12/9.6/8/6.85/6/5.33/4.8/4.36/ ..../1MHz frequencies.
SCIB clock frequency must be lower than CPU clock frequency.

During SCIB Reset, the CK_ISO input must be in the range 1 - 5 MHz according to ISO 7816. The SCIB clocks frequency is defined in Figure 42 on page 74 and Table 42 on page 74.

Two conditions must be met for a correct use of the SCIB:

• CK_CPU > 4/3 * CK_ISO and

• CK_CPU < 6 * CK_ISO.

If the CK_CPU <= 4/3 * CK_ISO, the SCIB doesn't work.

If the CK_CPU >= 6* CK_ISO, the programmer must take care in three cases:

- Read (or write) operation on a SCIB register followed immediatly with an other Read (or write) operation on the same register.
- Read (or write) operation on a SCIB register followed immediatly with an other Read (or write) operation on a linked register. The list of linked registers is in the table below.

Linked registers
Write in SCICR and after read of SCETU0-1
Write in SCIBUF and after read of SCISR

- Write operation on a register of the list below followed immediatly with a read operation on a SCIB register.

Wait after Write operation on this registers
SCICR, SCIER, SCETU0-1,SCGT0-1, SCWT0-3,SCCON

To avoid any trouble, a delay must be added between the two accesses on the SCIB register. The SCIB must complete the first read (or write) operation before to receive the second. A solution is to add NOP (no operation) instructions. The number of NOP to add depends of the rate between CK_CPU and CK_ISO (see table below).

Min CLK_CPU	Max CLK_CPU	Number of CPU cycles to add
CLK_CPU >= 6 * CLK_ISO	CLK_CPU <= 12 * CLK_ISO	6 (example1 NOP)
CLK_CPU >= 12* CLK_ISO	CLK_CPU <= 16 * CLK_ISO	12 (example 2 NOP)

Alternate Card Clock

The alternate Card uses the peripheral clock divided by the PR3 prescaler. (1; 1/2; 1/4; 1/8 division ratio). See Section "Alternate Card", page 78 for the definition of the alternate clock.

DC/DC Converter Clock

The DC/DC block needs a clock with a 50% duty cycle. The frequency must also be included in the range 3.68 MHz and 6 MHz. The PR4 prescaler is used to configure the DC/DC frequency.

XTAL1 (MHz)	DCCKPS3:0 value	Prescaler Factor	DC/DC converter CLK (MHz)
8	0	2	4

USB Interface Clock   The USB Interface uses two clocks :

– The first one is the CPU clock used for the interface with the microcontroller, CK_IDLE.
– The second one is the CK_USB supplied from the PLL through a divider by 2.

Registers

Table 24. Clock Selection Register - CKSEL (S:85h)

7	6	5	4	3	2	1	0

I/O Port Definition

Ports vs Packages **Table 30.** I/O Number vs Packages

	P0	P1	P2	P3	P4	P5	Total
VQFP64 QFN64	8	8	8	8	6	8	46
VQFP32 QFN32	-	8	-	8	-	1	17
PLCC28	-	6	-	6	-	1	13

Port 0 Port 0 has the following functions:

– Default function: Port 0 is an 8-bit I/O port.

– Alternate function: Port 0 is also the multiplexed low-order address and data bus during accesses to external Program and Data Memory. In this application, it uses strong internal pull-ups when emitting 1's and it can drive CMOS inputs without external pull-ups.

Port 0 has the following configurations:

– Default configuration: open drain bi-directional I/O port. Port 0 pins that have 1's written to them float, and in this state they can be used as high-impedance inputs.

– Configuration 2: Low speed output, "KB_OUT"

– Configuration 3: Push-pull output

Port 1   Port 1 has the following functions:

- – Default function : Only Port 1.2, P1.6 and P1.7 are standard I/O's; the other ports can be activated only with the SCIB function.
- – Alternate function and configuration: see Table 31.

Table 31. Port 1 Description.

| Port | Alternate Function | | Configuration | |
	Signal	Description	Mode	Comments
	CIO	**Smart card interface function** Card I/O	Quasi-bidirectional port supplied by DC/DC converter	Low level at reset. **Caution** : if DPU bit is set in AUXR register, the weak-pull of the port is disabled
	CC8	**Smart card interface function** Card contact 8	Quasi-bidirectional port supplied by DC/DC converter	Low level at reset **Caution** : if DPU bit is set in AUXR register, the weak-pull of the port is disabled
P1.2	CPRES	**Smart card interface function** Card presence	Quasi-bidirectional port supplied by VCC	Weak & medium pull-up's can be disconnected by CPRESRES bit in PMOD0 regsiter High Level at reset
	CC4	**Smart card interface function** Card contact 4	Quasi-bidirectional port supplied by DC/DC converter	Low level at reset **Caution** : if DPU bit is set in AUXR register, the weak-pull of the port is disabled
	CCLK	**Smart card interface function** Card clock	Push-Pull port supplied by DC/DC converter	Low level at reset
	CRST	**Smart card interface function** Card reset	Push-Pull port supplied by DC/DC converter	Low level at reset
P1.6	$\overline{SS}$	$\overline{SS}$ pin of the SPI function	Quasi-bidirectional supplied by VCC	
P1.7	CCLK1	Alternate Card Clock output	Quasi-bidirectional supplied by VCC	Alternate Card Clock function disabled
			Quasi-bidirectional supplied by VCC	Alternate Smart Card Clock enabled Switched automatically to Push-pull (see Table 47 on page 82)

Port 2   Port 2 has the following functions:

- – Default function: Port 2 is an 8-bit I/O port.
- – Alternate function 1: Port 2 is also the multiplexed high-order address during accesses to external Program and Data Memory. In this application, it uses strong internal pull-ups when emitting 1's and it can drive CMOS inputs without external pull-ups.

Port 2 has the following configurations:

- – Default configuration: Pseudo bi-directional "Port51" digital input/output with internal pull-ups.
- – Configuration 1: Push-pull output
- – Configuration 2: Low speed output, "KB_OUT
- – Configuration 3: Input with weak pull-up, "WPU input"

Port 3   Port 3 has the following functions:

– Default function: Port 3 is an 8-bit I/O port.
– Alternate functions: see table below

Port 3 has the following configurations:

– Default configuration: Pseudo bi-directional "Port51" digital input/output with internal pull-ups.
– Alternate configurations: See Table 32.

Table 32. Port 3 Description

Port	Alternate Functions		Configurations			
	Signal	Description	Mode 1	Mode 2	Mode 3	Mode 4
P3.0	RxD	Receiver data input (asynchronous) or data input/output (synchronous) of the serial interface	Push-pull	KB_OUT	Input WPU	
P3.1	TxD	Transmitter data output (asynchronous) or clock output (synchronous) of the serial interface	Push-pull	KB_OUT	Input WPU	
P3.2	INT0	External interrupt 0 input/timer 0 gate control input				LED0
P3.3	INT1	External interrupt 1input/timer 1 gate control input	Push-pull	KB_OUT	Input WPU	
P3.4	T0	Timer 0 counter input	Push-pull	KB_OUT	Input WPU	LED1
P3.5	T1	Timer 1 counter input				
P3.6	WR	External Data Memory write strobe; latches the data byte from port 0 into the external data memory				LED2
P3.7	RD	External Data Memory read strobe; Enables the external data memory. Port 3 can drive CMOS inputs without external pull-ups				LED3

Port 4

Port 4 has the following functions:
– Default function: Port 4 is an 6-bit I/O port.
– Alternate functions: see table below

Port 4 has the following configurations:
– Default configuration: Pseudo bi-directional "Port51" digital input/output with internal pull-ups.
– Alternate configurations: See Table 33.

Table 33. Port 4 Description

| Port | Alternate Functions | | Configurations | | |
	Signal	Description	Mode 1	Mode 2	Mode 3
P4.0	MISO	SPI Master In Slave Out I/O			
P4.1	MOSI	SPI Master Out Slave In I/O			
P4.2	SCK	SPI clock			
P4.3			Push-pull	KB_OUT	Input MPU
P4.4			Push-pull	KB_OUT	Input MPU
P4.5			Push-pull	KB_OUT	Input MPU

Port 5

Port 5 has the following functions:
– Default function: Port 5 is an 8-bit I/O port.
– Alternate function 1: Port 5 is an 8-bit keyboard port KB0 to KB7.

Port 5 has the following configurations:
– Default configuration: Pseudo bi-directional "Port51" digital input/output with internal pull-ups.
– Alternate configuration: see Table 34.

Table 34. Port 5 Description

| Port | Configurations | | | |
	Mode 1	Mode 2	Mode 3	Comments
P5.0	Push-pull	Input MPU	Input WPU	
P5.1	Push-pull	Input MPU	Input WPU	First cluster
P5.2	Push-pull	Input MPU	Input WPU	
P5.3	Push-pull	Input WPD	Input WPU	
P5.4	Push-pull	Input WPD	Input WPU	Second cluster
P5.5	Push-pull	Input WPD	Input WPU	
P5.6	Push-pull	Input WPD	Input WPU	Third cluster
P5.7	Push-pull	Input WPD	Input WPU	

Port Configuration

Standard I/O P0   The P0 port is described in Figure 23.

Figure 23. Standard Input/Output Port
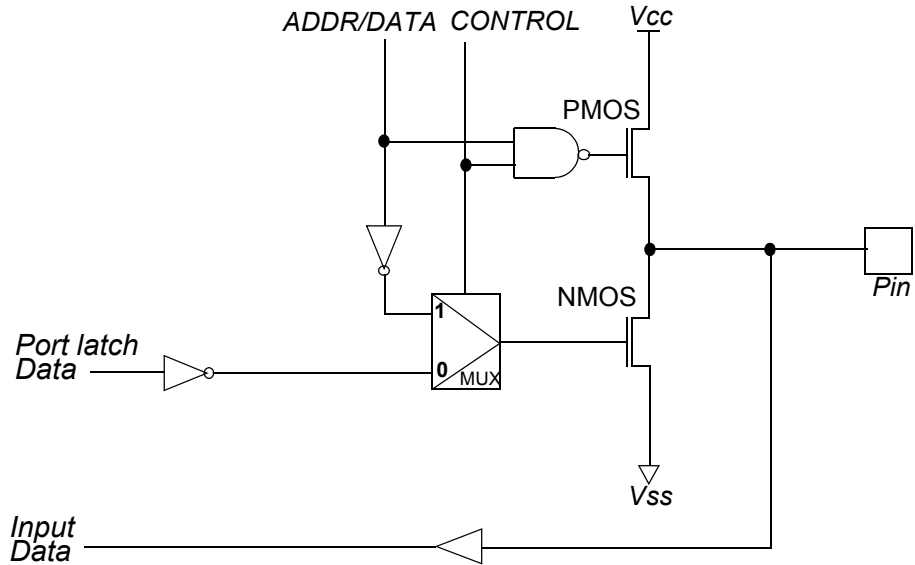

Quasi Bi-directional Port   The default port output configuration for standard I/O ports is the quasi-bi-directional output that is common on the 80C51 and most of its derivatives. The "Port51" output type can be used as both an input and output without the need to reconfigure the port. This is possible because when the port outputs a logic high, it is weakly driven, allowing an external device to pull the pin low.

When the port outputs a logic low state, it is driven strongly and is able to sink a fairly large current.

These features are somewhat similar to an open-drain output except that there are three pull-up transistors in the quasi-bi-directional output that serve different purposes.

One of these pull-ups, called the weak pull-up, is turned on whenever the port latch for the pin contains a logic 1. The weak pull-up sources a very small current that will pull the pin high if it is left floating. The weak pull-up can be turned off by the DPU bit in AUXR register.

A second pull-up, called the medium pull-up, is turned on when the port latch for the pin contains a logic 1 and the pin itself is also at a logic 1 level. This pull-up provides the primary source current for a quasi-bi-directional pin that is outputting a 1. If a pin that has a logic 1 on it is pulled low by an external device, the medium pull-up turns off, and only the weak pull-up remains on. In order to pull the pin low under these conditions, the external device has to sink enough current to overpower the medium pull-up and take the voltage on the port pin below its input threshold.

Note: for CIO, CC4, CC8 ports of SCIB interface , in input mode when the ICC (smart card) is driving the port pin :

– if 0 < Vin < CVCC/2 : weak pull-up is active (~100KOhm)

– if CVCC/2 < Vin < CVCC : weak (~100KOhm) and medium (~12KOhm) pull-up's are active

The "Port51" is described in Figure 24.

Figure 24. Quasi Bi-directional Port
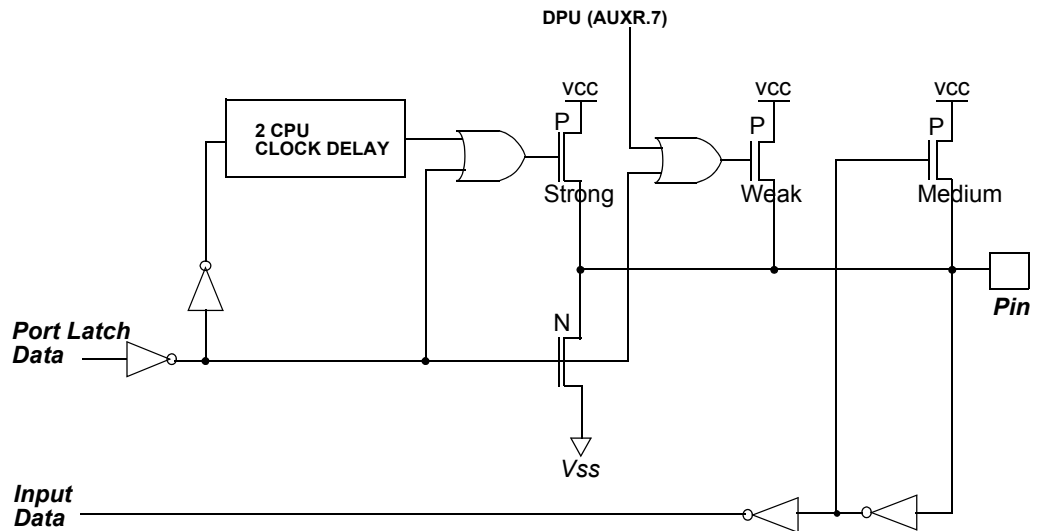

Push-pull Output Configuration

The push-pull output configuration has the same pull-down structure as both the open drain and the quasi-bi-directional output modes, but provides a continuous strong pull-up when the port latch contains a logic 1. The push-pull mode may be used when more source current is needed from a port output.

The Push-pull port configuration is shown in Figure 25.

Figure 25. Push-pull Output
Input with Medium or Weak Pull-up Configuration

The input with pull-up (Input MPU and Input WPU) configuration is shown in Figure 26.

Figure 26. Input with Pull-up
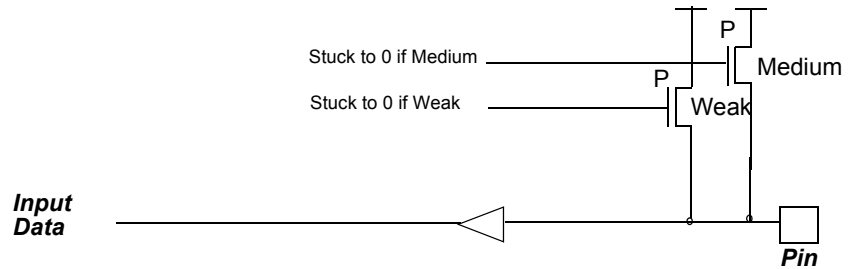

Input with Weak Pull-down Configuration

The input with pull-down (input WPD) configuration is shown in Figure 27

Figure 27. Input with Pull-down
Low Speed Output Configuration

The low speed output with low speed t_{FALL} and t_{RISE} can drive keyboard.

The current limitation of the LED2CTRL block requires a polarisation current of about 250 µA. This block is automatically disabled in power-down mode.

The low speed output configuration (KB_OUT) is shown in Figure 28.

Figure 28. Low-speed Output
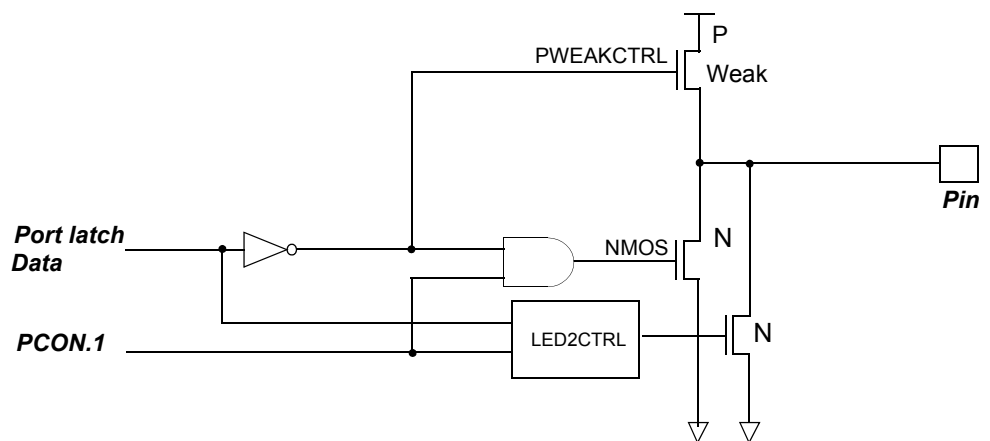

LED Source Current

The LED configuration is shown in Figure 29.

Figure 29. LED Source Current
Notes: 1. When switching a low level, LEDCTRL device has a permanent current of about N mA/15 (N is 2, 4 or 8).

2. The port must be configured as standard C51 port by means of PMOD0 and PMOD1 registers and the level of current must be programmed by means of LEDCON0 and LEDCON1 registers before switching the led on.

Table 35. LED Source Current

LEDx.1	LEDx.0	Port Latch Data	NMOS	PIN	Comments
0	0	0	1	0	LED control disabled
0	0	1	0	1	LED control disabled

Smart Card Interface Block (SCIB)

The SCIB provides all signals to interface directly with a smart card. The compliance with the ISO7816, EMV'2000, GSM and WHQL standards has been certified.

Both synchronous (e.g. memory card) and asynchronous smart cards (e.g. microprocessor card) are supported. The component supplies the different voltages requested by the smart card. The power off sequence is directly managed by the SCIB.

The card presence switch of the smart card connector is used to detect card insertion or card removal. In case of card removal, the SCIB de-activates the smart card using the de-activation sequence. An interrupt can be generated when a card is inserted or removed.

Any malfunction is reported to the microcontroller (interrupt + control register).

The different operating modes are configured by internal registers.

*   Support of ISO/IEC 7816
*   character mode
*   one transmit/receive buffer
*   11 bits ETU counter
*   9 bits guard time counter
*   32 bits waiting time counter
*   Auto character repetition on error signal detection in transmit mode
*   Auto error signal generation on parity error detection in receive mode
*   Power on and power off sequence generation
*   Manual mode to drive directly the card I/O

Block Diagram

The Smart Card Interface Block diagram is shown Figure 30:

Figure 30. SCIB Block Diagram
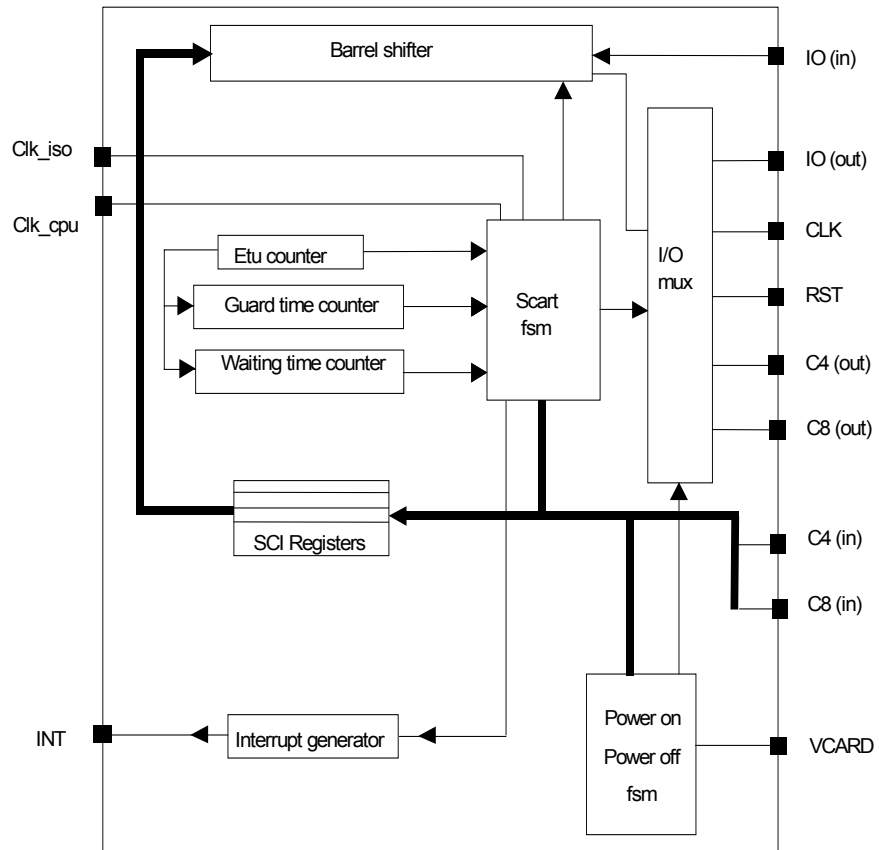

Definitions	This paragraph introduces some of the terms used in ISO 7816-3 and EMV recommendations. Please refer to the full recommendations for a complete list of terms.
Terminal and ICC	Terminal is the reader, ICC is the Integrated Circuit Card
ETU	Elementary Timing Unit (Bit time)
T=0	Character oriented half duplex protocol T=0
T=1	Block oriented half duplex protocol T=1
Activation: Cold Reset	Reset initiated by the Terminal with Vcc power-up. The card will answer with ATR (see below)
Activation: Warm Reset	Reset initiated by the Terminal with Vcc already powered-up, and after a prior ATR or Warm Reset
De-Activation	Deactivation by the Terminal as a result of : unresponsive ICC, or ICC removal.

ATR	Answer To Reset. Response from the ICC to a Reset initiated by the Terminal
F and D	F = Clock Rate Conversion Factor, D = Bit rate adjustment factor. ETU is defined as : ETU = F/(D*f) with f = Card Clock frequency. If f is in Hertz, ETU is in second. F and D are available in the ATR (byte TA1). The default values are F=372, D=1.
Guard Time	The time between 2 leading edges of the start bit of 2 consecutive characters is comprised of the character duration (10) plus the guard time. Be aware that the Guard Time counter and the Guard Time registers in the AT8xC5122/23 consider the time between 2 consecutive characters. So the equation is Guard Time Counter = Guard Time + 10. In other words, the Guard Time is the number of Stop Bits between 2 characters sent in the same direction.
Extra Guard Time	ISO IEC 7816-3 and EMV introduce the Extra Guard time to be added to the minimum Guard Time. Extra Guard Time only apply to consecutive characters sent by the terminal to the ICC. The TC1 byte in the ATR define the number N. For N=0 the character to character duration is 12 ETUs. For N=254 the character to character duration is 266. For N=255 (special case) The minimum character to character duration is to be used : 12 for T=0 protocol and 11 for T=1 protocol.
Block Guard Time	The time between the leading edges of 2 consecutive characters sent in opposit direction. ISO IEC 7816-3 and EMV recommend a fixed Block Guard Time of 22 ETUs.
Work Waiting Time (WWT)	In T=0 protocol WWT is the interval between the leading edge of any character sent by the ICC, and the leading edge of the previous character sent either by the ICC or the Terminal. If no character is received by the terminal after WWTmax time, the Terminal initiates a De-Activation Sequence.
Character Waiting Time (CWT)	In T=1 protocol CWT is the interval between the leading edge of 2 consecutive characters sent by the ICC. If the next character is not received by the Terminal after CWTmax time, the Terminal initiates a De-Activation Sequence.
Block Waiting Time (BWT)	In T=1 protocol BWT is the interval between the leading edge of the start bit of the last character sent by the Terminal that gives the right to sent to the ICC, and the leading edge of the start bit of the first character sent by the ICC. If the first character from the ICC is not received by the Terminal after BWTmax time, the Terminal initiates a De-Activation Sequence.
Waiting Time Extention (WTX)	In T=1 protocol the ICC can request a Waiting Time Extension with a S(WTX request) request. The Terminal should acknowlege it. The Waiting time between the leading edge of the start bit of the last character sent by the Terminal that gives the right to sent to the ICC, and the leading edge of the start bit of the first character sent by the ICC will be BWT*WTX ETUs.
Parity error in T=0 protocol	In T=0 protocol, a Terminal (respectively an ICC) detecting a parity error while receiving a character shall force the Card IO line at 0 starting at 10.5 ETUs, thus reducing the first Guard bit by half the time. The Terminal (respectively an ICC) shall maintain a 0 for 1 ETU min and 2 ETUs max (according to ISO IEC) or to 2 ETUs (according to EMV). The ICC (respectively a Terminal) shall monitor the Card IO to detect this error signal then attempt to repeat the character. According to EMV, following a parity error the character can be repeated one time, if parity error is detected again this procedure can be repeated 3 more times. The same character can be transmitted 5 times in total. ISO

IEC7816-3 says this procedure is mandatory in ATR for card supporting T=0 while EMV says this procedure is mandatory for T=0 but does not apply for ATR.

Functional Description   The architecture of the Smart Card Interface Block can be detailed as follows:

Barrel Shifter   The Barrel Shifter performs the translation between 1 bit serial data and 8 bits parallel data

The barrel function is useful for character repetition since the character is still present in the shifter at the end of the character transmission.

This shifter is able to shift the data in both directions and to invert the input or output value in order to manage both direct and inverse ISO7816-3 convention.

Coupled with the barrel shifter is a parity checker and generator.

There are 2 registers connected to this barrel shifter, one for the transmission and one for the reception. They act as buffers to relieve the CPU of timing constraints.

SCART FSM   (Smart Card Asynchronous Receiver Transmitter Finite State Machine)

This is the core of the block. Its purpose is to control the barrel shifter. To sequence correctly the barrel shifter for a reception or a transmission, it uses the signals issued by the different counters. One of the most important counters is the guard time counter that gives time slots corresponding to the character frame.

The SCART FSM is enabled only in UART mode.

The transition from the receipt mode to the transmit mode is done automatically. Priority is given to the transmission. Transmission refers to Terminal transmission to the ICC. Reception refers to reception by the Terminal from the ICC.

ETU Counter   The ETU (Elementary Timing Unit) counter controls the working frequency of the barrel shifter, in fact it generates the enable signal of the barrel shifter. It receives the Card Clock, and generates the ETU clock. The Card Clock frequency is called "f" below. The ETU counter is 11 bit wide.

A special compensation mode can be activated. It accomodates situations where the ETU is not an integer number of Card Clock (CK_ISO). The compensation mode is controlled by the COMP bit in SCETU1 register bit position 7. With COMP=1 the ETU of every character even bits is reduced by 1 Card Clock period. As a result, the average ETU is : ETU_average = (ETU - 0.5). One should bear in mind that the ETU counter should be programmed to deliver a faster ETU which will be reduced by the COMP mechanism, not the other way around. This allows to reach the required precision of the character duration specified by the ISO7816-3 standard.

Example1 : F=372, D=32 => ETU= F/D = 11.625 clock cycles.

We select ETU[10-0] = 12 , COMP=1. ETUaverage= 12 - (0.5*COMP) = 11.5

The result will be a full character duration (10 bit) = (10 - 0.107)*ETU. The EMV specification is (10 +/- 0.2)*ETU

Guard Time Counter   The minimum time between the leading edge of the start bit of 2 consecutive characters transmitted by the Terminal is controlled by the Guard Time counter, as described in Figure 33.

The Guard Time counter is an 9 bit counter It is initialized at 001h at the start of a transmission by the Terminal. It then increments itself at each ETU until it reach the 9 bit value loaded into the SCGT1[0] concatenated with SCGT0[7:0]. At this time a new Terminal transmission is enabled and the Guard Time Counter stop incrementing. As soon as a new transmission start, the Guard Time Counter is re-initialized at 1 decimal value.

It should be noted that the value of the Guard Time Counter cannot be red. Reading SCGT1,0 only gives the minimum time between 2 characters that the Guard Time Counter will allow.

Care must be taken with the Guard Time Counter which counts the duration between the leading edges of 2 consecutive characters. This correspond to the character duration (10 ETU) plus the Guard Time as defined by the ISO and EMV recommendations. To program Guard Time = 2 : 2 stop bits between 2 characters which is equivalent to the minimum delay of 12 ETUs between the leading edges of 2 consecutive characters, SCGT1[0],SCGT0[7:0] should be loaded with the value 12 decimal. See Figure 31

Figure 31. Guard Time.

TRANSMISSION to ICC
Block Guard Time Counter

The Block Guard Time counter provides a way to program a minimum time between the leading edge of the start bit of a character received from the ICC and the leading edge of the start bit of a character sent by the terminal. ISO IEC 7816-3 and EMV recommend a fixed Block Guard Time of 22 ETUs. The AT8xC5122/23 offer the possibility to extend this delay up to 512 ETUs.

The Block Guard Time is a 9 bit counter. When the Block Guard Time mode is enabled (BGTEN=1 in SCSR register) The Block Guard Time counter is initialized at 000h at the start of each character transmissions from the ICC. It then increments at each ETU until it reach the 9 bit value loaded into shadow SCGT1,0 registers, or until it is re-initialized by the start of an new transmission from the ICC. If the Block Guard Time counter reaches the 9 bit value loaded into shadow SCGT1,0 registers, a transmission by the TERMINAL is enabled, and the Block Guard Time counter stop incrementing. The Block Guard Time counter is re-initialized at the start of each TERMINAL transmission.

The SCGT1 SCGT0 shadow registers are loaded with the content of GT[8-0] contained in the registers SCGT1[0],SCGT0(7:0) with the rising edge of the bit BGTEN in the SCSR register. See Figure 33.

GT[8:0]

SCGT1　　　SCGT0
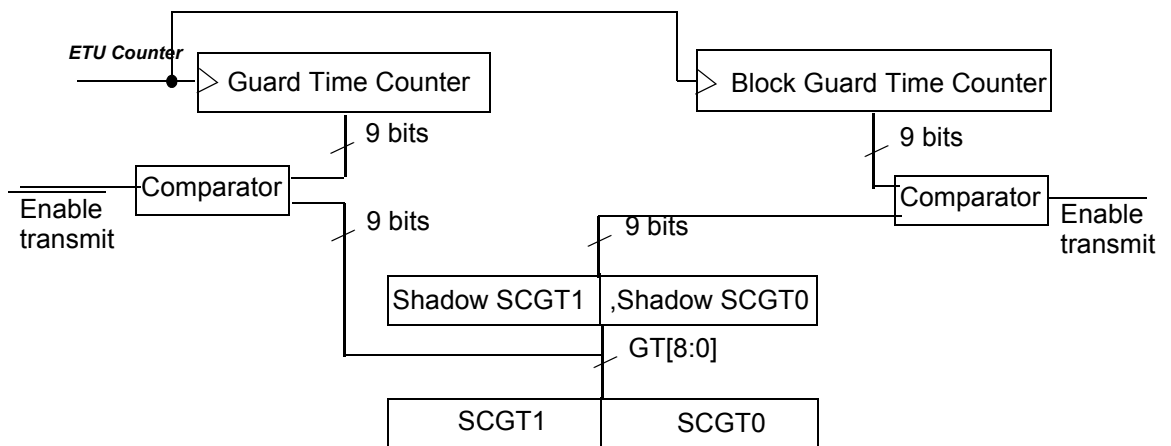

To illustrate the use of Guard Time and Block Guard Time, let us consider the ISO/IEC7816-3 recommendation : Guard Time = 2 (minimum delay between 2 consecutive characters sent by the Terminal = 12 ETUs), and Block Guard Time = 22 ETUs.

After A smart Card Reset

  – Write 00decimal in SCGT1, Write 21decimal in SCGT0
  – Set BGTEN in SCSR (BGTEN was 0 before as a result of the smart card reset)
  – Write 12decimal in SCGT0

Now the Guard Time and Block Guard Time are properly initialized. The TERMINAL will insure a minimun 12 ETUs between 2 leading edges of 2 consecutive characters transmitted. The TERMINAL will also insure a minimum of 22 ETUs between the leading edge of a character sent by the ICC, and the leading edge of a character sent by the TERMINAL. There is no need to write SCGT1,0 again and again.

Waiting Time (WT) Counter　　The WT counter is a 32 bits down counter which can be loaded with the value contained in the SCWT3, SCWT2, SCWT1, SCWT0 registers. Its main purpose is timeout signal generation. It is 32 bits wide and is decremented at the ETU rate. see Figure 34.

When the WT counter times out, an interrupt is generated and the SCIB function is locked: reception and emission are disabled. It can be enabled by resetting the macro or reloading the counter.

The Waiting Time Counter can be used in T=0 protocol for the Work Waiting Time. It can be used in T=1 protocol for the Character Waiting Time and for the Block Waiting Time. See the detailed explanation below.

Figure 34. Waiting Time Counter
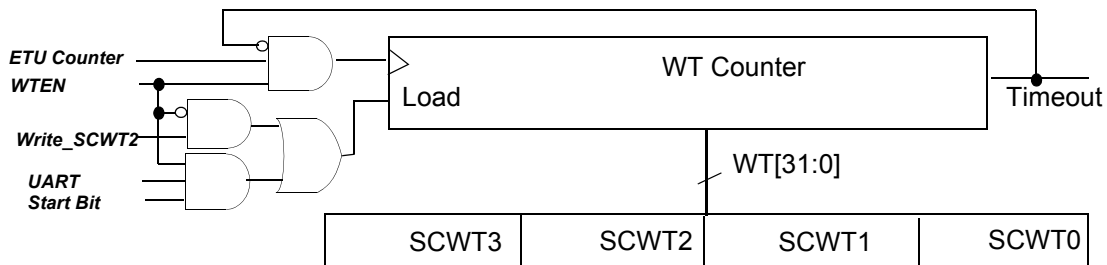

In the so called manuel mode, the counter is loaded, if WTEN = 0, during the write of SCWT2 register. The counter is loaded with a 32 bit word built with SCWT3 SCWT2 SCWT1 SCWT0 registers (SCWT0 contain WT[7-0] byte. WTEN is located in the SCICR register.

When WTEN=1 and in UART mode, the counter is re-loaded at the occurence of a start bit. This mode will be detailed below in T=0 protocol and T=1 protocol.

In manual mode, the WTEN signal controls the start of the counter (rising edge) and the stop of the counter (falling edge). After a timeout of the counter, a falling edge on WTEN, a reload of SCWT2 and a rising edge of WTEN are necessary to start again the counter and to release the SCIB macro. The reload of SCWT2 transfers all SCWT0, SCWT1, SCWT2 and SCWT3 registers to the WT counter.

In UART mode there is an automatic load on the start bit detection. This automatic load is very useful for changing on-the-fly the timeout value since there is a register to hold the load value. This is the case for T=1 protocol.

In T=0 protocol the maximun interval between the start leading edge of any character sent by the ICC and the start of the previous character sent by either the ICC or the Terminal is the maximum Work Waiting Time. The Work Waiting Time shall not exceed 960*D*WI ETUs with D and WI parameters are returned by the field TA1 and TC2 respectively in the Answer To Reset (ATR). This is the value the user shall write in the SCWT0,1,2,3 register. This value will be reloaded in the Waiting Time counter every start bit.

Figure 35. T=0 mode
In T=1 protocol : The maximum interval between the leading edge of the start bit of 2 consecutive characters sent by the ICC is called maximum Character Waiting Time. The Character Waiting Time shall not exceed (2**CWI + 11) ETUs with 0 =< BWI =< 5. Consequently 12 ETUs =< CWT =< 43 ETUs.

T=1 protocol also specify the maximum Block Waiting Time. This is the time between the leading edge of the last character sent by the Terminal giving the right to send to the ICC, and the leading edge of the start bit of the first character sent by the ICC. The Block Waiting Time shall not exceed (2**BWI*960 + 11) ETUs with 0 =< BWI =< 4. Consequently 971 ETUs =< BWT =< 15371 ETUs.

In T=1 protocol it is possible to extend the Block Waiting Time with the Waiting Time Extension (WTX). When selected the waiting time becomes BWT*WTX ETUs. The Waiting Time counter is 32 bit wide to accomodate this feature.

It is possible to take advantage of the automatic reload of the Waiting Time counter with a start bit in UART mode (T=1 protocol use UART mode) . If the Terminal sends a block of N characters, and the ICC is supposed to respond immediately after, then the following sequence can be used.

While sending the (N-1)th character of the block, the Terminal can write the SCWT0,1,2,3 with BWImax.

At the start bit of the Nth character, the BWImax is loaded in the Waiting Time counter

During the transmission of the Nth character, the Terminal can write SCWT0,1,2,3 with the CWImax.

At the start bit of the first character sent by the ICC, the CWImax will be loaded in the Waiting Time counter.

Figure 36. T=1 Mode
Power-on and Power-off FSM   The Power-on Power-off Finite State Machine (FSM) applies the signals on the smart card in accordance with ISO7816-3 standard. It conducts the Activation (Cold Reset and Warm Reset as well as De-Activation) it also manages the exception conditions such as overcurrent (see DC/DC Converter)

To be able to power on the SCIB, the card presence is mandatory. Upon detectection of a card presence, the Terminal initiate a Cold Reset Activation.

The Cold Reset Activation Terminal procedure is as follow and the Figure 37. Timing indications are given according to ISO IEC 7816

– RESET= Low , I/O in the receive state

– Power Vcc (see DC/DC Converter)

– Once Vcc is established, apply Clock at time Ta

– Maintain Reset Low until time Ta+tb (tb< 400 clocks)

– Monitor The I/O line for the Answer To Reset (ATR) between 400 and 40000 clock cycles after Tb. (400 clocks < tc < 40000clocks)

Figure 37. SCIB Activation Cold Reset Sequence after a Card Insertion
The Warm Reset Activation Terminal procedure is as follow and the Figure 38

– Vcc active, Reset = High, CLK active

– Terminal drive Reset low at time T to initiate the warm Reset. Reset=0 maintained for at least 400 clocks until time Td = T+te (400 clocks < te)

– Terminal keep the IO line in receive state

– Terminal drive Reset high after at least 400 clocks at time Td

– ICC shall respond with an ATR within 40000 clocks (tf<40000 clocks)

Figure 38. SCIB Activation Warm Reset Sequence
Removal of the smart card will automatically start the power off sequence as described in Figure 39.

The SCIB deactivation sequence after a reset of the CPU or after a lost of power supply is ISO7816-3 compliant. The switching order of the signals is the same as in Figure 39 but the delay between signals is analog and not clock dependant.

Figure 39. SCIB Deactivation Sequence after a Card Extraction
Interrupt Generator

There are several sources of interruption but the SCIB macro-cell issues only one interrupt signal: SCIBIT.

Figure 40. SCIB Interrupt Sources
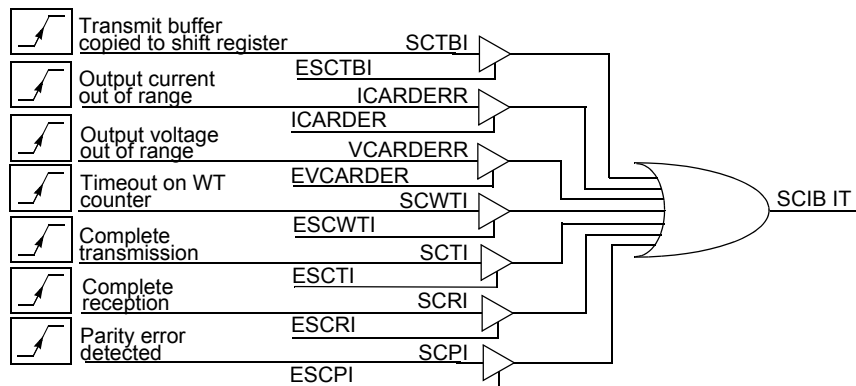

This signal is high level active. Each of the sources is able to activate the SCIB interruption which is cleared when the Smart Card Interrupt register is read by the microcontroller.

If during the read of the Smart Card Interrupt register another interrupt occurs, the activation of the corresponding bit in the Smart Card Interrupt register and the new SCIB interruption is delayed until the interrupt register is read by the microcontroller.

Warning : Each bit of the SCIIR register is irrelevant while the corresponding interruption is disabled in SCIER register. When the interruption mode is not used, the bits of the SCISR register must be used instead of the bits of the SCIIR register.

Additional Features

Clock

The CK_ISO input must be in the range 1 - 5 MHz according to ISO 7816.

The CK_ISO can be programmed up to 12 MHz. In this case, the timing specification of the output buffer will not comply to ISO 7816.

Figure 41. Clock Diagram of the SCIB Block
Figure 42. Prescaler 2 Description
The division factor SCICLK must be smaller than 49. If it is greater or equal to 49, the PR2 prescaler is locked.

See Figure 17 clock tree diagram in the clock controller chapter.

Table 42. Examples of Clock settings

XTAL1 (MHz)	EXT48	SCICLK	CK_ ISO
8	0	36	4
8	0	44	12
8	0	42	8
8	0	40	6
8	0	24	2
8	0	0	1

Card Presence Input

The internal pull-up (weak pull-up) on Card Presence input can be disconnected in order to reduce the consumption (CPRESRES, bit 3 in PMOD0).

In this case, an external resistor (typically 1 MΩ) must be externally tied to Vcc.

CPRES input can generate an interrupt (see Interrupt system section).
The detection level can be selected.

Transmit / Receive Buffer The contents of the SCIBUF Transmit / Receive Buffer is transferred or received into / from the Shift Register. The Shift Register is not accessible by microcontroller. Its role is to prepare the byte to be copied on the I/O pin for a transmission or in the SCIBUF buffer after a reception.

During a character transmission process, as soon as the contents of the SCIBUF buffer is transferred to the shift register, the SCTBE bit is set in SCISR register to indicate that the SCIBUF buffer is empty and ready to accept a new byte. This mechanism avoids to wait for the complete transmission of the previous byte before writing a new byte in the buffer and enables to speed up the transmission.

–   If the Character repetition mode is not selected (bit CREP=0 in SCICR), as soon as the contents of the Shift Register is transferred to I/O pin, the SCTC bit is set in SCISR register to indicate that the byte has been transmitted.

–   If the Character repetition mode is selected (bit CREP=1 in SCICR) The TERMINAL will be able to repeat characters as requested by the ICC (See the Parity Error in T=0 protocol description in the definition paragraph above). The SCTC bit in SCISR register will be set after a successful transmission (no retry or no further retry requested by the ICC). If the number of retries is exhausted (up to 4 retries depending on CREPSEL bit in SCSR) and the last retry is still unsuccessful, the SCTC bit in SCISR will not be set and the SCPE bit in SCISR register will be set instead.

During a character reception process, the contents of the Shift Register is transferred in the SCIBUF buffer.

–   If the Character repetition mode is not selected (bit CREP=0 in SCICR), as soon as the contents of the Shift Register is transferred to the SCIBUF the SCRC bit is set in SCISR register to indicate that the byte has been received, and the SCIBUF contains a valid character ready to be red by the microcontroller.

–   If the Character repetition mode is selected (bit CREP=1 in SCICR) The TERMINAL will be able to request repetition if the received character exhibit a parity error. Up to 4 retries can be requested depending on CREPSEL bit in SCSR. The SCRC bit will be set in SCISR register after a successful reception, first reception or after retry(ies). If the number of retries is exhausted (up to 4 retries depending on CREPSEL bit in SCSR) and the last retry is still unsuccessful, the SCRC bit and the SCPE bit in SCISR register will be set. It will be possible to read the erroneous character.

Warning : the SCTBI, SCTI SCRI and SCPI bits have the same function as SCTBE, SCTC, SCRC and SCPE bits. The first ones are able to generate interruptions if the interruptions are enabled in SCIER register while the second ones are only status bits to be used in pulling mode. If the interruption mode is not used, the status bits must be used. The SCTBI, SCTI and SCRI bits do not contain valid information while their respective interrupt enable bits ESCTBI, EXCTI, ESCRI are cleared.

Figure 43. CharacterTransmission Diagram
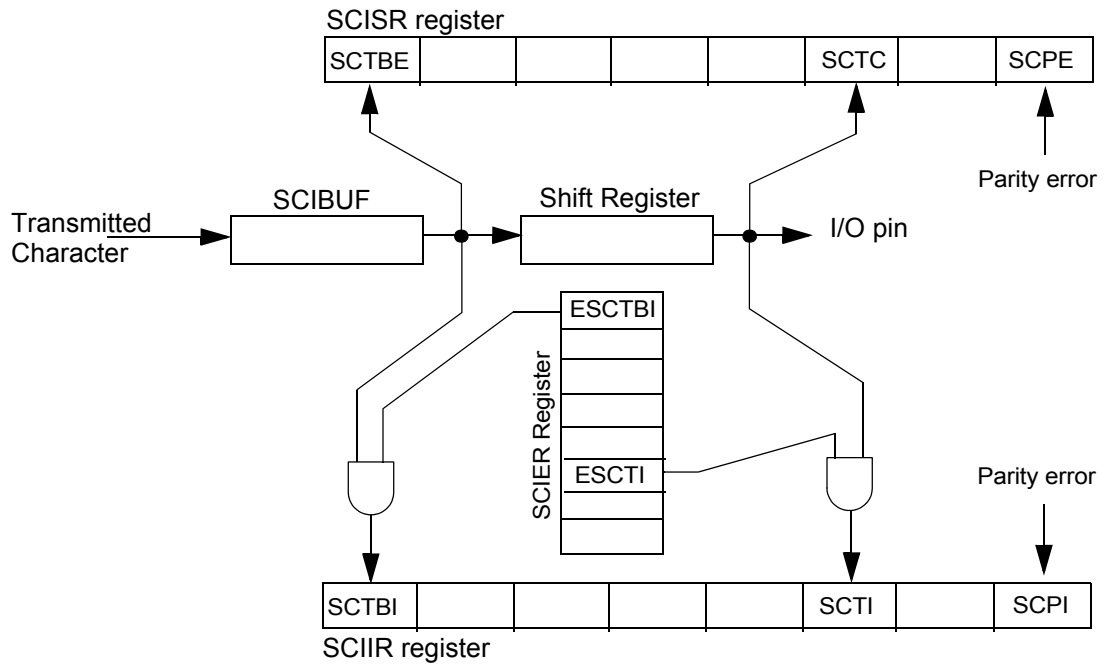

Figure 44. Character Reception Diagram
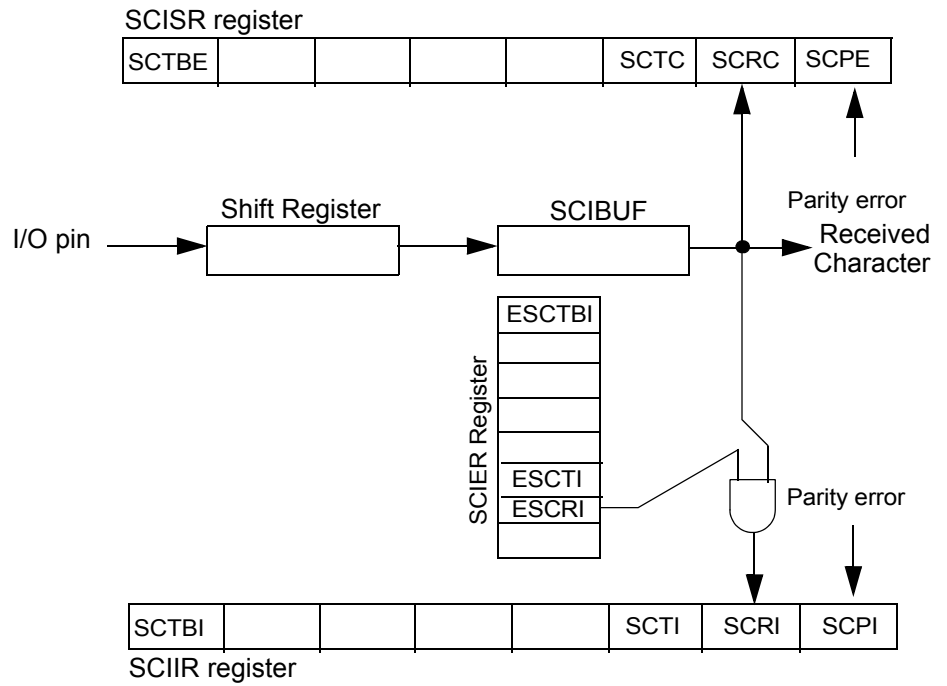

SCIB Reset   The SCICR register contains a reset bit. If set, this bit generates a reset of the SCIB and its registers. Table 43 defines the SCIB registers that are reset and their reset values.

Table 43. Reset Values for SCI Registers

Register Name	SCIB Reset Value (Binary)
SCICR	0000 0000

SCWT3, SCWT2, SCWT1, SCWT0	0000 0000, 0000 0000, 0010 0101, 1000 0000 (9600)
SCICLK	0X10 1111

Alternate Card

A second card named 'Alternate Card' can be controlled.

The Clock signal CCLK1 can be adapted to the XTAL frequency. Thanks to the clock prescaler which can divide the frequency by 1, 2, 4 or 8. The bits ALTKPS0 and ALTKPS1 in SCSR Register are used to set this factor.

Figure 45. Alternate Card
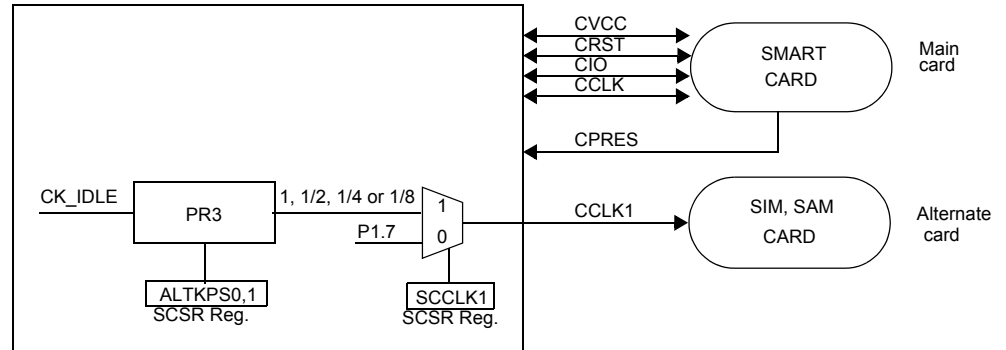

Registers

There are fifteen registers to control the SCIB macro-cell. They are described from Table 58 to Table 45.

Some of the register widths are greater than a byte. Despite the 8 bits access provided by the BIU, the address mapping of this kind of register respects the following rule :

The Low significant byte register is implemented at the higher address.

This implementation makes access to these registers easier when using high level programming languages (C,C++).

Table 44. Smart Card Interface Control Register - SCICR (S:B6h, SCRS = 1)

7	6	5	4	3	2	1	0
RESET	CARDDET	VCARD1	VCARD0	UART	WTEN	CREP	CONV

Bit Number	Bit Mnemonic	Description
7	RESET	**Reset** Set this bit to reset and deactivate the Smart Card Interface. Clear this bit to activate the Smart Card Interface. This bit acts as an active high software reset.
6	CARDDET	**Card Presence Detector Sense** Clear this bit to indicate the card presence detector is open when no card is inserted (CPRES is high). Set this bit to indicate the card presence detector is closed when no card is inserted (CPRES is low).
5-4	VCARD[1:0]	**Card Voltage Selection:** VCARD[1] VCARD[0] CVCC 0 0 0 V 0 1 1.8 V 1 0 3.0 V 1 1 5.0 V
3	UART	**Card UART Selection** Clear this bit to use the CARDIO bit (P1.0) bit to drive the Card I/O (P1.0) pin. Set this bit to use the Smart Card UART to drive the Card I/O pin (P1.0 pin). Controls also the Waiting Time Counter as described in Section "Waiting Time (WT) Counter", page 69
2	WTEN	**Waiting Time Counter Enable** Clear this bit to stop the counter and enable the load of the Waiting Time counter hold registers. The hold registers are loaded with SCWT0, SCWT1, SCWT2 and SCWT3 values when SCWT2 is written. Set this bit to start the Waiting Time Counter. The counters stop when it reaches the timeout value. If the UART bit is set, the Waiting Time Counter automatically reloads with the hold registers whenever a start bit is sent or received.
1	CREP	**Character Repetition** Clear this bit to disable parity error detection and indication on the Card I/O pin in receive mode and to disable character repetition in transmit mode. Set this bit to enable parity error indication on the Card I/O pin in receive mode and to set automatic character repetition when a parity error is indicated in transmit mode. Depending upon CREPSET bit is SCSR register, the receiver can indicate parity error up to 4times (3 repetitions) or up to 5times (4 repetitions) after which it will raise the parity error bit SCPE bit in the SCISR register. If parity interrupt is enabled, the SCPI bit in SCIIR register will be set too. Alternately, the transmitter will detect ICC character repetition request. After 3 or 4 unsuccessful repetitions (depending on CREPSEL bit in SCSR register), the transmitter will raise the parity error bit SCPE bit in the SCISR register. If parity interrupt is enabled, the SCPI bit in SCIIR register will be set too. **Note** : Character repetition mode is specified for T=0 protocol only and should not be used in T=1 protocol (block oriented protocol)
0	CONV	**ISO Convention** Clear this bit to use the direct convention: b0 bit (LSB) is sent first, the parity bit is added after b7 bit and a low level on the Card I/O pin represents a'0'. Set this bit to use the inverse convention: b7 bit (LSB) is sent first, the parity bit is added after b0 bit and a low level on the Card I/O pin represents a'1'.

Reset Value = 0000 0000b

7	6	5	4	3	2	1	0
CLK	-	CARDC8	CARDC4	CARDIO	CARDCLK	CARDRST	CARDVCC

Bit Number	Bit Mnemonic	Description
7	CLK	**Card Clock Selection** Clear this bit to use the Card CLK bit (CARDCLK bit below) to drive Card CLK (P1.4) pin. Set this bit to use CK_XTAL1 or CK_PLL signals for CK_ISO to drive the Card CLK pin (CCLK = P1.4 pin) **Note:** internal synchronization avoids glitches on the CLK pin when switching this bit.
6	-	**Reserved** This bit can be changed by software but the read value is indeterminate.
5	CARDC8	**Card C8** Clear this bit to drive a low level on the Card C8 pin (CC8 = P1.1 pin). Set this bit to set a high level on the Card C8 pin (CC8 = P1.1 pin).. The CC8 pin can be used as a pseudo bi-directional I/O when this bit is set. **Warning** : VCARDOK=1 (SCISR.4 bit) condition must be true to change the state of CC8 pin
4	CARDC4	**Card C4** Clear this bit to drive a low level on the Card C4 pin (CC4 = P1.3 pin). Set this bit to set a high level on the Card C4 pin (CC4 = P1.3 pin). The CC4 pin can be used as a pseudo bi-directional I/O when this bit is set. **Warning** : VCARDOK=1 (SCISR.4 bit) condition must be true to change the state of CC4 pin
3	CARDIO	**Card I/O** If UART bit is cleared in SCICR register, this bit enables the use of the Card IO pin (CIO = P1.0) as a C51 pseudo bi-directional port : To read from CIO (P1.0) port pin : set CARDIO (P1.0) bit then read CARDIO (P1.0) bit to have the CIO port value To write in CIO (P1.0) port pin : set CARDIO (P1.0) bit to write a 1 in CIO (P1.0) port pin , clear CARDIO (P1.0) bit to write a 0 in CIO (P1.0) port pin. **Warning** : VCARDOK=1 (SCISR.4 bit) condition must be true to change the state of CIO pin
2	CARDCLK	**Card CLK** When the CLK bit is cleared in SCCON Register, the value of this bit is driven to the Card CLK pin. **Warning** : VCARDOK=1 (SCISR.4 bit) condition must be true to change the state of Card CLK pin
1	CARDRST	**Card RST** Clear this bit to drive a low level on the Card RST pin. Set this bit to set a high level on the Card RST pin. **Warning** : VCARDOK=1 (SCISR.4 bit) condition must be true to change the state of Card RST pin
0	CARDVCC	**Card VCC Control** Clear this bit to desactivate the Card interface and set its power-off. The other bits of SCCON register have no effect while this bit is cleared. Set this bit to power-on the Card interface. The activation sequence should be handled by software.

Reset Value = 0X00 0000b

Table 46. Smart Card UART Interface Status Register -
SCISR (S:ADh, SCRS=0)

7	6	5	4	3	2	1	0
SCTBE	CARDIN	ICARDOVF	VCARDOK	SCWTO	SCTC	SCRC	SCPE

Bit Number	Bit Mnemonic	Description
7	SCTBE	**UART Transmit Buffer Empty Status** This bit is set by hardware when the Transmit Buffer is copied to the transmit shift register of the Smart Card UART. It is cleared by hardware when SCIBUF register is written.
6	CARDIN	**Card Presence Status** This bit is set by hardware if there is a card presence (debouncing filter has to be done by software). This bit is cleared by hardware if there is no card presence.
5	ICARDOVF	**Card Current Overflow Status** This bit is set when the current on card is above the limit specified by bit OVFADJ in DCCKPS register (Table 61 on page 94) It is cleared by hardware.
4	VCARDOK	**Card Voltage Correct Status** This bit is set when the output voltage is within the voltage range specified by VCARD[1:0] in SCICR register. It is cleared otherwise.
3	SCWTO	**Waiting Time Counter Timeout Status** This bit is set by hardware when the Waiting Time Counter has expired. It is cleared by the reload of the counter or by the reset of the SCIB.
2	SCTC	**UART Transmitted Character Status** This bit is set by hardware when the Smart Card UART has transmitted a character. If character repetition mode is selected, this bit will be set only after a successful transmission. If the last allowed repetition in not successful, this bit will not be set. It is cleared by software when this register is read.
1	SCRC	**UART Received Character Status** This bit is set by hardware when the Smart Card UART has received a character It is cleared by hardware when SCIBUF register is read. If character repetition mode is selected, this bit will be set only after a successful reception. If the last allowed repetition is still unsuccessful, this bit will be set to let the user read the erroneous value if necessary.
0	SCPE	**Character Reception Parity Error Status** This bit is set when a parity error is detected on the received character. It is cleared by software when this register is read. If character repetition mode is selected, this bit will be set only if the ICC report an error on the last allowed repetition of a TERMINAL transmission, or if a reception parity error is found on the last allowed ICC character repetition.

Reset Value = 1000 0000b

Table 47. Smart Card UART Interrupt Identification Register (Read Only)

7	SCTBI	**UART Transmit Buffer Empty Interrupt** This bit is set by hardware when the Transmit Buffer is copied into the transmit shift register of the Smart Card UART. It generates an interrupt if ESCTBI bit is set in SCIER register otherwise this bit is irrelevant. It is cleared by hardware when this register is read.
6	-	**Reserved** The value read from this bit is indeterminate. Do not change this bit.
5	ICARDERR	**Card Current Overflow Interrupt** This bit is set when the current on card is above the limit specified by bit OVFADJ in DCCKPS register (Table 61 on page 94). It generates an interrupt if ICARDER bit is set in SCIER register otherwise this bit is irrelevant. It is cleared by hardware when this register is read.
4	VCARDERR	**Card Voltage Error Interrupt** This bit is set when the output voltage goes out of the voltage range specified by VCARD field. It generates an interrupt if EVCARDER bit is set in SCIER register otherwise this bit is irrelevant. It is cleared by hardware when this register is read.
3	SCWTI	**Waiting Time Counter Timeout Interrupt** This bit is set by hardware when the Waiting Time Counter has expired. It generates an interrupt if ESCWTI bit is set in SCIER register otherwise this bit is irrelevant. It is cleared by hardware when this register is read.
2	SCTI	**UART Transmitted Character Interrupt** This bit is set by hardware when the Smart Card UART has completed the character transmission. It generates an interrupt if ESCTI bit is set in SCIER register otherwise this bit is irrelevant. It is cleared by hardware when this register is read.
1	SCRI	**UART Received Character Interrupt** This bit is set by hardware when the Smart Card UART has completed the character reception. It generates an interrupt if ESCRI bit is set in SCIER register otherwise this bit is irrelevant. It is cleared by hardware when this register is read.
0	SCPI	**Character Reception Parity Error Interrupt** This bit is set at the same time as SCTI or SCRI if a parity error is detected on the received character. It generates an interrupt if ESCPI bit is set in SCIER register otherwise this bit is irrelevant. It is cleared by hardware when this register is read.

Reset Value = 0X00 0000b

Note: 1) In case of multiple interrupts occuring at the same time (sampled by the same edge of the internal clock), the interrupts will be serviced in the following order from the highest to the lowest priority :
- UART Transmit Buffer Empty
- Card Current Overflow
- Card Voltage Error
- Waiting Time Counter Timeout
- UART Transmitted Character
- UART Received Character
- Character Reception Parity Error

2) It is recommended that the application saves the SCIIR register after reading it in order to avoid the loss of pending interruptions as the SCIIR register is cleared when it is read by the MCU.

Table 48. Smart Card UART Interrupt Enabling Register - SCIER (S:AEh, SCRS=1)

7	6	5	4	3	2	1	0
ESCTBI	-	ICARDER	EVCARDER	ESCWTI	ESCTI	ESCRI	ESCPI

Bit Number	Bit Mnemonic	Description
7	ESCTBI	**UART Transmit Buffer Empty Interrupt Enabled** Clear this bit to disable the Smart Card UART Transmit Buffer Empty interrupt. Set this bit to enable the Smart Card UART Transmit Buffer Empty interrupt.
6	-	**Reserved** The value read from this bit is indeterminate. Do not change this bit.
5	ICARDER	**Card Current Overflow Interrupt Enabled** Clear this bit to disable the Card Current Overflow interrupt. Set this bit to enable the Card Current Overflow interrupt.
4	EVCARDER	**Card Voltage Error Interrupt Enabled** Clear this bit to disable the Card Voltage Error interrupt. Set this bit to enable the Card Voltage Error interrupt.
3	ESCWTI	**WaitingTime Counter Timeout Interrupt Enabled** Clear this bit to disable the Waiting Time Counter timeout interrupt. Set this bit to enable the Waiting Time Counter timeout interrupt.
2	ESCTI	**UART Transmitted Character Interrupt Enabled** Clear this bit to disable the Smart Card UART Transmitted Character interrupt. Set this bit to enable the Smart Card UART Transmitted Character interrupt.
1	ESCRI	**UART Received Character Interrupt Enabled** Clear this bit to disable the Smart Card UART Received Character interrupt. Set this bit to enable the Smart Card UART Received Character interrupt.
0	ESCPI	**Character Reception Parity Error Interrupt Enabled** Clear this bit to disable the Smart Card Character Reception Parity Error interrupt. Set this bit to enable the Smart Card Character Reception Parity Error interrupt.

7	6	5	4	3	2	1	0
XTSCS	-	SCICLK5	SCICLK4	SCICLK3	SCICLK2	SCICLK1	SCICLK0

Bit Number	Bit Mnemonic	Description
7	XTSCS	**Smart Card Clock Selection Bit** If XTSCS bit is set OR EXT48 bit is set (in PLLCON register) , CK_PLL is used to generate CK_ISO. Otherwise, CK_XTAL1 is used to generate CK_ISO. See the Clock Tree diagram figure 17.
6	-	**Reserved** The value read from this bit is indeterminate. Do not change these bits.
5 - 0	SCICLK[5:0]	**SCIB clock reload register** Prescaler 2 reload value is used to defines the card clock frequency. If SCICLK[5:0] is smaller than 48 : Fck_iso = Fck_pll or Fck_XTAL1/ (2 * (48 - SCICLK[5:0])) If SCICLK[5:0] is equal to 48 : Fck_iso = Fck_XTAL1 SCICLK[5:0] must be smaller than 49.

Reset Value = 0X10 1111b *(default value for a divider by two)*

DC/DC Converter

The Smart Card voltage (CVCC) is supplied by the integrated DC/DC converter which is controlled by several registers:

- The SCICR register (Table 44 on page 79) controls the CVCC level by means of bits VCARD[1:0].
- The SCCON register (Table 45 on page 80) enables to switch the DC/DC converter on or off by means of bit CARDVCC.
- The DCCKPS register (Table 61 on page 94) controls the DC/DC clock and current.

The DC/DC converter cannot be switched on while the CPRES pin remains inactive. If CPRES pin becomes inactive while the DC/DC converter is operating an automatic shut down sequence of the DC/DC converter is initiated by the electronics.

It is mandatory to switch off the DC/DC Converter before entering in Power-down mode.

Configuration

The DC/DC Converter can work in two different modes which are selected by bit MODE in DCCKPS register:

- Pump Mode: an external inductance of 10 µH must be connected between pins LI and VCC. VCC can be higher or lower than CVCC.
- Regulator mode : no external inductance is required but VCC must be always higher than CVCC+0.3V. The Regulation mode will work even if an external inductance of 10 µH is connected between pins LI and VCC

The DC/DC clock prescaler which is controlled by bits DCCKPS[3:0], in DCCKPS register must be configured to set the DC/DC clock to a working frequency of 4 MHz which depends upon the value of the crystal. There is no need to change the default configuration set by the reset sequence if an 8 MHz crystal is used by the application.

The DC/DC Converter implements a current overflow controller which avoids permanent damage of the DC/DC converter in case of short circuit between CVCC and CVSS. The maximum limit is around 100 mA. It is possible to increase this limit in normal operating

mode by 20% by means of bit OVFADJ in DCCKPS register. When the current overflow controller is operating, the ICARDOVF is set by the hardware in SCISR register.

The current drawn from power supply by the DC/DC converter is controlled during the startup phase in order to avoid high transient current mainly in Pump Mode which could cause the power supply voltage to drop dramatically. This control is done by means of bits BOOST[1:0], which increases progressively the startup current level.

Initialization Procedure

The initialization procedure is different depending upon the required Card Vcc. One procedure apply for Card Vcc =< 3 volts and one procedure for Card Vcc = 5 volts.

The initialization procedure involves :
*   Select the CVCC level by means of bits VCARD[1:0] in SCICR register,
*   Set bits BOOST[1:0] in DCCKPS register following the current level control wanted.
*   Switch the DC/DC on by means of bit CARDVCC in SCCON register,
*   Monitor bit VCARDOK in SCISR register in order to know when the DC/DC Converter is ready (CVCC voltage has reached the expected level)

Procedure for CVcc =< 3 volts

The DC/DC regulation mode must be selected for Card Vcc = 1.8 volts and Card Vcc = 3 volts (MODE = 1 in DCCKPS register) The detailed procedures is described in flow chart of Figure 46. for Card Vcc = 1.8 volts and in the flow chart of Figure 47. for Card Vcc = 3 volts

                          Increment                Successful
                          BOOST [1:0]
                              │
                     DC/DC Initialization
                     Failure
```
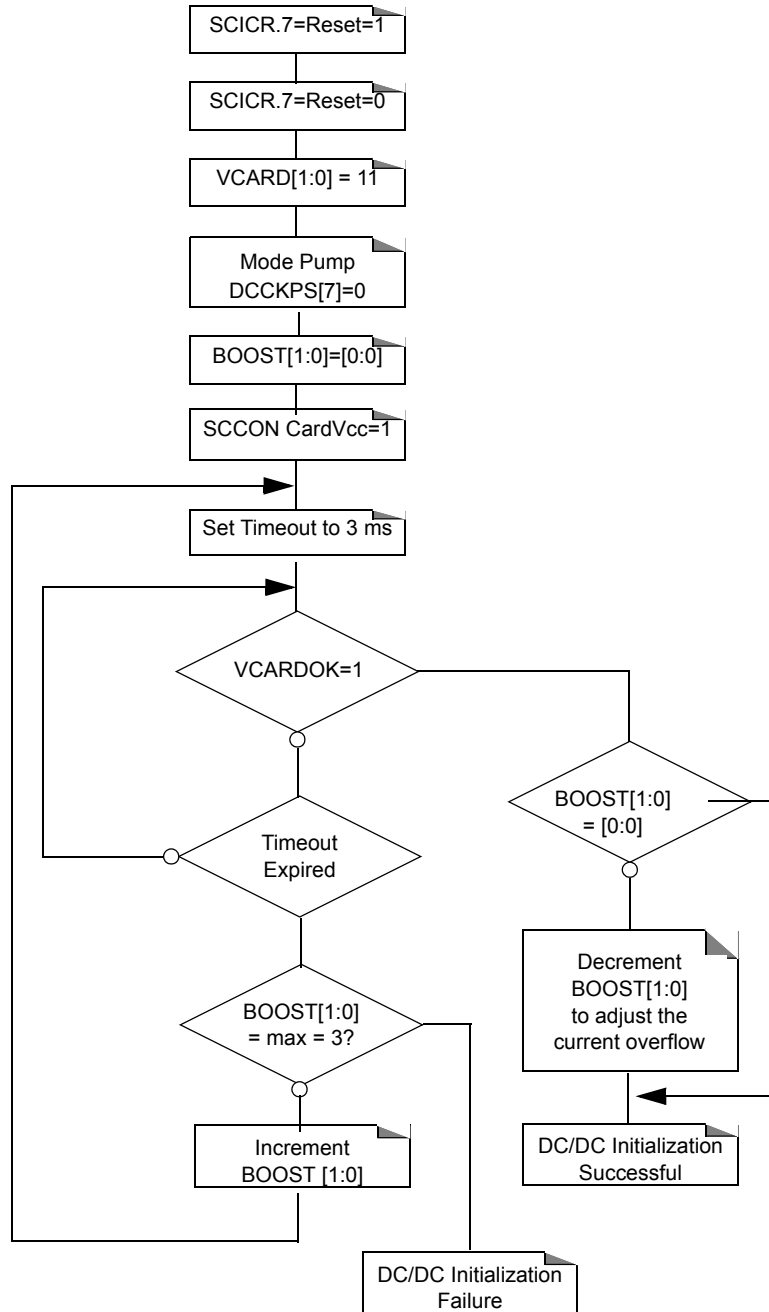

While VCC remains higher than 4.0V and startup current lower than 30 mA (depending on the load type), the DC/DC converter should be ready without having to increment BOOST[1:0] bits beyond [0:0] level. If VCC > 4.0V and startup current > 30 mA, it will be necessary to increment the BOOST[1:0] bits until the DC/DC converter is ready.

Incrementation of BOOST[1:0] bits increases at the same time the current overflow level in the same proportion as the startup current. So once the DC/DC converter is ready it is advised to decrement the BOOST[1:0] bits to restore the overflow current to its normal or desired value.

Monitoring Procedure

Once the DC/DC has been successfuly initialized, it is necessary to monitor the DC/DC converter by means of bits VCARDOK and ICARDOVF in the SCISR register.

Table 60. DC/DC converter status

VCARDOK	ICARDOVF	DC/DC Status
0	0	- Not Started or switched off by application. The current overflow sensor is disabled during the DC/DC converter startup. Then if a current overflow condition is applied during the DC/DC converter startup, the DC/DC converter is unable to start and both bits VCARDOK and ICARDOVF remains at 0.
		DC/DC converter correctly started then the output voltage is out of ISO/IEC 7816-3 specifications. In this case the firmware must take appropriate actions like deactivating the DC/DC converter in compliance with ISO/IEC 7816.
0	1	Started and automatically switched off by a current overflow condition
1	0	Operating properly according to ISO/IEC 7816-3 and EMV recommendations
1	1	Not applicable

DC/DC Converter register

USB Controller

The AT8xC5122D implements a USB device controller supporting Full Speed data transfer. In addition to the default control endpoint 0, it provides 6 other endpoints, which can be configured in Control, Bulk, Interrupt or Isochronous modes:

- Endpoint 0: 32-byte FIFO, default control endpoint
- Endpoint 1,2,3: 8-byte FIFO
- Endpoint 4,5: 64-byte FIFO
- Endpoint 6: 2 x 64-byte Ping-pong FIFO

This allows the firmware to be developed conforming to most USB device classes, for example:

- USB Mass Storage Class Control/Bulk/Interrupt (CBI) Transport, Revision 1.0 - December 14, 1998.
- USB Mass Storage Class Bulk-Only Transport, Revision 1.0 - September 31, 1999.
- USB Human Interface Device Class, Version 1.1 - April 7, 1999.
- USB Device Firmware Upgrade Class, Revision 1.0 - May 13, 1999.

USB Mass Storage Classes

USB Mass Storage Class CBI Transport

Within the CBI framework, the Control endpoint is used to transport command blocks as well as to transport standard USB requests. One Bulk-Out endpoint is used to transport data from the host to the device. One Bulk-In endpoint is used to transport data from the device to the host. And one interrupt endpoint may also be used to signal command completion (protocol 0); it is optional and may not be used (protocol 1).

The following configuration adheres to these requirements:

- Endpoint 0: 8 bytes, Control In-Out
- Endpoint 4: 64 bytes, Bulk-Out
- Endpoint 5: 64 bytes, Bulk-In
- Endpoint 1: 8 bytes, Interrupt In

USB Mass Storage Class Bulk-Only Transport

Within the Bulk-Only framework, the Control endpoint is only used to transport class-specific and standard USB requests for device set-up and configuration. One Bulk-Out endpoint is used to transport commands and data from the host to the device. One Bulk-In endpoint is used to transport status and data from the device to the host. No interrupt endpoint is needed.

The following configuration adheres to these requirements:

- Endpoint 0: 8 bytes, Control In-Out
- Endpoint 4: 64 bytes, Bulk-Out
- Endpoint 5: 64 bytes, Bulk-In

USB Device Firmware Upgrade (DFU)

The USB Device Firmware Update (DFU) protocol can be used to upgrade the on-chip program memory of the AT8xC5122D. This allows the implementation of product enhancements and patches to devices that are already in the field. Two different configurations and description sets are used to support DFU functions. The Run-Time configuration co-exists with the usual functions of the device, which may be USB Mass Storage for the AT8xC5122D. It is used to initiate DFU from the normal operating mode. The DFU configuration is used to perform the firmware update after device re-configuration and USB reset. It excludes any other function. Only the default control pipe (endpoint 0) is used to support DFU services in both configurations.

The only possible value for the wMaxPacketSize in the DFU configuration is 32 bytes, which is the size of the FIFO implemented for endpoint 0.

Description

The USB device controller provides the hardware that the AT8xC5122D and the AT83C5123 need to interface a USB link to a data flow stored in a double port memory (DPRAM).

The USB controller requires a 48 MHz reference clock, which is the output of the AT8xC5122D/23 PLL (see Section "Phase Lock Loop (PLL)", page 42) divided by a clock prescaler. This clock is used to generate a 12 MHz full speed bit clock from the received USB differential data and to transmit data according to full speed USB device tolerance. Clock recovery is done by a Digital Phase Locked Loop (DPLL) block, which is compliant with the jitter specification of the USB bus.

The Interface Engine (SIE) block performs NRZI encoding and decoding, bit stuffing, CRC generation and checking, and the serial-parallel data conversion. The Universal Function Interface (UFI) performs the interface between the data flow and the Dual Port Ram

Figure 49. USB Device Controller Block Diagram
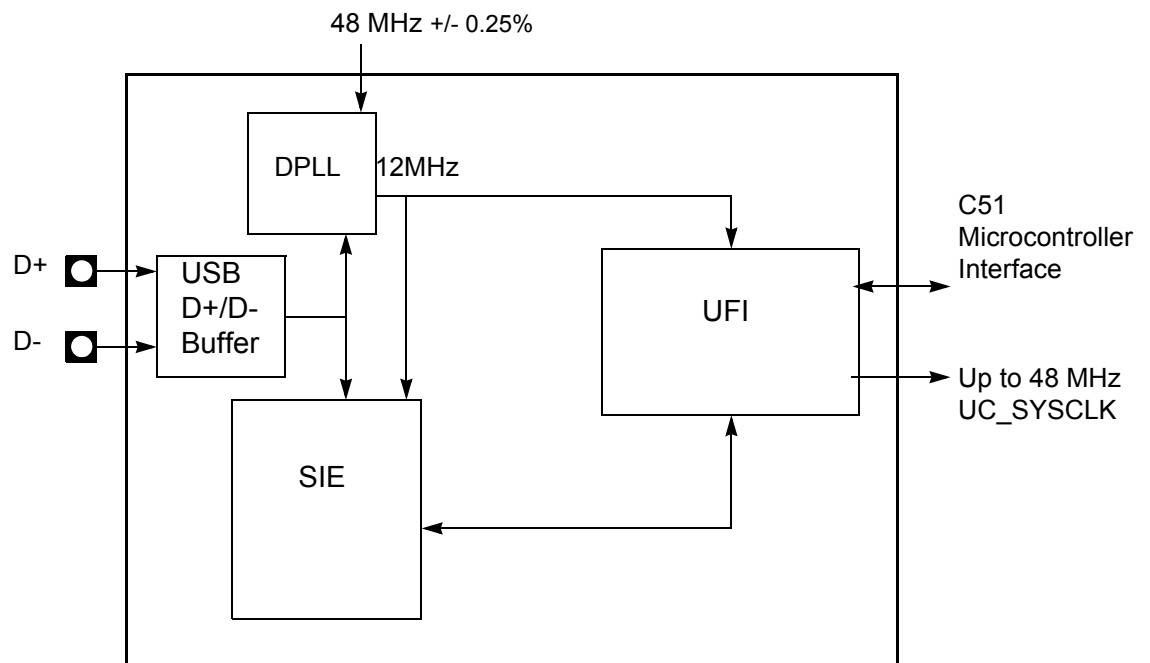

Serial Interface Engine (SIE)

The SIE performs the following functions:

- NRZI data encoding and decoding.
- Bit stuffing and unstuffing.
- CRC generation and checking.
- Handshakes.
- TOKEN type identifying.
- Address checking.
- Clock generation (via DPLL).

Figure 50. SIE Block Diagram
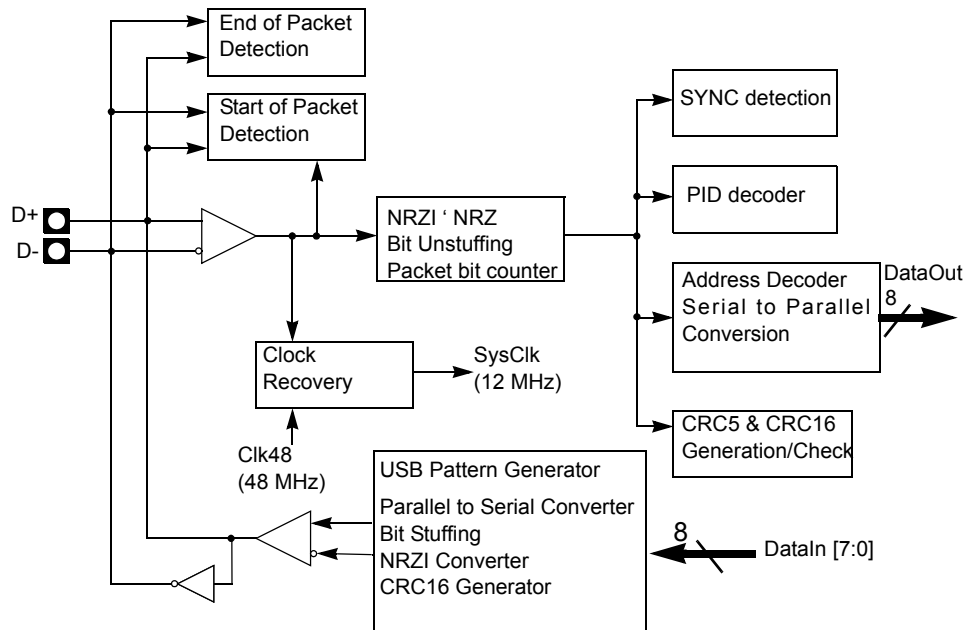

Function Interface Unit (UFI)   The Function Interface Unit provides the interface between the AT8xC5122D (or AT83C5123) and the SIE. It manages transactions at the packet level with minimal intervention from the device firmware, which reads and writes the endpoint FIFOs.

Figure 51. UFI Block Diagram
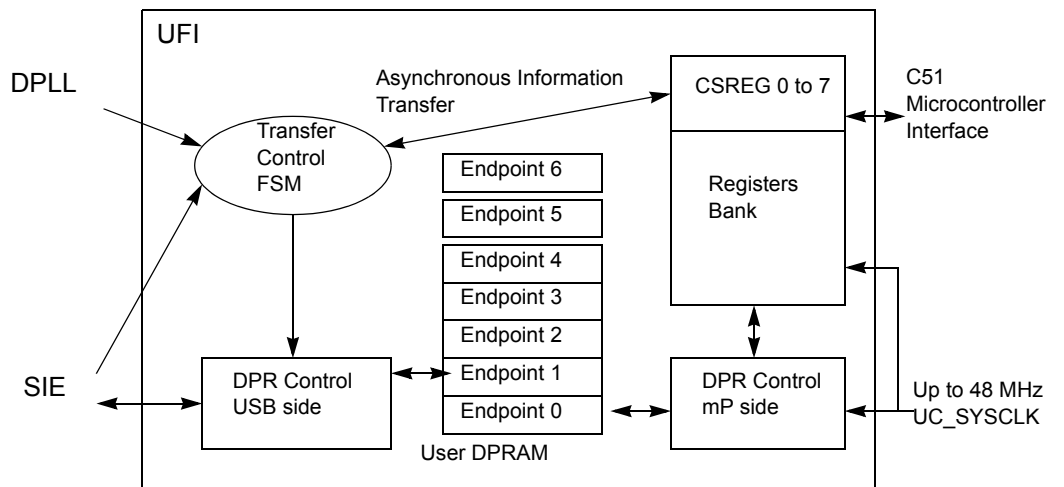

Figure 52. Minimum Intervention from the USB Device Firmware

OUT Transactions:

HOST | OUT | DATA0 (n Bytes) | | OUT | DATA1 | | OUT | DATA1
UFI | | ACK | interrupt C51 | | NACK | | | ACK
C51 | | | Endpoint FIFO read (n bytes)

IN Transactions:

HOST | IN | | IN | | IN | | ACK
UFI | | NACK | | DATA1 | | DATA1 | interrupt C51
C51 | Endpoint FIFO write | | | | | Endpoint FIFO write
Configuration

General Configuration
- USB controller enable

Before any USB transaction, the 48 MHz required by the USB controller must be correctly generated (Section "Clock Controller", page 41).

The USB controller should be then enabled by setting the USBE bit in the USBCON register.

- Set address

After a Reset or a USB reset, the software has to set the FEN (Function Enable) bit in the USBADDR register. This action will allow the USB controller to answer to the requests sent at the address 0.

When a SET_ADDRESS request has been received, the USB controller must only answer to the address defined by the request. The new address should be stored in the USBADDR register. The FEN bit and the FADDEN bit in the USBCON register should be set to allow the USB controller to answer only to requests sent at the new address.

- Set configuration

The CONFG bit in the USBCON register should be set after a SET_CONFIGURATION request with a non-zero value. Otherwise, this bit should be cleared.

Endpoint Configuration
- Selection of an Endpoint

The endpoint register access is performed using the UEPNUM register. The following registers

correspond to the endpoint whose number is stored in the UEPNUM register. To select an Endpoint, the firmware has to write the endpoint number in the UEPNUM register.

- UEPSTAX,
- UEPCONX,
- UEPDATX,
- UBYCTX,

Figure 53. Endpoint Selection
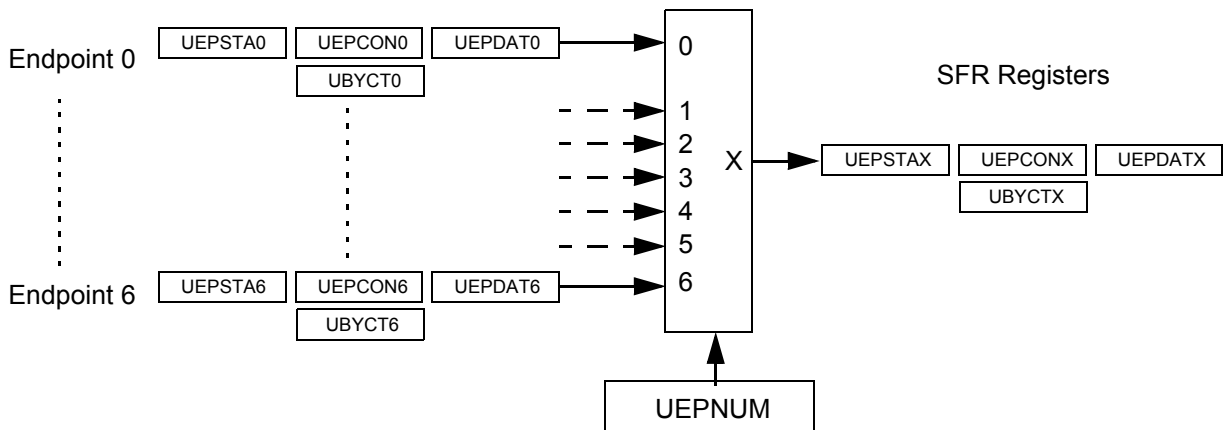

- Endpoint enable

Before using an endpoint, this one should be enabled by setting the EPEN bit in the UEPCONX register.

An endpoint which is not enabled won't answer to any USB request. The Default Control Endpoint (Endpoint 0) should always be enabled in order to answer to USB standard requests.

- Endpoint type configuration

All Standard Endpoints can be configured in Control, Bulk, Interrupt or Isochronous mode. The Ping-pong Endpoints can be configured in Bulk, Interrupt or Isochronous mode. The configuration of an endpoint is performed by setting the field EPTYPE with the following values:

- Control: EPTYPE = 00b
- Isochronous: EPTYPE = 01b
- Bulk: EPTYPE = 10b
- Interrupt: EPTYPE = 11b

The Endpoint 0 is the Default Control Endpoint and should always be configured in Control type.

- Endpoint direction configuration

For Bulk, Interrupt and Isochronous endpoints, the direction is defined with the EPDIR bit of the UEPCONX register with the following values:

- IN:EPDIR = 1b
- OUT:EPDIR = 0b

For Control endpoints, the EPDIR bit has no effect.

- Summary of Endpoint Configuration:

Make sure to select the correct endpoint number in the UEPNUM register before accessing to endpoint specific registers.

Table 62. Summary of Endpoint Configuration

Endpoint configuration	EPEN	EPDIR	EPTYPE	UEPCONX
Disabled	0b	Xb	XXb	0XXX XXXb
Control	1b	Xb	00b	80h
Bulk-In	1b	1b	10b	86h
Bulk-Out	1b	0b	10b	82h
Interrupt-In	1b	1b	11b	87h
Interrupt-Out	1b	0b	11b	83h
Isochronous-In	1b	1b	01b	85h
Isochronous-Out	1b	0b	01b	81h

• Endpoint FIFO reset

Before using an endpoint, its FIFO should be reset. This action resets the FIFO pointer to its original value, resets the byte counter of the endpoint (UBYCTX register), and resets the data toggle bit (DTGL bit in UEPCONX).

The reset of an endpoint FIFO is performed by setting to 1 and resetting to 0 the corresponding bit in the UEPRST register.

For example, in order to reset the Endpoint number 2 FIFO, write 0000 0100b then 0000 0000b in the UEPRST register.

Read/Write Data FIFO

Read Data FIFO

The read access for each OUT endpoint is performed using the UEPDATX register.

After a new valid packet has been received on an Endpoint, the data are stored into the FIFO and the byte counter of the endpoint is updated (UBYCTX register). The firmware has to store the endpoint byte counter before any access to the endpoint FIFO. The byte counter is not updated when reading the FIFO.

To read data from an endpoint, select the correct endpoint number in UEPNUM and read the UEPDATX register. This action automatically decreases the corresponding address vector, and the next data is then available in the UEPDATX register.

Write Data FIFO

The write access for each IN endpoint is performed using the UEPDATX register.

To write a byte into an IN endpoint FIFO, select the correct endpoint number in UEPNUM and write into the UEPDATX register. The corresponding address vector is automatically increased, and another write can be carried out.

Warning 1: The byte counter is not updated.
Warning 2: Do not write more bytes than supported by the corresponding endpoint.

Figure 54. Endpoint FIFO Configuration
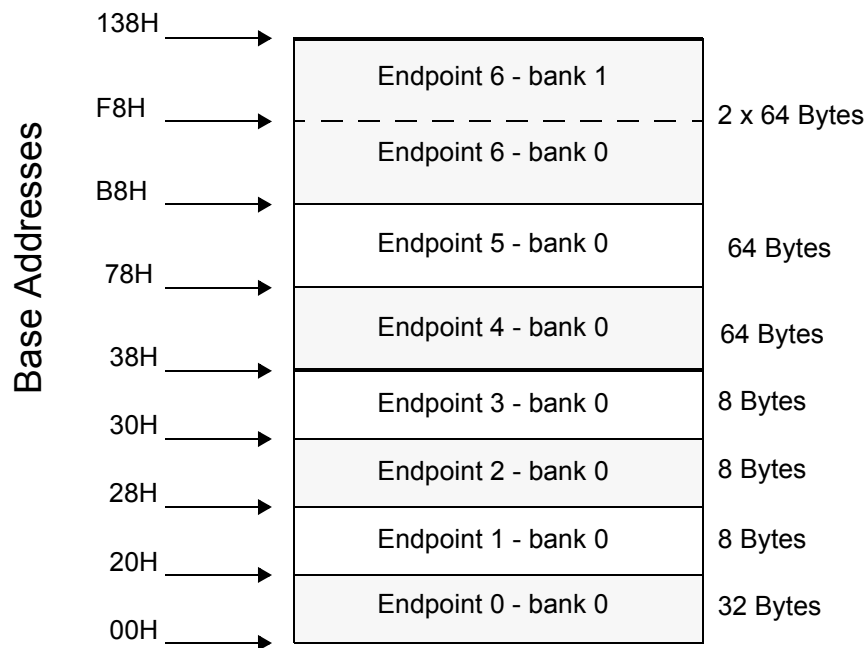

Bulk / Interrupt Transactions

Bulk and Interrupt transactions are managed in the same way.

Bulk/Interrupt OUT Transactions in Standard Mode

Figure 55. Bulk/Interrupt OUT transactions in Standard Mode
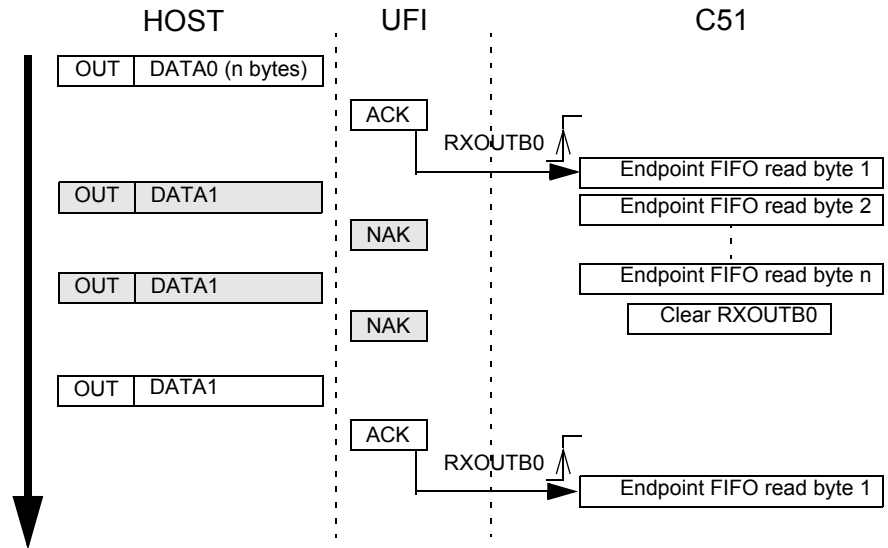

An endpoint should be first enabled and configured before being able to receive Bulk or Interrupt packets.

When a valid OUT packet is received on an endpoint, the RXOUTB0 bit is set by the USB controller. This triggers an interrupt if enabled. The firmware has to select the corresponding endpoint, store the number of data bytes by reading the UBYCTX register. If the received packet is a ZLP (Zero Length Packet), the UBYCTX register value is equal to 0 and no data has to be read.

When all the endpoint FIFO bytes have been read, the firmware should clear the RXOUTB0 bit to allow the USB controller to accept the next OUT packet on this endpoint. Until the RXOUTB0 bit has been cleared by the firmware, the USB controller will answer a NAK handshake for each OUT requests.

If the Host sends more bytes than supported by the endpoint FIFO, the overflow data won't be stored, but the USB controller will consider that the packet is valid if the CRC is correct and the endpoint byte counter contains the number of bytes sent by the Host.

**Bulk/Interrupt OUT
Transactions in Ping-Pong
Mode (Endpoints 6)**

Figure 56. Bulk / Interrupt OUT Transactions in Ping-Pong Mode
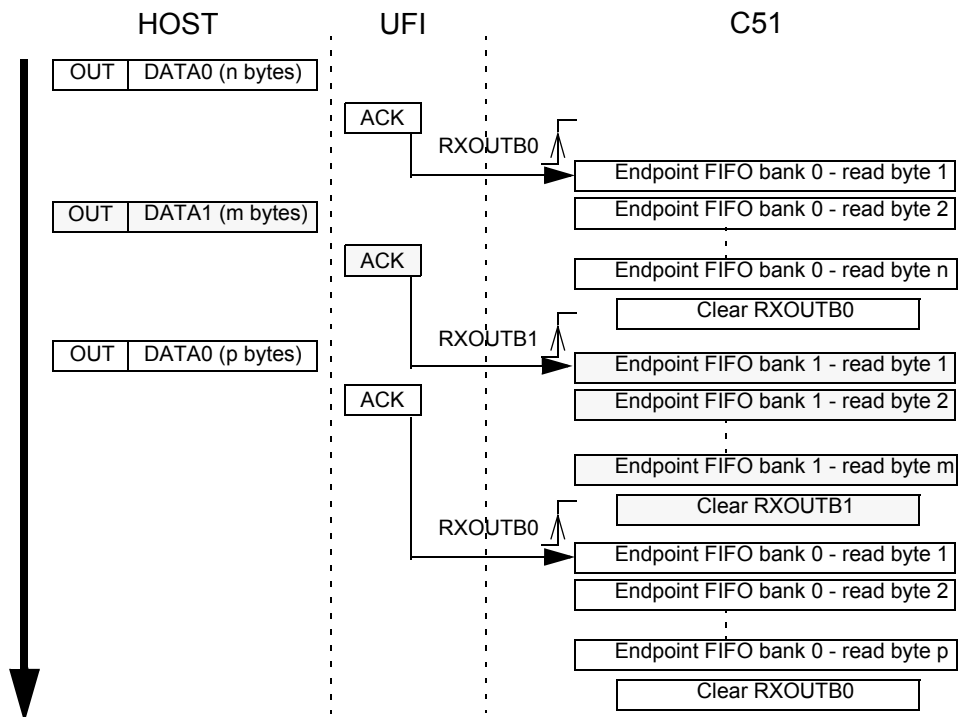

An endpoint should be first enabled and configured before being able to receive Bulk or Interrupt packets.

When a valid OUT packet is received on the endpoint bank 0, the RXOUTB0 bit is set by the USB controller. This triggers an interrupt if enabled. The firmware has to select the corresponding endpoint, store the number of data bytes by reading the UBYCTX register. If the received packet is a ZLP (Zero Length Packet), the UBYCTX register value is equal to 0 and no data has to be read.

When all the endpoint FIFO bytes have been read, the firmware should clear the RXOUB0 bit to allow the USB controller to accept the next OUT packet on the endpoint bank 0. This action switches the endpoint bank 0 and 1. Until the RXOUTB0 bit has been cleared by the firmware, the USB controller will answer a NAK handshake for each OUT requests on the bank 0 endpoint FIFO.

When a new valid OUT packet is received on the endpoint bank 1, the RXOUTB1 bit is set by the USB controller. This triggers an interrupt if enabled. The firmware empties the bank 1 endpoint FIFO before clearing the RXOUTB1 bit. Until the RXOUTB1 bit has been cleared by the firmware, the USB controller will answer a NAK handshake for each OUT requests on the bank 1 endpoint FIFO.

The RXOUTB0 and RXOUTB1 bits are alternatively set by the USB controller at each new valid packet receipt.

The firmware has to clear one of these two bits after having read all the data FIFO to allow a new valid packet to be stored in the corresponding bank.

A NAK handshake is sent by the USB controller only if the banks 0 and 1 has not been released by the firmware.

If the Host sends more bytes than supported by the endpoint FIFO, the overflow data won't be stored, but the USB controller will consider that the packet is valid if the CRC is correct.

Bulk/Interrupt IN Transactions In Standard Mode

Figure 57. Bulk/Interrupt IN Transactions in Standard Mode
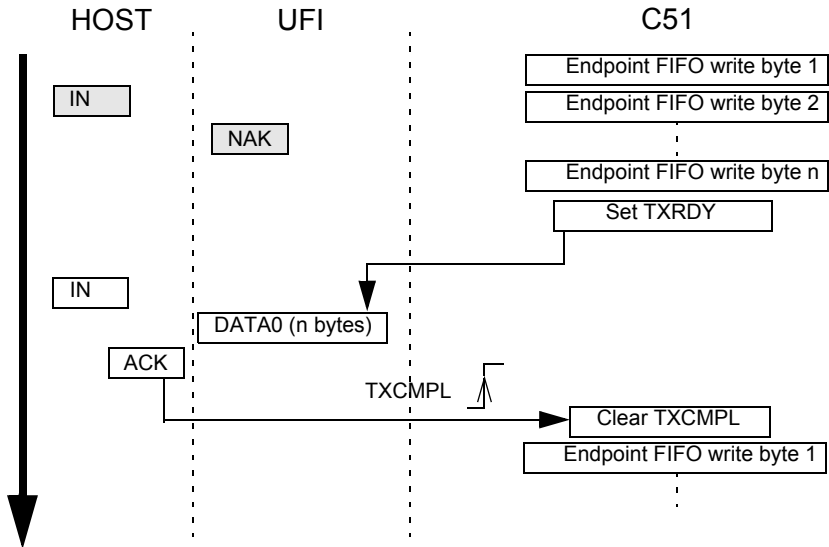

An endpoint should be first enabled and configured before being able to send Bulk or Interrupt packets.

The firmware should fill the FIFO with the data to be sent and set the TXRDY bit in the UEPSTAX register to allow the USB controller to send the data stored in FIFO at the next IN request concerning this endpoint. To send a Zero Length Packet, the firmware should set the TXRDY bit without writing any data into the endpoint FIFO.

Until the TXRDY bit has been set by the firmware, the USB controller will answer a NAK handshake for each IN requests.

To cancel the sending of this packet, the firmware has to reset the TXRDY bit. The packet stored in the endpoint FIFO is then cleared and a new packet can be written and sent.

When the IN packet has been sent and acknowledged by the Host, the TXCMPL bit in the UEPSTAX register is set by the USB controller. This triggers a USB interrupt if enabled. The firmware should clear the TXCMPL bit before filling the endpoint FIFO with new data.

The firmware should never write more bytes than supported by the endpoint FIFO.

All USB retry mechanisms are automatically managed by the USB controller.

Bulk/Interrupt IN Transactions in Ping-Pong Mode

Figure 58. Bulk / Interrupt IN transactions in Ping-Pong mode

```
        HOST            UFI                    C51

                                    Endpoint FIFO Bank 0 - Write Byte 1
         IN                         Endpoint FIFO Bank 0 - Write Byte 2
                       NACK
                                    Endpoint FIFO Bank 0 - Write Byte n
                                          Set TXRDY

         IN
                                    Endpoint FIFO Bank 1 - Write Byte 1
                  DATA0 (n Bytes)   Endpoint FIFO Bank 1 - Write Byte 2
        ACK
                                    Endpoint FIFO Bank 1 - Write Byte m
                  TXCMPL                   Clear TXCMPL
                                           Set TXRDY
         IN
                  DATA1 (m Bytes)   Endpoint FIFO Bank 0 - Write Byte 1
        ACK                         Endpoint FIFO Bank 0 - Write Byte 2

                                    Endpoint FIFO Bank 0 - Write Byte p
                  TXCMPL                   Clear TXCMPL
         IN                                Set TXRDY
                  DATA0 (p Bytes)   Endpoint FIFO Bank 1 - Write Byte 1
        ACK
```

An endpoint will be first enabled and configured before being able to send Bulk or Interrupt packets.

The firmware will fill the FIFO bank 0 with the data to be sent and set the TXRDY bit in the UEPSTAX register to allow the USB controller to send the data stored in FIFO at the next IN request concerning the endpoint. The FIFO banks are automatically switched, and the firmware can immediately write into the endpoint FIFO bank 1.

When the IN packet concerning the bank 0 has been sent and acknowledged by the Host, the TXCMPL bit is set by the USB controller. This triggers a USB interrupt if enabled. The firmware will clear the TXCMPL bit before filling the endpoint FIFO bank 0 with new data. The FIFO banks are then automatically switched.

When the IN packet concerning the bank 1 has been sent and acknowledged by the Host, the TXCMPL bit is set by the USB controller. This triggers a USB interrupt if enabled. The firmware will clear the TXCMPL bit before filling the endpoint FIFO bank 1 with new data.

The bank switch is performed by the USB controller each time the TXRDY bit is set by the firmware. Until the TXRDY bit has been set by the firmware for an endpoint bank, the USB controller will answer a NAK handshake for each IN requests concerning this bank.

Note that in the example above, the firmware clears the Transmit Complete bit (TXCMPL) before setting the Transmit Ready bit (TXRDY). This is done in order to avoid the firmware to clear at the same time the TXCMPL bit for bank 0 and the bank 1.

The firmware will never write more bytes than supported by the endpoint FIFO.

Control Transactions

Setup Stage

The DIR bit in the UEPSTAX register should be at 0.

Receiving Setup packets is the same as receiving Bulk Out packets, except that the Rxsetup bit in the UEPSTAX register is set by the USB controller instead of the RXOUTB0 bit to indicate that an Out packet with a Setup PID has been received on the Control endpoint. When the RXSETUP bit has been set, all the other bits of the UEP-STAX register are cleared and an interrupt is triggered if enabled.

The firmware has to read the Setup request stored in the Control endpoint FIFO before clearing the RXSETUP bit to free the endpoint FIFO for the next transaction.

Data Stage: Control Endpoint Direction

The data stage management is similar to Bulk management.

A Control endpoint is managed by the USB controller as a full-duplex endpoint: IN and OUT. All other endpoint types are managed as half-duplex endpoint: IN or OUT. The firmware has to specify the control endpoint direction for the data stage using the DIR bit in the UEPSTAX register.

- If the data stage consists of INs,
  the firmware has to set the DIR bit in the UEPSTAX register before writing into the FIFO and sending the data by setting to 1 the TXRDY bit in the UEPSTAX register. The IN transaction is complete when the TXCMPL has been set by the hardware. The firmware should clear the TXCMPL bit before any other transaction.

- If the data stage consists of OUTs,
  the firmware has to leave the DIR bit at 0. The RXOUTB0 bit is set by hardware when a new valid packet has been received on the endpoint. The firmware must read the data stored into the FIFO and then clear the RXOUTB0 bit to reset the FIFO and to allow the next transaction.

The bit DIR is used to send the correct data toggle in the data stage.

To send a STALL handshake, see "STALL Handshake" on page 110.

Status Stage

The DIR bit in the UEPSTAX register should be reset at 0 for IN and OUT status stage.

The status stage management is similar to Bulk management.

- For a Control Write transaction or a No-Data Control transaction, the status stage consists of a IN Zero Length Packet (see "Bulk/Interrupt IN Transactions In Standard Mode" on page 105). To send a STALL handshake, see "STALL Handshake" on page 110.

- For a Control Read transaction, the status stage consists of a OUT Zero Length Packet (see "Bulk/Interrupt OUT Transactions in Standard Mode" on page 103).

Isochronous Transactions

Isochronous OUT Transactions in Standard Mode

An endpoint should be first enabled and configured before being able to receive Isochronous packets.

When an OUT packet is received on an endpoint, the RXOUTB0 bit is set by the USB controller. This triggers an interrupt if enabled. The firmware has to select the corresponding endpoint, store the number of data bytes by reading the UBYCTX register. If the received packet is a ZLP (Zero Length Packet), the UBYCTX register value is equal to 0 and no data has to be read.
The STLCRC bit in the UEPSTAX register is set by the USB controller if the packet stored in FIFO has a corrupted CRC. This bit is updated after each new packet receipt.

When all the endpoint FIFO bytes have been read, the firmware should clear the RXOUTB0 bit to allow the USB controller to store the next OUT packet data into the endpoint FIFO. Until the RXOUTB0 bit has been cleared by the firmware, the data sent by the Host at each OUT transaction will be lost.
If the RXOUTB0 bit is cleared while the Host is sending data, the USB controller will store only the remaining bytes into the FIFO.

If the Host sends more bytes than supported by the endpoint FIFO, the overflow data won't be stored, but the USB controller will consider that the packet is valid if the CRC is correct.

Isochronous OUT Transactions in Ping-pong Mode

An endpoint should be first enabled and configured before being able to receive Isochronous packets.

When a OUT packet is received on the endpoint bank 0, the RXOUTB0 bit is set by the USB controller. This triggers an interrupt if enabled. The firmware has to select the corresponding endpoint, store the number of data bytes by reading the UBYCTX register. If the received packet is a ZLP (Zero Length Packet), the UBYCTX register value is equal to 0 and no data has to be read.
The STLCRC bit in the UEPSTAX register is set by the USB controller if the packet stored in FIFO has a corrupted CRC. This bit is updated after each new packet receipt.

When all the endpoint FIFO bytes have been read, the firmware should clear the RXOUB0 bit to allow the USB controller to store the next OUT packet data into the endpoint FIFO bank 0. This action switches the endpoint bank 0 and 1. Until the RXOUTB0 bit has been cleared by the firmware, the data sent by the Host on the bank 0 endpoint FIFO will be lost.
If the RXOUTB0 bit is cleared while the Host is sending data on the endpoint bank 0, the USB controller will store only the remaining bytes into the FIFO.

When a new OUT packet is received on the endpoint bank 1, the RXOUTB1 bit is set by the USB controller. This triggers an interrupt if enabled. The firmware empties the bank 1 endpoint FIFO before clearing the RXOUTB1 bit. Until the RXOUTB1 bit has been cleared by the firmware, the data sent by the Host on the bank 1 endpoint FIFO will be lost.

The RXOUTB0 and RXOUTB1 bits are alternatively set by the USB controller at each new packet receipt.
The firmware has to clear one of these two bits after having read all the data FIFO to allow a new packet to be stored in the corresponding bank.

If the Host sends more bytes than supported by the endpoint FIFO, the overflow data won't be stored, but the USB controller will consider that the packet is valid if the CRC is correct.

Isochronous IN Transactions in Standard Mode

An endpoint should be first enabled and configured before being able to send Isochronous packets.

The firmware should fill the FIFO with the data to be sent and set the TXRDY bit in the UEPSTAX register to allow the USB controller to send the data stored in FIFO at the next IN request concerning this endpoint.

If the TXRDY bit is not set when the IN request occurs, nothing will be sent by the USB controller.

When the IN packet has been sent, the TXCMPL bit in the UEPSTAX register is set by the USB controller. This triggers a USB interrupt if enabled. The firmware should clear the TXCMPL bit before filling the endpoint FIFO with new data. The firmware should never write more bytes than supported by the endpoint FIFO.

Isochronous IN Transactions in Ping-Pong Mode

An endpoint should be first enabled and configured before being able to send Isochronous packets.

The firmware should fill the FIFO bank 0 with the data to be sent and set the TXRDY bit in the UEPSTAX register to allow the USB controller to send the data stored in FIFO at the next IN request concerning the endpoint. The FIFO banks are automatically switched, and the firmware can immediately write into the endpoint FIFO bank 1.
If the TXRDY bit is not set when the IN request occurs, nothing will be sent by the USB controller.

When the IN packet concerning the bank 0 has been sent, the TXCMPL bit is set by the USB controller. This triggers a USB interrupt if enabled. The firmware should clear the TXCMPL bit before filling the endpoint FIFO bank 0 with new data. The FIFO banks are then automatically switched.

When the IN packet concerning the bank 1 has been sent, the TXCMPL bit is set by the USB controller. This triggers a USB interrupt if enabled. The firmware should clear the TXCMPL bit before filling the endpoint FIFO bank 1 with new data.

The bank switch is performed by the USB controller each time the TXRDY bit is set by the firmware. Until the TXRDY bit has been set by the firmware for an endpoint bank, the USB controller won't send anything at each IN requests concerning this bank.

The firmware should never write more bytes than supported by the endpoint FIFO.

Miscellaneous

USB Reset

The EORINT bit in the USBINT register is set by hardware when a End of Reset has been detected on the USB bus. This triggers a USB interrupt if enabled. The USB controller is still enabled, but all the USB registers are reset by hardware. The firmware should clear the EORINT bit to allow the next USB reset detection.

STALL Handshake

This function is only available for Control, Bulk, and Interrupt endpoints.

The firmware has to set the STALLRQ bit in the UEPSTAX register to send a STALL handshake at the next request of the Host on the endpoint selected with the UEPNUM register. The RXSETUP, TXRDY, TXCMPL, RXOUTB0 and RXOUTB1 bits must be first reset to 0. The bit STLCRC is set at 1 by the USB controller when a STALL has been sent. This triggers an interrupt if enabled.

The firmware should clear the STALLRQ and STLCRC bits after each STALL sent. The STALLRQ bit is cleared automatically by hardware when a valid SETUP PID is received on a CONTROL type endpoint.

Start of Frame Detection

The SOFINT bit in the USBINT register is set when the USB controller detects a Start Of Frame PID. This triggers an interrupt if enabled. The firmware should clear the SOFINT bit to allow the next Start of Frame detection.

Frame Number

When receiving a Start of Frame, the frame number is automatically stored in the UFNUML and UFNUMH registers. The CRCOK and CRCERR bits indicate if the CRC of the last Start Of Frame is valid (CRCOK set at 1) or corrupt (CRCERR set at 1). The UFNUML and UFNUMH registers are automatically updated when receiving a new Start of Frame.

Data Toggle Bit

The Data Toggle bit is set by hardware when a DATA 0 packet is received and accepted by the USB controller and cleared by hardware when a DATA 1 packet is received and accepted by the USB controller. This bit is reset when the firmware resets the endpoint FIFO using the UEPRST register.

For Control endpoints, each SETUP transaction starts with a DATA 0 and data toggling is then used as for Bulk endpoints until the end of the Data stage (for a control write transfer). The Status stage completes the data transfer with a DATA 1 (for a control read transfer).

For Isochronous endpoints, the device firmware should ignore the data-toggle.

NAK Handshakes

When a NAK handshake is sent by the USB controller to a IN or OUT request from the Host, the NAKIN or NAKOUT bit is set by hardware. This information can be used to determine the direction of the communication during a Control transfer.
These bits are cleared by software.

Suspend/Resume Management

Suspend

The Suspend state can be detected by the USB controller if all the clocks are enabled and if the USB controller is enabled. The bit SPINT is set by hardware when an idle state is detected for more than 3 ms. This triggers a USB interrupt if enabled.

In order to reduce current consumption, the firmware can put the USB PAD in idle mode, stop the clocks and put the C51 in Idle or Power-down mode. The Resume detection is still active.
The USB PAD is put in idle mode when the firmware clear the SPINT bit. In order to avoid a new suspend detection 3ms later, the firmware has to disable the USB clock input using the SUSPCLK bit in the USBCON Register. The USB PAD automatically exits of idle mode when a wake-up event is detected.

The stop of the 48 MHz clock from the PLL should be done in the following order:

1. Disable of the 48 MHz clock input of the USB controller by setting to 1 the SUS-PCLK bit in the USBCON register.

2. Disable the PLL by clearing the PLLEN bit in the PLLCON register.

Resume

When the USB controller is in Suspend state, the Resume detection is active even if all the clocks are disabled and if the C51 is in Idle or Power-down mode. The WUPCPU bit is set by hardware when a non-idle state occurs on the USB bus. This triggers an interrupt if enabled. This interrupt wakes up the CPU from its Idle or Power-down state and the interrupt function is then executed. The firmware will first enable the 48 MHz generation and then reset to 0 the SUSPCLK bit in the USBCON register if needed.

The firmware has to clear the SPINT bit in the USBINT register before any other USB operation in order to wake up the USB controller from its Suspend mode.

The USB controller is then re-activated.

Figure 59. Example of a Suspend/Resume Management
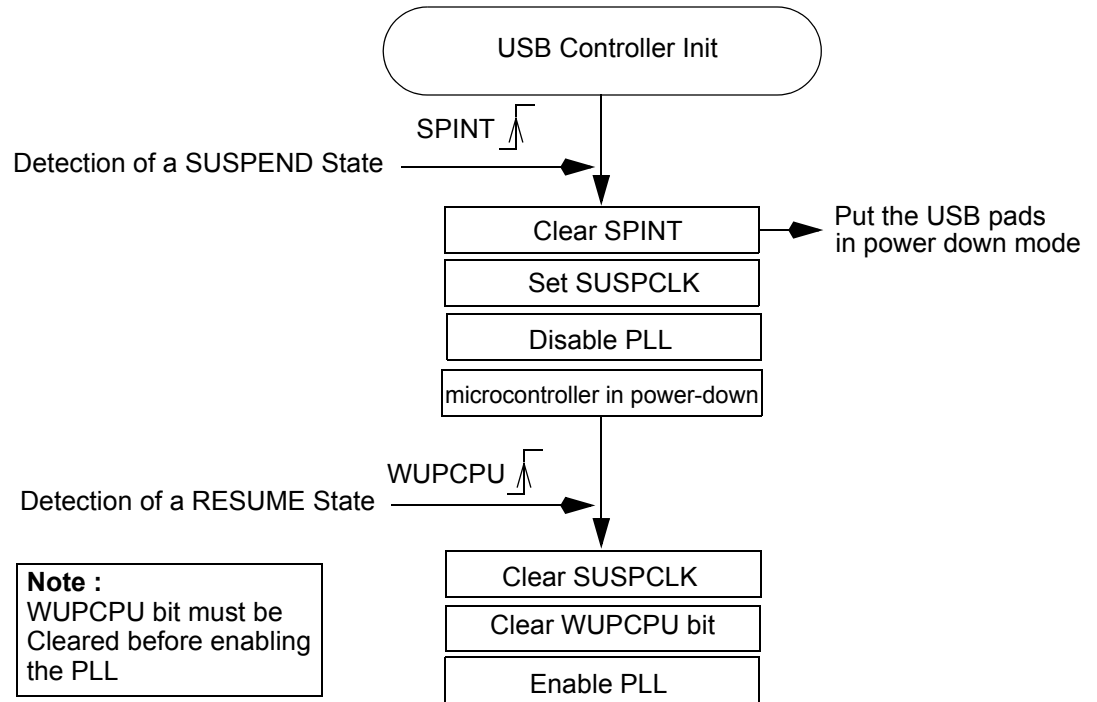

Upstream Resume

A USB device can be allowed by the Host to send an upstream resume for Remote Wake-up purpose.

When the USB controller receives the SET_FEATURE request: DEVICE_REMOTE_WAKEUP, the firmware should set to 1 the RMWUPE bit in the USBCON register to enable this function. RMWUPE value should be 0 in the other cases.

If the device is in SUSPEND mode, the USB controller can send an upstream resume by clearing first the SPINT bit in the USBINT register and by setting then to 1 the SDRM-WUP bit in the USBCON register. The USB controller sets to 1 the UPRSM bit in the USBCON register. All clocks must be enabled first. The Remote Wake is sent only if the USB bus was in Suspend state for at least 5 ms. When the upstream resume is completed, the UPRSM bit is reset to 0 by hardware. The firmware should then clear the SDRMWUP bit.

Figure 60. Example of REMOTE WAKEUP Management
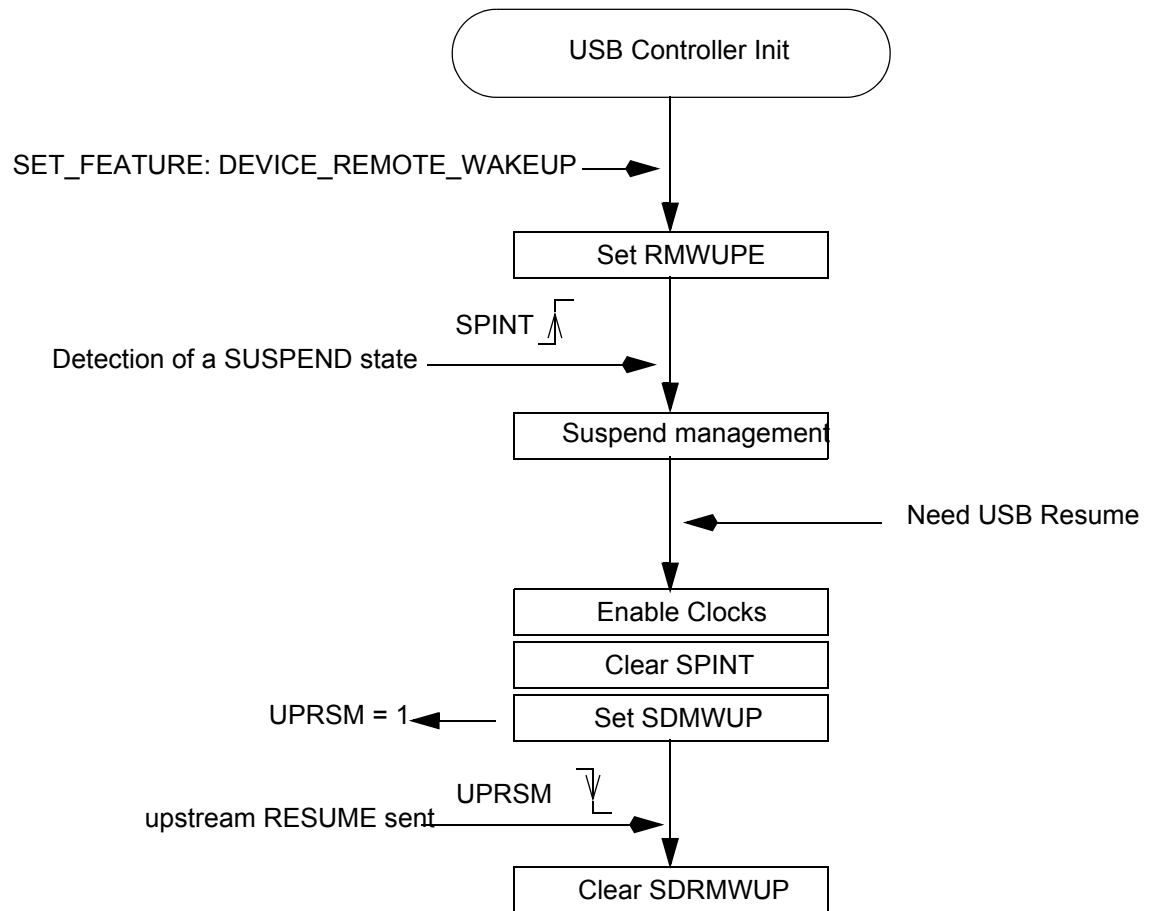

Detach Simulation

In order to be re-enumerated by the Host, the AT8xC5122/23 has the possibility to simulate a DETACH-ATTACH of the USB bus.

The V_{REF} output voltage is between 3.0V and 3.6V. This output can be connected to the D+ pull-up as shown in Figure 61. This output can be put in high-impedance when the DETACH bit is set to 1 in the USBCON register. Maintaining this output in high impedance for more than 3 µs will simulate the disconnection of the device. When resetting the DETACH bit, an ATTACH is then simulated. The USB controller should be enabled to use this feature.

Interrupt Control System

As shown in Figure 64, many events can produce a USB interrupt:

- TXCMPL: Transmitted In Data (Table 70 on page 121). This bit is set by hardware when the Host accept a In packet.

- RXOUTB0: Received Out Data Bank 0 (Table 70 on page 121). This bit is set by hardware when an Out packet is accepted by the endpoint and stored in bank 0.

- RXOUTB1: Received Out Data Bank 1 (only for Ping-Pong endpoints) (Table 70 on page 121). This bit is set by hardware when an Out packet is accepted by the endpoint and stored in bank 1.

- RXSETUP: Received Setup (Table 70 on page 121). This bit is set by hardware when an SETUP packet is accepted by the endpoint.

- NAKIN and NAKOUT: These bits are set by hardware when a Nak Handshake has been received on the corresponding endpoint. These bits are cleared by software.

- STLCRC: STALLED (only for Control, Bulk and Interrupt endpoints) (Table on page 122). This bit is set by hardware when a STALL handshake has been sent as requested by STALLRQ, and is reset by hardware when a SETUP packet is received.

- SOFINT: Start Of Frame Interrupt (Table 65 on page 118). This bit is set by hardware when a USB start of frame packet has been received.

- WUPCPU: Wake-Up CPU Interrupt (Table 65 on page 118). This bit is set by hardware when a USB resume is detected on the USB bus, after a SUSPEND state.

- SPINT: Suspend Interrupt (Table 65 on page 118). This bit is set by hardware when a USB suspend is detected on the USB bus.

Figure 64. USB Interrupt Control Block Diagram
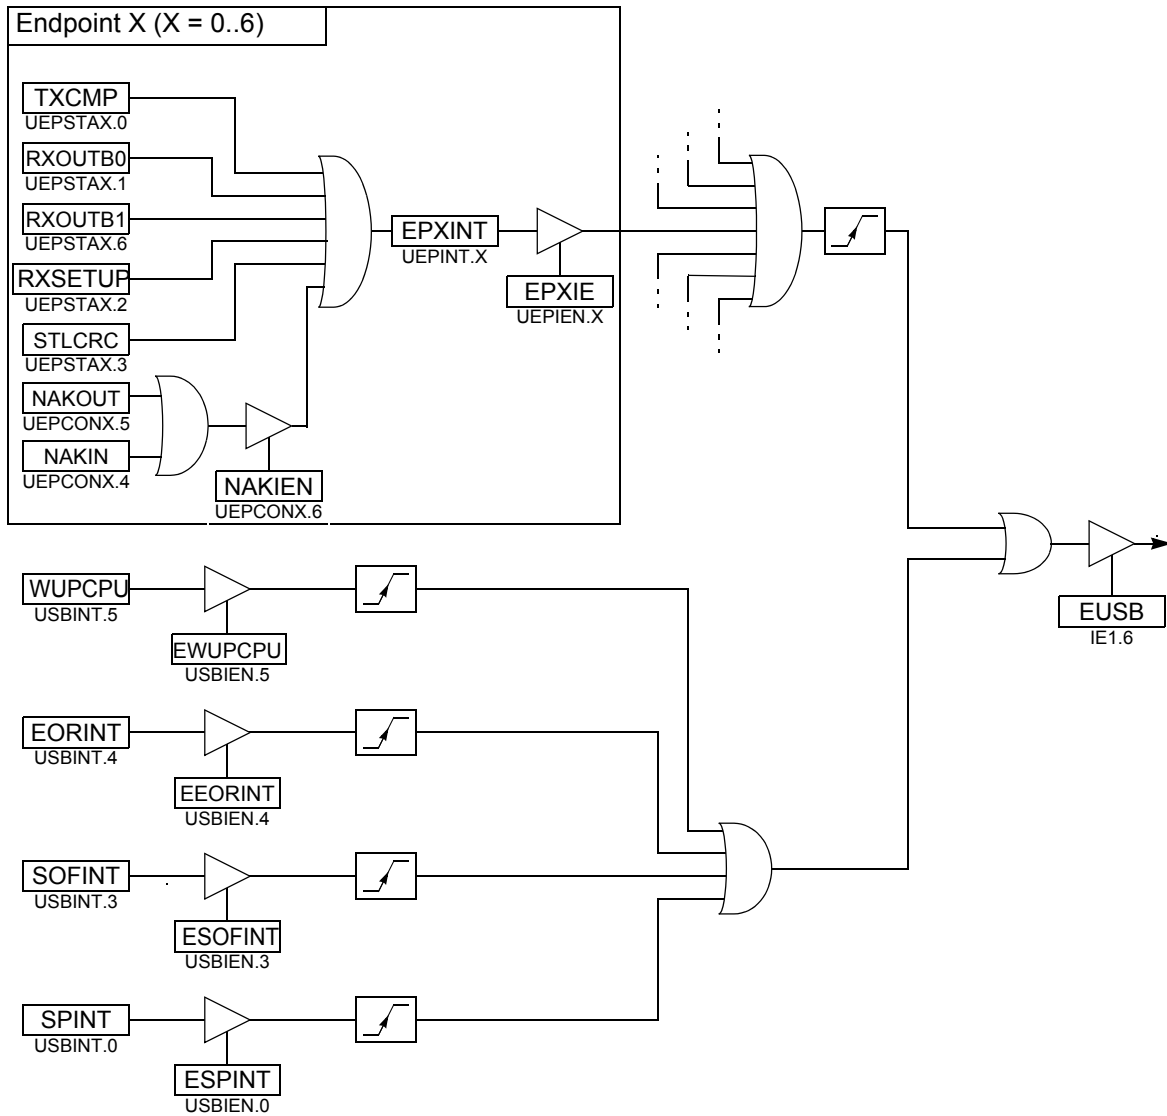

Registers

Table 64. USB Global Control Register - USBCON (S:BCh)

7	6	5	4	3	2	1	0
USBE	SUSPCLK	SDRMWUP	DETACH	UPRSM	RMWUPE	CONFG	FADDEN

Bit Number	Bit Mnemonic	Description
7	USBE	**USB Enable** Set this bit to enable the USB controller. Clear this bit to disable and reset the USB controller, to disable the USB transceiver and to disable the USB controller clock inputs.
6	SUSPCLK	**Suspend USB Clock** Set this bit to disable the 48MHz clock input (Resume Detection is still active). Clear this bit to enable the 48MHz clock input.
5	SDRMWUP	**Send Remote Wake-up** Set this bit to force an external interrupt on the USB controller for Remote Wake UP purpose. An upstream resume is send only if the bit RMWUPE is set, all USB clocks are enabled AND the USB bus was in SUSPEND state for at least 5 ms. See UPRSM below. This bit is cleared by software.
4	DETACH	**Detach Command** Set this bit to simulate a Detach on the USB line. The V_{REF} pin is then in a floating state. Clear this bit to maintain V_{REF} at 3.3V.
3	UPRSM	**Upstream Resume (read only)** This bit is set by hardware when SDRMWUP has been set and if RMWUPE is enabled. This bit is cleared by hardware after the upstream resume has been sent.
2	RMWUPE	**Remote Wake-Up Enable** Set this bit to enabled request an upstream resume signaling to the host. Clear this bit otherwise. Note: Do not set this bit if the host has not set the DEVICE_REMOTE_WAKEUP feature for the device.
1	CONFG	**Configured** This bit should be set by the device firmware after a SET_CONFIGURATION request with a non-zero value has been correctly processed. It should be cleared by the device firmware when a SET_CONFIGURATION request with a zero value is received. It is cleared by hardware on hardware reset or when an USB reset is detected on the bus (SE0 state for at least 32 Full Speed bit times: typically 2.7 μs).
0	FADDEN	**Function Address Enable** This bit should be set by the device firmware after a successful status phase of a SET_ADDRESS transaction. It should not be cleared afterwards by the device firmware. It is cleared by hardware on hardware reset or when an USB reset is received (see above). When this bit is cleared, the default function address is used (0).

Reset Value = 0000 0000b

Table 65. USB Global Interrupt Register - USBINT (S:BDh)

7	6	5	4	3	2	1	0
-	-	WUPCPU	EORINT	SOFINT	-	-	SPINT

Bit Number	Bit Mnemonic	Description
7 - 6	-	**Reserved** The value read from these bits is always 0. Do not change these bits.
5	WUPCPU	**Wake-up CPU Interrupt** This bit is set by hardware when the USB controller is in SUSPEND state and is re-activated by a non-idle signal FROM USB line (not by an upstream resume). This triggers a USB interrupt when EWUPCPU is set in the Table on page 119. When receiving this interrupt, user has to enable all USB clock inputs. This bit should be cleared by software (USB clocks must be enabled before).
4	EEORINT	**End of Reset Interrupt** This bit is set by hardware when a End of Reset has been detected by the USB controller. This triggers a USB interrupt when EEORINT is set in the Table on page 119. This bit should be cleared by software.
3	SOFINT	**Start Of Frame Interrupt** This bit is set by hardware when an USB Start Of Frame PID (SOF) has been detected. This triggers a USB interrupt when ESOFINT is set in the Table on page 119. This bit should be cleared by software.
2-1	-	**Reserved** The value read from these bits is always 0. Do not change these bits.
0	SPINT	**Suspend Interrupt** This bit is set by hardware when a USB Suspend (Idle bus for three frame periods: a J state for 3 ms) is detected. This triggers a USB interrupt when ESPINT is set in USBIEN register (Table 66 on page 119). This bit must be cleared by software before powering the microcontroller down as it disables the USB pads to reduce the power consumption.

Reset Value = 0000 0000b

Reset Value = 0000 0000b otherwise

Table 70. USB Endpoint Status and Control Register X - UEPSTAX (S:CEh) X=EPNUM set in UEPNUM Register)

7	6	5	4	3	2	1	0
DIR	RXOUTB1	STALLRQ	TXRDY	STL/CRC	RXSETUP	RXOUTB0	TXCMP

Bit Number	Bit Mnemonic	Description
7	DIR	**Control Endpoint Direction** This bit is used only if the endpoint is configured in the control type (see"USB Endpoint X Control Register - UEPCONX (S:D4h)" on page 120). This bit determines the Control data and status direction. The device firmware should set this bit ONLY for the IN data stage, before any other USB operation. Otherwise, the device firmware should clear this bit.
6	RXOUTB1	**Received OUT Data Bank 1 for Endpoint 6 (Ping-pong Mode)** This bit is set by hardware after a new packet has been stored in the endpoint FIFO Data bank 1 (only in Ping-pong mode). Then, the endpoint interrupt is triggered if enabled (see "USB Global Interrupt Register - USBINT (S:BDh)" on page 118) and all the following OUT packets to the endpoint bank 1 are rejected (NAK'ed) until this bit has been cleared, excepted for Isochronous Endpoints. This bit should be cleared by the device firmware after reading the OUT data from the endpoint FIFO.
5	STALLRQ	**Stall Handshake Request** Set this bit to request a STALL answer to the host for the next handshake. Clear this bit otherwise. For CONTROL endpoints: cleared by hardware when a valid SETUP PID is received.
4	TXRDY	**TX Packet Ready** Set this bit after a packet has been written into the endpoint FIFO for IN data transfers. Data should be written into the endpoint FIFO only after this bit has been cleared. Set this bit without writing data to the endpoint FIFO to send a Zero Length Packet. This bit is cleared by hardware, as soon as the packet has been sent for Isochronous endpoints, or after the host has acknowledged the packet for Control, Bulk and Interrupt endpoints. When this bit is cleared, the endpoint interrupt is triggered if enabled (see Table 65 on page 118).
3	STLCRC	**Stall Sent / CRC error flag** - For Control, Bulk and Interrupt Endpoints: This bit is set by hardware after a STALL handshake has been sent as requested by STALLRQ. Then, the endpoint interrupt is triggered if enabled (see"" on page 118) It should be cleared by the device firmware. - For Isochronous Endpoints **(Read-Only)**: This bit is set by hardware if the last received data is corrupted (CRC error on data). This bit is updated by hardware when a new data is received.
2	RXSETUP	**Received SETUP** This bit is set by hardware when a valid SETUP packet has been received from the host. Then, all the other bits of the register are cleared by hardware and the endpoint interrupt is triggered if enabled (see Table 65 on page 118). It should be cleared by the device firmware after reading the SETUP data from the endpoint FIFO.
1	RXOUTB0	**Received OUT Data Bank 0** (see also RXOUTB1 bit for Ping-pong Endpoints) This bit is set by hardware after a new packet has been stored in the endpoint FIFO data bank 0. Then, the endpoint interrupt is triggered if enabled (see"" on page 118) and all the following OUT packets to the endpoint bank 0 are rejected (NAK'ed) until this bit has been cleared, excepted for Isochronous Endpoints. However, for control endpoints, an early SETUP transaction may overwrite the content of the endpoint FIFO, even if its Data packet is received while this bit is set. This bit should be cleared by the device firmware after reading the OUT data from the endpoint FIFO.
0	TXCMPL	**Transmitted IN Data Complete** This bit is set by hardware after an IN packet has been transmitted for Isochronous endpoints and after it has been accepted (ACK'ed) by the host for Control, Bulk and Interrupt endpoints. Then, the endpoint interrupt is triggered if enabled (see Table 65). This bit should be cleared by the device firmware before setting TXRDY.

6	EP6INT	**Endpoint 6 Interrupt** This bit is set by hardware when an interrupt has been detected on the endpoint 6. The interrupt sources are part of UEPSTAX register and can be : TXCMP, RXOUTB0, RXOUTB1, RXSETUP or STLCRC. A USB interrupt is triggered when the EP6INTE bit in the UEPIEN register is set. This bit is cleared by hardware when all the interrupt sources are cleared.
5	EP5INT	**Endpoint 5 Interrupt** This bit is set by hardware when an interrupt has been detected on the endpoint 5. The interrupt sources are part of UEPSTAX register and can be : TXCMP, RXOUTB0, RXOUTB1, RXSETUP or STLCRC. A USB interrupt is triggered when the EP5INTE bit in the UEPIEN register is set. This bit is cleared by hardware when all the interrupt sources are cleared.
4	EP4INT	**Endpoint 4 Interrupt** This bit is set by hardware when an interrupt has been detected on the endpoint 4. The interrupt sources are part of UEPSTAX register and can be : TXCMP, RXOUTB0, RXOUTB1, RXSETUP or STLCRC. A USB interrupt is triggered when the EP4INTE bit in the UEPIEN register is set. This bit is cleared by hardware when all the interrupt sources are cleared.
3	EP3INT	**Endpoint 3 Interrupt** This bit is set by hardware when an interrupt has been detected on the endpoint 3. The interrupt sources are part of UEPSTAX register and can be : TXCMP, RXOUTB0, RXOUTB1, RXSETUP or STLCRC. A USB interrupt is triggered when the EP3INTE bit in the UEPIEN register is set. This bit is cleared by hardware when all the interrupt sources are cleared.
2	EP2INT	**Endpoint 2 Interrupt** This bit is set by hardware when an interrupt has been detected on the endpoint 2. The interrupt sources are part of UEPSTAX register and can be : TXCMP, RXOUTB0, RXOUTB1, RXSETUP or STLCRC. A USB interrupt is triggered when the EP2INTE bit in the UEPIEN register is set. This bit is cleared by hardware when all the interrupt sources are cleared.
1	EP1INT	**Endpoint 1 Interrupt** This bit is set by hardware when an interrupt has been detected on the endpoint 1. The interrupt sources are part of UEPSTAX register and can be : TXCMP, RXOUTB0, RXOUTB1, RXSETUP or STLCRC. A USB interrupt is triggered when the EP1INTE bit in the UEPIEN register is set. This bit is cleared by hardware when all the interrupt sources are cleared.
0	EP0INT	**Endpoint 0 Interrupt** This bit is set by hardware when an interrupt has been detected on the endpoint 0. The interrupt sources are part of UEPSTAX register and can be : TXCMP, RXOUTB0, RXOUTB1, RXSETUP or STLCRC. A USB interrupt is triggered when the EP0INTE bit in the UEPIEN register is set. This bit is cleared by hardware when all the interrupt sources are cleared.

Serial I/O Port

The serial I/O port in the AT8xC5122/23 is compatible with the serial I/O port in the 80C52.

The I/O port provides both synchronous and asynchronous communication modes. It operates as an Universal Asynchronous Receiver and Transmitter (UART) in three full-duplex modes (Modes 1, 2 and 3). Asynchronous transmission and reception can occur simultaneously and at different baud rates

Serial I/O port includes the following enhancements:
- Framing error detection
- Automatic address recognition

Framing Error Detection

Framing bit error detection is provided for the three asynchronous modes (Modes 1, 2 and 3). To enable the framing bit error detection feature, set SMOD0 bit in PCON register (See Figure 65).

Figure 65. Framing Error Block Diagram
| SM0/FE | SM1 | SM2 | REN | TB8 | RB8 | TI | RI | SCON (98h) |

Set FE Bit if Stop Bit is 0 (Framing Error) (SMOD0 = 1)

SM0 to UART Mode Control (SMOD0 = 0)

| SMOD1 | SMOD0 | - | POF | GF1 | GF0 | PD | IDL | PCON (87h) |

To UART Framing Error Control

When this feature is enabled, the receiver checks each incoming data frame for a valid stop bit. An invalid stop bit may result from noise on the serial lines or from simultaneous transmission by two CPUs. If a valid stop bit is not found, the Framing Error bit (FE) in SCON register (See Figure 70 on page 130) bit is set.

Software may examine FE bit after each reception to check for data errors. Once set, only software or a reset can clear FE bit. Subsequently received frames with valid stop bits cannot clear FE bit. When FE feature is enabled, RI rises on stop bit instead of the last data bit (See Figure 66 and Figure 67).

Figure 66. UART Timings in Mode 1
Figure 67. UART Timings in Modes 2 and 3
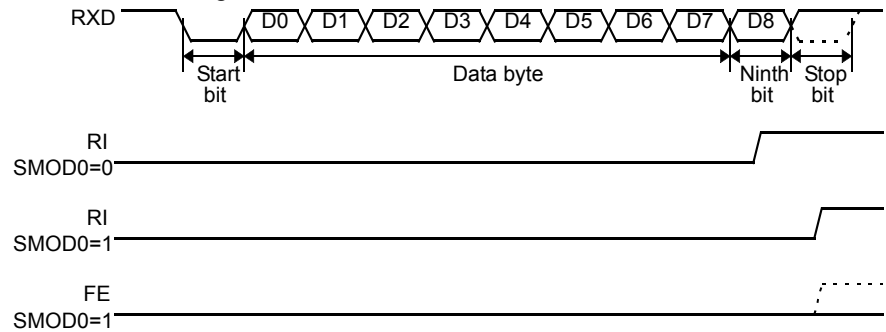

Automatic Address Recognition

The automatic address recognition feature is enabled when the multiprocessor communication feature is enabled (SM2 bit in SCON register is set).

Implemented in hardware, automatic address recognition enhances the multiprocessor communication feature by allowing the serial port to examine the address of each incoming command frame. Only when the serial port recognizes its own address, the receiver sets RI bit in SCON register to generate an interrupt. This ensures that the CPU is not interrupted by command frames addressed to other devices.

If desired, you may enable the automatic address recognition feature in mode 1. In this configuration, the stop bit takes the place of the ninth data bit. Bit RI is set only when the received command frame address matches the device's address and is terminated by a valid stop bit.

To support automatic address recognition, a device is identified by a given address and a broadcast address.

Note: The multiprocessor communication and automatic address recognition features cannot be enabled in mode 0 (i.e. setting SM2 bit in SCON register in mode 0 has no effect).

Given Address

Each device has an individual address that is specified in SADDR register; the SADEN register is a mask byte that contains don't care bits (defined by zeros) to form the device's given address. The don't care bits provide the flexibility to address one or more slaves at a time. The following example illustrates how a given address is formed.

To address a device by its individual address, the SADEN mask byte must be `1111 1111b`.

For example:
```
SADDR    0101 0110b
SADEN    1111 1100b
Given    0101 01XXb
```

The following is an example of how to use given addresses to address different slaves:
```
Slave A: SADDR    1111 0001b
         SADEN    1111 1010b
         Given    1111 0X0Xb
```

```
Slave B: SADDR    1111 0011b
         SADEN    1111 1001b
         Given    1111 0XX1b
```

```
Slave C: SADDR    1111 0011b
         SADEN    1111 1101b
         Given    1111 00X1b
```

127

The SADEN byte is selected so that each slave may be addressed separately.

For slave A, bit 0 (the LSB) is a don't care bit; for slaves B and C, bit 0 is a 1. To communicate with slave A only, the master must send an address where bit 0 is clear (e.g. `1111 0000b`).

For slave A, bit 1 is a 1; for slaves B and C, bit 1 is a don't care bit. To communicate with slaves B and C, but not slave A, the master must send an address with bits 0 and 1 both set (e.g. `1111 0011b`).

To communicate with slaves A, B and C, the master must send an address with bit 0 set, bit 1 clear, and bit 2 clear (e.g. `1111 0001b`).

Broadcast Address

A broadcast address is formed from the logical OR of the SADDR and SADEN registers with zeros defined as don't care bits, e.g.:

SADDR0101 0110b
SADEN1111 1100b
Broadcast =SADDR OR SADEN1111 111Xb

The use of don't care bits provides flexibility in defining the broadcast address, however in most applications, a broadcast address is FFh. The following is an example of using broadcast addresses:

Slave A:SADDR1111 0001b
SADEN1111 1010b
Broadcast1111 1X11b,

Slave B:SADDR1111 0011b
SADEN1111 1001b
Broadcast1111 1X11B,

Slave C:SADDR=1111 0010b
SADEN1111 1101b
Broadcast1111 1111b

For slaves A and B, bit 2 is a don't care bit; for slave C, bit 2 is set. To communicate with all of the slaves, the master must send an address FFh. To communicate with slaves A and B, but not slave C, the master can send and address FBh.

Reset Addresses

On reset, the SADDR and SADEN registers are initialized to 00h, i.e. the given and broadcast addresses are `XXXX XXXXb` (all don't care bits). This ensures that the serial port will reply to any address, and so, that it is backwards compatible with the 80C51 microcontrollers that does not support automatic address recognition.

Timer 1

When using the Timer 1, the Baud Rate is derived from the overflow of the timer. As shown in Figure 68 the Timer 1 is used in its 8-bit auto-reload mode). SMOD1 bit in PCON register allows doubling of the generated baud rate.

Figure 68. Timer 1 Baud Rate Generator Block Diagram
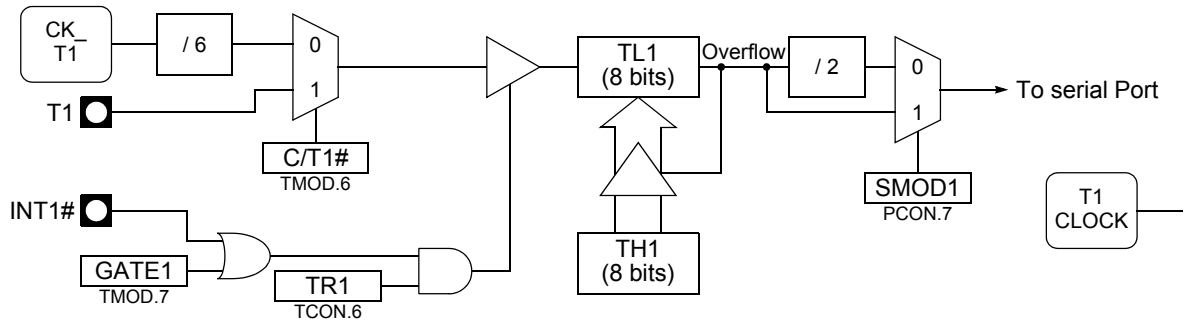

Internal Baud Rate Generator

When using the Internal Baud Rate Generator, the Baud Rate is derived from the overflow of the timer. As shown in Figure 69 the Internal Baud Rate Generator is an 8-bit auto-reload timer feed by the peripheral clock or by the peripheral clock divided by 6 depending on the SPD bit in BDRCON register (see Table 82 on page 136). The Internal Baud Rate Generator is enabled by setting BRR bit in BDRCON register. SMOD1 bit in PCON register allows doubling of the generated baud rate.

Figure 69. Internal Baud Rate Generator Block Diagram
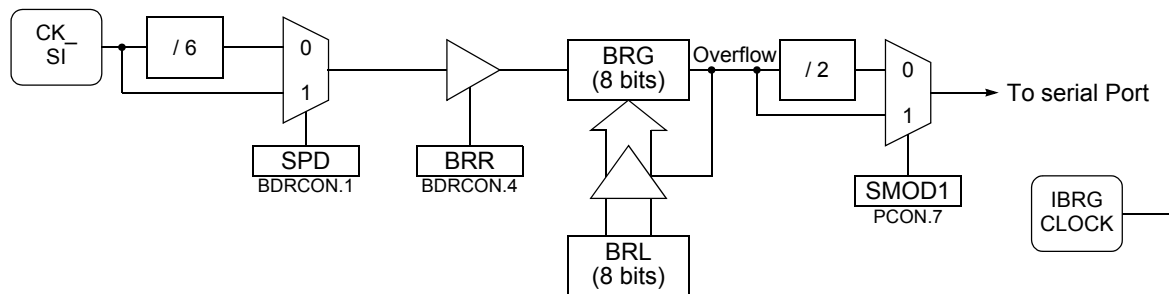

Synchronous Mode (Mode 0)

Mode 0 is a half-duplex, synchronous mode, which is commonly used to expand the I/0 capabilities of a device with shift registers. The transmit data (TXD) pin outputs a set of eight clock pulses while the receive data (RXD) pin transmits or receives a byte of data. The 8-bit data are transmitted and received least-significant bit (LSB) first. Shifts occur at a fixed Baud Rate (see Section "Baud Rate Selection (Mode 0)"). Figure 70 shows the serial port block diagram in Mode 0.

Figure 70. Serial I/O Port Block Diagram (Mode 0)
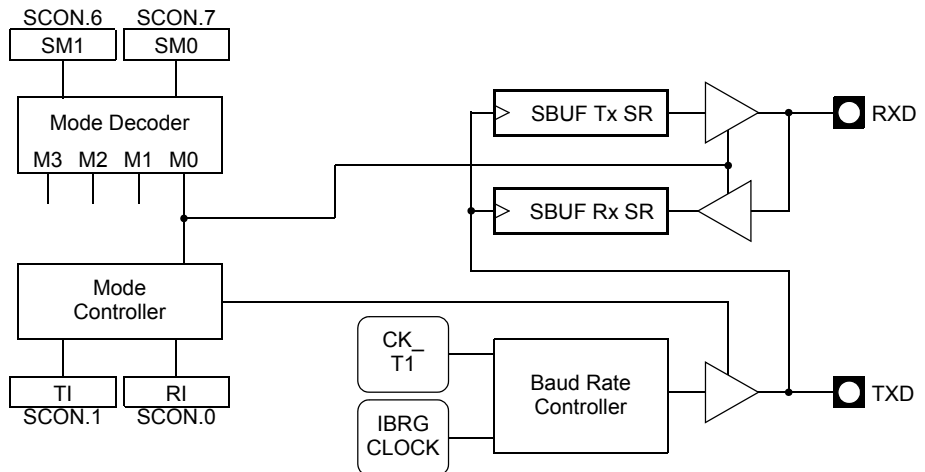

Transmission (Mode 0)

To start a transmission mode 0, write to SCON register clearing bits SM0, SM1. As shown in Figure 71, writing the byte to transmit to SBUF register starts the transmission. Hardware shifts the LSB (D0) onto the RXD pin during the first clock cycle composed of a high level then low level signal on TXD. During the eighth clock cycle the MSB (D7) is on the RXD pin. Then, hardware drives the RXD pin high and asserts TI to indicate the end of the transmission.

Figure 71. Transmission Waveforms (Mode 0)
Reception (Mode 0)

To start a reception in mode 0, write to SCON register clearing SM0, SM1 and RI bits and setting the REN bit.

As shown in Figure 72, Clock is pulsed and the LSB (D0) is sampled on the RXD pin. The D0 bit is then shifted into the shift register. After eight sampling, the MSB (D7) is shifted into the shift register, and hardware asserts RI bit to indicate a completed reception. Software can then read the received byte from SBUF register.

Figure 72. Reception Waveforms (Mode 0)
Baud Rate Selection (Mode 0)   In mode 0, baud rate can be either fixed or variable.

As shown in Figure 73, the selection is done using M0SRC bit in BDRCON register.

Figure 74 gives the baud rate calculation formulas for each baud rate source.

Figure 73. Baud Rate Source Selection (Mode 0)
Figure 74. Baud Rate Formulas (Mode 0)

$$\text{Baud\_Rate} = \frac{2^{\text{SMOD1}} \cdot F_{\text{CK\_SI}}}{6^{(1\text{-SPD})} \cdot 32 \cdot (256 - \text{BRL})}$$

$$\text{Baud\_Rate} = \frac{F_{\text{CK\_SI}}}{6}$$

$$\text{BRL} = 256 - \frac{2^{\text{SMOD1}} \cdot F_{\text{CK\_SI}}}{6^{(1\text{-SPD})} \cdot 32 \cdot \text{Baud\_Rate}}$$

a. Fixed Formula   **b. Variable Formula**

Asynchronous Modes (Modes 1, 2 and 3)   The Serial Port has one 8-bit and two 9-bit asynchronous modes of operation. Figure 75 shows the Serial Port block diagram in such asynchronous modes.

Figure 75. Serial I/O Port Block Diagram (Modes 1, 2 and 3)
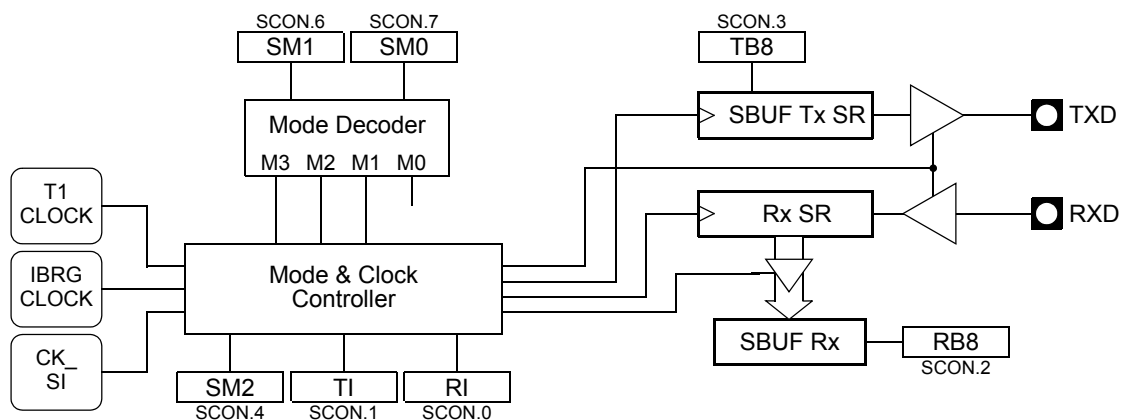

Mode 1   Mode 1 is a full-duplex, asynchronous mode. The data frame (see Figure 76) consists of 10 bits: one start, eight data bits and one stop bit. Serial data is transmitted on the TXD pin and received on the RXD pin. When a data is received, the stop bit is read in the RB8 bit in SCON register.

Figure 76. Data Frame Format (Mode 1)
Modes 2 and 3

Modes 2 and 3 are full-duplex, asynchronous modes. The data frame (see Figure 77) consists of 11 bits: one start bit, eight data bits (transmitted and received LSB first), one programmable ninth data bit and one stop bit. Serial data is transmitted on the TXD pin and received on the RXD pin. On receive, the ninth bit is read from RB8 bit in SCON register. On transmit, the ninth data bit is written to TB8 bit in SCON register. Alternatively, you can use the ninth bit as a command/data flag.

Figure 77. Data Frame Format (Modes 2 and 3)
Transmission (Modes 1, 2 and 3)

To initiate a transmission, write to SCON register, setting SM0 and SM1 bits according to Figure 70 on page 130, and setting the ninth bit by writing to TB8 bit. Then, writing the byte to be transmitted to SBUF register starts the transmission.

Reception (Modes 1, 2 and 3)

To prepare for a reception, write to SCON register, setting SM0 and SM1 bits according to Figure 70 on page 130, and setting REN bit. The actual reception is then initiated by a detected high-to-low transition on the RXD pin.

Framing Error Detection (Modes 1, 2 and 3)

Framing error detection is provided for the three asynchronous modes. To enable the framing bit error detection feature, set SMOD0 bit in PCON register as shown in Figure 78.

When this feature is enabled, the receiver checks each incoming data frame for a valid stop bit. An invalid stop bit may result from noise on the serial lines or from simultaneous transmission by two devices. If a valid stop bit is not found, the software sets FE bit in SCON register.

Software may examine FE bit after each reception to check for data errors. Once set, only software or a chip reset clear FE bit. Subsequently received frames with valid stop bits cannot clear FE bit. When the framing error detection feature is enabled, RI rises on stop bit instead of the last data bit as detailed in Figure 76 and Figure 77.

Figure 78. Framing Error Block Diagram
**Baud Rate Selection
(Modes 1 and 3)**

In modes 1 and 3, the Baud Rate is derived either from the Timer 1 or the Internal Baud Rate Generator and allows different baud rate in reception and transmission.

As shown in Figure 79 the selection is done using RBCK and TBCK bits in BDRCON register.

Figure 80 gives the baud rate calculation formulas for each baud rate source while Table 76 details Internal Baud Rate Generator configuration for different peripheral clock frequencies and giving baud rates closer to the standard baud rates.

Baud Rate Selection (Mode 2)   In mode 2, the baud rate can only be programmed to two fixed values: 1/16 or 1/32 of the peripheral clock frequency.

As shown in Figure 81 the selection is done using SMOD1 bit in PCON register.

Figure 82 gives the baud rate calculation formula depending on the selection.

Serial Port Interface (SPI)

Only for AT8xC5122.

The Serial Peripheral Interface module (SPI) which allows full-duplex, synchronous, serial communication between the MCU and peripheral devices, including other MCUs.

Features

Features of the SPI module include the following:

- Full-duplex, three-wire synchronous transfers
- Master or Slave operation
- Eight programmable Master clock rates
- Serial clock with programmable polarity and phase
- Master Mode fault error flag with MCU interrupt capability
- Write collision flag protection

Signal Description

Figure 83 shows a typical SPI bus configuration using one Master controller and many Slave peripherals. The bus is made of three wires connecting all the devices:

Figure 83. Typical SPI Bus
The Master device selects the individual Slave devices by using four pins of a parallel port to control the four $\overline{SS}$ pins of the Slave devices.

Master Output Slave Input (MOSI)

This 1-bit signal is directly connected between the Master Device and a Slave Device. The MOSI line is used to transfer data in series from the Master to the Slave. Therefore, it is an output signal from the Master, and an input signal to a Slave. A byte (8-bit word) is transmitted most significant bit (MSB) first, least significant bit (LSB) last.

Master Input Slave Output (MISO)

This 1-bit signal is directly connected between the Slave Device and a Master Device. The MISO line is used to transfer data in series from the Slave to the Master. Therefore, it is an output signal from the Slave, and an input signal to the Master. A byte (8-bit word) is transmitted most significant bit (MSB) first, least significant bit (LSB) last.

SPI Serial Clock (SCK)

This signal is used to synchronize the data movement both in and out the devices through their MOSI and MISO lines. It is driven by the Master for eight clock cycles which allows to exchange one byte on the serial lines.

Slave Select (SS)

Each Slave peripheral is selected by one Slave Select pin (SS). This signal must stay low for any message for a Slave. Only one Master (SS high level) can drive the network. The Master may select each Slave device by software through port pins (Figure 83). To prevent bus conflicts on the MISO line, only one slave should be selected at a time by the Master for a transmission.

In a Master configuration, the SS line can be used in conjunction with the MODF flag in the SPI Status register (SPSTA) to prevent multiple masters from driving MOSI and SCK (see Section "Error Conditions", page 142).

A high level on the SS pin puts the MISO line of a Slave SPI in a high-impedance state.

The SS pin could be used as a general-purpose if the following conditions are met:

- The device is configured as a Master and the SSDIS control bit in SPCON is set. This kind of configuration can be found when only one Master is driving the network and there is no way that the SS pin will be pulled low. Therefore, the MODF flag in the SPSTA will never be set [1].

- The Device is configured as a Slave with CPHA and SSDIS control bits set [2]. This kind of configuration can happen when the system comprises one Master and one Slave only. Therefore, the device should always be selected and there is no reason that the Master uses the SS pin to select the communicating Slave device.

Baud Rate

In Master mode, the baud rate can be selected from a baud rate generator which is controled by three bits in the SPCON register: SPR2, SPR1 and SPR0. The Master clock is chosen from one of six clock rates resulting from the division of the internal clock by 4, 8, 16, 32, 64 or 128.

Table 83 gives the different clock rates selected by SPR2:SPR1:SPR0

Table 83. SPI Master Baud Rate Selection

SPR2:SPR1:SPR0	Clock Rate	Baud Rate Divisor (BD)
000	Reserved	N/A
001	F_{CK_SPI} /4	4
010	F_{CK_SPI} / 8	8
011	F_{CK_SPI} /16	16
100	F_{CK_SPI} /32	32
101	F_{CK_SPI} /64	64
110	F_{CK_SPI} /128	128
111	Reserved	N/A

1. Clearing SSDIS control bit does not clear MODF.
2. Special care should be taken not to set SSDIS control bit when CPHA = '0' because in this mode, the SS is used to start the transmission.

Operating Modes   The Serial Peripheral Interface can be configured as one of the two modes: Master mode or Salve mode. The configuration and initialization of the SPI module is made through one register:

•   The Serial Peripheral Control register (SPCON)

Once the SPI is configured, the data exchange is made using:

•   SPCON
•   The Serial Peripheral Status register (SPSTA)
•   The Serial Peripheral Data register (SPDAT)

During an SPI transmission, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line (SCK) synchronizes shifting and sampling on the two serial data lines (MOSI and MISO). A Slave Select line (SS) allows individual selection of a Slave SPI device; Slave devices that are not selected do not interfere with SPI bus activities.

When the Master device transmits data to the Slave device via the MOSI line, the Slave device responds by sending data to the Master device via the MISO line. This implies full-duplex transmission with both data out and data in synchronized with the same clock (Figure 85).

Figure 85. Full-duplex Master-Slave Interconnection
Master Mode

The SPI operates in Master mode when the Master bit, MSTR [3], in the SPCON register is set. Only one Master SPI device can initiate transmissions. Software begins the transmission from a Master SPI module by writing to the Serial Peripheral Data Register (SPDAT). If the shift register is empty, the byte is immediately transferred to the shift register. The byte begins shifting out on MOSI pin under the control of the serial clock, SCK. Simultaneously, another byte shifts in from the Slave on the Master's MISO pin. The transmission ends when the Serial Peripheral transfer data flag, SPIF, in SPSTA becomes set. At the same time that SPIF becomes set, the received byte from the Slave is transferred to the receive data register in SPDAT. Software clears SPIF by reading the Serial Peripheral Status register (SPSTA) with the SPIF bit set, and then reading the SPDAT.

When the pin SS is pulled down during a transmission, the data is interrupted and when the transmission is established again, the data present in the SPDAT is resent.

Slave Mode

The SPI operates in Slave mode when the Master bit, MSTR [4], in the SPCON register is cleared. Before a data transmission occurs, the Slave Select pin, SS, of the Slave device must be set to '0'. SS must remain low until the transmission is complete.

In a Slave SPI module, data enters the shift register under the control of the SCK from the Master SPI module. After a byte enters the shift register, it is immediately transferred to the receive data register in SPDAT, and the SPIF bit is set. To prevent an overflow condition, Slave software must then read the SPDAT before another byte enters the shift register [5]. A Slave SPI must complete the write to the SPDAT (shift register) at least one bus cycle before the Master SPI starts a transmission. If the write to the data register is late, the SPI transmits the data already in the shift register from the previous transmission.

Transmission Formats

Software can select any of four combinations of serial clock (SCK) phase and polarity using two bits in the SPCON: the Clock Polarity (CPOL [6]) and the Clock Phase (CPHA[4]). CPOL defines the default SCK line level in idle state. It has no significant effect on the transmission format. CPHA defines the edges on which the input data are sampled and the edges on which the output data are shifted (Figure 86 and Figure 87). The clock phase and polarity should be identical for the Master SPI device and the communicating Slave device.

3. The SPI module should be configured as a Master before it is enabled (SPEN set). Also the Master SPI should be configured before the Slave SPI.

4. The SPI module should be configured as a Slave before it is enabled (SPEN set).

5. The maximum frequency of the SCK for an SPI configured as a Slave is the bus clock speed.

6. Before writing to the CPOL and CPHA bits, the SPI should be disabled (SPEN = '0').

Figure 86. Data Transmission Format (CPHA = 0)
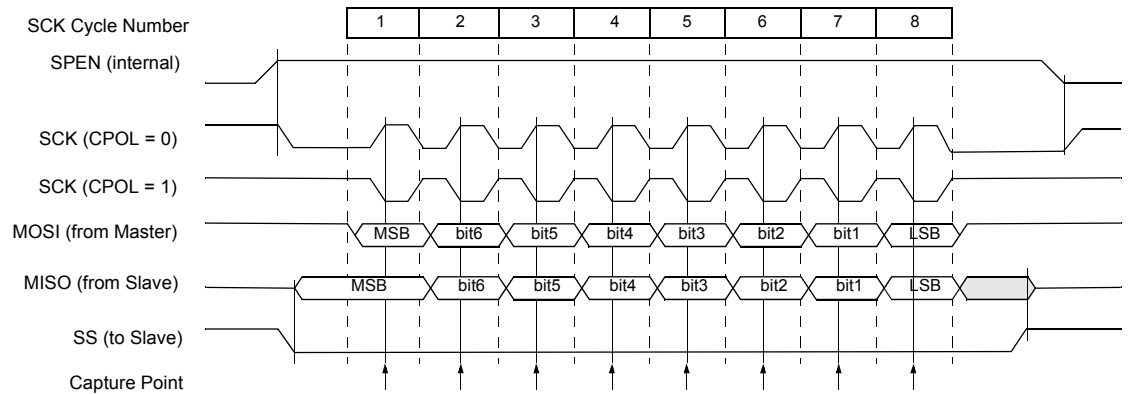

Figure 87. Data Transmission Format (CPHA = 1)
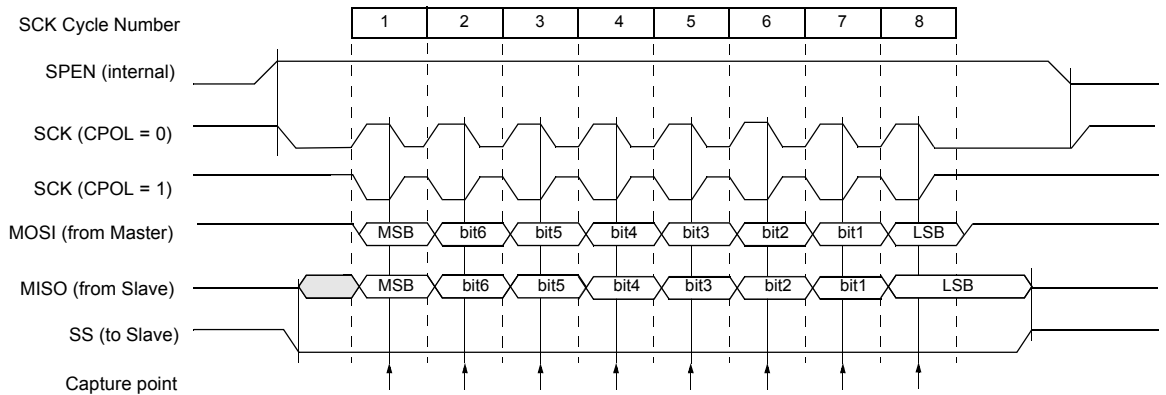

As shown in Figure 86, the first SCK edge is the MSB capture strobe. Therefore the Slave must begin driving its data before the first SCK edge, and a falling edge on the SS pin is used to start the transmission. The SS pin must be toggled high and then low between each byte transmitted (Figure 88).

Figure 88. CPHA/SS Timing
Figure 87 shows an SPI transmission in which CPHA is "1". In this case, the Master begins driving its MOSI pin on the first SCK edge. Therefore, the Slave uses the first SCK edge as a start transmission signal. The SS pin can remain low between transmis-

sions (Figure 88). This format may be preferable in systems having only one Master and only one Slave driving the MISO data line.

Error Conditions   The following flags in the SPSTA signal SPI error conditions.

Mode Fault (MODF)   MODF error bit in Master mode SPI indicates that the level on the Slave Select ($\overline{SS}$) pin is inconsistent with the actual mode of the device. MODF is set to warn that there may have a multi-master conflict for system control. In this case, the SPI system is affected in the following ways:

- An SPI receiver/error CPU interrupt request is generated.
- The SPEN bit in SPCON is cleared. This disable the SPI.
- The MSTR bit in SPCON is cleared.

When $\overline{SS}$ Disable (SSDIS) bit in the SPCON register is cleared, the MODF flag is set when the $\overline{SS}$ signal becomes '0'.

However, as stated before, for a system with one Master, if the $\overline{SS}$ pin of the Master device is pulled low, there is no way that another Master is attempting to drive the network. In this case, to prevent the MODF flag from being set, software can set the SSDIS bit in the SPCON register and therefore making the $\overline{SS}$ pin as a general-purpose I/O pin.

Clearing the MODF bit is accomplished by a read of SPSTA register with MODF bit set, followed by a write to the SPCON register. SPEN Control bit may be restored to its original set state after the MODF bit has been cleared.

Write Collision (WCOL)   A Write Collision (WCOL) flag in the SPSTA is set when a write to the SPDAT register is done during a transmit sequence.

WCOL does not cause an interruption, and the transfer continues uninterrupted.

Clearing the WCOL bit is done through a software sequence of an access to SPSTA and an access to SPDAT.

Overrun Condition   An overrun condition occurs when the Master device tries to send several data bytes and the Slave device has not cleared the SPIF bit issuing from the previous data byte transmitted. In this case, the receiver buffer contains the byte sent after the SPIF bit was last cleared. A read of the SPDAT returns this byte. All others bytes are lost.

This condition is not detected by the SPI peripheral.

SS Error Flag (SSERR)   A Synchronous Serial Slave Error occurs when $\overline{SS}$ goes high before the end of a received data in slave mode. SSERR does not cause in interruption, this bit is cleared by writing 0 to SPEN bit (reset of the SPI state machine).

Interrupts   Two SPI status flags can generate a CPU interrupt requests:

Table 84. SPI Interrupts

Flag	Request
SPIF (SP data transfer)	SPI Transmitter Interrupt request
MODF (Mode Fault)	SPI Receiver/Error Interrupt Request (if SSDIS = '0')

Serial Peripheral data transfer flag, SPIF: This bit is set by hardware when a transfer has been completed. SPIF bit generates transmitter CPU interrupt requests.

Mode Fault flag, MODF: This bit becomes set to indicate that the level on the $\overline{SS}$ is inconsistent with the mode of the SPI. MODF with SSDIS reset, generates receiver/error CPU interrupt requests.

Figure 89 gives a logical view of the above statements.

Figure 89. SPI Interrupt Requests Generation
Registers

There are three registers in the module that provide control, status and data storage functions. These registers are describes in the following paragraphs.

Serial Peripheral Control Register (SPCON)

The Serial Peripheral Control Register does the following:

• Selects one of the Master clock rates
• Configures the SPI module as Master or Slave
• Selects serial clock polarity and phase
• Enables the SPI module
• Frees the $\overline{SS}$ pin for a general-purpose

Bit Number	Bit Mnemonic	R/W Mode	Description
7	SPR2	RW	**Serial Peripheral Rate 2** Bit with SPR1 and SPR0 define the clock rate
6	SPEN	RW	**Serial Peripheral Enable** Clear to disable the SPI interface (internal reset of the SPI) Set to enable the SPI interface
5	SSDIS	RW	**$\overline{SS}$ Disable** Clear to enable $\overline{SS}$ in both Master and Slave modes Set to disable $\overline{SS}$ in both Master and Slave modes. In Slave mode, this bit has no effect if CPHA = '0'
4	MSTR	RW	**Serial Peripheral Master** Clear to configure the SPI as a Slave Set to configure the SPI as a Master
3	CPOL	RW	**Clock Polarity** Clear to have the SCK set to '0' in idle state Set to have the SCK set to '1' in idle low
2	CPHA	RW	**Clock Phase** Clear to have the data sampled when the SPSCK leaves the idle state (see CPOL) Set to have the data sampled when the SPSCK returns to idle state (see CPOL)
1	SPR1	RW	**Serial Peripheral Rate** (SPR2:SPR1:SPR0) 000: Reserved 001: F_{CK_SPI}/4 010: F_{CK_SPI}/8 011: F_{CK_SPI}/16
0	SPR0	RW	100: F_{CK_SPI}/32 101: F_{CK_SPI}/64 110: F_{CK_SPI}/128 111: Reserved

Reset Value = 00010100b

Serial Peripheral Status Register (SPSTA)

The Serial Peripheral Status Register contains flags to signal the following conditions:

• Data transfer complete

• Write collision

• Inconsistent logic level on $\overline{\text{SS}}$ pin (mode fault error)

Table 86. Serial Peripheral Status and Control Register - SPSTA (C4h)

7	6	5	4	3	2	1	0
SPIF	WCOL	SSERR	MODF	-	-	-	-

Bit Number	Bit Mnemonic	R/W Mode	Description
7	SPIF	R	**Serial Peripheral data transfer flag** Clear by hardware to indicate data transfer is in progress or has been approved by a clearing sequence. Set by hardware to indicate that the data transfer has been completed.
6	WCOL	R	**Write Collision flag** Cleared by hardware to indicate that no collision has occurred or has been approved by a clearing sequence. Set by hardware to indicate that a collision has been detected.
5	SSERR	R	**Synchronous Serial Slave Error flag** Set by hardware when $\overline{\text{SS}}$ is modified before the end of a received data. Cleared by disabling the SPI (clearing SPEN bit in SPCON).
4	MODF	R	**Mode Fault** Cleared by hardware to indicate that the $\overline{\text{SS}}$ pin is at appropriate logic level, or has been approved by a clearing sequence. Set by hardware to indicate that the $\overline{\text{SS}}$ pin is at inappropriate logic level
3 - 0	-	RW	**Reserved** The value read from this bit is indeterminate. Do not change these bits.

Reset Value = 00X0XXXXb

Serial Peripheral DATa Register (SPDAT)

The Serial Peripheral Data Register (Table 87) is a read/write buffer for the receive data register. A write to SPDAT places data directly into the shift register. No transmit buffer is available in this model.

A read of the SPDAT returns the value located in the receive buffer and not the content of the shift register.

Table 87. Serial Peripheral Data Register - SPDAT (C5h)

7	6	5	4	3	2	1	0
R7	R6	R5	R4	R3	R2	R1	R0

Bit Number	Bit Mnemonic	Description
7-0	R7:0	**Receive data bits** SPCON, SPSTA and SPDAT registers may be read and written at any time while there is no on-going exchange. However, special care should be taken when writing to them while a transmission is on-going: Do not change SPR2, SPR1 and SPR0 Do not change CPHA and CPOL Do not change MSTR Clearing SPEN would immediately disable the peripheral Writing to the SPDAT will cause an overflow

Reset Value = XXXX XXXXb

Timers/Counters

The AT8xC5122D implements two general-purpose, 16-bit Timers/Counters. Although they are identified as Timer 0, Timer 1, you can independently configure each to operate in a variety of modes as a Timer or as an event Counter. When operating as a Timer, a Timer/Counter runs for a programmed length of time, then issues an interrupt request. When operating as a Counter, a Timer/Counter counts negative transitions on an external pin. After a preset number of counts, the Counter issues an interrupt request.

The Timer registers and associated control registers are implemented as addressable Special Function Registers (SFRs). Two of the SFRs provide programmable control of the Timers as follows:

• Timer/Counter mode control register (TMOD) and Timer/Counter control register (TCON) control respectively Timer 0 and Timer 1.

The various operating modes of each Timer/Counter are described below.

Timer/Counter Operations

For example, a basic operation is Timer registers THx and TLx (x= 0, 1) connected in cascade to form a 16-bit Timer. Setting the run control bit (TRx) in the TCON register (see Table 88 on page 152) turns the Timer on by allowing the selected input to increment TLx. When TLx overflows, it increments THx and when THx overflows it sets the Timer overflow flag (TFx) in the TCON register. Setting the TRx does not clear the THx and TLx Timer registers. Timer registers can be accessed to obtain the current count or to enter preset values. They can be read at any time but the TRx bit must be cleared to preset their values, otherwise the behavior of the Timer/Counter is unpredictable.

The C/Tx# control bit selects Timer operation or Counter operation by selecting the divided-down system clock or the external pin Tx as the source for the counted signal. The TRx bit must be cleared when changing the operating mode, otherwise the behavior of the Timer/Counter is unpredictable.

For Timer operation (C/Tx#= 0), the Timer register counts the divided-down system clock. The Timer register is incremented once every peripheral cycle.

Exceptions are the Timer 2 Baud Rate and Clock-out modes in which the Timer register is incremented by the system clock divided by two.

For Counter operation (C/Tx#= 1), the Timer register counts the negative transitions on the Tx external input pin. The external input is sampled during every S5P2 state. The Programmer's Guide describes the notation for the states in a peripheral cycle. When the sample is high in one cycle and low in the next one, the Counter is incremented. The new count value appears in the register during the next S3P1 state after the transition has been detected. Since it takes 12 states (24 oscillator periods) to recognize a negative transition, the maximum count rate is 1/24 of the oscillator frequency. There are no restrictions on the duty cycle of the external input signal, but to ensure that a given level is sampled at least once before it changes, it should be held for at least one full peripheral cycle.

Timer 0

Timer 0 functions as either a Timer or an event Counter in four operating modes. Figure 90 through Figure 96 show the logic configuration of each mode.

Timer 0 is controlled by the four lower bits of the TMOD register (see Table 89 on page 153) and bits 0, 1, 4 and 5 of the TCON register (see Table 88 on page 152). The TMOD register selects the method of Timer gating (GATE0), Timer or Counter operation (T/C0#) and the operating mode (M10 and M00). The TCON register provides Timer 0 control functions: overflow flag (TF0), run control bit (TR0), interrupt flag (IE0) and interrupt type control bit (IT0).

For normal Timer operation (GATE0= 0), setting TR0 allows TL0 to be incremented by the selected input. Setting GATE0 and TR0 allows external pin INT0# to control Timer operation.

Timer 0 overflow (count rolls over from all 1s to all 0s) sets the TF0 flag and generates an interrupt request.

It is important to stop the Timer/Counter before changing modes.

Mode 0 (13-bit Timer)   Mode 0 configures Timer 0 as a 13-bit Timer which is set up as an 8-bit Timer (TH0 register) with a modulo-32 prescaler implemented with the lower five bits of the TL0 register (see Figure 90). The upper three bits of the TL0 register are indeterminate and should be ignored. Prescaler overflow increments the TH0 register.

Figure 91 gives the overflow period calculation formula.

Figure 90. Timer/Counter x (x= 0 or 1) in Mode 0
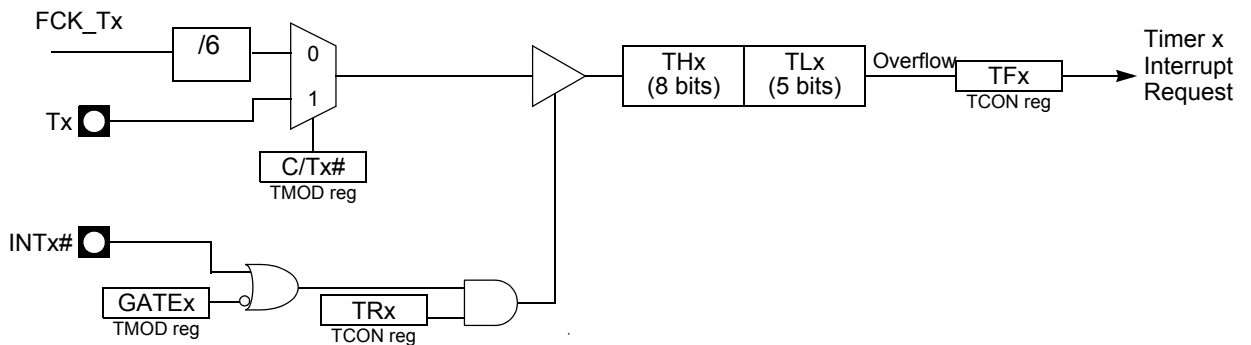

Figure 91. Mode 0 Overflow Period Formula

$$TFx_{PER} = \frac{6 \cdot (16384 - (THx, TLx))}{F_{CK\_Tx}}$$

Mode 1 (16-bit Timer)   Mode 1 configures Timer 0 as a 16-bit Timer with the TH0 and TL0 registers connected in a cascade (see Figure 92). The selected input increments the TL0 register.

Figure 93 gives the overflow period calculation formula when in timer mode.

Figure 92. Timer/Counter x (x = 0 or 1) in Mode 1
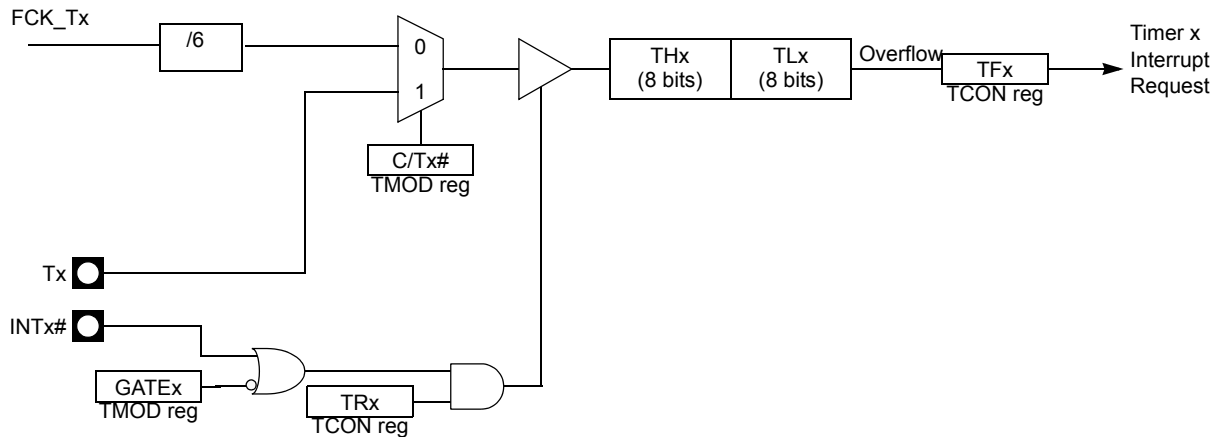

Figure 93. Mode 1 Overflow Period Formula

$$TFx_{PER} = \frac{6 \cdot (65536 - (THx, TLx))}{F_{CK\_Tx}}$$

Mode 2 (8-bit Timer with Auto-Reload)

Mode 2 configures Timer 0 as an 8-bit Timer (TL0 register) that automatically reloads from the TH0 register (see Figure 94). TL0 overflow sets the TF0 flag in the TCON register and reloads TL0 with the contents of TH0, which is preset by the software. When the interrupt request is serviced, the hardware clears TF0. The reload leaves TH0 unchanged. The next reload value may be changed at any time by writing it to the TH0 register.

Figure 95 gives the autoreload period calculation formula when in timer mode.

Figure 94. Timer/Counter x (x = 0 or 1) in Mode 2
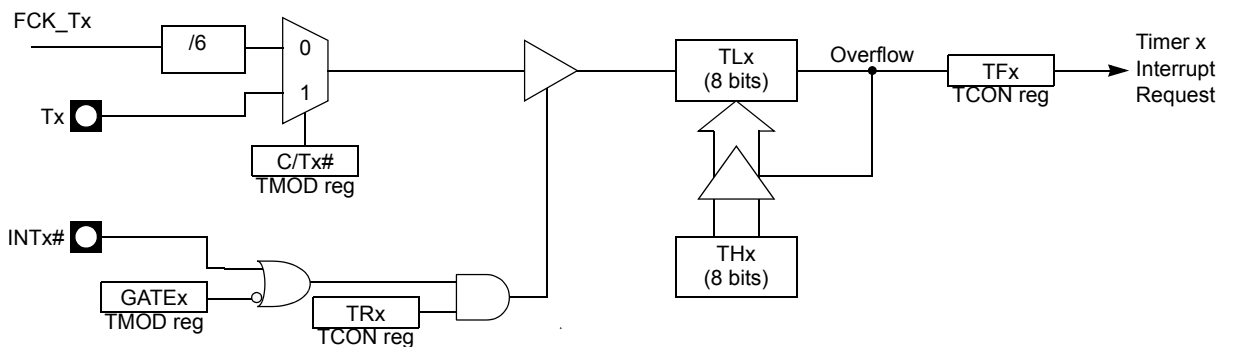

Figure 95. Mode 2 Autoreload Period Formula

$$TFx_{PER} = \frac{6 \cdot (256 - THx)}{F_{CK\_Tx}}$$

Mode 3 (Two 8-bit Timers)   Mode 3 configures Timer 0 so that registers TL0 and TH0 operate as 8-bit Timers (see Figure 96). This mode is provided for applications requiring an additional 8-bit Timer or Counter. TL0 uses the Timer 0 control bits C/T0# and GATE0 in the TMOD register, and TR0 and TF0 in the TCON register in the normal manner. TH0 is locked into a Timer function (counting F_{UART}) and takes over use of the Timer 1 interrupt (TF1) and run control (TR1) bits. Thus, operation of Timer 1 is restricted when Timer 0 is in mode 3.

Figure 97 gives the autoreload period calculation formulas for both TF0 and TF1 flags.

Figure 96. Timer/Counter 0 in Mode 3: Two 8-bit Counters
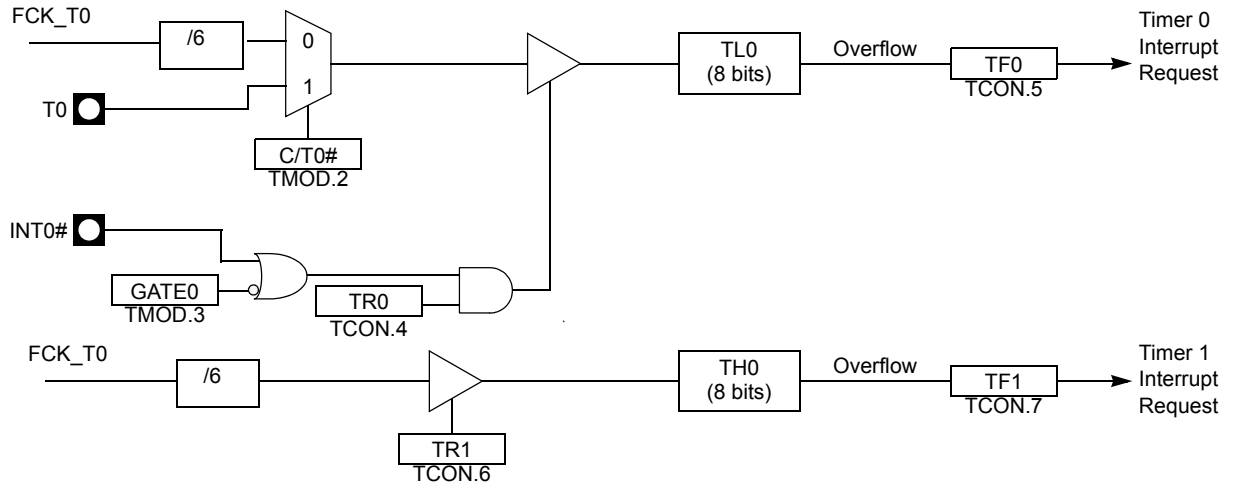

Figure 97. Mode 3 Overflow Period Formula

$$TF0_{PER =} \frac{6 \cdot (256 - TL0)}{F_{CK\_T0}} \qquad\qquad TF1_{PER =} \frac{6 \cdot (256 - TH0)}{F_{CK\_T0}}$$

Timer 1   Timer 1 is identical to Timer 0 except for Mode 3 which is a hold-count mode. The following comments help to understand the differences:

- Timer 1 functions as either a Timer or an event Counter in three operating modes. Figure 90 through Figure 94 show the logical configuration for modes 0, 1, and 2. Mode 3 of Timer 1 is a hold-count mode.

- Timer 1 is controlled by the four high-order bits of the TMOD register (see Table 89 on page 153) and bits 2, 3, 6 and 7 of the TCON register (see Table 88 on page 152). The TMOD register selects the method of Timer gating (GATE1), Timer or Counter operation (C/T1#) and the operating mode (M11 and M01). The TCON register provides Timer 1 control functions: overflow flag (TF1), run control bit (TR1), interrupt flag (IE1) and the interrupt type control bit (IT1).

- Timer 1 can serve as the Baud Rate Generator for the Serial Port. Mode 2 is best suited for this purpose.

- For normal Timer operation (GATE1 = 0), setting TR1 allows TL1 to be incremented by the selected input. Setting GATE1 and TR1 allows external pin INT1# to control Timer operation.

- Timer 1 overflow (count rolls over from all 1s to all 0s) sets the TF1 flag and generates an interrupt request.

- When Timer 0 is in mode 3, it uses Timer 1's overflow flag (TF1) and run control bit (TR1). For this situation, use Timer 1 only for applications that do not require an interrupt (such as a Baud Rate Generator for the Serial Port) and switch Timer 1 in and out of mode 3 to turn it off and on.

- It is important to stop the Timer/Counter before changing modes.

Mode 0 (13-bit Timer)   Mode 0 configures Timer 1 as a 13-bit Timer, which is set up as an 8-bit Timer (TH1 register) with a modulo-32 prescaler implemented with the lower 5 bits of the TL1 register (see Figure 90). The upper 3 bits of TL1 register are ignored. Prescaler overflow increments the TH1 register.

Mode 1 (16-bit Timer)   Mode 1 configures Timer 1 as a 16-bit Timer with TH1 and TL1 registers connected in cascade (see Figure 92). The selected input increments the TL1 register.

Mode 2 (8-bit Timer with Auto-Reload)   Mode 2 configures Timer 1 as an 8-bit Timer (TL1 register) with automatic reload from the TH1 register on overflow (see Figure 94). TL1 overflow sets the TF1 flag in the TCON register and reloads TL1 with the contents of TH1, which is preset by the software. The reload leaves TH1 unchanged.

Mode 3 (Halt)   Placing Timer 1 in mode 3 causes it to halt and hold its count. This can be used to halt Timer 1 when the TR1 run control bit is not available i.e. when Timer 0 is in mode 3.

Keyboard Interface   Only for AT8xC5122.

Introduction   The AT8xC5122/23 implements a keyboard interface allowing the connection of a 8 x n matrix keyboard. It is based on 8 inputs with programmable interrupt capability on both high or low level. These inputs are available as alternate function of P5 and allow to exit from idle and power-down modes.

Description   The keyboard interfaces with the C51 core through 3 special function registers: KBLS, the Keyboard Level Selection register (Table 96 on page 158), KBE, The Keyboard interrupt Enable register (Table 95 on page 157), and KBF, the Keyboard Flag register (Table).

Interrupt   The keyboard inputs are considered as 8 independent interrupt sources sharing the same interrupt vector. An interrupt enable bit (KBD in IE1) allows global enable or disable of the keyboard interrupt (see Figure 98). As detailed in Figure 99 each keyboard input has the capability to detect a programmable level according to KBLS.x bit value. Level detection is then reported in interrupt flags KBF.x that can be masked by software using KBE.x bits.

This structure allows keyboard arrangement from 1 by n to 8 by n matrix and allows usage of P5 inputs for other purpose.

The KBF.x flags are set by hardware when an active level is on input P5.x. They are automatically reset after any read access on KBF. If the content of KBF must be analyzed, the first read instruction must transfer KBF contend to another location. The KBF register cannot be written by software.

Figure 98. Keyboard Interface Block Diagram
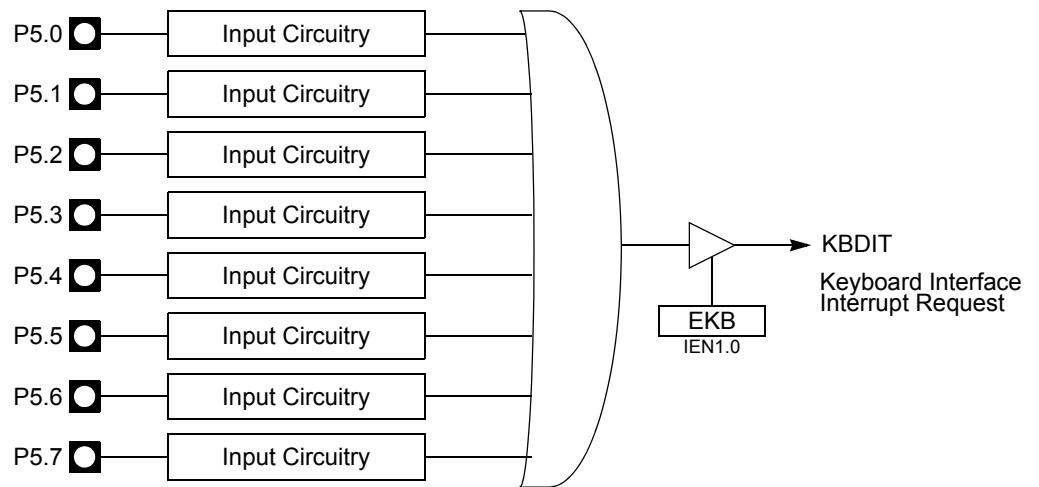

Figure 99. Keyboard Input Circuitry
Power Reduction Mode   P5 inputs allow exit from idle and power-down modes as detailed in Section "Power-Down Mode".

Interrupt System

Introduction

The AT8xC5122/23 implements an interrupt controller with 15 inputs but only 9 are used for :

–   two external interrupts ($\overline{INT0}$ and $\overline{INT1}$)
–   two timer interrupts (timers 0, 1),
–   the UART interface
–   the SPI interface
–   the keyboard interface
–   the USB interface
–   the Smart Card Interface.

Interrupt System Description

Each of the interrupt sources can be individually enabled or disabled by setting or clearing a bit in the Interrupt Enable registers (Table 98 on page 162 and Table 99 on page 163). These registers also contain a global disable bit, which must be cleared to disable all interrupts at once.

Each interrupt source can also be individually programmed to one out of four priority levels by setting or clearing a bit in the Interrupt Priority Low registers (Table 101 on page 164 and Table 103 on page 166) and in the Interrupt Priority High register (Table 102 on page 165 and Table 105 on page 168) shows the bit values and priority levels associated with each combination.

A low-priority interrupt can be interrupted by a high priority interrupt, but not by another low-priority interrupt. A high-priority interrupt can't be interrupted by any other interrupt source.

If two interrupt requests of different priority levels are received simultaneously, the request of higher priority level is serviced. If interrupt requests of the same priority level are received simultaneously, an internal polling sequence determines which request is serviced first. Thus within each priority level there is a second priority structure determined by the polling sequence.

Table 97. Priority Level Bit Values

IPH.x	IPL.x	Interrupt Level Priority
0	0	0 (Lowest)
0	1	1
1	0	2
1	1	3 (Highest)

Figure 100. Interrupt Control System

note (1) : Not applicable to AT83C5123
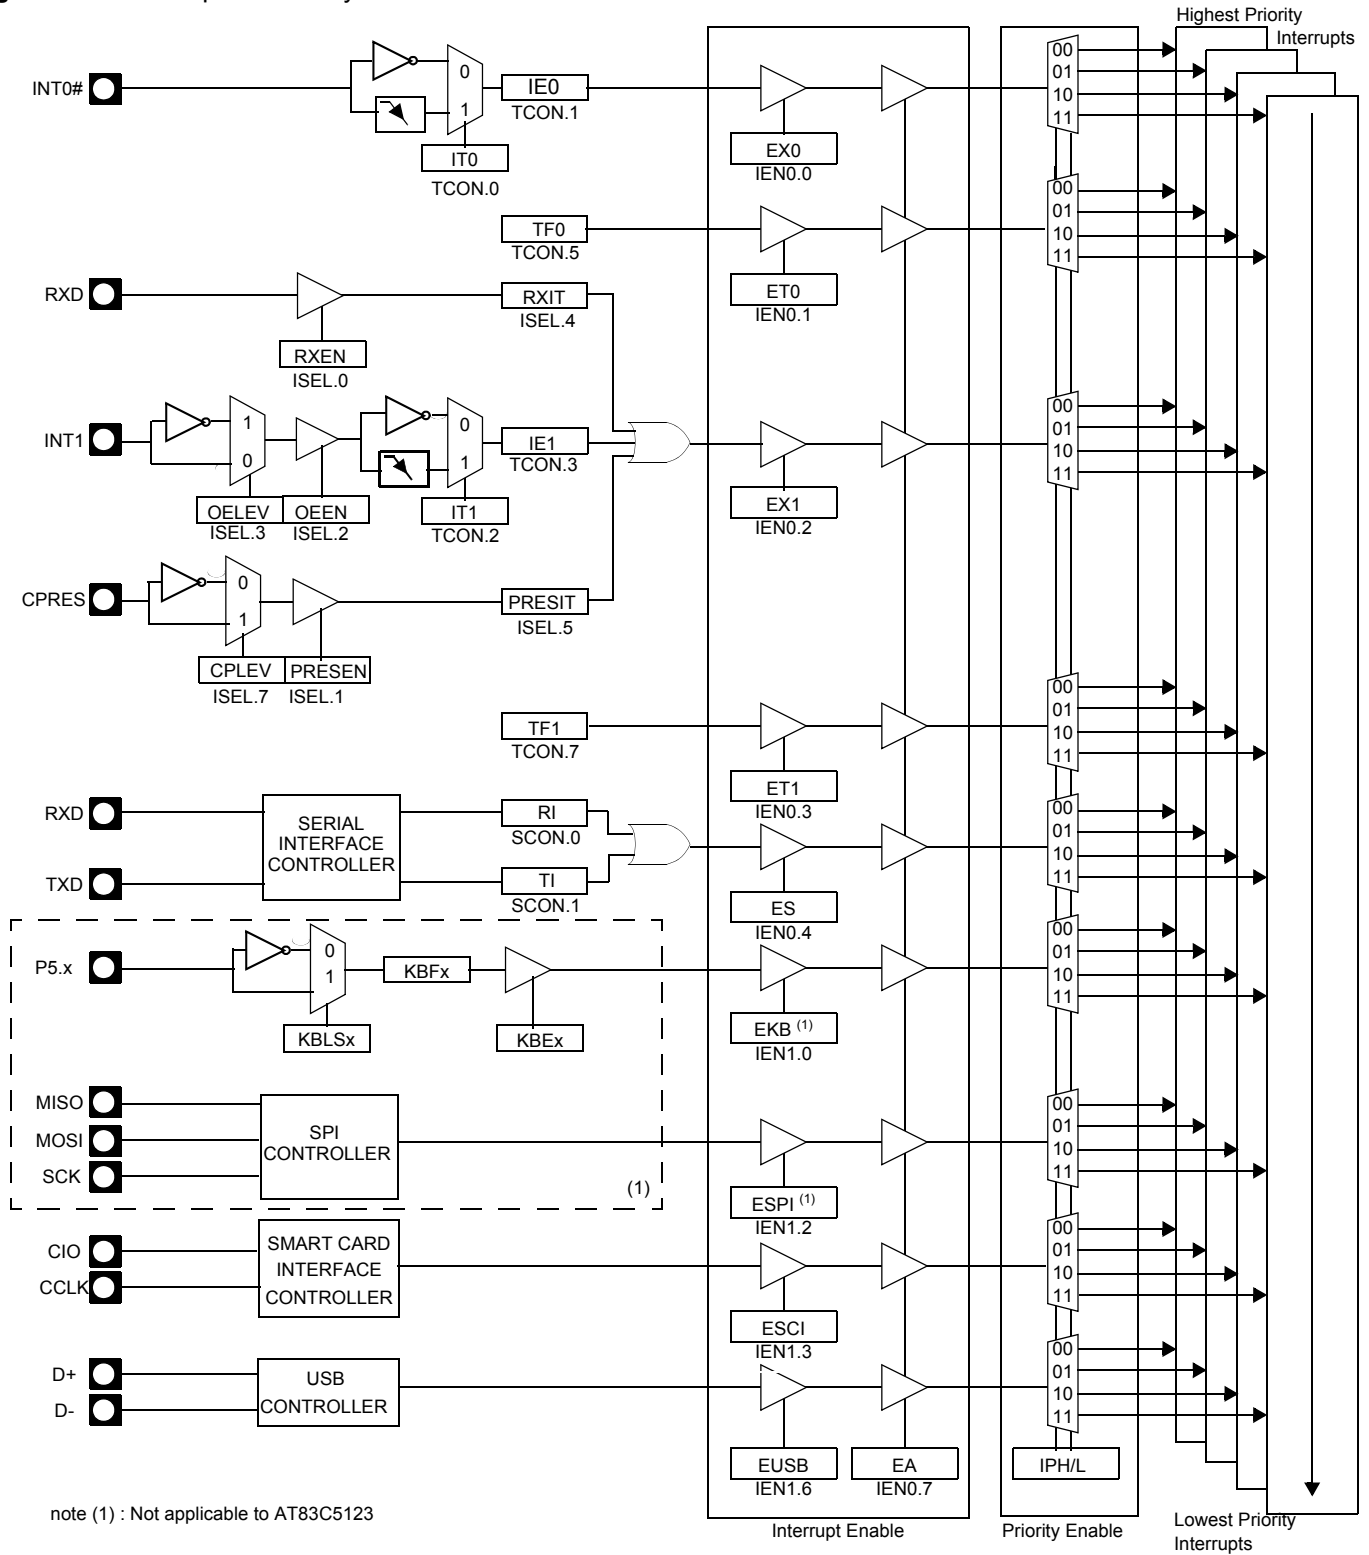

INT1 Interrupt Vector   The INT1 interrupt is multiplexed with the following three inputs:

- INT1 : Standard 8051 interrupt input
- RXD : Received data on UART
- CPRES: Insertion or remove of the main card

The setting configurations for each input is detailed below.

INT1 Input   This interrupt input is active under the following conditions :

- It must be enabled by OEEN Bit (ISEL Register)
- It can be active on a level or falling edge following IT1 Bit (TCON Register) status
- If level triggering selection is set, the active level 0 or 1 can be selected with OELEV Bit (ISEL Register)

The Bit IE1 (TCON Register) is set by hardware when external interrupt detected. It is cleared when interrupt is processed.

RXD Input   A second vector interrupt input is the reception of a character. UART Rx input can generate an interrupt if enabled with Bit RXEN (ISEL.0). The global enable bits EX1 and EA must also be set.

Then, the Bit RXIT (ISEL Register) is set by hardware when a low level is detected on P3.0/RXD input.

CPRES Input   The third input is the detection of a level change on CPRES input (P1.2). This input can generate an interrupt if enabled with PRESEN (ISEL.1) , EX1 (IE0.2) and EA (IE0.7) Bits.

This detection is done according to the level selected with Bit CPLEV (ISEL.7).

Then the Bit PRESIT (ISEL.5) is set by hardware when the triggering conditions are met. This Bit must be cleared by software.

Registers

Table 98. Interrupt Enable Register 0 - IEN0 (A8h)

7	6	5	4	3	2	1	0
EA	-	-	ES	ET1	EX1	ET0	EX0

Bit Number	Bit Mnemonic	Description
7	EA	**Enable All interrupt bit** Cleared to disable all interrupts. Set to enable all interrupts.
6 - 5	-	**Reserved** The value read from this bit is indeterminate. Do not change these bits.
4	ES	**Serial port Enable bit** Cleared to disable serial port interrupt. Set to enable serial port interrupt.
3	ET1	**Timer 1 overflow interrupt Enable bit** Cleared to disable timer 1 overflow interrupt. Set to enable timer 1 overflow interrupt.
2	EX1	**External interrupt 1 Enable bit** Cleared to disable external interrupt 1. Set to enable external interrupt 1.
1	ET0	**Timer 0 overflow interrupt Enable bit** Cleared to disable timer 0 overflow interrupt. Set to enable timer 0 overflow interrupt.
0	EX0	**External interrupt 0 Enable bit** Cleared to disable external interrupt 0. Set to enable external interrupt 0.

Microcontroller Reset

Introduction

The internal reset is used to start up (cold reset) or to re-start (warm reset) the micro-controller activity. When the reset is applied (active state), all internal registers are initialized so that the microcontroller starts from a known and clean state for the program always runs as expected.

The reset is released (inactive state) when the following conditions are internally met :

– The power supply has reatched a minimum level which garantees that the microcontroller works properly
– The on-chip oscillator has reached a minimum oscillation level which ensures a good noise to signal ratio and a correct internal duty cycle
– the active state duration is at least two machine cycles.

If one of the above conditions is not met the microcontroller is not correctly reset and might not work properly.

The internal reset comes from four different sources :

– Reset pin
– Power On Reset (POR)
– Power Fail Detector (PFD)
– Hardware Watch-Dog Timer (WDT)

Figure 101. Reset bock diagram
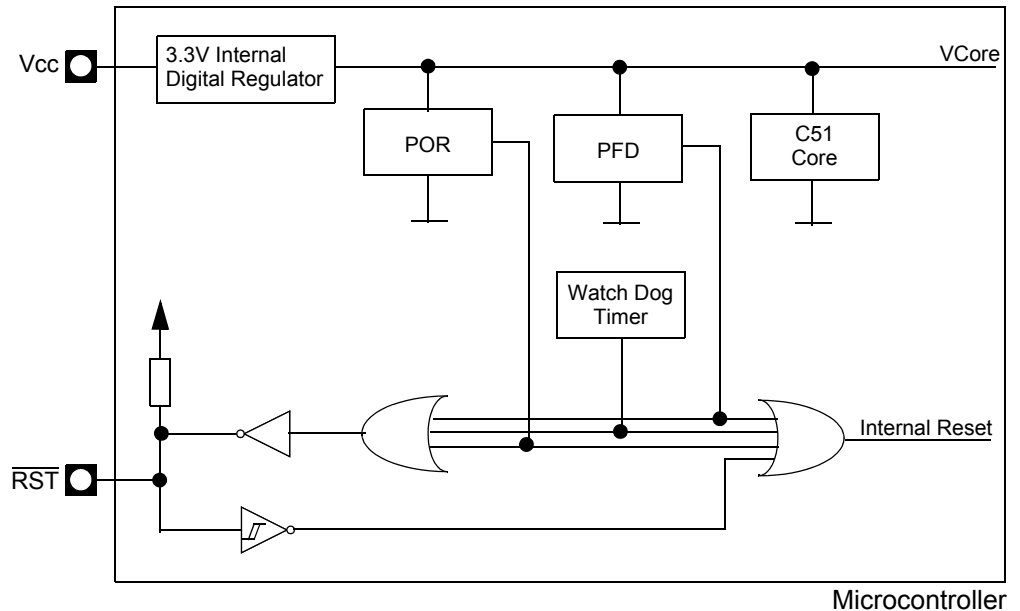

Power On Reset (POR)

The role of the POR is to monitor the power supply rise of the microcontroller core and release the internal reset only when the internal voltage exceeds the VPFDP threshold from which the microcontroller core is stable (see Figure 102). This feature replaces the external reset function and therefore avoid the use of external components on the reset pin.

Power Fail Detector (PFD)

The role of the PFD is to monitor the power supply falls during a steady state condition in order to suspend the microcontroller and peripherals activity as soon as the power supply drops below the VPFDM threshold from which the microcontroller's core might become instable (see Figure 102). The PDF suspends the microcontroller's activity by holding the microcontroller under a reset state to avoid an unpredictable behaviour.

A filter prevents the system from reseting when glitches lower than 50 ns duration are carried on Vcore. See Figure 102 and Figure 103 on page 174.

Figure 102. Static behaviour of POR and PFD
Figure 103. Dynamic behaviour of POR and PFD
Reset pin

As explained in the POR section there is no need to use the reset pin as the internal reset function at power up is ensured by the POR. Anyway, if some applications requires a long reset, a reset controlled by the user or a reset controlled by external superviser device, the use of the reset pin is necessary.

Long Reset

As the pad integrates an internal pull-up of 10K, only an external capacitor of at least 10 µF is required to have an impact on the reset duration.

Figure 104. Long Reset
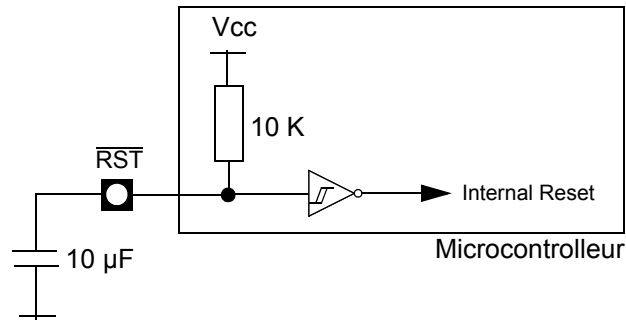

Reset Controlled by the User

The external capacitor is not needed if no long reset is required.

Figure 105. Reset Controlled by the User
Reset Controlled by an External Superviser Device

As the reset pin can be forced in output by the Watch-Dog timer (WDT) or the POR/PFD features, there can be a conflict between the external superviser device and the micro-controller's reset pin when in one side the external superviser is pulling the reset pin to VCC and in another side the WDT or POR/PFD features tries to force the reset pin to ground. Therefore, it recommended to insert a series resistor of 1.8K +/-10% or a diode (1N4148 for instance) between the external superviser device and the reset pin as detailed in the following figures.

Figure 106. Use of an External Serial Resistor
Figure 107. Use of an External Diode
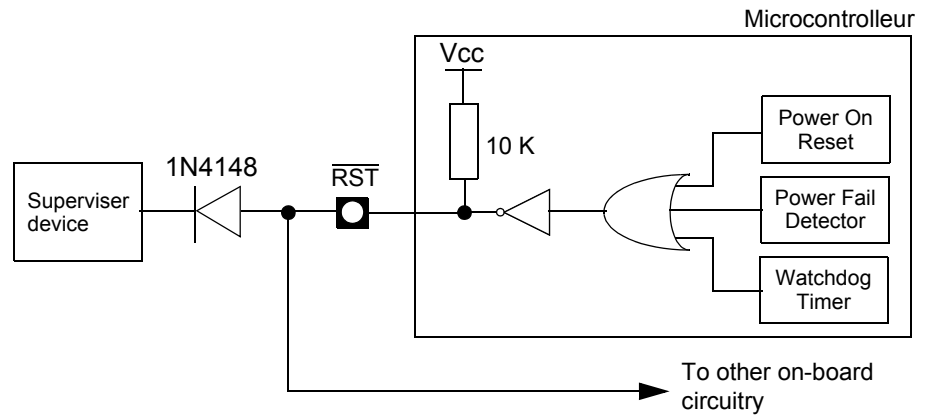

Watchdog Timer

The AT8xC5122/23 microcontrollers contain a powerfull programmable hardware Watchdog Timer (WDT) that automatically resets the chip if its software fails to reset the WDT before the selected time interval has elapsed. It permits large timeout ranking from 4ms to 524ms @ F_{CK_WD} = 24 MHz / X2

This WDT consist of a 14-bit counter plus a 7-bit programmable counter, a Watchdog Timer reset register (WDTRST) and a Watchdog Timer programmation (WDTPRG) register. When exiting the reset, the WDT is, by default, disabled. To activate the WDT, the user has to write the sequence 1EH and E1H into WDRST register. When the Watchdog Timer is enabled, it will increment every machine cycle while the oscillator is running and there is no way to disable the WDT except through reset (either hardware reset or WDT overflow reset). When WDT overflows, it will generate an output RESET pulse at the RST pin. The RESET pulse duration is $96xT_{OSC}$, where T_{OSC}=1/F_{OSC}. To make the best use of the WDT, it should be serviced in those sections of code that will periodically be executed within the time required to prevent a WDT reset.

The WDT is controlled by two registers (WDTRST and WDTPRG).

Figure 108. Watchdog Timer
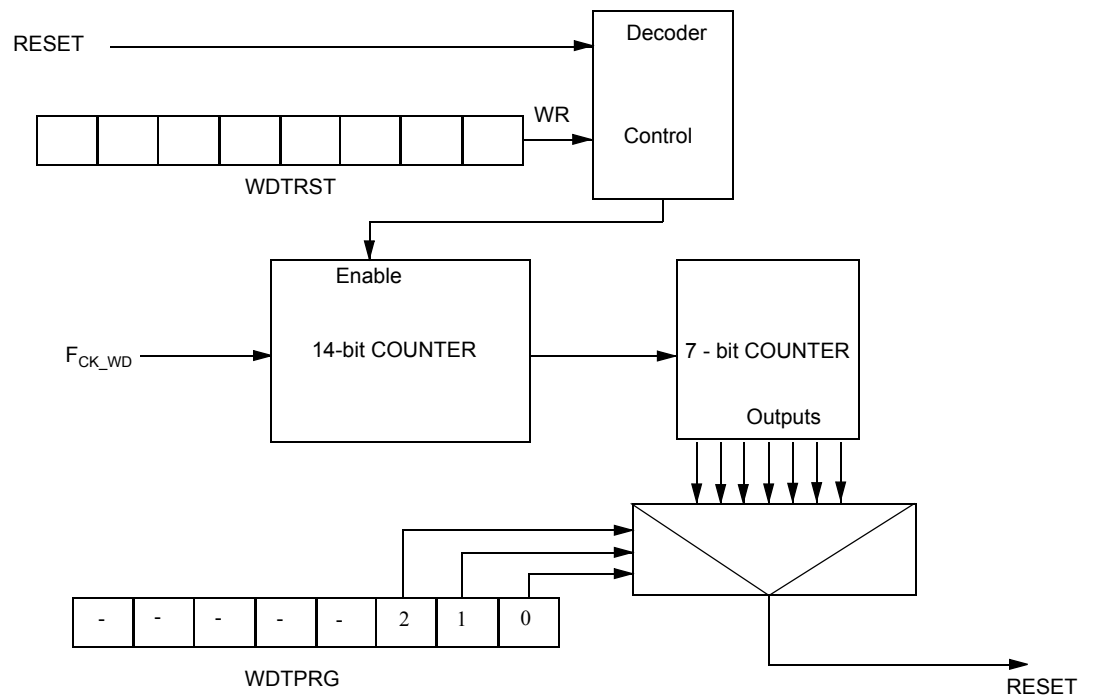

Table 109. Watchdog Timer Out Register - WDTPRG (0A7h)

7	6	5	4	3	2	1	0
-	-	-	-	-	S2	S1	S0

Bit Number	Bit Mnemonic	Description
7 - 3	-	**Reserved** The value read from this bit is indeterminate. Do not change these bits.
2	S2	WDT Time-out select bit 2
1	S1	WDT Time-out select bit 1
0	S0	WDT Time-out select bit 0

Reset Value = XXXX X000b

The three lower bits (S0, S1, S2) located into WDTPRG register enables to program the WDT duration.

Table 110. Machine Cycle Count

S2	S1	S0	Machine Cycle Count
0	0	0	$2^{14} - 1$
0	0	1	$2^{15} - 1$
0	1	0	$2^{16} - 1$
0	1	1	$2^{17} - 1$
1	0	0	$2^{18} - 1$
1	0	1	$2^{19} - 1$
1	1	0	$2^{20} - 1$
1	1	1	$2^{21} - 1$

To compute WD Timeout, the following formula must be applied:

$$\text{Time Out} = 6 * (2^{14} * 2^{\text{Svalue}} - 1) / F_{CK\_WD}$$

Note: Svalue represents the decimal value of (S2 S1 S0)

Table 111. Timeout value for F_{CK_WD} = 24 MHz / X2

S2	S1	S0	Timeout for F_{CK_WD}= 24 MHz / X2
0	0	0	4.10 ms
0	0	1	8.19 ms
0	1	0	16.38 ms
0	1	1	32.77 ms
1	0	0	65.54 ms
1	0	1	131.07 ms
1	1	0	262.14 ms
1	1	1	524.29 ms

Table 112. Watchdog Timer Enable register (Write Only) - WDTRST (A6h)

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	-

Reset Value = XXXX XXXXb

The WDTRST register is used to reset / enable the WDT by writing 1EH then E1H in sequence.

Power Management

Before activating the Idle Mode or Power Down Mode, the CPU clock must be switched to on-chip oscillator source if the PLL is used to fed the CPU clock.

Idle Mode

An instruction that sets PCON.0 indicates that it is the last instruction to be executed before going into the Idle mode. In the Idle mode, the internal clock signal is gated off to the CPU, but not to the interrupt, Timer, and Serial Port functions. The CPU status is preserved in its entirety: the Stack Pointer, Program Counter, Program Status Word, Accumulator and all other registers maintain their data during Idle. The port pins hold the logical states they had at the time Idle was activated. ALE and PSEN hold at logic high level.

There are two ways to terminate the Idle mode. Activation of any enabled interrupt will cause PCON.0 to be cleared by hardware, terminating the Idle mode. The interrupt will be serviced, and following RETI the next instruction to be executed will be the one following the instruction that put the device into idle.

The flag bits GF0 and GF1 can be used to give an indication if an interrupt occured during normal operation or during an Idle. For example, an instruction that activates Idle can also set one or both flag bits. When Idle is terminated by an interrupt, the interrupt service routine can examine the flag bits.

The other way of terminating the Idle mode is with a hardware reset. Since the clock oscillator is still running, the hardware reset needs to be held active for only two machine cycles (24 oscillator periods) to complete the reset.

Power Down Mode

To save maximum power, a power-down mode can be invoked by software (see Table 13, PCON register).

WARNING: To minimize power consumption, all peripherals and I/Os with static current consumption must be set in the proper state. I/Os programmed with low speed output configuration (KB_OUT) must be switch to push-pull or Standard C51 configuration before entering power-down. The CVCC generator must also be switch off.

In power-down mode, the oscillator is stopped and the instruction that invoked power-down mode is the last instruction executed. The internal RAM and SFRs retain their value until the power-down mode is terminated. V_{CC} can be lowered to save further power. Either a hardware reset or an external interrupt can cause an exit from power-down. To properly terminate power-down, the reset or external interrupt should not be executed before V_{CC} is restored to its normal operating level and must be held active long enough for the oscillator to restart and stabilize.

Only external interrupts $\overline{INT0}$, $\overline{INT1}$, Keyboard, Card insertion/removal and USB Interrupts are useful to exit from power-down. For that, interrupt must be enabled and configured as level or edge sensitive interrupt input. When Keyboard Interrupt occurs after a power-down mode, 1024 clocks are necessary to exit to power-down mode and enter in operating mode.

Holding the pin low restarts the oscillator but bringing the pin high completes the exit as detailed in Figure 109. When both interrupts are enabled, the oscillator restarts as soon as one of the two inputs is held low and power-down exit will be completed when the first input is released. In this case, the higher priority interrupt service routine is executed. Once the interrupt is serviced, the next instruction to be executed after RETI will be the one following the instruction that put AT8xC5122/23 into power-down mode.

Figure 109. Power-down Exit Waveform
Exit from power-down by reset redefines all the SFRs, exit from power-down by external interrupt does no affect the SFRs.

Exit from power-down by either reset or external interrupt does not affect the internal RAM content.

Note: If idle mode is activated with power-down mode (IDL and PD bits set), the exit sequence is unchanged, when execution is vectored to interrupt, PD and IDL bits are cleared and idle mode is not entered.

Table shows the state of ports during idle and power-down modes.

Table State of Ports

Mode	Program Memory	ALE	PSEN	P0	P1	P2	P3	P4	P5
Idle	Internal	1	1	Port Data[1]	Port Data	Port Data	Port Data	Port Data	Port Data
Idle	External	1	1	Floating	Port Data	Address	Port Data	Port Data	Port Data
Power-down	Internal	0	0	Port Dat*	Port Data	Port Data	Port Data	Port Data	Port Data
Power-down	External	0	0	Floating	Port Data	Port Data	Port Data	Port Data	Port Data

Note: 1.   Port 0 can force a 0 level. A "one" will leave port floating.

Reduced EMI Mode   The ALE signal is used to demultiplex address and data buses on port 0 when used with external program or data memory. Nevertheless, during internal code execution, ALE signal is still generated. In order to reduce EMI, ALE signal can be disabled by setting AO bit.

The AO bit is located in AUXR register at bit location 0. As soon as AO is set, ALE is no longer output but remains active during MOVX and MOVC instructions and external fetches. During ALE disabling, ALE pin is weakly pulled high.

USB Interface

Suspend

The Suspend state can be detected by the USB controller if all the clocks are enabled and if the USB controller is enabled. The bit SPINT is set by hardware when an idle state is detected for more than 3 ms. This triggers a USB interrupt if enabled.

In order to reduce current consumption, the firmware can put the USB PAD in idle mode, stop the clocks and put the C51 in Idle or Power-down mode. The Resume detection is still active.

The USB PAD is put in idle mode when the firmware clear the SPINT bit. In order to avoid a new suspend detection 3ms later, the firmware has to disable the USB clock input using the SUSPCLK bit in the USBCON Register. The USB PAD automatically exits of idle mode when a wake-up event is detected.

The stop of the 48 MHz clock from the PLL should be done in the following order:

1. Disable of the 48 MHz clock input of the USB controller by setting to 1 the SUS-PCLK bit in the USBCON register.

2. If CPU clock is fed from PLL, the on-chip oscillator must be selected to fed the CPU clock.

3. Disable the PLL by clearing the PLLEN bit in the PLLCON register.

Resume

When the USB controller is in Suspend state, the Resume detection is active even if all the clocks are disabled and if the C51 is in Idle or Power-down mode. The WUPCPU bit is set by hardware when a non-idle state occurs on the USB bus. This triggers an interrupt if enabled. This interrupt wakes up the CPU from its Idle or Power-down state and the interrupt function is then executed. The firmware will first enable the 48 MHz generation and then reset to 0 the SUSPCLK bit in the USBCON register if needed.

The firmware has to clear the SPINT bit in the USBINT register before any other USB operation in order to wake up the USB controller from its Suspend mode.

The USB controller is then re-activated.

Figure 110. Example of a Suspend/Resume Management
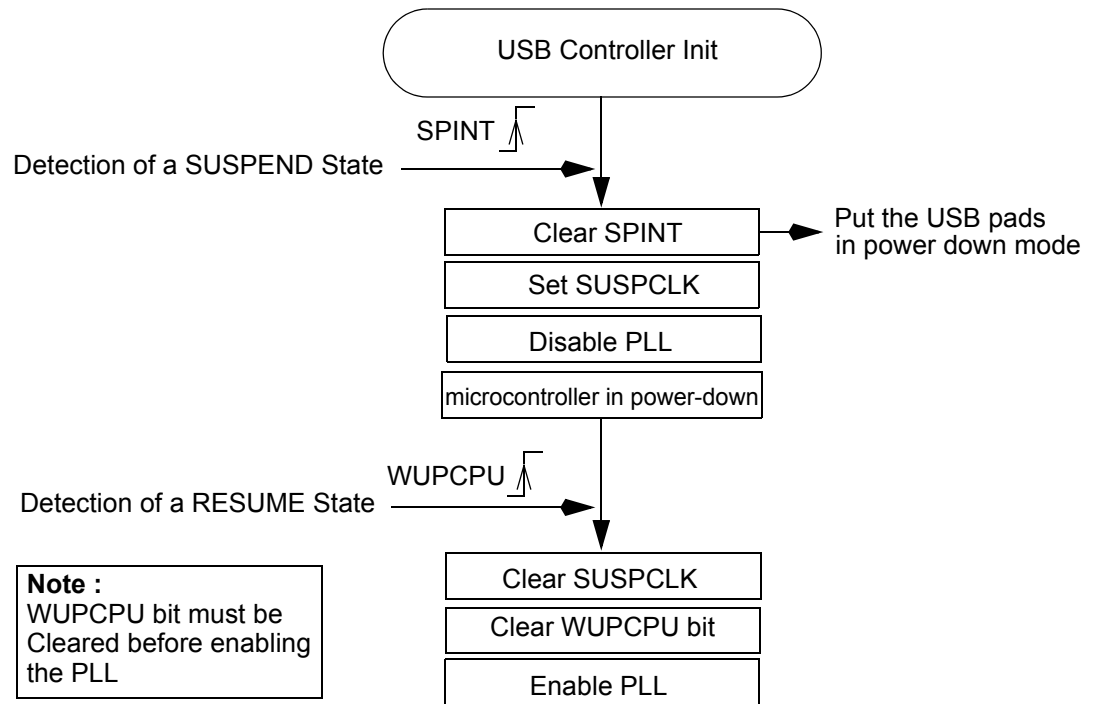

Smart Card Interface

Entering in Power-down Mode   In order to reduce the power consumption, a power-down or idle mode can be invoked by software (see Table 13, PCON register). Before activating these modes the application will need to:

Power-off the Smart Card Interface by applying the following sequence:

•   Set CRST pin at low level by clearing the bit CARDRST in SCCON register.

•   Set CCLK pin at low level by clearing the bit CLK then the CARDCLK in SCCON register.

•   Set CIO pin at low level by clearing the bit UART in SCICR register then the bit CARDIO in SCCON register.

•   Power the Smart Interface off by clearing the CARDVCC bit in SCCON register. This instruction enables to switch DC/DC converter off.

CPRES input:

•   Set the bit PRSEN in ISEL register

•   Set the bit EX1 in IE0 register

•   Set the bit EA in the IE0 register

•   Invert the bit CPLEV in ISEL register (INT1 interrupt vector)

•   Clear the bit PRESIT in the ISEL register

Exiting from Power-down Mode   The microcontroller will exit from Power-down or Idle modes upon a reset or INT1 interrupt which is a multiplexing of the interruptions generated by the CPRES pin (Card detection), RxD flag (UART reception) and INT1 pin.

Keyboard Interface   The keyboard interface applies only to AT8xC5122 version.

Entering in Power-down Mode   In order to reduce the power consumption, the microcontroller can be set in power-down or idle mode by software (see Table 13, PCON register). Before activating these modes the application will need to configure the keyboard interface as follows:

- Set all keyboard's ouputs pins KB Rx at low level by writing a 0 on the ports. This operation has a double effect:
    - any key that is pressed generates an interrupt capable of waking-up the microcontroller,
    - Set all bits KBE.x in KBE registers to enable interrupts.

Exiting from Power-down Mode   The microcontroller will exit from Power-down Mode upon a reset or any interrupt generated by a key press. Note that 1024 clocks are necessary to exit from power-down mode when a keyboard interrupt occurs. This means that there will be a delay between the time at which the key is pressed and the time at which the application is able to identify the key.

Watchdog Timer during Power-down and Idle Mode   In Power-down mode the oscillator stops, which means the WDT also stops. While in Power-down mode the user does not need to service the WDT. There are 2 methods of exiting Power-down mode : by a hardware reset or by a level activated external interrupt which is enabled prior to entering power-down mode. When Power-down is exited with hardware reset, servicing the WDT should occur as it normally does whenever AT8xC5122D is reset. Exiting Power-down with an interrupt is significantly different. The interrupt is held low long enough for the oscillator to stabilize. When the interrupt is brought high, the interrupt is serviced. To prevent the WDT from resetting the device while the interrupt pin is held low, the WDT is not started until the interrupt is pulled high. It is suggested that the WDT be reset during the interrupt service for the interrupt used to exit Power-down.

To ensure that the WDT does not overflow within a few states of exiting of powerdown, it is best to reset the WDT just before entering powerdown.

In the Idle mode, the oscillator continues to run. To prevent the WDT from resetting while the microcontroller is in Idle mode, the user should always set up a timer that will periodically exit Idle, service the WDT, and re-enter Idle mode.

Registers

Table 113. Power Control Register - PCON (S:87h)

7	6	5	4	3	2	1	0
SMOD1	SMOD0	-	POF	GF1	GF0	PD	IDL

Bit Number	Bit Mnemonic	Description
7	SMOD1	**Serial port Mode bit 1 for UART** Set to select double baud rate in mode 1,2 or 3
6	SMOD0	**Serial port Mode bit 0 for UART** Cleared to select SM0 bit in SCON register Set to select FE bit in SCON register
5	-	**Reserved** The value read from this bit is indeterminate. Do not change this bit.
4	POF	**Power-Off Flag (Only for ROM version parts)** Cleared to recognize next reset type Set by hardware when VCC rises from 0 to its nominal voltage. Can also be set by software **Warning** : in CRAM and FLASH versions, this bit is reserved.
3	GF1	**General purpose Flag** Cleared by user for general-purpose usage Set by user for general-purpose usage
2	GF0	**General purpose Flag** Cleared by user for general-purpose usage Set by user for general-purpose usage
1	PD	**Power-Down mode bit** Cleared by hardware when reset occurs Set to enter power-down mode
0	IDL	**Idle mode bit** Cleared by hardware when interrupt or reset occurs Set to enter idle mode

Reset Value = 00X1 0000b

Power-off flag reset value will be 1 only after a power on (cold reset). A warm reset doesn't affect the value of this bit.

Electrical Characteristics

Absolute Maximum Ratings

Ambiant Temperature Under Bias ....-25°C to 85°C
Storage Temperature .... -65°C to + 150°C
Voltage on V_{CC} to V_{SS} ....-0.5 V to + 6.0V
Voltage on Any Pin to V_{SS}........................-0.5 V to V_{CC} + 0.5 V
Power Dissipation 1 W

Note: Stresses at or above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

Power Dissipation value is based on the maximum allowable die temperature and the thermal resistance of the package.

DC Parameters

T_A = -40 to +85°C; V_{SS} = 0 V, F_{CK_CPU}= 0 to 24 MHz , V_{CC} = 3.6V to 5.5V

Symbol	Parameter	Min	Typ	Max	Unit	Test Conditions

	Voltage Stability	-0.25 CV_{CC}-0.5		$0.4 \times CV_{CC}$ CV_{CC} + 0.25		Low level High level

Note: 1. The voltage on RST should remain between -0.3V and V_{CC}+0.3V during dynamic operation.

Card Presence (P1.2) DC Parameters

Symbol	Parameter	Min	Typ	Max	Unit	Test Conditions
I_{OL1}	CPRES weak pull-up output current	3	10	25	μA	P1.2=1, short to VSS Pull-up enabled

USB Interface

Figure 113. USB Interface

Symbol	Parameter	Min	Typ[5]	Max	Unit
V_{REF}	USB Reference Voltage	3.0		3.6	V
V_{IH}	Input High Voltage for D+ and D- (driven)	2.0		4.0	V
V_{IHZ}	Input High Voltage for D+ and D- (floating)	2.7		3.6	V
V_{IL}	Input Low Voltage for D+ and D-			0.8	V
V_{OH}	Output High Voltage for D+ and D-	2.8		3.6	V
V_{OL}	Output Low Voltage for D+ and D-	0.0		0.3	V

AC Parameters

Explanation of the AC Symbols

Each timing symbol has 5 characters. The first character is always a "T" (stands for time). The other characters, depending on their positions, stand for the name of a signal or the logical status of that signal. The following is a list of all the characters and what they stand for.

Example: T_{AVLL} = Time for Address Valid to ALE Low.
T_{LLPL} = Time for ALE Low to $\overline{PSEN}$ Low.

T_A = -40°C to +85°C; V_{SS} = 0V; V_{CC} = 3.6V to 5.5V ; F_{CK_CPU} = 0 to 24 MHz.

(Load Capacitance for port 0, ALE and PSEN = 60 pF; Load Capacitance for all other outputs = 60 pF.)

Table and Table 118 give the description of each AC symbols.

Table 117 and Table 120 give for each range the AC parameter.

Table 115, Table 117 and Table 119 give the frequency derating formula of the AC parameter for each speed range description. To calculate each AC symbols. take the x value and use this value in the formula.

Example: T_{LLIV} and 20 MHz, Standard clock.
x = 30 ns
T = 50 ns
T_{CCIV} = 4T - x = 170 ns

External Program Memory Characteristics

Table 114. Symbol Description

Symbol	Parameter
T	CPU clock period (F_{CK_CPU})
T_{LHLL}	ALE pulse width
T_{AVLL}	Address Valid to ALE
T_{LLAX}	Address Hold After ALE
T_{LLIV}	ALE to Valid Instruction In
T_{LLPL}	ALE to $\overline{PSEN}$
T_{PLPH}	$\overline{PSEN}$ Pulse Width
T_{PLIV}	$\overline{PSEN}$ to Valid Instruction In
T_{PXIX}	Input Instruction Hold After $\overline{PSEN}$
T_{PXIZ}	Input Instruction Float After $\overline{PSEN}$
T_{AVIV}	Address to Valid Instruction In
T_{PLAZ}	$\overline{PSEN}$ Low to Address Float

Table 115. AC Parameters for a Variable Clock

Symbol	Type	Standard clock	X2 Clock	X parameter	Units
T_{LHLL}	Min	2T - x	T - x	15	ns
T_{AVLL}	Min	T - x	0.5 T - x	20	ns
T_{LLAX}	Min	T - x	0.5 T - x	20	ns
T_{LLIV}	Max	4T - x	2 T - x	35	ns
T_{LLPL}	Min	T - x	0.5 T - x	15	ns
T_{PLPH}	Min	3T - x	1.5 T - x	25	ns
T_{PLIV}	Max	3T - x	1.5 T - x	45	ns
T_{PXIX}	Min	x	x	0	ns
T_{PXIZ}	Max	T - x	0.5 T - x	15	ns
T_{AVIV}	Max	5T - x	2.5 T - x	45	ns
T_{PLAZ}	Max	x	x	10	ns

External Program Memory Read Cycle
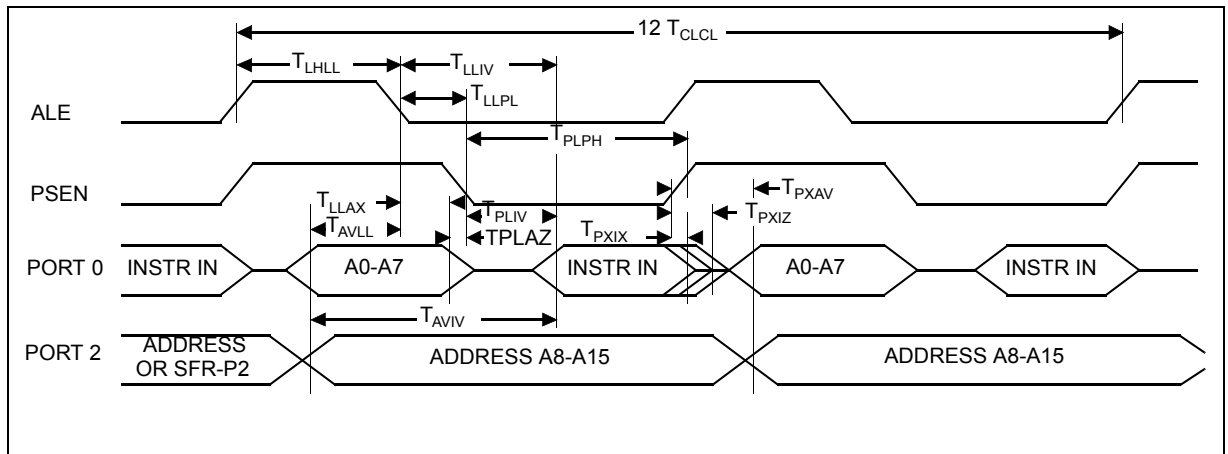

External Data Memory Characteristics

Table 116. Symbol Description

Symbol	Parameter
T_{RLRH}	$\overline{RD}$ Pulse Width
T_{WLWH}	$\overline{WR}$ Pulse Width
T_{RLDV}	$\overline{RD}$ to Valid Data In
T_{RHDX}	Data Hold After $\overline{RD}$
T_{RHDZ}	Data Float After $\overline{RD}$
T_{LLDV}	ALE to Valid Data In
T_{AVDV}	Address to Valid Data In
T_{LLWL}	ALE to $\overline{WR}$ or $\overline{RD}$
T_{AVWL}	Address to $\overline{WR}$ or $\overline{RD}$
T_{QVWX}	Data Valid to $\overline{WR}$ Transition
T_{QVWH}	Data set-up to $\overline{WR}$ High
T_{WHQX}	Data Hold After $\overline{WR}$
T_{RLAZ}	$\overline{RD}$ Low to Address Float
T_{WHLH}	$\overline{RD}$ or $\overline{WR}$ High to ALE high

Table 117. AC Parameters for a Variable Clock

Symbol	Type	Standard Clock	X2 Clock	X parameter	Units
T_{RLRH}	Min	6T - x	3 T - x	20	ns
T_{WLWH}	Min	6T - x	3 T - x	20	ns
T_{RLDV}	Max	5T - x	2.5 T - x	25	ns
T_{RHDX}	Min	x	x	0	ns
T_{RHDZ}	Max	2T - x	T - x	20	ns
T_{LLDV}	Max	8T - x	4T - x	40	ns
T_{AVDV}	Max	9T - x	4.5 T - x	60	ns
T_{LLWL}	Min	3T - x	1.5 T - x	25	ns
T_{LLWL}	Max	3T + x	1.5 T + x	25	ns
T_{AVWL}	Min	4T - x	2 T - x	25	ns
T_{QVWX}	Min	T - x	0.5 T - x	15	ns
T_{QVWH}	Min	7 T - x	3.5 T - x	25	ns
T_{WHQX}	Min	T - x	0.5 T - x	10	ns
T_{RLAZ}	Max	x	x	0	ns
T_{WHLH}	Min	T - x	0.5 T - x	15	ns
T_{WHLH}	Max	T - x	0.5 T + x	15	ns

(warning x value differ from AT89C51RD2)

External Data Memory Write Cycle

Serial Port Timing - Shift Register Mode

Table 118. Symbol Description (F = 40 MHz)

Symbol	Parameter
T_{XLXL}	Serial port clock cycle time
T_{QVHX}	Output data set-up to clock rising edge
T_{XHQX}	Output data hold after clock rising edge
T_{XHDX}	Input data hold after clock rising edge
T_{XHDV}	Clock rising edge to input data valid

Table 119. AC Parameters for a Variable Clock

Symbol	Type	Standard Clock	X2 Clock	X parameter	Units
T_{XLXL}	Min	12T	6 T		ns
T_{QVHX}	Min	10T - x	5 T - x	50	ns
T_{XHQX}	Min	2T - x	T - x	20	ns
T_{XHDX}	Min	x	x	0	ns
T_{XHDV}	Max	10T - x	5 T- x	133	ns

Shift Register Timing Waveform
External Clock Drive Characteristics (XTAL1)

Table 120. AC Parameters

Symbol	Parameter	Min	Max	Units
T_{CLCL}	Oscillator Period	125		ns
T_{CHCX}	High Time	5		ns
T_{CLCX}	Low Time	5		ns
T_{CLCH}	Rise Time		5	ns
T_{CHCL}	Fall Time		5	ns
T_{CHCX}/T_{CLCX}	Cyclic ratio in X2 mode	40	60	%

External Clock Drive Waveforms
AC Testing Input/Output Waveforms
AC inputs during testing are driven at V_{CC} - 0.5 for a logic "1" and 0.45V for a logic "0".
Timing measurement are made at V_{IH} min for a logic "1" and V_{IL} max for a logic "0".

Float Waveforms
For timing purposes as port pin is no longer floating when a 100 mV change from load voltage occurs and begins to float when a 100 mV change from the loaded V_{OH}/V_{OL} level occurs. $I_{OL}/I_{OH} \geq \pm 20$ mA.

Clock Waveforms Valid in normal clock mode. In X2 mode XTAL2 must be changed to XTAL2/2.
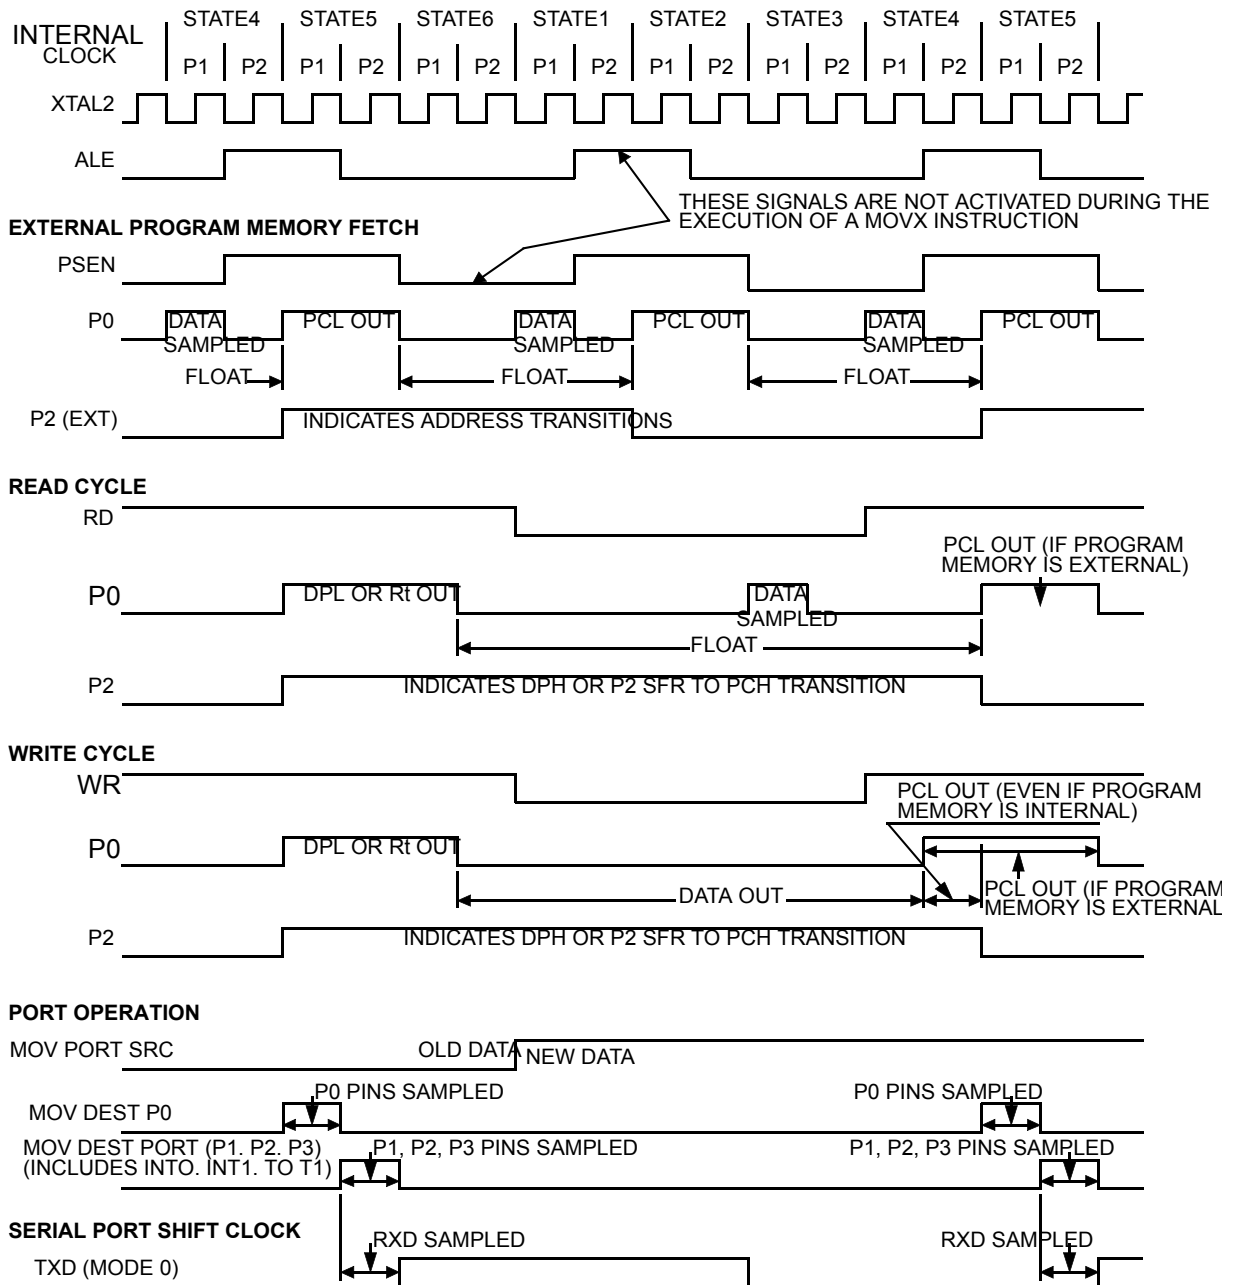

This diagram indicates when signals are clocked internally. The time it takes the signals to propagate to the pins, however, ranges from 25 to 125 ns. This propagation delay is dependent on variables such as temperature and pin loading. Propagation also varies from output to output and component. Typically though (T_A=25°C fully loaded) $\overline{RD}$ and $\overline{WR}$ propagation delays are approximately 50 ns. The other signals are typically 85 ns. Propagation delays are incorporated in the AC specifications.

USB Interface
Symbol	Parameter	Min	Typ[5]	Max	Unit
t_R	Rise Time	4		20	ns
t_F	Fall Time	4		20	ns
t_{FDRATE}	Full-speed Data Rate	11.9700		12.0300	Mb/s
V_{CRS}	Crossover Voltage	1.3		2.0	V
t_{DJ1}	Source Jitter Total to next transaction	-3.5		3.5	ns
t_{DJ2}	Source Jitter Total for paired transactions	-4		4	ns
t_{JR1}	Receiver Jitter to next transaction	-18.5		18.5	ns
t_{JR2}	Receiver Jitter for paired transactions	-9		9	ns

Change Log

Changes from 4202A to 4202B

1. Product AT8xEC5122 added.
2. Products AT83C5123 and AT83EC5123 added.

Changes from 4202B to 4202C

1. All sections updated.
2. QFN64 and QFN32 packages added.
3. SCIB section : VCC must be higher than 4.0V when DC/DC is operated at 5V.

Changes from 4202C to 4202D

1. Product AT89C5122DS added (EA pin changed to VCC)
2. Typical applications section: external pull-up shown on CIO pin
3. Ports section : Detailed explanations on CIO, CC4, CC8 quasi-bidirectional ports
4. Ordering information section: AT89C5122DS part-numbers added
