

## HIGH PERFORMANCE CURRENT MODE PWM CONTROLLERS

# Description

GM384XA series is high performance with fixed-frequency current mode PWM controllers. They are specially designed for off-Line and DC-to-DC converter applications. They require minimal external components to precisely tailor performance in a wide variety of applications.

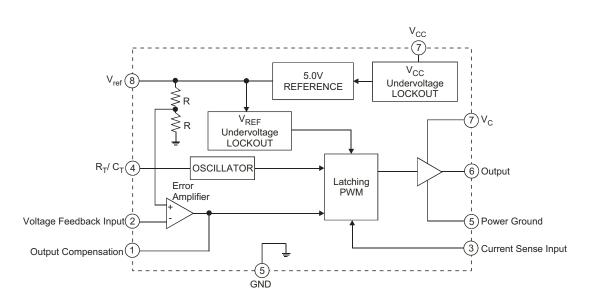

GM384XA series includes a trimmed oscillator for precise duty cycle control, a temperature-compensated reference, high gain error amplifier, a current-sensing comparator, and a high-current totem pole output for driving a power MOSFET.

On-chip protection features include undervoltage lockouts with hysteresis for both input and reference, cycle-by-cycle current limiting, programmable output deadtime, and a latch for single pulse metering. All these are in a simple DIP-8 or SOP-8 package!

GM3842A and GM3844A have UVLO thresholds of 16V (on)/10V(off); GM3843A and GM3845A have UVLO thresholds of 8.4V (on)/ 7.6V (off). GM3842A and GM3843A operate within 100% duty cycle; GM3844A and GM3845A operate within 50% duty cycle.

# **Features**

- Low Start-Up and Operating Current
- Automatic Feed Forward Compensation
- Current Mode Operating Frequency up to 500kHz
- Trimmed Oscillator Discharge Current for Precise Duty Cycle Control
- Latching PWM for Cycle-By-Cycle Current Limiting
- Undervoltage Lockout with Hysteresis
- High Current Totem Pole Output
- The GM384XA Have Start-up Current 0.17mA

HIGH PERFORMANCE CURRENT MODE PWM CONTROLLERS

# ♦ ABSOLUTE MAXIMUM RATINGS

PARAMETER	SYMBOL	VALUE	UNIT
Supply Voltage (low impedance source)	V <sub>cc</sub>	30	V
Output Current, Source or Sink *	Ι <sub>ο</sub>	±1.0	А
Input Voltage (analog inputs pins 2)	V	- 0.3 to + 5.5	V
Maximum Power Dissipation (T <sub>A</sub> = 25°C)	P <sub>D</sub>	1.0	W
Error Amp Output Sink Current	I <sub>SINK(E.A)</sub>	10	mA
Storage Temperature Range	T <sub>stg</sub>	- 65 to + 150	°C
Lead Temperature (soldering 5 sec.)	Τ <sub>L</sub>	260	°C

\* Note: Maximum Package Power Dissipation Limits must be observed.

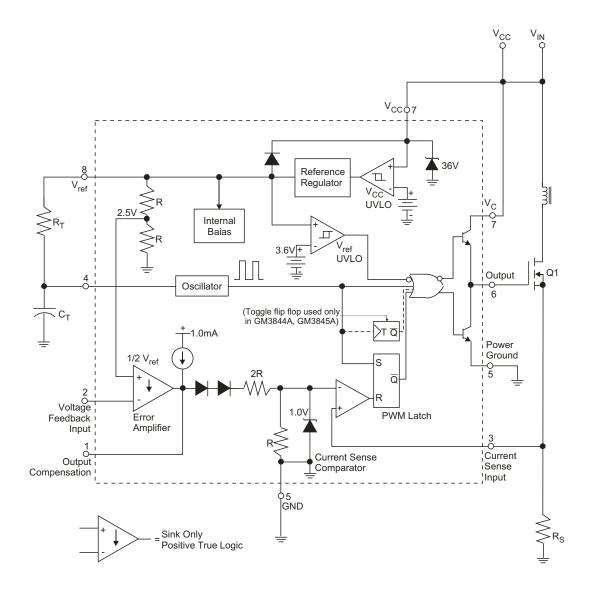

# ♦ PACKAGE PIN DESCRIPTION

PIN lead	FUNCTION	FUNCTION
1	COMP	This pin is Error Amplifier output and is made available for loop compensation.
2	$V_{FB}$	This is the inverting input of the Error Amplifier. It is normally connected to the switching power supply output through a resistor divider.
3	ISENSE	A voltage proportional to inductor current connected to this input. The PWM uses this information to terminate the output switch conduction.
4	R <sub>T</sub> / C <sub>T</sub>	Oscillator frequency and maximum Output cycle are programmed by connecting resistor $\rm R_T$ to $\rm V_{REF}$ and capacitor $\rm C_T$ to ground.
5	GND	This pin is the combined control circuitry and power ground.
6	Output	This output directly drives the gate of a power MOSFET. Peak current up to 1.0A are sourced and sunk by this pin.
7	V <sub>CC</sub>	This pin is the positive supply of the control integrated circuit (IC)
8	V <sub>REF</sub>	This is the reference output. It provides charging current for capacitor $C_{\mbox{T}}$ through resistor $R_{\mbox{T}}$

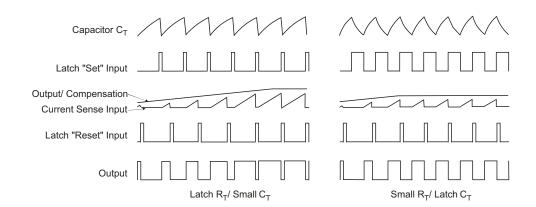

HIGH PERFORMANCE CURRENT MODE PWM CONTROLLERS

# ♦ TYPICAL PERFORMANCE CHARACTERISTICS

GM3842A, GM3843A, GM3844A, GM3845A

#### HIGH PERFORMANCE CURRENT MODE PWM CONTROLLERS

# OPERATING DESCRIPTION

GM3842A, GM3843A, GM3844A and GM3845A are high performance with fixed frequency, current mode controllers. They are designed for off-ine and DC-to-DC converter applications offering great versatility with minimal external components. A representative block diagram is shown on page 4.

#### Oscillator

The oscillator frequency is determined by the values of the timing components  $R_T$  and  $C_T$ . Capacitor  $C_T$  is charged from the 5.0 V reference through resistor  $R_T$  to approximately 2.8 V and discharged to 1.2 V by an internal current sink. During the of  $C_T$ , the oscillator generates an internal blanking pulse that holds the center input of the NOR gate high. This causes the output to be in a low state, thus producing a controlled amount of Figure 2 show  $R_T$  versus oscillator frequency and Figure 2, Output deadtime versus frequency, both for given values of  $C_T$  output deadtime.

Note that different values of  $R_T$  and  $C_T$  will give the same oscillator frequency, but only one combination will yield a specific output deadtime at a given frequency. The oscillator thresholds are temperature compensated. These interned circuit vefinements minimizes refinements of oscillator frequency and maximum output duty cycle. In many noise sensitive applications, it may be desirable to frequency-lock the converter to an external system clock. This can be accmplished by applying a clock signal to the circuit shown in Figure 9. For best locking results, set the free-unning oscillator frequency to about 10% less than the clock frequency. A method for multi unit synchronization is shown in Figure 10. You can get very accurate output duty cycle clamping by tweaking the clock waveform.

#### **Error Amplifier**

GM384XA series has a fully compensated error amplifier with access to both the inverting input and output, and providing DC voltage gain of 90 dB (typical). The noninverting input is internally biased at 2.5 V and is not pinned out. The converter output voltage is typically divided down and monitored by the inverting input. The maximum input bias current is -2.0  $\mu$ A, which can cause an output voltage error that is equal to the product of the input bias current and the equivalent input divider source resistance.

The Error Amplifier Output (Pin 1) allows external loop compensation. The output voltage is offset by the two diode drops ( $\approx$  1.4 V) and divided by three before it connects to the inverting input of the Current Sense Comparator. This assures that no drive pulses appear at the Output (Pin 6) when Pin 1 is at its lowest state (V<sub>OL</sub>). This happens when the power supply is operating and the load is removed, or at the beginning of a soft-start interval (Figures 11, 12). The Error Amp minimum feedback resistance is limited by the amplifier's source current (0.5 mA) and the required output voltage (V<sub>OH</sub>) to reach the comparator's 1.0 V clamp level:

$$R_{f(min)} \approx \frac{3.0(1.0V) + 1.4V}{0.5mA} = 8800$$

#### **Current Sense Comparator and PWM Latch**

GM384XA series operates as a current mode controller, whereby output switch conduction is initiated by the oscillator and terminated when the peak inductor current reaches the threshold level established by the Error Amplifier Output/Compensation (Pin1). The error signal controls the peak inductor current cycle-by-cycle basis. The Current Sense Comparator PWM Latch configuration assures that only a single pulse appears at the Output during any given oscillator cycle. The inductor current is converted to a voltage by inserting the ground-referenced sense resistor  $R_{\rm S}$  in series with the source of output switch Q1. This voltage is monitored by the Current Sense Input (Pin 3) and compared to a level derived from the Error Amp Output. The peak inductor current under normal operating conditions is controlled by the voltage at pin 1 where:

$$I_{pk} = \frac{V_{(PIN1)} - 1.4V}{3 R_S}$$

When the power supply output is overloaded or if output voltage sensing is lost, the chip operation is not normal. In these situations, the Current Sense Comparator threshold will be internally clamped to 1.0 V and the maximum peak switch current is:

$$I_{pk(mak)} = \frac{1.0V}{R_S}$$

#### HIGH PERFORMANCE CURRENT MODE PWM CONTROLLERS

When designing a high power switching regulator, it becomes desirable to reduce the internal clamp voltage in order, to keep a reasonable level of power dissipation of  $R_s$ . Adjusting the internal clamp voltage is very simple, as shown in Figure 11. The two external diodes compensate the internal diodes so you get a constant clamp voltage over temperature. Avoid too much reduction of the  $I_{pk(max)}$  clamp voltage, or you will get noise pickup and erratic results.

A narrow spike on the leading edge of the current waveform often occurs and can cause the power supply instability when the output load is light. This spike is caused by power transformer interwinding capacitance and output rectifier recovery time. You can eliminate this problem by adding an RC filter on the Current Sense Input, with a time constant similar to the spike's duration; see Figure 16.

#### Undervoltage Lockout

Two UVLO comparators in GM384XA series assure that the chips are fully functional before the output stage is enabled. The positive power supply terminal ( $V_{CC}$ ) and the reference output ( $V_{ref}$ ) have separate comparators. Each has built-in hysteresis to prevent erratic output behavior as their thresholds are reached. The  $V_{CC}$  comparator's upper and lower thresholds are 16 V/10 V for GM3842A and GM3844A, and 8.4V/7.6V for GM3843A and GM3845A.

The  $V_{ref}$  comparator's upper and lower thresholds are 3.6V/3.4 V. The large hysteresis and low startup current of the GM3842A and GM3844A makes them ideal for off-line converter applications where efficient bootstrap startup is required.

GM3843A and GM3845A are intended for lower voltage DC-to-DC converter applications. A 36 V zener is connected as a shunt regulator from  $V_{CC}$  to ground. Its purpose is to protect the IC from excessive voltage that can occur during system startup. The minimum operating voltage for GM3842A and GM3844A is 11V; for GM3843A and GM3845A it is 8.2V.

#### Output

GM384XA series has a single totem pole output stage that was designed for direct drive of power MOSFETs. It provides up to ±1.0 A peak drive current and has a typical rise/ fall time of 50 ns with a 1.0 nF load. Additional internal circuitry keeps the output in a sinking mode whenever a UVLO is active. This eliminates the need for an external pull-down resistor.

#### Reference

The 5.0 V bandgap reference is trimmed to  $\pm 1.0\%$  tolerance at  $T_J = 25^{\circ}C$  on the GM384XA series. Its primary purpose is to supply charging current to the oscillator timing capacitor. The reference has short circuit protection and it can provide more than 20mA for powering additional control system circuitry.

#### **Design Considerations**

Do not make your converter to use wire-wrap or plug-in prototype boards. High-frequency circuit layout techniques must be observed to prevent pulsewidth jitter. This is usually caused by excessive noise pick-up imposed on the Current Sense or Voltage Feedback inputs. You can improve noice immunity by lowering circuit impedances at these points. The PCB layout should have a ground plane with low-current signal and high-current switch and output grounds returning on separate paths to the input filter capacitor. Ceramic bypass capacitors (0.1  $\mu$ F) connected directly to V<sub>CC</sub>, V<sub>C</sub>, and V<sub>ref</sub> may be required, depending upon circuit layout, to provide a low impedance path for filtering high frequency noise. All high-current loops should be as short as possible and use heavy copper runs to minimize radiated EMI. The Error Amp compensation circuitry and the converter output voltage divider should be placed as close as possible to the GM384XA, and as far as possible from the power switch and other noise- generating components.

#### HIGH PERFORMANCE CURRENT MODE PWM CONTROLLERS

Current mode converters can exhibit subharmonic oscillations when operating at a duty cycle greater than 50% with continuous inductor current. This instability is independent of the regulators closed–loop characteristics and is caused by the simultaneous operating conditions of fixed frequency and peak current detecting. Figure 9.A shows the phenomenon graphically. At to, switch conduction begins and causes causing the inductor current to rise at a slope of m1. This slope is a function of the input voltage divided by the inductance. At t1, the Current Sense Input

reaches the threshold established by the control voltage.

This causes the switch to turn off and the current to decay at a slope of m2 until the next oscillator cycle. The unstable condition can be shown if a pertubation is added to the control voltage, and resulting in a small I (dashed line). With a fixed oscillator period, the current decay time is reduced and the minimum current at switch turn–on (t2) is increased by I + I m2/m1. The minimum current at next cycle (t3) decreases to (I + I m2/m1) (m2/m1). This pertubation is multiplied by m2.m1 on each succeeding cycle, alternately increasing and decreasing the inductor current at switch turn–on. Several oscillator cycles may be required before the inductor current reaches zero, which caused causing the process to commence again. If m2/m1 is greater than 1, the converter will be unstable. Figure 9.B shows that by adding an artificial ramp, that is synchronized with the PWM clock to the control voltage, the I pertubation will decrease to zero on succeeding cycles. This compensation ramp (m3) must have a slope equal to or slightly greater than m2/2 for stability. With m2/2 slope compensation, the average inductor current follows the control voltage yielding true current mode operation. The compensating ramp can be
