

# PRoC<sup>™</sup> LP Features

- Single Device, Two Functions
  - 8-bit, Flash based USB peripheral MCU function and 2.4 GHz radio transceiver function in a single device
- Flash-based Microcontroller Function
  - M8C based 8-bit CPU, optimized for Human Interface Devices (HID) applications
  - 256 Bytes of SRAM
- 8 Kbytes of Flash memory with EEPROM emulation
- In-System reprogrammable through D+/D- pins.
- 16-bit free running timer
- Low power wake up timer
- 12-bit Programmable Interval Timer with interrupts
- Watchdog timer
- Industry-Leading 2.4 GHz Radio Transceiver Function
  - Operates in the unlicensed worldwide Industrial, Scientific and Medical (ISM) band (2.4 GHz–2.483 GHz)
  - DSSS data rates of up to 250 Kbps
  - GFSK data rate of 1 Mbps
  - –97 dBm receive sensitivity
  - Programmable output power of up to +4 dBm
  - Auto Transaction Sequencer (ATS)
- Framing CRC and Auto ACK

# Programmable Radio on Chip Low Power

- Received Signal Strength Indication (RSSI)
- Automatic Gain Control (AGC)
- Component Reduction
  - Integrated 3.3V regulator
  - Integrated pull up on D-
- GPIOs that require no external components
- Operates off a single crystal
- Flexible I/O
  - High current drive on GPIO pins. Configurable 8-mA or 50-mA/pin current sink on designated pins
  - Each GPIO pin supports high-impedance inputs, configurable pull up, open-drain output, CMOS/TTL inputs and CMOS output
- Maskable intrrupts on all I/O pins
- USB Specification Compliance
  - Conforms to USB Specification Version 2.0
  - Conforms to USB HID Specification Version 1.1
  - Supports one Low Speed USB device address
  - Supports one control endpoint and two data end points
  - Integrated USB Transceiver
- Operating voltage from 4.0V to 5.5V DC
- Operating temperature from 0 to 70°C
- Lead-free 40-lead QFN package
- Advanced development tools based on Cypress's  $\mathsf{PSoC}^{\textcircled{R}}$  Tools

Cypress Semiconductor Corporation Document #: 001-07552 Rev. \*B 198 Champion Court

San Jose, CA 95134-1709 • 408-943-2600 Revised February 20, 2007

# Applications

The CYRF69213 PRoC LP Low Speed is targeted for the following applications:

- USB Bridge for Human Interface Devices (HID)
  - Wireless mice
  - Wireless keyboards
  - Remote controls
  - Gaming applications
- USB Bridge for General Purpose Applications
- Consumer electronics
- Industrial applications
- White goods
- Home automation
- Personal health

# **Functional Description**

PRoC LP devices are integrated radio and microcontroller functions in the same package to provide a dual-role single-chip solution.

Communication between the microcontroller and the radio is via the SPI interface between both functions.

# **Functional Overview**

The CYRF69213 is a complete Radio System-on-Chip device, providing a complete RF system solution with a single device and a few discrete components. The CYRF69213 is designed to implement low-cost wireless systems operating in the worldwide 2.4-GHz Industrial, Scientific, and Medical (ISM) frequency band (2.400 GHz–2.4835 GHz).

# 2.4 GHz Radio Function

The radio meets the following world-wide regulatory requirements:

- Europe
  - ETSI EN 301 489-1 V1.4.1
  - ETSI EN 300 328-1 V1.3.1
- North America
  - FCC CFR 47 Part 15
- Japan
  - ARIB STD-T66

## **Data Transmission Modes**

The radio supports four different data transmission modes:

- In GFSK mode, data is transmitted at 1 Mbps without any DSSS
- In 8DR mode, 1 byte is encoded in each PN code symbol transmitted
- In DDR mode, 2 bits are encoded in each PN code symbol transmitted
- In SDR mode, a single bit is encoded in each PN code symbol transmitted

Both 64-chip and 32-chip data PN codes are supported. The four data transmission modes apply to the data after the Start of Packet (SOP). In particular, the packet length, data and CRC are all sent in the same mode.

#### **USB Microcontroller Function**

The microcontroller function is based on the powerful CYRF69213 microcontroller. It is an 8-bit Flash programmable microcontroller with integrated low speed USB interface.

The microcontroller has up to 14 GPIO pins to support USB, PS/2 and other applications. Each GPIO port supports high-impedance inputs, configurable pull up, open drain output, CMOS/TTL inputs and CMOS output. Up to two pins support programmable drive strength of up to 50 mA. Additionally each I/O pin can be used to generate a GPIO interrupt to the microcontroller. Each GPIO port has its own GPIO interrupt vector with the exception of GPIO Port 0.

The microcontroller features an internal oscillator. With the presence of USB traffic, the internal oscillator can be set to precisely tune to USB timing requirements (24 MHz  $\pm$  1.5%).

The PRoC LP has up to 8 Kbytes of Flash for user's firmware code and up to 256 bytes of RAM for stack space and user variables.

The PRoC LP includes a Watchdog timer, a vectored interrupt controller, a 12-bit programmable interval timer with configurable 1-ms interrupt and a 16-bit free running timer with capture registers.

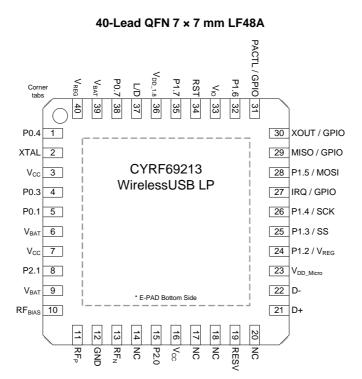

# Pinout

Pin	Name	Function					
1	P0.4	Individually configured GPIO					
2	Xtal_in	12 MHz Crystal. External Clock in					
3, 7, 16	V <sub>CC</sub>	Connected to pin 24 via 0.047-µF Capacitor.					
4	P0.3	Individually configured GPIO					
5	P0.1	Individually configured GPIO					
6, 9, 39	V <sub>bat</sub>	Connected to pin 24 via 0.047-µFshunt capacitor					
8	P2.1	GPIO. Port 2 Bit 1					
10	RF Bias	RF pin voltage reference					
11	RF <sub>p</sub>	Differential RF input to/from antenna					
12	GND	Ground					
13	RF <sub>n</sub>	Differential RF to/from antenna					
14, 17, 18, 20, 36	NC						
15	P2.0	GPIO. Port 2 Bit 0					
19	RESV	Reserved. Must connect to GND					
21	D+	Low-speed USB IO					
22	D-	Low-speed USB IO					
23	V <sub>DD_micro</sub>	4.0-5.5 for 12 MHz CPU/4.75-5.5 for 24 MHz CPU					
24	P1.2 / V <sub>REG</sub>	Must be configured as 3.3V output. It must have a 1–2 $\mu$ F output capacitor					
25	P1.3 / nSS	Slave select SPI Pin					
26	P1.4 / SCK	Serial Clock Pin from MCU function to radio function					
27	IRQ	Interrupt output, configure high/low or GPIO					
28	P1.5 / MOSI	Master Out Slave In.					
29	MISO	Master In Slave Out, from radio function.Can be configured as GPIO					
30	XOUT	Bufferd CLK, PACTL_n or GPIO					
31	PACTL	Control for external PA or GPIO					
32	P1.6	GPIO. Port 1 Bit 6					
33	V <sub>IO</sub>	I/O interface voltage. Connected to pin 24 via 0.047 $\mu$ F					
34	Reset	Radio Reset. Connected to $V_{DD}$ via 0.47 $\mu$ F Capacitor or to microcontroller GPIO pin. Must have a RESET = HIGH event the very first time power is applied to the radio otherwise the state of the radio function control registers is unknown.					
35	P1.7	GPIO. Port 1 Bit 7					
36	V <sub>DD_1.8</sub>	Regulated logic bypass. Connected via 0.47 µF to GND					
37	L/D	Connected to GND					
38	P0.7	GPIO. Port 0 Bit 7					
40	V <sub>reg</sub>	Connected to pin 24					
41	E-pad	Connected to GND					

# **Pinout Diagram**

# **PRoC LP Functional Overview**

The SoC is designed to implement wireless device links operating in the worldwide 2.4-GHz ISM frequency band. It is intended for systems compliant with world-wide regulations covered by ETSI EN 301 489-1 V1.41, ETSI EN 300 328-1 V1.3.1 (Europe), FCC CFR 47 Part 15 (USA and Industry Canada) and TELEC ARIB\_T66\_March, 2003 (Japan).

The SoC contains a 2.4-GHz 1-Mbps GFSK radio transceiver, packet data buffering, packet framer, DSSS baseband controller, Received Signal Strength Indication (RSSI), and SPI interface for data transfer and device configuration.

The radio supports 98 discrete 1-MHz channels (regulations may limit the use of some of these channels in certain jurisdictions). In DSSS modes the baseband performs DSSS spreading/despreading, while in GFSK Mode (1 Mb/s - GFSK) the baseband performs Start of Frame (SOF), End of Frame (EOF) detection and CRC16 generation and checking. The baseband may also be configured to automatically transmit Acknowledge (ACK) handshake packets whenever a valid packet is received.

When in receive mode, with packet framing enabled, the device is always ready to receive data transmitted at any of the supported bit rates, except SDR, enabling the implementation of mixed-rate systems in which different devices use different data rates. This also enables the implementation of dynamic data rate systems, which use high data rates at shorter distances and/or in a low-moderate interference environment,

and change to lower data rates at longer distances and/or in high interference environments.

The MCU function is an 8-bit Flash-programmable microcontroller with integrated low-speed USB interface. The instruction set has been optimized specifically for USB operations, although it can be used for a variety of other embedded applications.

The MCU function has up to eight Kbytes of Flash for user's code and up to 256 bytes of RAM for stack space and user variables.

In addition, the MCU function includes a Watchdog timer, a vectored interrupt controller, a 16-bit Free-Running Timer, and 12-bit Programmable Interrupt Timer.

The MCU function supports in-system programming by using the D+ and D– pins as the serial programming mode interface. The programming protocol is not USB.

#### **Backward Compatibility**

The CYRF69213 IC is fully interoperable with the main modes of other Cypress radios CYWUSB6934 and CYRF6936. The 62.5-kbps mode is supported by selecting 32-chip DATA\_CODE\_ADR codes, DDR mode, and disabling the SOP, length, and CRC16 fields. Similarly, the 15.675-kHz mode is supported by selecting 64-chip DATA\_CODE\_ADR codes and SDR mode.

In this way, a suitably configured CYRF69213 IC device may transmit data to and/or receive data from a first generation device.

# **Functional Block Overview**

All the blocks that make up the PRoC LP are presented here.

## 2.4-GHz Radio

The radio transceiver is a dual conversion low IF architecture optimized for power and range/robustness. The radio employs channel-matched filters to achieve high performance in the presence of interference. An integrated Power Amplifier (PA) provides up to +4 dBm transmit power, with an output power control range of 34 dB in 7 steps. The supply current of the device is reduced as the RF output power is reduced.

#### Table 1. Internal PA Output Power Step Table

Typical Output Power (dBm)
+4
0
-5
-10
-15
-20
-25
-30

#### **Frequency Synthesizer**

Before transmission or reception may commence, it is necessary for the frequency synthesizer to settle. The settling time varies depending on channel; 25 fast channels are provided with a maximum settling time of  $100 \ \mu s$ .

The 'fast channels' (<100- $\mu$ s settling time) are every third frequency, starting at 2400 MHz up to and including 2472 MHz (for example, 0,3,6,9......69 & 72).

#### **Baseband and Framer**

The baseband and framer blocks provide the DSSS encoding and decoding, SOP generation and reception and CRC16 generation and checking, as well as EOP detection and length field.

## Data Rates and Data Transmission Modes

The SoC supports four different data transmission modes:

- In GFSK mode, data is transmitted at 1 Mbps, without any DSSS.
- In 8DR mode, 8 bits are encoded in each DATA\_CODE\_ADR derived code symbol transmitted.
- In DDR mode, 2-bits are encoded in each DATA\_CODE\_ADR derived code symbol transmitted. (As in the CYWUSB6934 DDR mode).
- In SDR mode, 1 bit is encoded in each DATA\_CODE\_ADR derived code symbol transmitted. (As in the CYWUSB6934 standard modes.)

Both 64-chip and 32-chip DATA\_CODE\_ADR codes are supported. The four data transmission modes apply to the data after the SOP. In particular the length, data, and CRC16 are all

sent in the same mode. In general, lower data rates reduces packet error rate in any given environment.

By combining the DATA\_CODE\_ADR code lengths and data transmission modes described above, the CYRF69213 IC supports the following data rates:

- 1000-kbps (GFSK)
- 250-kbps (32-chip 8DR)
- 125-kbps (64-chip 8DR)
- 62.5-kbps (32-chip DDR)
- 31.25-kbps (64-chip DDR)
- 15.625-kbps (64-chip SDR)

Lower data rates typically provide longer range and/or a more robust link.

#### Link Layer Modes

The CYRF69213 IC device supports the following data packet framing features:

**SOP** – Packets begin with a 2-symbol Start of Packet (SOP) marker. This is required in GFSK and 8DR modes, but is optional in DDR mode and is not supported in SDR mode; if framing is disabled then an SOP event is inferred whenever two successive correlations are detected. The SOP\_CODE\_ADR code used for the SOP is different from that used for the 'body' of the packet, and if desired may be a different length. SOP must be configured to be the same length on both sides of the link.

**EOP** – There are two options for detecting the end of a packet. If SOP is enabled, then a packet length field may be enabled. GFSK and 8DR must enable the length field. This is the first 8 bits after the SOP symbol, and is transmitted at the payload data rate. If the length field is enabled, an End of Packet (EOP) condition is inferred after reception of the number of bytes defined in the length field, plus two bytes for the CRC16 (if enabled—see below). The alternative to using the length field is to infer an EOP condition from a configurable number of successive non-correlations; this option is not available in GFSK mode and is only recommended when using SDR mode.

**CRC16** – The device may be configured to append a 16-bit CRC16 to each packet. The CRC16 uses the USB CRC polynomial with the added programmability of the seed. If enabled, the receiver will verify the calculated CRC16 for the payload data against the received value in the CRC16 field. The starting value for the CRC16 calculation is configurable, and the CRC16 transmitted may be calculated using either the loaded seed value or a zero seed; the received data CRC16 will be checked against both the configured and zero CRC16 seeds.

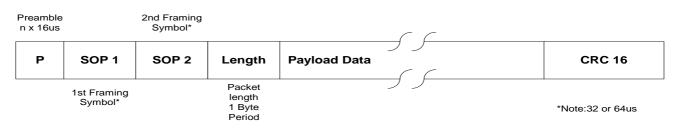

CRC16 detects the following errors:

- Any one bit in error
- Any two bits in error (no matter how far apart, which column, and so on)
- Any odd number of bits in error (no matter where they are)
- · An error burst as wide as the checksum itself

Figure 2 shows an example packet with SOP, CRC16 and lengths fields enabled.

#### Figure 2. Example Default Packet Format

## **Packet Buffers**

Packet data and configuration registers are accessed through the SPI interface. All configuration registers are directly addressed through the address field in the SPI packet. Configuration registers are provided to allow configuration of DSSS PN codes, data rate, operating mode, interrupt masks, interrupt status, and others.

#### Packet Buffers

All data transmission and reception uses the 16-byte packet buffers—one for transmission and one for reception.

The transmit buffer allows a complete packet of up to 16 bytes of payload data to be loaded in one burst SPI transaction, and then transmitted with no further MCU intervention. Similarly, the receive buffer allows an entire packet of payload data up to 16 bytes to be received with no firmware intervention required until packet reception is complete.

The CYRF69213 IC supports packet length of up to 40 bytes; interrupts are provided to allow an MCU to use the transmit and receive buffers as FIFOs. When transmitting a packet longer than 16 bytes, the MCU can load 16 bytes initially, and add further bytes to the transmit buffer as transmission of data creates space in the buffer. Similarly, when receiving packets longer than 16 bytes, the MCU function must fetch received data from the FIFO periodically during packet reception to prevent it from overflowing.

## Auto Transaction Sequencer (ATS)

The CYRF69213 IC provides automated support for transmission and reception of acknowledged data packets.

When transmitting a data packet, the device automatically starts the crystal and synthesizer, enters transmit mode, transmits the packet in the transmit buffer, and then automatically switches to receive mode and waits for a handshake packet—and then automatically reverts to sleep mode or idle mode when either an ACK packet is received, or a timeout period expires.

Similarly, when receiving in transaction mode, the device waits in receive mode for a valid packet to be received, then automatically transitions to transmit mode, transmits an ACK packet, and then switches back to receive mode to await the next packet. The contents of the packet buffers are not affected by the transmission or reception of ACK packets.

In each case, the entire packet transaction takes place without any need for MCU firmware action; to transmit data the MCU simply needs to load the data packet to be transmitted, set the length, and set the TX GO bit. Similarly, when receiving packets in transaction mode, firmware simply needs to retrieve

Below are the requirements for the crystal to be directly

the fully received packet in response to an interrupt request indicating reception of a packet.

### Interrupts

The radio function provides an interrupt (IRQ) output, which is configurable to indicate the occurrence of various different events. The IRQ pin may be programmed to be either active high or active low, and be either a CMOS or open drain output. The IRQ pin can be multiplexed on the SPI if routed to an external pin.

The radio function features three sets of interrupts: transmit, receive, and system interrupts. These interrupts all share a single pin (IRQ), but can be independently enabled/disabled. In transmit mode, all receive interrupts are automatically disabled, and in receive mode all transmit interrupts are automatically disabled. However, the contents of the enable registers are preserved when switching between transmit and receive modes.

If more than one radio interrupt is enabled at any time, it is necessary to read the relevant status register to determine which event caused the IRQ pin to assert. Even when a given interrupt source is disabled, the status of the condition that would otherwise cause an interrupt can be determined by reading the appropriate status register. It is therefore possible to use the devices without making use of the IRQ pin by polling the status register(s) to wait for an event, rather than using the IRQ pin.

The microcontroller function supports 23 maskable interrupts in the vectored interrupt controller. Interrupt sources include a USB bus reset, LVR/POR, a programmable interval timer, a 1.024-ms output from the Free Running Timer, three USB endpoints, two capture timers, five GPIO Ports, three GPIO pins, two SPI, a 16-bit free running timer wrap, an internal wake-up timer, and a bus active interrupt. The wake-up timer causes periodic interrupts when enabled. The USB endpoints interrupt after a USB transaction complete is on the bus. The capture timers interrupt whenever a new timer value is saved due to a selected GPIO edge event. A total of eight GPIO interrupts support both TTL or CMOS thresholds. For additional flexibility, on the edge sensitive GPIO pins, the interrupt polarity is programmable to be either rising or falling.

# Clocks

The radio function has a 12-MHz crystal (30-ppm or better) directly connected between XTAL and GND without the need for external capacitors. A digital clock out function is provided, with selectable output frequencies of 0.75, 1.5, 3, 6, or 12 MHz. This output may be used to clock an external micro-controller (MCU) or ASIC. This output is enabled by default, but may be disabled.

connected to XTAL pin and GND:

- Nominal Frequency: 12 MHz
- Operating Mode: Fundamental Mode
- Resonance Mode: Parallel Resonant
- Frequency Initial Stability: ±30 ppm
- Series Resistance: <a href="#"><60 ohms</a>
- Load Capacitance: 10 pF
- Drive Level: 10  $\mu$ W–100  $\mu$ W

The MCU function features an internal oscillator. With the presence of USB traffic, the internal oscillator can be set to precisely tune to USB timing requirements (24 MHz  $\pm$ 1.5%). The clock generator provides the 12-MHz and 24-MHz clocks that remain internal to the microcontroller.

#### **GPIO** Interface

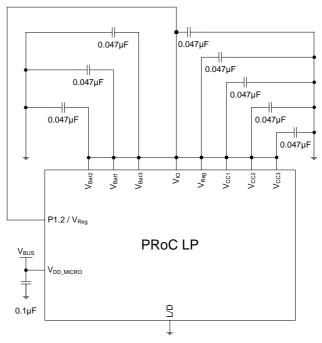

The MCU function features up to 20 general-purpose I/O (GPIO) pins to support USB, PS/2, and other applications. The I/O pins are grouped into five ports (Port 0 to 4). The pins on Port 0 and Port 1 may each be configured individually while the pins on Ports 2, 3, and 4 may only be configured as a group. Each GPIO port supports high-impedance inputs, configurable pull up, open drain output, CMOS/TTL inputs, and CMOS output with up to five pins that support programmable drive strength of up to 50-mA sink current. GPIO Port 1 features four pins that interface at a voltage level of 3.3 volts. Additionally, each I/O pin can be used to generate a GPIO interrupt to the microcontroller. Each GPIO port 0. GPIO Port 0 has three dedicated pins that have independent interrupt vectors (P0.2–P0.4).

#### Power-On Reset/Low-Voltage Detect

The power-on reset circuit detects logic when power is applied to the device, resets the logic to a known state, and begins executing instructions at Flash address 0x0000. When power falls below a programmable trip voltage, it generates reset or may be configured to generate interrupt. There is a low-voltage detect circuit that detects when  $V_{CC}$  drops below a programmable trip voltage. It may be configurable to generate an LVD interrupt to inform the processor about the low-voltage event. POR and LVD share the same interrupt. There is not a separate interrupt for each. The Watchdog timer can be used to ensure the firmware never gets stalled in an infinite loop.

#### **Power Management**

The device draws its power supply from the USB V<sub>bus</sub> line. The V<sub>bus</sub> supplies power to the MCU function, which has an internal 3.3 V regulator. This 3.3 V is supplied to the radio function via P1.2/V<sub>REG</sub> after proper filtering as shown in Figure 3.

#### Figure 3. Power Management From Internal Regulator

# Timers

The free-running 16-bit timer provides two interrupt sources: the programmable interval timer with  $1-\mu s$  resolution and the 1.024-ms outputs. The timer can be used to measure the duration of an event under firmware control by reading the timer at the start and at the end of an event, then calculating the difference between the two values.

#### **USB** Interface

The MCU function includes an integrated USB serial interface engine (SIE) that allows the chip to easily interface to a USB host. The hardware supports one USB device address with three endpoints.

# Low Noise Amplifier (LNA) and Received Signal Strength Indication (RSSI)

The gain of the receiver may be controlled directly by clearing the AGC EN bit and writing to the Low Noise Amplifier (LNA) bit of the RX\_CFG\_ADR register. When the LNA bit is cleared, the receiver gain is reduced by approximately 20 dB, allowing accurate reception of very strong received signals (for example when operating a receiver very close to the transmitter). An additional 20 dB of receiver attenuation can be added by setting the Attenuation (ATT) bit; this allows data reception to be limited to devices at very short ranges. Disabling AGC and enabling LNA is recommended unless receiving from a device using external PA.

The RSSI register returns the relative signal strength of the on-channel signal power.

When receiving, the device may be configured to automatically measure and store the relative strength of the signal being received as a 5-bit value. When enabled, an RSSI reading is taken and may be read through the SPI interface.

An RSSI reading is taken automatically when the start of a packet is detected. In addition, a new RSSI reading is taken every time the previous reading is read from the RSSI register, allowing the background RF energy level on any given channel to be easily measured when RSSI is read when no signal is being received. A new reading can occur as fast as once every 12  $\mu$ s.

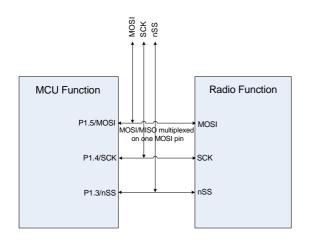

# **SPI Interface**

The SPI interface between the MCU function and the radio function is a 3-wire SPI Interface. The three pins are MOSI (Master Out Slave In), SCK (Serial Clock), SS (Slave Select). There is an alternate 4-wire MISO Interface that requires the connection of two external pins. The SPI interface is controlled by configuring the SPI Configure Register (SICR Address: 0x3D).

#### **3-Wire SPI Interface**

The radio function receives a clock from the MCU function on the SCK pin. The MOSI pin is multiplexed with the MISO pin. Bidirectional data transfer takes place between the MCU function and the radio function through this multiplexed MOSI pin. When using this mode the user firmware should ensure that the MOSI pin on the MCU function is in a high impedance state, except when the MCU is actively transmitting data. Firmware must also control the direction of data flow and switch directions between MCU function and radio function by setting the SWAP bit [Bit 7] of the SPI Configure Register. The SS pin is asserted prior to initiating a data transfer between the MCU function and the radio function. The IRQ function may be optionally multiplexed with the MOSI pin; when this option is enabled the IRQ function is not available while the SS pin is low. When using this configuration, user firmware should ensure that the MOSI function on MCU function is in a high-impedance state whenever SS is high.

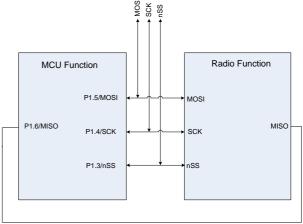

# 4-Wire SPI Interface

The 4-wire SPI communications interface consists of MOSI, MISO, SCK, and SS.

The device receives SCK from the MCU function on the SCK pin. Data from the MCU function is shifted in on the MOSI pin. Data to the MCU function is shifted out on the MISO pin. The active low SS pin must be asserted for the two functions to communicate. The IRQ function may be optionally multiplexed with the MOSI pin; when this option is enabled the IRQ function is not available while the SS pin is low. When using this configuration, user firmware should ensure that the MOSI function on MCU function is in a high-impedance state whenever SS is high.

This connection is external to the PRoC LP Chip

# **SPI** Communication and Transactions

The SPI transactions can be single byte or multi-byte. The MCU function initiates a data transfer through a Command/Address byte. The following bytes are data bytes. The SPI transaction format is shown in Figure 6.

The DIR bit specifies the direction of data transfer. 0 = Master reads from slave. 1 = Master writes to slave.

The INC bit helps to read or write consecutive bytes from contiguous memory locations in a single burst mode operation.

If Slave Select is asserted and INC = 1, then the master MCU function reads a byte from the radio, the address is incremented by a byte location, and then the byte at that location is read, and so on.

If Slave Select is asserted and INC = 0, then the MCU function reads/writes the bytes in the same register in burst mode, but if it is a register file then it reads/writes the bytes in that register file.

The SPI interface between the radio function and the MCU is not dependent on the internal 12-MHz oscillator of the radio. Therefore, radio function registers can be read from or written into while the radio is in sleep mode.

## **SPI IO Voltage References**

The SPI interfaces between MCU function and the radio and the IRQ and RST have a separate voltage reference  $V_{IO}$ , enabling the radio function to directly interface with the MCU

function, which operates at higher supply voltage. The internal SPIO pins between the MCU function and radio function should be connected with a regulated voltage of 3.3V (by setting [bit4] of Registers P13CR, P14CR, P15CR, and P16CR of the MCU function) and the internal 3.3V regulator of the MCU function should be turned on.

## **SPI Connects to External Devices**

The three SPI wires, MOSI, SCK, and SS are also drawn out of the package as external pins to allow the user to interface their own external devices (such as optical sensors and others) through SPI. The radio function also has its own SPI wires MISO and IRQ, which can be used to send data back to the MCU function or send an interrupt request to the MCU function. They can also be configured as GPIO pins.

## Figure 6. SPI Transaction Format

			Byte 1	Byte 1+N
Bit#	7	6	[5:0]	[7:0]
Bit Name	DIR	INC	Address	Data

# **CPU** Architecture

This family of microcontrollers is based on a high-performance, 8-bit, Harvard-architecture microprocessor. Five registers control the primary operation of the CPU core. These registers are affected by various instructions, but are not directly accessible through the register space by the user.

#### Table 2. CPU Registers and Register Names

Register	Register Name
Flags	CPU_F
Program Counter	CPU_PC
Accumulator	CPU_A
Stack Pointer	CPU_SP
Index	CPU_X

The 16-bit Program Counter Register (CPU\_PC) allows for direct addressing of the full eight Kbytes of program memory space.

The Flags Register can only be set or reset with logical instruction.

## Table 3. CPU Flags Register (CPU\_F) [R/W]

Bit #	7	6	5	4	3	2	1	0
Field		Reserved		XIO	Super	Carry	Zero	Global IE
Read/Write	-	-	-	R/W	R	RW	RW	RW
Default	0	0	0	0	0	0	1	0

The Accumulator Register (CPU\_A) is the general-purpose register that holds the results of instructions that specify any of the source addressing modes.

The Index Register (CPU\_X) holds an offset value that is used in the indexed addressing modes. Typically, this is used to address a block of data within the data memory space.

The Stack Pointer Register (CPU\_SP) holds the address of the current top-of-stack in the data memory space. It is affected by the PUSH, POP, LCALL, CALL, RETI, and RET instructions, which manage the software stack. It can also be affected by the SWAP and ADD instructions.

The Flag Register (CPU\_F) has three status bits: Zero Flag bit [1]; Carry Flag bit [2]; Supervisory State bit [3]. The Global Interrupt Enable bit [0] is used to globally enable or disable interrupts. The user cannot manipulate the Supervisory State status bit [3]. The flags are affected by arithmetic, logic, and shift operations. The manner in which each flag is changed is dependent upon the instruction being executed (for example, AND, OR, XOR). See Table 19.

# **CPU Registers**

#### **Flags Register**

# Table 3. CPU Flags Register (CPU\_F) [R/W]

Bits 7:5	Reserved
Bit 4	XIO Set by the user to select between the register banks 0 = Bank 0 1 = Bank 1
Bit 3	Super Indicates whether the CPU is executing user code or Supervisor Code. (This code cannot be accessed directly by the user.) 0 = User Code 1 = Supervisor Code
Bit 2	Carry Set by CPU to indicate whether there has been a carry in the previous logical/arithmetic operation 0 = No Carry 1 = Carry
Bit 1	Zero Set by CPU to indicate whether there has been a zero result in the previous logical/arithmetic operation 0 = Not Equal to Zero 1 = Equal to Zero
Bit 0	Global IE Determines whether all interrupts are enabled or disabled 0 = Disabled 1 = Enabled
Note CPU_ clear the C	F register is only readable with explicit register address 0xF7. The OR F, expr and AND F, expr instructions must be used to set and PU_F bits

# **Addressing Modes**

Examples of the different addressing modes are discussed in this section and example code is given.

#### Source Immediate

The result of an instruction using this addressing mode is placed in the A register, the F register, the SP register, or the X register, which is specified as part of the instruction opcode. Operand 1 is an immediate value that serves as a source for the instruction. Arithmetic instructions require two sources. Instructions using this addressing mode are two bytes in length.

#### Table 9. Source Immediate

	Оро	code	e Operand 1
Instruction			Immediate Value
Exam	ples		
ADD	A,	7	;In this case, the immediate value ;of 7 is added with the Accumulator, ;and the result is placed in the ;Accumulator.
MOV	Х,	8	;In this case, the immediate value ;of 8 is moved to the X register.
AND	F,	9	;In this case, the immediate value ;of 9 is logically ANDed with the F ;register and the result is placed ;in the F register.

# Source Direct

The result of an instruction using this addressing mode is placed in either the A register or the X register, which is specified as part of the instruction opcode. Operand 1 is an address that points to a location in either the RAM memory space or the register space that is the source for the instruction. Arithmetic instructions require two sources; the second source is the A register or X register specified in the opcode. Instructions using this addressing mode are two bytes in length.

# Table 10.Source Direct

Opcode		ode	Operand 1
Instruction			Source Address
Exam	ples		
ADD	A,	[7]	;In this case, the value in ;the RAM memory location at ;address 7 is added with the ;Accumulator, and the result ;is placed in the Accumulator.
MOV	Х,	REG[8]	;In this case, the value in ;the register space at address ;8 is moved to the X register.

## Source Indexed

The result of an instruction using this addressing mode is placed in either the A register or the X register, which is

specified as part of the instruction opcode. Operand 1 is added to the X register forming an address that points to a location in either the RAM memory space or the register space that is the source for the instruction. Arithmetic instructions require two sources; the second source is the A register or X register specified in the opcode. Instructions using this addressing mode are two bytes in length.

## Table 11.Source Indexed

Opcode	Operand 1
Instruction	Source Index

#### Examples

ADD	Α,	[X+7]	;In this case, the value in ;the memory location at ;address X + 7 is added with ;the Accumulator, and the ;result is placed in the ;Accumulator.
MOV	Х,	REG[X+8]	;In this case, the value in ;the register space at ;address X + 8 is moved to ;the X register.

### **Destination Direct**

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is an address that points to the location of the result. The source for the instruction is either the A register or the X register, which is specified as part of the instruction opcode. Arithmetic instructions require two sources; the second source is the location specified by Operand 1. Instructions using this addressing mode are two bytes in length.

#### **Table 12.Destination Direct**

Opcode	Operand 1
Instruction	Destination Address

#### Examples

ADD	[7],	Α	;In this case, the value in ;the memory location at ;address 7 is added with the ;Accumulator, and the result ;is placed in the memory ;location at address 7. The ;Accumulator is unchanged.
MOV	REG[8],	A	;In this case, the Accumula- ;tor is moved to the regis- ;ter space location at ;address 8. The Accumulator ;is unchanged.

#### **Destination Indexed**

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is added to the X register forming the address that points to the location of the result. The source for

the instruction is the A register. Arithmetic instructions require two sources; the second source is the location specified by Operand 1 added with the X register. Instructions using this addressing mode are two bytes in length.

#### **Table 13.Destination Indexed**

Opcode	Operand 1
Instruction	Destination Index

#### Example

ADD [X+7

X+7],	A	;In this case, the value in the
		;memory location at address X+7
		; is added with the Accumulator,
		;and the result is placed in
		;the memory location at address
		;x+7. The Accumulator is
		;unchanged.

#### **Destination Direct Source Immediate**

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is the address of the result. The source for the instruction is Operand 2, which is an immediate value. Arithmetic instructions require two sources; the second source is the location specified by Operand 1. Instructions using this addressing mode are three bytes in length.

#### **Table 14.Destination Direct Immediate**

### **Destination Indexed Source Immediate**

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is added to the X register to form the address of the result. The source for the instruction is Operand 2, which is an immediate value. Arithmetic instructions require two sources; the second source is the location specified by Operand 1 added with the X register. Instructions using this addressing mode are three bytes in length.

## Table 15.Destination Indexed Immediate

Opcode	Operand 1	Operand 2
Instruction	Destination Index	Immediate Value

#### Examples

ADD	[X+7],	5	<pre>;In this case, the value in ;the memory location at ;address X+7 is added with ;the immediate value of 5, ;and the result is placed ;in the memory location at ;address X+7.</pre>
MOV	REG[X+8],	6	;In this case, the immedi- ;ate value of 6 is moved ;into the location in the ;register space at ;address X+8.

#### Destination Direct Source Direct

The result of an instruction using this addressing mode is placed within the RAM memory. Operand 1 is the address of the result. Operand 2 is an address that points to a location in the RAM memory that is the source for the instruction. This addressing mode is only valid on the MOV instruction. The instruction using this addressing mode is three bytes in length.

## **Table 16.Destination Direct Source Direct**

Opcode	Operand 1	Operand 2
Instruction	Destination Address	Source Address

#### Example

MOV [7], [8] ;In this case, the value in the ;memory location at address 8 is ;moved to the memory location at ;address 7.

#### **Source Indirect Post Increment**

The result of an instruction using this addressing mode is placed in the Accumulator. Operand 1 is an address pointing to a location within the memory space, which contains an address (the indirect address) for the source of the instruction. The indirect address is incremented as part of the instruction execution. This addressing mode is only valid on the MVI instruction. The instruction using this addressing mode is two bytes in length. Refer to the *PSoC Designer: Assembly Language User Guide* for further details on MVI instruction.

#### Table 17.Source Indirect Post Increment

#### Notes

Interrupt routines take 13 cycles before execution resumes at interrupt vector table.
 The number of cycles required by an instruction is increased by one for instructions that span 256-byte boundaries in the Flash memory space.

# **Data Memory Organization**

The MCU function has 256 bytes of data RAM

## Flash

This section describes the Flash block of the CYRF69213. Much of the user-visible Flash functionality, including programming and security, are implemented in the M8C Supervisory Read Only Memory (SROM). CYRF69213 Flash has an endurance of 1000 cycles and 10-year data retention.

#### Flash Programming and Security

All Flash programming is performed by code in the SROM. The registers that control the Flash programming are only visible to the M8C CPU when it is executing out of SROM. This makes it impossible to read, write, or erase the Flash by bypassing the security mechanisms implemented in the SROM.

Customer firmware can only program the Flash via SROM calls. The data or code images can be sourced by way of any interface with the appropriate support firmware. This type of programming requires a 'boot-loader'—a piece of firmware resident on the Flash. For safety reasons this boot-loader should not be overwritten during firmware rewrites.

The Flash provides four auxiliary rows that are used to hold Flash block protection flags, boot time calibration values, configuration tables, and any device values. The routines for accessing these auxiliary rows are documented in the SROM section. The auxiliary rows are not affected by the device erase function.

#### In-System Programming

Most designs that include an CYRF69213 part will have a USB connector attached to the USB D+/D- pins on the device. These designs require the ability to program or reprogram a part through these two pins alone.

CYRF69213 device enables this type of in-system programming by using the D+ and D- pins as the serial programming mode interface. This allows an external controller to cause the CYRF69213 part to enter serial programming mode and then to use the test queue to issue Flash access functions in the SROM. The programming protocol is not USB.

# SROM

The SROM holds code that is used to boot the part, calibrate circuitry, and perform Flash operations. (Table 20 lists the SROM functions.) The functions of the SROM may be accessed in normal user code or operating from Flash. The SROM exists in a separate memory space from user code. The SROM functions are accessed by executing the Supervisory System Call instruction (SSC), which has an opcode of 00h. Prior to executing the SSC, the M8C's accumulator needs to be loaded with the desired SROM function code from Table 20. Undefined functions will cause a HALT if called from user code. The SROM functions are executing code with calls; therefore, the functions require stack space. With the exception of Reset, all of the SROM functions have a parameter block in SRAM that must be configured before executing the SSC. Table 21 lists all possible parameter block variables. The meaning of each parameter, with regards to a specific SROM function, is described later in this section.

#### Table 20.SROM Function Codes

Function Code	Function Name	Stack Space
00h	SWBootReset	0
01h	ReadBlock	7
02h	WriteBlock	10
03h	EraseBlock	9
05h	EraseAll	11
06h	TableRead	3
07h	CheckSum	3

Two important variables that are used for all functions are KEY1 and KEY2. These variables are used to help discriminate between valid SSCs and inadvertent SSCs. KEY1 must always have a value of 3Ah, while KEY2 must have the same value as the stack pointer when the SROM function begins execution. This would be the Stack Pointer value when the SSC opcode is executed, plus three. If either of the keys do

not match the expected values, the M8C will halt (with the exception of the SWBootReset function). The following code puts the correct value in KEY1 and KEY2. The code starts with a halt, to force the program to jump directly into the setup code and not run into it.

```
halt
SSCOP: mov [KEY1], 3ah
mov X, SP
mov A, X
add A, 3
mov [KEY2], A
```

#### **Table 21.SROM Function Parameters**

Variable Name	SRAM Address
Key1/Counter/Return Code	0,F8h
Key2/TMP	0,F9h
BlockID	0,FAh
Pointer	0,FBh
Clock	0,FCh
Mode	0,FDh
Delay	0,FEh
PCL	0,FFh

The SROM also features Return Codes and Lockouts.

#### Return Codes

Return codes aid in the determination of success or failure of a particular function. The return code is stored in KEY1's position in the parameter block. The CheckSum and TableRead functions do not have return codes because KEY1's position in the parameter block is used to return other data.

#### **Table 22.SROM Return Codes**

Return Code	Description
00h	Success
01h	Function not allowed due to level of protection on block
02h	Software reset without hardware reset
03h	Fatal error, SROM halted

Read, write, and erase operations may fail if the target block is read or write protected. Block protection levels are set during device programming.

The EraseAll function overwrites data in addition to leaving the entire user Flash in the erase state. The EraseAll function loops through the number of Flash macros in the product, executing the following sequence: erase, bulk program all zeros, erase. After all the user space in all the Flash macros are erased, a second loop erases and then programs each protection block with zeros.

#### **SROM Function Descriptions**

All SROM functions are described in the following sections.

#### SWBootReset Function

The SROM function, SWBootReset, is the function that is responsible for transitioning the device from a reset state to running user code. The SWBootReset function is executed whenever the SROM is entered with an M8C accumulator value of 00h; the SRAM parameter block is not used as an input to the function. This will happen, by design, after a hardware reset, because the M8C's accumulator is reset to 00h or when user code executes the SSC instruction with an accumulator value of 00h. The SWBootReset function will not execute when the SSC instruction is executed with a bad key value and a nonzero function code. A CYRF69213 device will execute the HALT instruction if a bad value is given for either KEY1 or KEY2.

The SWBootReset function verifies the integrity of the calibration data by way of a 16-bit checksum, before releasing the M8C to run user code.

#### ReadBlock Function

The ReadBlock function is used to read 64 contiguous bytes from Flash—a block.

The first thing this function does is to check the protection bits and determine if the desired BLOCKID is readable. If read protection is turned on, the ReadBlock function will exit, setting the accumulator and KEY2 back to 00h. KEY1 will have a value of 01h, indicating a read failure. If read protection is not enabled, the function will read 64 bytes from the Flash using a ROMX instruction and store the results in SRAM using an MVI instruction. The first of the 64 bytes will be stored in SRAM at the address indicated by the value of the POINTER parameter. When the ReadBlock completes successfully, the accumulator, KEY1, and KEY2 will all have a value of 00h.

### Table 23.ReadBlock Parameters

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value, when SSC is executed
BLOCKID	0,FAh	Flash block number
POINTER	0,FBh	First of 64 addresses in SRAM where returned data should be stored

#### WriteBlock Function

The WriteBlock function is used to store data in the Flash. Data is moved 64 bytes at a time from SRAM to Flash using this function. The first thing the WriteBlock function does is to check the protection bits and determine if the desired BLOCKID is writable. If write protection is turned on, the Write-Block function will exit, setting the accumulator and KEY2 back to 00h. KEY1 will have a value of 01h, indicating a write failure. The configuration of the WriteBlock function is straightforward. The BLOCKID of the Flash block, where the data is stored, must be determined and stored at SRAM address FAh.

The SRAM address of the first of the 64 bytes to be stored in Flash must be indicated using the POINTER variable in the parameter block (SRAM address FBh). Finally, the CLOCK

and DELAY values must be set correctly. The CLOCK value determines the length of the write pulse that will be used to store the data in the Flash. The CLOCK and DELAY values are dependent on the CPU speed. Refer to 'Clocking' Section for additional information.

## Table 24.WriteBlock Parameters

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value, when SSC is executed
BLOCKID	0,FAh	8-KB Flash block number (00h–7Fh) 4-KB Flash block number (00h–3Fh) 3-KB Flash block number (00h–2Fh)
POINTER	0,FBh	First of 64 addresses in SRAM, where the data to be stored in Flash is located prior to calling WriteBlock
CLOCK	0,FCh	Clock divider used to set the write pulse width
DELAY	0,FEh	For a CPU speed of 12 MHz set to 56h

## EraseBlock Function

The EraseBlock function is used to erase a block of 64 contiguous bytes in Flash. The first thing the EraseBlock function does is to check the protection bits and determine if the desired BLOCKID is writable. If write protection is turned on, the EraseBlock function will exit, setting the accumulator and KEY2 back to 00h. KEY1 will have a value of 01h, indicating a write failure. The EraseBlock function is only useful as the first step in programming. Erasing a block will not cause data in a block to be one hundred percent unreadable. If the objective is to obliterate data in a block, the best method is to perform an EraseBlock followed by a WriteBlock of all zeros.

To set up the parameter block for the EraseBlock function, correct key values must be stored in KEY1 and KEY2. The block number to be erased must be stored in the BLOCKID variable and the CLOCK and DELAY values must be set based on the current CPU speed.

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value when SSC is executed
BLOCKID	0,FAh	Flash block number (00h–7Fh)
CLOCK	0,FCh	Clock divider used to set the erase pulse width
DELAY	0,FEh	For a CPU speed of 12 MHz set to 56h

## Table 25. EraseBlock Parameters

#### ProtectBlock Function

The CYRF69213 device offers Flash protection on a block-by-block basis. Table 26 lists the protection modes available. In the table, ER and EW are used to indicate the

ability to perform external reads and writes. For internal writes, IW is used. Internal reading is always permitted by way of the ROMX instruction. The ability to read by way of the SROM ReadBlock function is indicated by SR. The protection level is stored in two bits according to Table 26. These bits are bit packed into the 64 bytes of the protection block. Therefore, each protection block byte stores the protection level for four Flash blocks. The bits are packed into a byte, with the lowest numbered block's protection level stored in the lowest numbered bits.

The first address of the protection block contains the protection level for blocks 0 through 3; the second address is for blocks 4 through 7. The 64th byte will store the protection level for blocks 252 through 255.

#### **Table 26.Protection Modes**

Mode	Se	ttings	Des	Description			Marketing		
00b	SR EI	R EW IV	V Unpro	Unprotected			Unprotected		
01b	SR EI	R EW IV	V Read	Read protect			Factory upgrade		
10b	SR EI	R EW IV	V Disab write	Disable external write			Field upgrade		
11b	SR EI	REWIV	V Disab write	le interr	nal	Ful	l protec	tion	
7	6	5	4	3		2	1	0	
Block	ock n+3 Block r		(n+2	n+2 Block n+			1 Block n		

The level of protection is only decreased by an EraseAll, which places zeros in all locations of the protection block. To set the level of protection, the ProtectBlock function is used. This function takes data from SRAM, starting at address 80h, and ORs it with the current values in the protection block. The result of the OR operation is then stored in the protection block. The EraseBlock function does not change the protection level for a block. Because the SRAM location for the protection data is fixed and there is only one protection block per Flash macro, the ProtectBlock function expects very few variables in the parameter block to be set prior to calling the function. The parameter block values that must be set, besides the keys, are the CLOCK and DELAY values.

#### Table 27.ProtectBlock Parameters

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value when SSC is executed
CLOCK	0,FCh	Clock divider used to set the write pulse width
DELAY	0,FEh	For a CPU speed of 12 MHz set to 56h

#### EraseAll Function

The EraseAll function performs a series of steps that destroy the user data in the Flash macros and resets the protection block in each Flash macro to all zeros (the unprotected state). The EraseAll function does not affect the three hidden blocks above the protection block in each Flash macro. The first of

these four hidden blocks is used to store the protection table for its eight Kbytes of user data.

The EraseAll function begins by erasing the user space of the Flash macro with the highest address range. A bulk program of all zeros is then performed on the same Flash macro, to destroy all traces of the previous contents. The bulk program is followed by a second erase that leaves the Flash macro in a state ready for writing. The erase, program, erase sequence is then performed on the next lowest Flash macro in the address space if it exists. Following the erase of the user space, the protection block for the Flash macro with the highest address range is erased. Following the erase of the protection block, zeros are written into every bit of the protection table. The next lowest Flash macro in the address space then has its protection block erased and filled with zeros.

The end result of the EraseAll function is that all user data in the Flash is destroyed and the Flash is left in an unprogrammed state, ready to accept one of the various write commands. The protection bits for all user data are also reset to the zero state.

The parameter block values that must be set, besides the keys, are the CLOCK and DELAY values.

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value when SSC is executed
CLOCK	0,FCh	Clock divider used to set the write pulse width
DELAY	0,FEh	For a CPU speed of 12 MHz set to 56h

# Table 28. EraseAll Parameters

#### TableRead Function

The TableRead function gives the user access to part-specific data stored in the Flash during manufacturing. It also returns a Revision ID for the die (not to be confused with the Silicon ID).

#### **Table 29. Table Read Parameters**

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value when SSC is executed
BLOCKID	0,FAh	Table number to read

The table space for the CYRF69213 is simply a 64-byte row broken up into eight tables of eight bytes. The tables are numbered zero through seven. All user and hidden blocks in the CYRF69213 parts consist of 64 bytes.

An internal table holds the Silicon ID and returns the Revision ID. The Silicon ID is returned in SRAM, while the Revision ID is returned in the CPU\_A and CPU\_X registers. The Silicon ID is a value placed in the table by programming the Flash and is controlled by Cypress Semiconductor Product Engineering.

The Revision ID is hard coded into the SROM. The Revision ID is discussed in more detail later in this section.

An internal table holds alternate trim values for the device and returns a one-byte internal revision counter. The internal revision counter starts out with a value of zero and is incremented each time one of the other revision numbers is not incremented. It is reset to zero each time one of the other revision numbers is incremented. The internal revision count is returned in the CPU\_A register. The CPU\_X register will always be set to FFh when trim values are read. The BLOCKID value, in the parameter block, is used to indicate which table should be returned to the user. Only the three least significant bits of the BLOCKID parameter are used by the TableRead function for the CYRF69213. The upper five bits are ignored. When the function is called, it transfers bytes from the table to SRAM addresses F8h–FFh.

The M8C's A and X registers are used by the TableRead function to return the die's Revision ID. The Revision ID is a 16-bit value hard coded into the SROM that uniquely identifies the die's design.

#### **Checksum Function**

The Checksum function calculates a 16-bit checksum over a user specifiable number of blocks, within a single Flash macro (Bank) starting from block zero. The BLOCKID parameter is used to pass in the number of blocks to calculate the checksum over. A BLOCKID value of 1 will calculate the checksum of only block 0, while a BLOCKID value of 0 will calculate the checksum of all 256 user blocks. The 16-bit checksum is returned in KEY1 and KEY2. The parameter KEY1 holds the lower eight bits of the checksum and the parameter KEY2 holds the upper eight bits of the checksum.

The checksum algorithm executes the following sequence of three instructions over the number of blocks times 64 to be checksummed.

romx add [KEY1], A adc [KEY2], 0

## Table 30.Checksum Parameters

Name	Address	Description

BLOCKID	0,FAh	Number of Flash blocks to calculate checksum on

# Clocking

The CYRF69213 internal oscillator outputs two frequencies, the Internal 24-MHz Oscillator and the 32-KHz Low-power Oscillator.

The Internal 24-MHz Oscillator is designed such that it may be trimmed to an output frequency of 24 MHz over temperature and voltage variation. With the presence of USB traffic, the Internal 24-MHz Oscillator can be set to precisely tune to USB timing requirements (24 MHz  $\pm$  1.5%). Without USB traffic, the Internal 24-MHz Oscillator accuracy is 24 MHz  $\pm$  5% (between

 $0^{\circ}\text{--}70^{\circ}\text{C}\text{)}.$  No external components are required to achieve this level of accuracy.

The internal low-speed oscillator of nominally 32 KHz provides a slow clock source for the CYRF69213 in suspend mode, particularly to generate a periodic wake-up interrupt and also to provide a clock to sequential logic during power-up and power-down events when the main clock is stopped. In addition, this oscillator can also be used as a clocking source for the Interval Timer clock (ITMRCLK) and Capture Timer clock (TCAPCLK). The 32-KHz Low-power Oscillator can operate in low-power mode or can provide a more accurate clock in normal mode. The Internal 32-KHz Low-power Oscillator accuracy ranges (between  $0^{\circ} - 70^{\circ}$  C) as follows:

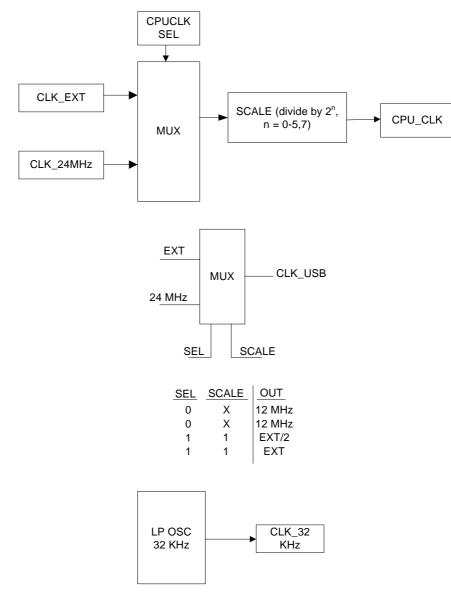

5V Normal mode: -8% to + 16%

5V LP mode: +12% to + 48%

When using the 32-KHz oscillator the PITMRL/H should be read until two consecutive readings match before sending/receiving data. The following firmware example assumes the developer is interested in the lower byte of the PIT.

Read\_PIT\_counter: mov A, reg[PITMRL] mov [57h], A mov A, reg[PITMRL] mov [58h], A mov [59h], A mov A, reg{PITMRL] mov [60h], A ;;;Start comparison mov A, [60h] mov X, [59h] sub A, [59h] jz done mov A, [59h] mov X, [58h] sub A, [58h] jz done mov X, [57h] ;;;correct data is in memory location 57h done: mov [57h], X ret

## Figure 9. Clock Block Diagram

#### **Clock Architecture Description**

The CYRF69213 clock selection circuitry allows the selection of independent clocks for the CPU, USB, Interval Timers, and Capture Timers.

The CPU clock, CPUCLK, can be sourced from the external crystal oscillator or the Internal 24-MHz Oscillator. The selected clock source can optionally be divided by  $2^n$  where *n* is 0–5,7 (see Table 34).

USBCLK, which must be 12 MHz for the USB SIE to function properly, can be sourced by the Internal 24-MHz Oscillator or the external crystal oscillator. An optional divide-by-two allows the use of the 24-MHz source.

The Interval Timer clock (ITMRCLK), can be sourced from the external crystal oscillator, the Internal 24-MHz Oscillator, the

Internal 32-KHz Low-power Oscillator, or from the timer capture clock (TCAPCLK). A programmable prescaler of 1, 2, 3, 4 then divides the selected source.

The Timer Capture clock (TCAPCLK) can be sourced from the external crystal oscillator, Internal 24-MHz Oscillator, or the Internal 32-KHz Low-power Oscillator.

When it is not being used by the external crystal oscillator, the CLKOUT pin can be driven from one of many sources. This is used for test and can also be used in some applications. The sources that can drive the CLKOUT are:

- CLKIN after the optional EFTB filter
- Internal 24-MHz Oscillator
- Internal 32-KHz Low-power Oscillator
- · CPUCLK after the programmable divider

## Interval Timer Clock (ITMRCLK)

The Interval Timer Clock (ITMRCLK) can be sourced from the external crystal oscillator, the Internal 24-MHz oscillator, the internal 32-KHz low-power oscillator, or the timer capture clock. A programmable prescaler of 1, 2, 3, or 4 then divides the selected source. The 12-bit Programmable Interval Timer is a simple down counter with a programmable reload value. It provides a 1- $\mu$ s resolution by default. When the down counter reaches zero, the next clock is spent reloading. The reload value can be read and written while the counter is running, but care should be taken to ensure that the counter does not unintentionally reload while the 12-bit reload value is only partially stored—for example, between the two writes of the 12-bit value. The programmable interval timer generates an interrupt to the CPU on each reload.

The parameters to be set will appear on the device editor view of PSoC Designer once you place the CYRF69213 Timer User Module. The parameters are PITIMER\_Source and PITIMER\_Divider. The PITIMER\_Source is the clock to the timer and the  $\ensuremath{\mathsf{PITMER\_Divider}}$  is the value the clock is divided by.

The interval register (PITMR) holds the value that is loaded into the PIT counter on terminal count. The PIT counter is a down counter.

The Programmable Interval Timer resolution is configurable. For example:

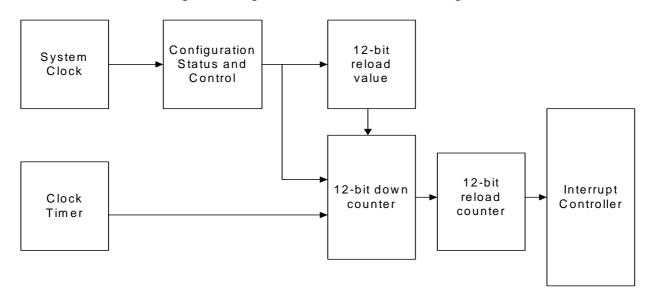

TCAPCLK divide by x of CPU clock (for example TCAPCLK divide by 2 of a 24-MHz CPU clock will give a frequency of 12 MHz)

ITMRCLK divide by x of TCAPCLK (for example, ITMRCLK divide by 3 of TCAPCLK is 4 MHz so resolution is 0.25  $\mu s)$ 

#### Timer Capture Clock (TCAPCLK)

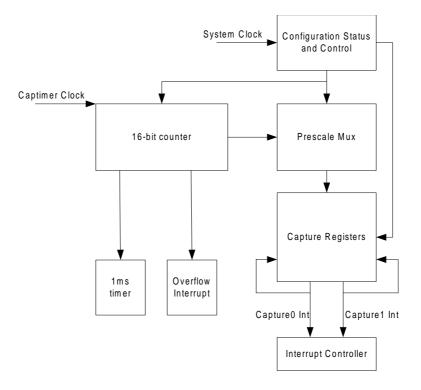

The Timer Capture clock can be sourced from the external crystal oscillator, internal 24-MHz oscillator or the Internal 332-KHz low-power oscillator. A programmable prescaler of 2, 4, 6, or 8 then divides the selected source.

# **CPU Clock During Sleep Mode**

When the CPU enters sleep mode the CPUCLK Select (Bit [0], Table 33) is forced to the internal oscillator, and the oscillator is stopped. When the CPU comes out of sleep mode it is running on the internal oscillator. The internal oscillator recovery time is three clock cycles of the Internal 32-KHz Low-power Oscillator.

If the system requires the CPU to run off the external clock after awakening from sleep mode, firmware will need to switch the clock source for the CPU.

# Reset

The microcontroller supports two types of resets: Power-on Reset (POR) and Watchdog Reset (WDR). When reset is

initiated, all registers are restored to their default states and all interrupts are disabled.

The occurrence of a reset is recorded in the System Status and Control Register (CPU\_SCR). Bits within this register record the occurrence of POR and WDR Reset respectively. The firmware can interrogate these bits to determine the cause of a reset.

The microcontroller resumes execution from Flash address 0x0000 after a reset. The internal clocking mode is active after a reset, until changed by user firmware.

**Note** The CPU clock defaults to 3 MHz (Internal 24-MHz Oscillator divide-by-8 mode) at POR to guarantee operation at the low  $V_{CC}$  that might be present during the supply ramp.

## Table 38.System Status and Control Register (CPU\_SCR) [0xFF] [R/W]

## **Power-on Reset**

POR occurs every time the power to the device is switched on. POR is released when the supply is typically 2.6V for the upward supply transition, with typically 50 mV of hysteresis during the power-on transient. Bit 4 of the System Status and Control Register (CPU\_SCR) is set to record this event (the register contents are set to 00010000 by the POR). After a POR, the microprocessor is held off for approximately 20 ms for the V<sub>CC</sub> supply to stabilize before executing the first instruction at address 0x00 in the Flash. If the V<sub>CC</sub> voltage drops below the POR downward supply trip point, POR is reasserted. The V<sub>CC</sub> supply needs to ramp linearly from 0 to 4V in 0 to 200 ms.

**Important** The PORS status bit is set at POR and can only be cleared by the user. It cannot be set by firmware.

#### Watchdog Timer Reset

The user has the option to enable the WDT. The WDT is enabled by clearing the PORS bit. Once the PORS bit is

Note

3. C = Clear. This bit can only be cleared by the user and cannot be set by firmware

cleared, the WDT cannot be disabled. The only exception to this is if a POR event takes place, which will disable the WDT.

The sleep timer is used to generate the sleep time period and the Watchdog time period. The sleep timer is clocked by the Internal 32-KHz Low-power Oscillator system clock. The user can program the sleep time period using the Sleep Timer bits of the OSC\_CR0 Register (Table 34). When the sleep time elapses (sleep timer overflows), an interrupt to the Sleep Timer Interrupt Vector will be generated.

The Watchdog Timer period is automatically set to be three counts of the Sleep Timer overflows. This represents between two and three sleep intervals depending on the count in the Sleep Timer at the previous WDT clear. When this timer reaches three, a WDR is generated.

The user can either clear the WDT, or the WDT and the Sleep Timer. Whenever the user writes to the Reset WDT Register (RES\_WDT), the WDT will be cleared. If the data that is written is the hex value 0x38, the Sleep Timer will also be cleared at the same time.

Bits 7:0	Reset Watchdog	Timer [7:0]									

# **Sleep Mode**

The CPU can only be put to sleep by the firmware. This is accomplished by setting the Sleep bit in the System Status and Control Register (CPU\_SCR). This stops the CPU from executing instructions, and the CPU will remain asleep until an interrupt comes pending, or there is a reset event (either a Power-on Reset, or a Watchdog Timer Reset).

The Low-voltage Detection circuit (LVD) drops into fully functional power-reduced states, and the latency for the LVD is increased. The actual latency can be traded against power consumption by changing the Sleep Duty Cycle field of the ECO\_TR Register.

The Internal 32-KHz Low-speed Oscillator remains running. Prior to entering suspend mode, firmware can optionally configure the 32-KHz Low-speed Oscillator to operate in a low-power mode to help reduce the overall power consumption (using Bit 7, Table 32). This will help save approximately 5  $\mu$ A; however, the trade off is that the 32-KHz Low-speed Oscillator will be less accurate.

All interrupts remain active. Only the occurrence of an interrupt will wake the part from sleep. The Stop bit in the System Status and Control Register (CPU\_SCR) must be cleared for a part to resume out of sleep. The Global Interrupt Enable bit of the CPU Flags Register (CPU\_F) does not have any effect. Any unmasked interrupt will wake the system up. As a result, any interrupts not intended for waking must be disabled through the Interrupt Mask Registers.

When the CPU enters sleep mode the CPUCLK Select (Bit 1, Table 33) is forced to the Internal Oscillator. The internal oscillator recovery time is three clock cycles of the Internal 32-KHz Low-power Oscillator. The Internal 24-MHz Oscillator restarts immediately on exiting Sleep mode. If an external clock is used, firmware will need to switch the clock source for the CPU.

On exiting sleep mode, once the clock is stable and the delay time has expired, the instruction immediately following the sleep instruction is executed before the interrupt service routine (if enabled).

The Sleep interrupt allows the microcontroller to wake up periodically and poll system components while maintaining very low average power consumption. The Sleep interrupt may also be used to provide periodic interrupts during non-sleep modes.

#### **Sleep Sequence**

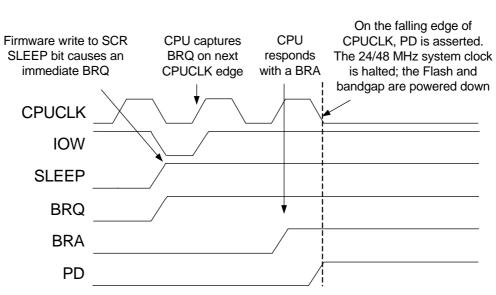

The SLEEP bit is an input into the sleep logic circuit. This circuit is designed to sequence the device into and out of the hardware sleep state. The hardware sequence to put the device to sleep is shown in Figure 12 and is defined as follows.

- 1. Firmware sets the SLEEP bit in the CPU\_SCR0 register. The Bus Request (BRQ) signal to the CPU is immediately asserted. This is a request by the system to halt CPU operation at an instruction boundary. The CPU samples BRQ on the positive edge of CPUCLK.
- 2. Due to the specific timing of the register write, the CPU issues a Bus Request Acknowledge (BRA) on the following positive edge of the CPU clock. The sleep logic waits for the following negative edge of the CPU clock and then asserts a system-wide Power Down (PD) signal. In Figure 12 the CPU is halted and the system-wide power down signal is asserted.
- 3. The system-wide PD (power down) signal controls several major circuit blocks: The Flash memory module, the internal 24-MHz oscillator, the EFTB filter and the bandgap voltage reference. These circuits transition into a zero power state. The only operational circuits on chip are the Low Power oscillator, the bandgap refresh circuit, and the supply voltage monitor (POR/LVD) circuit.

**Note** To achieve the lowest possible power consumption during suspend/sleep, the following conditions must be observed in addition to considerations for the sleep timer.

- All GPIOs must be set to outputs and driven low
- The USB pins P1.0 and P1.1 should be configured as inputs with their pull ups enabled.

# Figure 12. Sleep Timing

# Wakeup Sequence

Once asleep, the only event that can wake the system up is an interrupt. The global interrupt enable of the CPU flag register does not need to be set. Any unmasked interrupt will wake the system up. It is optional for the CPU to actually take the interrupt after the wakeup sequence. The wakeup sequence is synchronized to the 32-KHz clock for purposes of sequencing a startup delay, to allow the Flash memory module enough time to power up before the CPU asserts the first read access. Another reason for the delay is to allow the oscillator, Bandgap, and LVD/POR circuits time to settle before actually being used in the system. As shown in Figure 13, the wakeup sequence is as follows:

- 1. The wakeup interrupt occurs and is synchronized by the negative edge of the 32-KHz clock.
- 2. At the following positive edge of the 32-KHz clock, the system-wide PD signal is negated. The Flash memory

module, internal oscillator, EFTB, and bandgap circuit are all powered up to a normal operating state.

- 3. At the following positive edge of the 32-KHz clock, the current values for the precision POR and LVD have settled and are sampled.
- 4. At the following negative edge of the 32-KHz clock (after about 15 μs nominal), the BRQ signal is negated by the sleep logic circuit. On the following CPUCLK, BRA is negated by the CPU and instruction execution resumes. Note that in Figure 13 fixed function blocks, such as Flash, internal oscillator, EFTB, and bandgap, have about 15 μs start up. The wakeup times (interrupt to CPU operational) will range from 75 μs to 105 μs.

#### **GPIO Port Configuration**

All the GPIO configuration registers have common configuration controls. The following are the bit definitions of the GPIO configuration registers.

#### Int Enable

When set, the Int Enable bit allows the GPIO to generate interrupts. Interrupt generate can occur regardless of whether the pin is configured for input or output. All interrupts are edge sensitive, however for any interrupt that is shared by multiple sources (that is, Ports 2, 3, and 4) all inputs must be deasserted before a new interrupt can occur.

When clear, the corresponding interrupt is disabled on the pin.

It is possible to configure GPIOs as outputs, enable the interrupt on the pin and then to generate the interrupt by driving the appropriate pin state. This is useful in test and may have value in applications as well.

#### Int Act Low

When set, the corresponding interrupt is active on the falling edge.

When clear, the corresponding interrupt is active on the rising edge.

## TTL Thresh

When set, the input has TTL threshold. When clear, the input has standard CMOS threshold.

#### High Sink

When set, the output can sink up to 50 mA.

When clear, the output can sink up to 8 mA.

On the CYRF69213, only the P1.7–P1.3 have 50-mA sink drive capability. Other pins have 8-mA sink drive capability.

#### Open Drain

When set, the output on the pin is determined by the Port Data Register. If the corresponding bit in the Port Data Register is set, the pin is in high-impedance state. If the corresponding bit in the Port Data Register is clear, the pin is driven low.

When clear, the output is driven LOW or HIGH.

#### Pull-up Enable

When set the pin has a 7K pull up to  $V_{CC}$  (or VREG for ports with V3.3 enabled).

When clear, the pull up is disabled.

#### Output Enable

When set, the output driver of the pin is enabled.

When clear, the output driver of the pin is disabled.

For pins with shared functions there are some special cases.

#### VREG Output/SPI Use

The P1.2 (VREG), P1.3 (SSEL), P1.4 (SCLK), P1.5 (SMOSI) and P1.6 (SMISO) pins can be used for their dedicated functions or for GPIO.

To enable the pin for GPIO, clear the corresponding VREG Output or SPI Use bit. The SPI function controls the output enable for its dedicated function pins when their GPIO enable bit is clear.

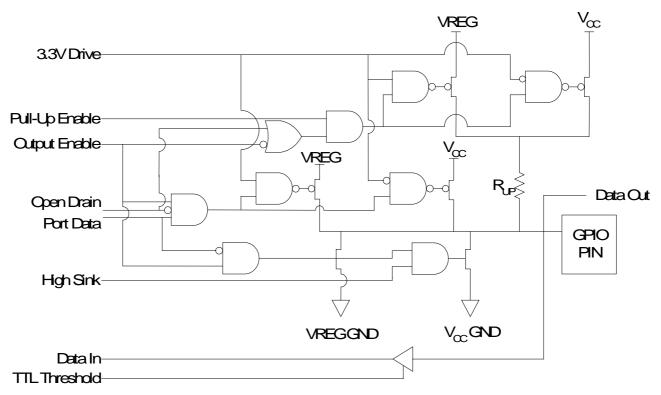

# 3.3V Drive

The P1.3 (SSEL), P1.4 (SCLK), P1.5 (SMOSI) and P1.6 (SMISO) pins have an alternate voltage source from the voltage regulator. If the 3.3V Drive bit is set a high level is driven from the voltage regulator instead of from  $V_{CC}$ .

Setting the 3.3V Drive bit does not enable the voltage regulator. That must be done explicitly by setting the VREG Enable bit in the VREGCR Register (Table 75).

#### Table 46.P0.2/INT0-P0.4/INT2 Configuration (P02CR-P04CR) [0x07-0x09] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Rese	erved	Int Act Low	TTL Thresh	Reserved	Open Drain	Pull-up Enable	Output Enable
Read/Write	_	_	R/W	R/W	_	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

These registers control the operation of pins P0.2–P0.4, respectively. These pins are shared between the P0.2–P0.4 GPIOs and the INT0–INT2. These registers exist in all CYRF69213 parts. The INT0–INT2 interrupts are different than all the other GPIO interrupts. These pins are connected directly to the interrupt controller to provide three edge-sensitive interrupts with independent interrupt vectors. These interrupts occur on a rising edge when Int act Low is clear and on a falling edge when Int act Low is set. These pins are enabled as interrupt sources in the interrupt controller registers (Table 72 and Table 70)

To use these pins as interrupt inputs configure them as inputs by clearing the corresponding Output Enable. If the INTO-INT2 pins are configured as outputs with interrupts enabled, firmware can generate an interrupt by writing the appropriate value to the P0.2, P0.3 and P0.4 data bits in the P0 Data Register

Regardless of whether the pins are used as Interrupt or GPIO pins the Int Enable, Int act Low, TTL Threshold, Open Drain, and Pull-up Enable bits control the behavior of the pin

The P0.2/INT0-P0.4/INT2 pins are individually configured with the P02CR (0x07), P03CR (0x08), and P04CR (0x09), respectively.

Note Changing the state of the Int Act Low bit can cause an unintentional interrupt to be generated. When configuring these interrupt sources, it is best to follow the following procedure:

1. Disable interrupt source

2. Configure interrupt source

3. Clear any pending interrupts from the source

4. Enable interrupt source

## Table 47.P0.7 Configuration (P07CR) [0x0C] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low	TTL Thresh	Reserved	Open Drain	Pull-up Enable	Output Enable

Default	0	0	0	0	0	0	0	0
This register co	ntrols the opera	tion of pin P0.7.	•	•		•	•	

This register controls the operation of pin P0.7.

# Table 48.P1.0/D+ Configuration (P10CR) [0x0D] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low		Reserved		Reserved	Output Enable
Read/Write	R/W	R/W	R/W	_	_	_	-	R/W
Default	0	0	0	0	0	0	0	0

This register controls the operation of the P1.0 (D+) pin when the USB interface is not enabled, allowing the pin to be used as a PS2 interface or a GPIO. See Table 76 for information on enabling USB. When USB is enabled, none of the controls in this register have any effect on the P1.0 pin

Note The P1.0 is an open drain only output. It can actively drive a signal low, but cannot actively drive a signal high

PS/2 Pull-up Enable

Bit 1

0 = Disable the 5K-ohm pull-up resistors

1 = Enable 5K-ohm pull-up resistors for both P1.0 and P1.1. Enable the use of the P1.0 (D+) and P1.1 (D–) pins as a PS2 style interface

# Table 49.P1.1/D– Configuration (P11CR) [0x0E] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low	Rese	erved	Open Drain	Reserved	Output Enable
Read/Write	_	R/W	R/W	_	_	R/W	_	R/W
Default	0	0	0	0	0	0	0	0

This register controls the operation of the P1.1 (D–) pin when the USB interface is not enabled, allowing the pin to be used as a PS2 interface or a GPIO. See Table 76 for information on enabling USB. When USB is enabled, none of the controls in this register have any effect on the P1.1 pin. When USB is disabled, the 5-Kohm pull-up resistor on this pin can be enabled by the PS/2 Pull-up Enable bit of the P10CR Register (Table 48)

Note There is no 2-mA sourcing capability on this pin. The pin can only sink 5 mA at  $V_{OL3}$ 

# Table 50.P1.2 Configuration (P12CR) [0x0F] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	CLK Output	Int Enable	Int Act Low	TTL Threshold	Reserved	Open Drain	Pull-up Enable	Output Enable
Read/Write	R/W	R/W	R/W	R/W	-	R/W	R/W	R/W

This register co	ontrols the opera	tion of the P1.2						
	CLK Output ) = The internally I = When CLK C			onto P1.2 pin ted clock is sent	out onto P1.2 p	in		

#### Table 51.P1.3 Configuration (P13CR) [0x10] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low	3.3V Drive	High Sink	Open Drain	Pull-up Enable	Output Enable
Read/Write	-	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register controls the operation of the P1.3 pin. This register exists in all CYRF69213 parts

The P1.3 GPIO's threshold is always set to TTL

When the SPI hardware is enabled, the output enable and output state of the pin is controlled by the SPI circuitry. When the SPI hardware is disabled, the pin is controlled by the Output Enable bit and the corresponding bit in the P1 data register

Regardless of whether the pin is used as an SPI or GPIO pin the Int Enable, Int act Low, 3.3V Drive, High Sink, Open Drain, and Pull-up Enable control the behavior of the pin

The 50-mA sink drive capability is only available in the CY7C638xx.

#### Table 52.P1.4-P1.6 Configuration (P14CR-P16CR) [0x11-0x13] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	SPI Use	Int Enable	Int Act Low	3.3V Drive	High Sink	Open Drain	Pull-up Enable	Output Enable
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

These registers control the operation of pins P1.4–P1.6, respectively

The P1.4–P1.6 GPIO's threshold is always set to TTL

When the SPI hardware is enabled, pins that are configured as SPI Use have their output enable and output state controlled by the SPI circuitry. When the SPI hardware is disabled or a pin has its SPI Use bit clear, the pin is controlled by the Output Enable bit and the corresponding bit in the P1 data register

Regardless of whether any pin is used as an SPI or GPIO pin the Int Enable, Int act Low, 3.3V Drive, High Sink, Open Drain, and Pull-up Enable control the behavior of the pin

Bit 7 SPI Use

0 = Disable the SPI alternate function. The pin is used as a GPIO

1 = Enable the SPI function. The SPI circuitry controls the output of the pin

Important Note for Comm Modes 01 or 10 (SPI Master or SPI Slave, see Table 56)

When configured for SPI (SPI Use = 1 and Comm Modes [1:0] = SPI Master or SPI Slave mode), the input/output direction of pins P1.3, P1.5, and P1.6 is set automatically by the SPI logic. However, pin P1.4's input/output direction is NOT automatically set; it must be explicitly set by firmware. For SPI Master mode, pin P1.4 must be configured as an output; for SPI Slave mode, pin P1.4 must be configured as an input

#### Table 53. P1.7 Configuration (P17CR) [0x14] [R/W]

Bit #	7	6	5	4	3	2	1	0			
Field	Reserved	Int Enable	Int Act Low	TTL Thresh	High Sink	Open Drain	Pull-up Enable	Output Enable			
Read/Write	-	R/W	R/W	R/W	R/W	R/W	R/W	R/W			
Default	0	0	0	0	0	0	1	0			
U	This register controls the operation of pin P1.7. This register only exists in CY7C638xx The 50-mA sink drive capability is only available in the CY7C638xx. The P1.7 GPIO's threshold is always set to TTL										

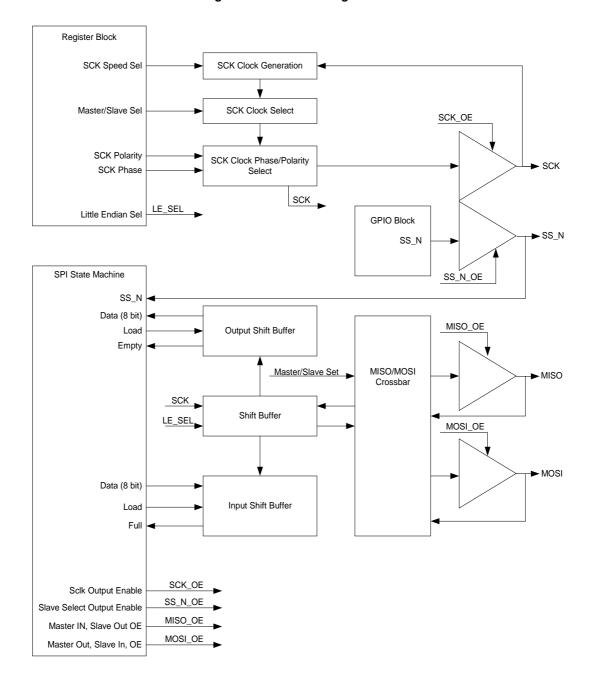

#### Table 54.P2 Configuration (P2CR) [0x15] [R/W]

Bit #	7	6	5	4	3	2	1	0			
Field	Reserved	Int Enable	Int Act Low	TTL Thresh	High Sink	Open Drain	Pull-up Enable	Output Enable			
Read/Write	_	R/W	R/W	R/W	R/W	R/W	R/W	R/W			
Default	0	0	0	0	0	0	0	0			
	This register only exists in CY7C638xx. This register controls the operation of pins P2.0–P2.1. In the CY7C638xx, only 8-mA sink drive capability is available on this pin regardless of the setting of the High Sink bit										

## Serial Peripheral Interface (SPI)

The SPI Master/Slave Interface core logic runs on the SPI clock domain, making its functionality independent of system clock speed. SPI is a four pin serial interface comprised of a clock, an enable and two data pins.

### Figure 15. SPI Block Diagram

#### **SPI Data Register**

## Table 55.SPI Data Register (SPIDATA) [0x3C] [R/W]

Bit #	7	6	5	4	3	2	1	0			
Field				SPIDa	ta[7:0]						
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W			
Default	0	0	0	0	0	0	0	0			
When read, th	s register returns	register returns the contents of the receive buffer. When written, it loads the transmit holding register									
Bits 7:0	SPI Data [7:0]										

When an interrupt occurs to indicate to firmware that a byte of receive data is available, or the transmitter holding register is empty, firmware has 7 SPI clocks to manage the buffers—to empty the receiver buffer, or to refill the transmit holding register. Failure to meet this timing requirement will result in incorrect data transfer.

#### **SPI Configure Register**

11	96	125 KHz	250 KHz				

#### **Timer Registers**

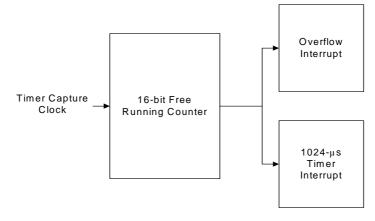

All timer functions of the CYRF69213 are provided by a single timer block. The timer block is asynchronous from the CPU clock.

#### Registers

#### Free-Running Counter

The 16-bit free-running counter is clocked by a 4/6-MHz source. It can be read in software for use as a general-purpose time base. When the low order byte is read, the high order byte is registered. Reading the high order byte reads this register allowing the CPU to read the 16-bit value atomically (loads all bits at one time). The free-running timer generates an interrupt at a 1024- $\mu$ s rate. It can also generate an interrupt when the free-running counter overflow occurs—every 16.384 ms. This allows extending the length of the timer in software.

#### Figure 16. 16-Bit Free-Running Counter Block Diagram

#### Table 59.Free-Running Timer Low-Order Byte (FRTMRL) [0x20] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field				Free-running	g Timer [7:0]			
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0
Bits 7:0	Free-running Tim	ner [7:0]						

This register holds the low-order byte of the 16-bit free-running timer. Reading this register causes the high-order byte to be moved into a holding register allowing an automatic read of all 16 bits simultaneously.

For reads, the actual read occurs in the cycle when the low order is read. For writes, the actual time the write occurs is the cycle when the high order is written

When reading the free-running timer, the low-order byte should be read first and the high-order second. When writing, the low-order byte should be written first then the high-order byte

#### Table 60.Free-Running Timer High-Order Byte (FRTMRH) [0x21] [R/W]

# CYRF69213

## Interrupt Controller

The interrupt controller and its associated registers allow the user's code to respond to an interrupt from almost every functional block in the CYRF69213 devices. The registers associated with the interrupt controller allow interrupts to be disabled either globally or individually. The registers also provide a mechanism by which a user may clear all pending and posted interrupts, or clear individual posted or pending interrupts.

The following table lists all interrupts and the priorities that are available in the CYRF69213.

#### Table 65.Interrupt Numbers, Priorities, Vectors

Interrupt Priority	Interrupt Address	Name
0	0000h	Reset
1	0004h	POR/LVD
2	0008h	INT0
3	000Ch	SPI Transmitter Empty
4	0010h	SPI Receiver Full
5	0014h	GPIO Port 0
6	0018h	GPIO Port 1
7	001Ch	INT1
8	0020h	EP0
9	0024h	EP1
10	0028h	EP2
11	002Ch	USB Reset
12	0030h	USB Active
13	0034h	1-ms Interval timer
14	0038h	Programmable Interval Timer
15	003Ch	Reserved
16	0040h	Reserved

#### Table 65.Interrupt Numbers, Priorities, Vectors (continued)

Interrupt Priority	Interrupt Address	Name
17	0044h	16-bit Free Running Timer Wrap
18	0048h	INT2
19	004Ch	Reserved
20	0050h	GPIO Port 2
21	0054h	Reserved
22	0058h	Reserved
23	005Ch	Reserved
24	0060h	Reserved
25	0064h	Sleep Timer

#### **Architectural Description**

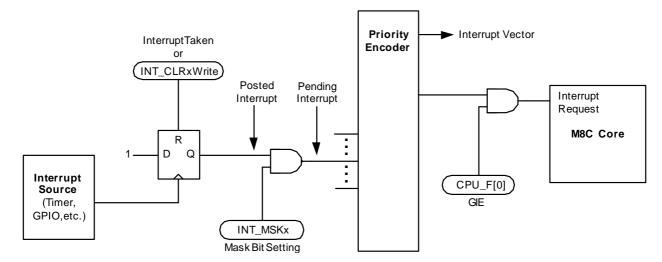

An interrupt is posted when its interrupt conditions occur. This results in the flip-flop in Figure 19 clocking in a '1'. The interrupt will remain posted until the interrupt is taken or until it is cleared by writing to the appropriate INT\_CLRx register.

A posted interrupt is not pending unless it is enabled by setting its interrupt mask bit (in the appropriate INT\_MSKx register). All pending interrupts are processed by the Priority Encoder to determine the highest priority interrupt which will be taken by the M8C if the Global Interrupt Enable bit is set in the CPU\_F register.

Disabling an interrupt by clearing its interrupt mask bit (in the INT\_MSKx register) does not clear a posted interrupt, nor does it prevent an interrupt from being posted. It simply prevents a posted interrupt from becoming pending.

Nested interrupts can be accomplished by re-enabling interrupts inside an interrupt service routine. To do this, set the IE bit in the Flag Register.

A block diagram of the CYRF69213 Interrupt Controller is shown in Figure 19.

#### Figure 19. Interrupt Controller Block Diagram

# CYRF69213

#### Interrupt Processing

The sequence of events that occur during interrupt processing is as follows:

1. An interrupt becomes active, either because:

- a. The interrupt condition occurs (for example, a timer expires).
- b. A previously posted interrupt is enabled through an update of an interrupt mask register.
- c. An interrupt is pending and GIE is set from 0 to 1 in the CPU Flag register.
- 2. The current executing instruction finishes.
- 3. The internal interrupt is dispatched, taking 13 cycles. During this time, the following actions occur:
  - a. The MSB and LSB of Program Counter and Flag registers (CPU\_PC and CPU\_F) are stored onto the program stack by an automatic CALL instruction (13 cycles) generated during the interrupt acknowledge process.
  - b. The PCH, PCL, and Flag register (CPU\_F) are stored onto the program stack (in that order) by an automatic CALL instruction (13 cycles) generated during the interrupt acknowledge process.
  - c. The CPU\_F register is then cleared. Since this clears the GIE bit to 0, additional interrupts are temporarily disabled
  - d. The PCH (PC[15:8]) is cleared to zero.
  - e. The interrupt vector is read from the interrupt controller and its value placed into PCL (PC[7:0]). This sets the program counter to point to the appropriate address in the interrupt table (for example, 0004h for the POR/LVD interrupt).
- Program execution vectors to the interrupt table. Typically, a LJMP instruction in the interrupt table sends execution to the user's Interrupt Service Routine (ISR) for this interrupt.
- 5. The ISR executes. Note that interrupts are disabled since GIE = 0. In the ISR, interrupts can be re-enabled if desired

#### Table 66. Interrupt Clear 0 (INT\_CLR0) [0xDA] [R/W]

by setting GIE = 1 (care must be taken to avoid stack overflow).

- 6. The ISR ends with a RETI instruction which restores the Program Counter and Flag registers (CPU\_PC and CPU\_F). The restored Flag register re-enables interrupts, since GIE = 1 again.
- 7. Execution resumes at the next instruction, after the one that occurred before the interrupt. However, if there are more pending interrupts, the subsequent interrupts will be processed before the next normal program instruction.

#### Interrupt Latency

The time between the assertion of an enabled interrupt and the start of its ISR can be calculated from the following equation.

Latency = Time for current instruction to finish + Time for internal interrupt routine to execute + Time for LJMP instruction in interrupt table to execute.

For example, if the 5-cycle JMP instruction is executing when an interrupt becomes active, the total number of CPU clock cycles before the ISR begins would be as follows:

(1 to 5 cycles for JMP to finish) + (13 cycles for interrupt routine) + (7 cycles for LJMP) = 21 to 25 cycles.

In the example above, at 24 MHz, 25 clock cycles take 1.042  $\mu s.$ 

#### Interrupt Registers

The Interrupt Registers are discussed it the following sections.

#### Interrupt Clear Register

The Interrupt Clear Registers (INT\_CLRx) are used to enable the individual interrupt sources' ability to clear posted interrupts.

When an INT\_CLRx register is read, any bits that are set indicates an interrupt has been posted for that hardware resource. Therefore, reading these registers gives the user the ability to determine all posted interrupts.

Bit #	7	6	5	4	3	2	1	0
Field	GPIO Port 1	Sleep Timer	INT1	GPIO Port 0	SPI Receive	SPI Transmit	INT0	POR/LVD
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

When reading this register,

0 = There's no posted interrupt for the corresponding hardware

1 = Posted interrupt for the corresponding hardware present

Writing a '0' to the bits will clear the posted interrupts for the corresponding hardware. Writing a '1' to the bits AND to the ENSWINT (Bit 7 of the INT\_MSK3 Register) will post the corresponding hardware interrupt

#### Table 67. Interrupt Clear 1 (INT\_CLR1) [0xDB] [R/W]

Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

When reading this register,

0 = There's no posted interrupt for the corresponding hardware

1 = Posted interrupt for the corresponding hardware present

Writing a '0' to the bits will clear the posted interrupts for the corresponding hardware. Writing a '1' to the bits AND to the ENSWINT (Bit 7 of the INT\_MSK3 Register) will post the corresponding hardware interrupt

Bits 7,6,5,3,0 Reserved

#### Interrupt Mask Registers

The Interrupt Mask Registers (INT\_MSKx) are used to enable the individual interrupt sources' ability to create pending interrupts.

There are four Interrupt Mask Registers (INT\_MSK0, INT\_MSK1, INT\_MSK2, and INT\_MSK3), which may be referred to in general as INT\_MSKx. If cleared, each bit in an INT\_MSKx register prevents a posted interrupt from becoming a pending interrupt (input to the priority encoder). However, an interrupt can still post even if its mask bit is zero. All INT\_MSKx bits are independent of all other INT\_MSKx bits.

If an INT\_MSKx bit is set, the interrupt source associated with that mask bit may generate an interrupt that will become a pending interrupt. The Enable Software Interrupt (ENSWINT) bit in INT\_MSK3[7] determines the way an individual bit value written to an INT\_CLRx register is interpreted. When is cleared, writing 1's to an INT\_CLRx register has no effect. However, writing 0's to an INT\_CLRx register, when ENSWINT is cleared, will cause the corresponding interrupt to clear. If the ENSWINT bit is set, any 0's written to the INT\_CLRx registers are ignored. However, 1's written to an INT\_CLRx register, while ENSWINT is set, will cause an interrupt to post for the corresponding interrupt.

Software interrupts can aid in debugging interrupt service routines by eliminating the need to create system level interactions that are sometimes necessary to create a hardware-only interrupt.

Bit #	7	6	5	4	3	2	1	0

3.3V regulato the bandgap ( wakeup follow up following a pulse occurrir the bandgap	USB transceiver has a dedicated 3.3V regulator for USB signalling purposes and to provide for the 1.5K D– pull up. Unlike the othe ator, this regulator cannot be controlled/accessed by firmware. When the device is suspended, this regulator is disabled along with ap (which provides the reference voltage to the regulator) and the D– line is pulled up to 5V through an alternate 6.5K resistor. During lowing a suspend, the band gap and the regulator are switched on in any order. Under an extremely rare case when the device wakes g a bus reset condition and the voltage regulator and the band gap turn on in that particular order, there is possibility of a glitch/low ring on the D– line. The host can misinterpret this as a deattach condition. This condition, although rare, can be avoided by keeping ap circuitry enabled during sleep. This is achieved by setting the 'No Buzz' bit, bit[5] in the OSC_CR0 register. This is an issue only the is put to sleep during a bus reset condition.

## **USB Serial Interface Engine (SIE)**

The SIE allows the microcontroller to communicate with the USB host at low-speed data rates (1.5 Mbps). The SIE simplifies the interface between the microcontroller and USB by incorporating hardware that handles the following USB bus activity independently of the microcontroller:

- Translating the encoded received data and formatting the data to be transmitted on the bus
- CRC checking and generation. Flagging the microcontroller if errors exist during transmission
- Address checking. Ignoring the transactions not addressed to the device
- Sending appropriate ACK/NAK/STALL handshakes

## **USB** Device

#### Table 76.USB Device Address (USBCR) [0x40] [R/W]

- Identifying token type (SETUP, IN, or OUT). Setting the appropriate token bit once a valid token is received
- Placing valid received data in the appropriate endpoint FIFOs
- Sending and updating the data toggle bit (Data1/0)
- Bit stuffing/unstuffing.

Firmware is required to handle the rest of the USB interface with the following tasks:

- · Coordinate enumeration by decoding USB device requests
- · Fill and empty the FIFOs
- Suspend/Resume coordination
- · Verify and select Data toggle values

## Endpoint 0 Mode

Because both firmware and the SIE are allowed to write to the Endpoint 0 Mode and Count Registers the SIE provides an interlocking mechanism to prevent accidental overwriting of data. When the SIE writes to these registers they are locked and the processor cannot write to them until after it has read them. Writing to this register clears the upper four bits regardless of the value written.

## Table 78.Endpoint 0 Mode (EP0MODE) [0x44] [R/W]

Bit #	7	6	5	4	3	2	1	0

Bit 6	Reserved												
Bit 5	NAK Int Enable This bit, when set, causes an endpoint interrupt to be generated even when a transfer completes with a NAK. Unlike enCoRe, CYRF69213 family members do not generate an endpoint interrupt under these conditions unless this bit is set 0 = Disable interrupt on NAK'd transactions 1 = Enable interrupt on NAK'd transaction												
Bit 4	ACK'd Transaction The ACK'd trans ACK packet This bit is cleared 0 = The transaction 1 = The transaction	action bit is set d by any writes t ion does not cor	o the register nplete with an A		transaction to th	e register's end	point that compl	etes with an					
Bits 3:0	Mode [3:0] The endpoint mo the USB SIE res endpoint.												
respectively (i EP1MODE an to EP2MODE can put the er	/hen the SIE writes to the EP1MODE or the EP2MODE register it blocks firmware writes to the EP2MODE or the EP1MODE registers, tively (if both writes occur in the same clock cycle). This is because the design employs only one common 'update' signal for both ODE and EP2MODE registers. Thus, when SIE writes to the EP1MODE register, the update signal is set and this prevents firmware writes MODE register. SIE writes to the endpoint mode registers have higher priority than firmware writes. This mode register write block situation t the endpoints in incorrect modes. Firmware must read the EP1/2MODE registers immediately following a firmware write and rewrite if us read is incorrect												

#### **Endpoint Data Buffers**

The three data buffers are used to hold data for both IN and OUT transactions. Each data buffer is 8 bytes long.

The reset values of the Endpoint Data Registers are unknown.

Unlike past enCoRe parts the USB data buffers are only accessible in the I/O space of the processor.

## Table 80.Endpoint 0 Data (EP0DATA) [0x50-0x57] [R/W]

Bit #	7	6	5	4	3	2	1	0						
Field		Endpoint 0 Data Buffer [7:0]												
Read/Write	R/W	R/W R/W R/W R/W R/W R/W R/W												
Default	Unknown	Unknown Unknown Unknown Unknown Unknown Unknown Unknown Unknown												
The Endpoint 0	buffer is comprised of 8 bytes located at address 0x50 to 0x57													

#### Table 81.Endpoint 1 Data (EP1DATA) [0x58-0x5F] [R/W]

Bit #	7	6	5	4	3	2	1	0						
Field		Endpoint 1 Data Buffer [7:0]												
Read/Write	R/W	R/W R/W R/W R/W R/W R/W R/W												
Default	Unknown	Unknown Unknown Unknown Unknown Unknown Unknown Unknown Unknown												
The Endpoint 1	Ibuffer is comprised of 8 bytes located at address 0x58 to 0x5F													

#### Table 82.Endpoint 2 Data (EP2DATA) [0x60-0x67] [R/W]

Bit #	7	6	5	4	3	2	1	0					
Field		Endpoint 2 Data Buffer [7:0]											
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W					
Default	Unknown Unknown Unknown Unknown Unknown Unknown Unknown Unknown												
The Endpoint 2	It 2 buffer is comprised of 8 bytes located at address 0x60 to 0x67												

### **USB Mode Tables**

Mode	Encoding	SETUP	IN	OUT	Comments
DISABLE	0000	Ignore	Ignore	Ignore	Ignore all USB traffic to this endpoint. Used by Data and Control endpoints
NAK IN/OUT	0001	Accept	NAK	NAK	NAK IN and OUT token. Control endpoint only
STATUS OUT ONLY	0010	Accept	STALL	Check	STALL IN and ACK zero byte OUT. Control endpoint only
STALL IN/OUT	0011	Accept	STALL	STALL	STALL IN and OUT token. Control endpoint only
STATUS IN ONLY	0110	Accept	TX0 byte	STALL	STALL OUT and send zero byte data for IN token. Control end- point only
ACK OUT – STATUS IN	1011	Accept	TX0 byte	ACK	ACK the OUT token or send zero byte data for IN token. Control endpoint only
ACK IN – STATUS OUT	1111	Accept	TX Count	Check	Respond to IN data or Status OUT. Control endpoint only
NAK OUT	1000	Ignore	Ignore	NAK	Send NAK handshake to OUT token. Data endpoint only
ACK OUT (STALL = 0)	1001	Ignore	Ignore	ACK	This mode is changed by the SIE to mode 1000 on issuance of ACK handshake to an OUT. Data endpoint only
ACK OUT (STALL = 1)	1001	Ignore	Ignore	STALL	STALL the OUT transfer
NAK IN	1100	Ignore	NAK	Ignore	Send NAK handshake for IN token. Data endpoint only
ACK IN (STALL = 0)	1101	Ignore	TX Count	Ignore	This mode is changed by the SIE to mode 1100 after receiving ACK handshake to an IN data. Data endpoint only
ACK IN (STALL = 1)	1101	Ignore	STALL	Ignore	STALL the IN transfer. Data endpoint only
Reserved	0101	Ignore	Ignore	Ignore	These modes are not supported by SIE. Firmware should not use this mode in Control and Data endpoints
Reserved	0111	Ignore	Ignore	Ignore	
Reserved	1010	Ignore	Ignore	Ignore	
Reserved	0100	Ignore	Ignore	Ignore	]
Reserved	1110	Ignore	Ignore	Ignore	1

#### Mode Column

The 'Mode' column contains the mnemonic names given to the modes of the endpoint. The mode of the endpoint is determined by the four-bit binaries in the 'Encoding' column as discussed in the following section. The Status IN and Status OUT represent the status IN or OUT stage of the control transfer.

#### **Encoding Column**

The contents of the 'Encoding' column represent the Mode Bits [3:0] of the Endpoint Mode Registers (Table 78 and Table 79). The endpoint modes determine how the SIE responds to different tokens that the host sends to the endpoints. For example, if the Mode Bits [3:0] of the Endpoint 0 Mode Register are set to '0001', which is NAK IN/OUT mode, the SIE will send an ACK handshake in response to SETUP tokens and NAK any IN or OUT tokens.

#### SETUP, IN, and OUT Columns

Depending on the mode specified in the 'Encoding' column, the 'SETUP', 'IN', and 'OUT' columns contain the SIE's responses when the endpoint receives SETUP, IN, and OUT tokens, respectively.

A 'Check' in the Out column means that upon receiving an OUT token the SIE checks to see whether the OUT is of zero length and has a Data Toggle (Data1/0) of 1. If these conditions are true, the SIE responds with an ACK. If any of the above conditions is not met, the SIE will respond with either a STALL or Ignore.

A 'TX Count' entry in the IN column means that the SIE will transmit the number of bytes specified in the Byte Count Bit [3:0] of the Endpoint Count Register (Table 77) in response to any IN token.

 b = Both Read and Write

 r = Read Only

 w = Write Only

 c = Read/Clear

 ? = Unknown

 d = calibration value. Should not change during normal use

## **Radio Function Register Descriptions**

All registers are read and writeable, except where noted. Registers may be written to or read from either individually or in sequential groups. A single-byte read or write reads or writes from the addressed register. Incrementing burst read and write is a sequence that begins with an address, and then reads or writes to/from each register in address order for as long as clocking continues. It is possible to repeatedly read (poll) a single register using a non-incrementing burst read.

These registers are managed and configured over SPI by the user firmware running in the microcontroller function.

#### **Table 83.Register Map Summary**

Bit 6	Reserved. Must no		сі.								
Bit 5			s. This bit is set	whenever the r	eceive buffer is	full. and cleare	d otherwise.				
Bit 3	Receive Buffer Full Interrupt Status. This bit is set whenever the receive buffer is full, and cleared otherwise. Receive Buffer Half Full Interrupt Status. This bit is set whenever there are eight or more bytes remaining in the receive buffer. Firmware must read exactly eight bytes when reading RXB8 IRQ. It is possible, in rare cases, that the last byte of a packet may remain in the buffer even though the RXB1_IRQ flag has cleared. This can ONLY happen on the last byte of a packet and only if the packet data is being read out of the buffer while the packet is still being received. The flag is trustworthy under all other conditions, and for all bytes prior to the last. When using RXB1_IRQ and unloading the packet data during reception, the user should be sure to check the RX_COUNT_ADR value after the RXC/RXE is set and unload the last remaining byte if the number of bytes unloaded is less than the reported count, even though the RXB1_IRQ is not set Receive Buffer Not Empty Interrupt Status. This bit is set at any time that there are 1 or more bytes in the receive buffer, and cleared when the receive buffer is empty. RXB1 IRQ must not be set when RXB8 IRQ is set and vice versa.										
Bit 2	Receive Buffer En	ror Interrupt Stat ad data; (2) Wh	us. This IRQ is	triggered in one	e of two ways: (	1) When the rec	eive buffer is em				
Bit 1	Receive Buffer Error Interrupt Status. This IRQ is triggered in one of two ways: (1) When the receive buffer is empty and there is an attempt to read data; (2) When the receive buffer is full and more data is received. This flag is cleared when RX GO is set and a SOP is received. Packet Receive Complete Interrupt Status. This IRQ is triggered when a packet has been received. If transaction mode is enabled, then this bit is not set until after transmission of the ACK. If transaction mode is not enabled then this bit is set as soon as a valid packet is received. This bit is cleared when this register is read. RXC IRQ and RXE IRQ flags may change value at different times in response to a single event. There are cases when this bit is not triggered when ACK EN = 1 and there is an error in reception. Therefore, firmware should examine RXC IRQ, RXE IRQ, and CRC 0 to determine receive status. If the first read of this register returns RXC IRQ = 1 and RXE IRQ = 0 then firmware must execute a second read to this register to determine if an error occurred by examining the status of RXE IRQ. If the first read of this register returns RXC IRQ = 1 and RXE IRQ = 1 then the firmware must not execute a second read to this register for a given transaction.										
Bit 0	Receive Error Inter received with a babecause the received reading RX_STAT	d CRC16, an ur ve buffer is still	nexpected EOP not empty when	is detected, a p the next packe	acket type (data t starts. The exa	a or ACK) mism	atch, or a packe	t is dropped

Function	S	SOP EN	SOP LEN	LEN EN	SOP TH						
Bit 7	SOP Enable. When this bit is set, each transmitted packet begins with a SOP field, and only packets beginning with a valid SOP field will be received. If this bit is cleared, no SOP field will be generated when a packet is transmitted, and packet reception will begin whenever two successive correlations against the DATA_CODE_ADR code are detected. SOP PN Code Length. When this bit is set the SOP_CODE_ADR code length is 64 chips. When this bit is cleared the										
Bit 6	SOP PN Code Length. When this bit is set the SOP_CODE_ADR code length is 64 chips. When this bit is cleared the SOP_CODE_ADR code length is 32 chips.										
Bit 5	SOP fie bit is cle	<b>5 1 5 1</b>									
Bits 4:0	is a thre fields. T When S	SOP Correlator Threshold. This is the receive data correlator threshold used when attempting to detect a SOP symbol. There is a threshold for the SOP_CODE_ADR code. This (single) threshold is applied independently to each of SOP1 and SOP2 fields. There are then two thresholds for each of the 64-chip DATA_CODE_ADR codes and 32-chip DATA_CODE_ADR codes. When SOP LEN is set, all 5 bits of this field are used. When SOP LEN is cleared, the most significant bit is disregarded. Typical applications configure SOP TH = 04h for SOP32 and SOP TH = 0Eh for SOP64.									

Mnemonic		DATA32	_THOLD_ADR				Address	0x11

Function	Not Used	Not Used	Not Used			TH64			
Bits 4:0	4 Chip Data PN Code Correlator Threshold. This register sets the correlator threshold used in DSSS modes when the DATA CODE LENGTH (see TX_CFG_ADR) is set to 64. Typical applications configure TH64 = 0Eh.								

Mnemonic			RSSI_ADR				Address	0x13
Bit	7	6	5	4	3	2	1	0
Default	0	-	1	0	0	0	0	0
Read/Write	R	-	R	R	R	R	R	R
Function	SOP	Not Used	ΙΝΑ		•	RSSI		

A Received Signal Strength Indicator (RSSI) reading is taken automatically when an SOP symbol is detected. In addition, an RSSI reading is taken whenever RSSI\_ADR is read. The contents of this register are not valid after the device is configured for receive mode until either a SOP symbol is detected, or the register is read. The conversion can occur as often as once every 12 µs.

To measure the background RF signal strength on a channel before a packet has been received, the MCU should perform a 'dummy' read of this register, the results of which should be discarded. This 'dummy' read will cause an RSSI measurement to be taken, and therefore subsequent readings of the register will yield valid data.

Bit 7 SOP RSSI Reading. When set, this bit indicates that the reading in the RSSI field was taken when a SOP symbol was detected. When cleared, this bit indicates that the reading stored in the RSSI field was triggered by a previous SPI read of this register.

Bit 5 LNA State. This bit indicates the LNA state when the RSSI reading was taken. When cleared, this bit indicates that the LNA was disabled when the RSSI reading was taken; if set, this bit indicates that the LNA was enabled when the RSSI reading was taken.

Bits 4:0 RSSI Reading. This field indicates the instantaneous strength of the RF signal being received at the time that the RSSI reading was taken. A larger value indicates a stronger signal. The signal strength measured is for the RF signal on the configured channel, and is measured after the LNA stage.

#### **Register Files**

Files are written to or read from using non-incrementing burst read or write transactions. In most cases reading a file may be destructive; the file must be completely read, otherwise the contents may be altered.

Mnemonic	TX_BUFFER_ADR	Address	0x20	
Length	16 Bytes	R/W	W	
Default	0xXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX			
The transmit buffer is a FIFO. Writing to this file adds a byte to the packet being sent. Writing more bytes to this file than the packet length in				

TX\_LENGTH\_ADR will have no effect, and these bytes will be lost after successful packet transmission. It is **NOT** possible to load two 8-byte packets into this register, and then transmit them sequentially by enabling the TX GO bit twice; this would have the effect of sending the first eight bytes twice.

Mnemonic	RX_BUFFER_ADR	Address	0x21
Length	16 Bytes	R/W	R
Default	0xXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX		

The receive buffer is a FIFO. Received bytes may be read from this file register at any time that it is not empty, but when reading from this file register before a packet has been completely received care must be taken to ensure that error packets (for example with bad CRC16) are handled correctly.

When the receive buffer is configured to be overwritten by new packets (the alternative is for new packets to be discarded if the receive buffer is not empty), similar care must be taken to verify after the packet has been read from the buffer that no part of it was overwritten by a newly received packet while this file register is being read.

When the VLD EN bit in RX\_CFG\_ADR is set, the bytes in this file register alternate—the first byte read is data, the second byte is a valid flag for each bit in the first byte, the third byte is data, the fourth byte valid flag, and so on. In SDR and DDR modes the valid flag for a bit is set if the correlation coefficient for the bit exceeded the correlator threshold, and is cleared if it did not. In 8DR mode, the MSB of a valid flag byte indicates whether or not the correlation coefficient of the corresponding received symbol exceeded the threshold. The seven LSBs contain the number of erroneous chips received for the data.

Mnemonic	SOP_CODE_ADR	Address	0x22
Length	8 Bytes	R/W	R/W
Default	0x17FF9E213690C782		
these four bytes r are 64-chip code auto-correlation a file and used for When reading thi	thip SOP_CODE_ADR codes, only the first four bytes of the must be followed by four bytes of 'dummy' data. However, a swith good auto-correlation and cross-correlation properties and cross-correlation properties when used as 32-chip cor- both 32-chip and 64-chip SOP symbols. is file, all eight bytes must be read; if fewer than eight bytes	a class of codes known as 'multiplicative codes' may be ties where the least significant 32 chips themselves ha des. In this case the same eight-byte value may be load	used; there ve good ded into this
by the number of Recommended S	f bytes read. This applies to writes, as well.

0x49C1DF62490	COB1DF		
0x72141A7F721	14E597		
Do not access or	modify this register during Transmit or Receive.		

Mnemonic	DATA_CODE_ADR	Address	0x23
Length	16 Bytes	R/W	R/W
Default	0x02F9939702FA5CE3012BF1DB0132BE6F		

This file is ignored when using the device in 1-Mbps GFSK mode. In 64-SDR mode, only the first eight bytes are used; in order to complete the file write process, these eight bytes must be followed by eight bytes of 'dummy' data. In 32-SDR mode, only four bytes are used, and in 32-DDR mode only eight bytes are used. In 64-DDR and 8DR modes, all sixteen bytes are used. Certain sixteen-byte sequences have been calculated that provide excellent auto-correlation and cross-correlation properties, and it is recommended that such sequences be used; the default value of this register is one such sequence. In typical applications, all devices use the same DATA\_CODE\_ADR codes, and devices and systems are addressed by using different SOP\_CODE\_ADR codes; in such cases it may never be necessary to change the contents of this register from the default value.

When reading this file, all sixteen bytes must be read; if fewer than sixteen bytes are read from the file, the contents of the file will have been rotated by the number of bytes read. This applies to writes, as well.

Typical applications should use the default code.

Do not access or modify this register during Transmit or Receive.

Mnemonic	PREAMBLE_ADR	Address	0x24		
Length	3 Bytes	R/W	R/W		
Default	0x333302				
Byte 1 – The number of repetitions of the preamble sequence that are to be transmitted. The preamble may be disabled by writing 0x00 to this byte.					

Byte 2 - Least significant eight chips of the preamble sequence

Byte 3– Most significant eight chips of the preamble sequence

If using 64-SDR to communicate with CYWUSB69xx devices, set number of repetitions to four for optimum performance

When reading this file, all three bytes must be read; if fewer than three bytes are read from the file, the contents of the file will have been rotated by the number of bytes read. This applies to writes, as well.

Do not access or modify this register during Transmit or Receive.

Mnemonic	MFG_ID_ADR	Address	0x25
Length	6 Bytes	R	R
Default	NA		
Byte 1 – 4 bits ve	rsion + 2 bits vendor ID + high 2 bits of Year yte 6: Manufacturing ID for the device.		

To minimize  $\sim$ 190  $\mu$ A of current consumption (default), execute a 'dummy' single-byte SPI write to this address with a zero data stage after the contents have been read. Non-zero to enable reading of fuses. Zero to disable reading fuses.

## **Absolute Maximum Ratings**

Storage Temperature .......-65°C to +150°C Ambient Temperature with Power Applied .......0°C to +70°C Supply Voltage on any power supply pin relative to  $V_{SS}$ -0.3V to +3.9V

DC Voltage to Logic Inputs<sup>[8]</sup> .....-0.3V to  $V_{IO}$  +0.3V

DC Voltage applied to Outputs in High-Z State .. –0.3V to  $\rm V_{IO}$  +0.3V

Static Discharge Voltage (Digital) <sup>[9]</sup>	>2000V
Static Discharge Voltage (RF) <sup>[9]</sup>	1100V
Latch-up Current	+200 mA, -200 mA
Ground Voltage	0V
F <sub>OSC</sub> (Crystal Frequency)	12 MHz ±30 ppm

Notes

8. It is permissible to connect voltages above V<sub>IO</sub> to inputs through a series resistor limiting input current to 1 mA. AC timing not guaranteed.

9. Human Body Model (HBM).

# **DC Characteristics** (T = 25°C)

Parameter	Description	Conditions	Min.	Тур.	Max.	Unit
Radio Functio	on Operating Voltages	•
