NOTES FOR CMOS DEVICES

① VOLTAGE APPLICATION WAVEFORM AT INPUT PIN

Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between V_{IL} (MAX) and V_{IH} (MIN) due to noise, etc., the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between V_{IL} (MAX) and V_{IH} (MIN).

② HANDLING OF UNUSED INPUT PINS

Unconnected CMOS device inputs can be cause of malfunction. If an input pin is unconnected, it is possible that an internal input level may be generated due to noise, etc., causing malfunction. CMOS devices behave differently than Bipolar or NMOS devices. Input levels of CMOS devices must be fixed high or low by using pull-up or pull-down circuitry. Each unused pin should be connected to V_{DD} or GND via a resistor if there is a possibility that it will be an output pin. All handling related to unused pins must be judged separately for each device and according to related specifications governing the device.

③ PRECAUTION AGAINST ESD

A strong electric field, when exposed to a MOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop generation of static electricity as much as possible, and quickly dissipate it when it has occurred. Environmental control must be adequate. When it is dry, a humidifier should be used. It is recommended to avoid using insulators that easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors should be grounded. The operator should be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions need to be taken for PW boards with mounted semiconductor devices.

④ STATUS BEFORE INITIALIZATION

Power-on does not necessarily define the initial status of a MOS device. Immediately after the power source is turned ON, devices with reset functions have not yet been initialized. Hence, power-on does not guarantee output pin levels, I/O settings or contents of registers. A device is not initialized until the reset signal is received. A reset operation must be executed immediately after power-on for devices with reset functions.

⑤ POWER ON/OFF SEQUENCE

In the case of a device that uses different power supplies for the internal operation and external interface, as a rule, switch on the external power supply after switching on the internal power supply. When switching the power supply off, as a rule, switch off the external power supply and then the internal power supply. Use of the reverse power on/off sequences may result in the application of an overvoltage to the internal elements of the device, causing malfunction and degradation of internal elements due to the passage of an abnormal current.

The correct power on/off sequence must be judged separately for each device and according to related specifications governing the device.

⑥ INPUT OF SIGNAL DURING POWER OFF STATE

Do not input signals or an I/O pull-up power supply while the device is not powered. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements.

Input of signals during the power off state must be judged separately for each device and according to related specifications governing the device.

- **The information contained in this document is being issued in advance of the production cycle for the product. The parameters for the product may change before final production or NEC Electronics Corporation, at its own discretion, may withdraw the product prior to its production.**
- **Not all products and/or types are available in every country. Please check with an NEC Electronics sales representative for availability and additional information.**
- No part of this document may be copied or reproduced in any form or by any means without the prior written consent of NEC Electronics. NEC Electronics assumes no responsibility for any errors that may appear in this document.
- NEC Electronics does not assume any liability for infringement of patents, copyrights or other intellectual property rights of third parties by or arising from the use of NEC Electronics products listed in this document or any other liability arising from the use of such products. No license, express, implied or otherwise, is granted under any patents, copyrights or other intellectual property rights of NEC Electronics or others.
- Descriptions of circuits, software and other related information in this document are provided for illustrative purposes in semiconductor product operation and application examples. The incorporation of these circuits, software and information in the design of a customer's equipment shall be done under the full responsibility of the customer. NEC Electronics assumes no responsibility for any losses incurred by customers or third parties arising from the use of these circuits, software and information.
- While NEC Electronics endeavors to enhance the quality, reliability and safety of NEC Electronics products, customers agree and acknowledge that the possibility of defects thereof cannot be eliminated entirely. To minimize risks of damage to property or injury (including death) to persons arising from defects in NEC Electronics products, customers must incorporate sufficient safety measures in their design, such as redundancy, fire-containment and anti-failure features.
- NEC Electronics products are classified into the following three quality grades: "Standard", "Special" and "Specific". The "Specific" quality grade applies only to NEC Electronics products developed based on a customer-designated "quality assurance program" for a specific application. The recommended applications of an NEC Electronics products depend on its quality grade, as indicated below. Customers must check the quality grade of each NEC Electronics product before using it in a particular application.

  "Standard": Computers, office equipment, communications equipment, test and measurement equipment, audio and visual equipment, home electronic appliances, machine tools, personal electronic equipment and industrial robots.

  "Special": Transportation equipment (automobiles, trains, ships, etc.), traffic control systems, anti-disaster systems, anti-crime systems, safety equipment and medical equipment (not specifically designed for life support).

  "Specific": Aircraft, aerospace equipment, submersible repeaters, nuclear reactor control systems, life support systems and medical equipment for life support, etc.

The quality grade of NEC Electronics products is "Standard" unless otherwise expressly specified in NEC Electronics data sheets or data books, etc. If customers wish to use NEC Electronics products in applications not intended by NEC Electronics, they must contact an NEC Electronics sales representative in advance to determine NEC Electronics' willingness to support a given application.

(Note)

(1) "NEC Electronics" as used in this statement means NEC Electronics Corporation and also includes its majority-owned subsidiaries.

(2) "NEC Electronics products" means any product developed or manufactured by or for NEC Electronics (as defined above).

INTRODUCTION

Readers

This manual is intended for user engineers who wish to understand the functions of the 78K0R/Kx3-L and design and develop application systems and programs for these devices.

The target products are as follows.

- 78K0R/KC3-L: μPD78F1000, 78F1001, 78F1002, 78F1003
- 78K0R/KD3-L: μPD78F1004, 78F1005, 78F1006
- 78K0R/KE3-L: μPD78F1007, 78F1008, 78F1009

Purpose

This manual is intended to give users an understanding of the functions described in the **Organization** below.

Organization

The 78K0R/Kx3-L manual is separated into two parts: this manual and the instructions edition (common to the 78K0R Microcontroller).

78K0R/Kx3-L User's Manual (This Manual)	**78K0R Microcontroller User's Manual Instructions**
• Pin functions • Internal block functions • Interrupts • Other on-chip peripheral functions • Electrical specifications (target)	• CPU functions • Instruction set • Explanation of each instruction

How to Read This Manual

It is assumed that the readers of this manual have general knowledge of electrical engineering, logic circuits, and microcontrollers.

- To gain a general understanding of functions:
  → Read this manual in the order of the **CONTENTS**.
- How to interpret the register format:
  → For a bit number enclosed in angle brackets, the bit name is defined as a reserved word in the RA78K0R, and is defined as an sfr variable using the #pragma sfr directive in the CC78K0R.
- To know details of the 78K0R Microcontroller instructions:
  → Refer to the separate document **78K0R Microcontroller Instructions User's Manual (U17792E)**.

Conventions

Data significance:	Higher digits on the left and lower digits on the right	
Active low representations:	$\overline{\times\times\times}$ (overscore over pin and signal name)	
Note:	Footnote for item marked with **Note** in the text	
Caution:	Information requiring particular attention	
Remark:	Supplementary information	
Numerical representations:	Binary	···×××× or ××××B
	Decimal	···××××
	Hexadecimal	···××××H

2. Under development

- On-chip internal high-speed oscillation clocks
  - 20 MHz Internal high-speed oscillation clock: 20 MHz±1 % (target)
  - 8 MHz Internal high-speed oscillation clock: 8 MHz±1 % (target)
  - 1 MHz Internal high-speed oscillation clock: 1 MHz±5 %
- On-chip single-power-supply flash memory (with prohibition of chip erase/block erase/writing function)
- Self-programming (with boot swap function/flash shield window function)
- On-chip debug function
- On-chip power-on-clear (POC) circuit and low-voltage detector (LVI)
- On-chip watchdog timer (operable with the dedicated internal low-speed oscillation clock)
- On-chip multiplier/divider (16 bits × 16 bits, 32 bits ÷ 32 bits)
- On-chip key interrupt function
- On-chip clock output/buzzer output controller[Note]
- On-chip BCD adjustment
- I/O ports: 37 to 55 (N-ch open drain: 2[Note])
- Timer: 10 channels
  - 16-bit timer: 8 channels
  - Watchdog timer: 1 channel
  - Real-time counter: 1 channel
- On-chip comparator/programmable gain amplifier function
- Serial interface
  - CSI: 2 channels/UART (LIN-bus supported): 1 channel
  - CSI: 1 channel/UART: 1 channel/simplified I^2C: 1 channel
  - I^2C: 1 channel[Note]
- 10-bit resolution A/D converter (AV_{REF} = 1.8 to 5.5 V): 10 to 12 channels
- Power supply voltage: V_{DD} = 1.8 to 5.5 V
- Operating ambient temperature: T_A = −40 to +85°C

Note This is not mounted onto 44-pin products of the 78K0R/KC3-L.

1.2 Applications

- Audio visual equipment
- Home appliances
- Industrial equipment

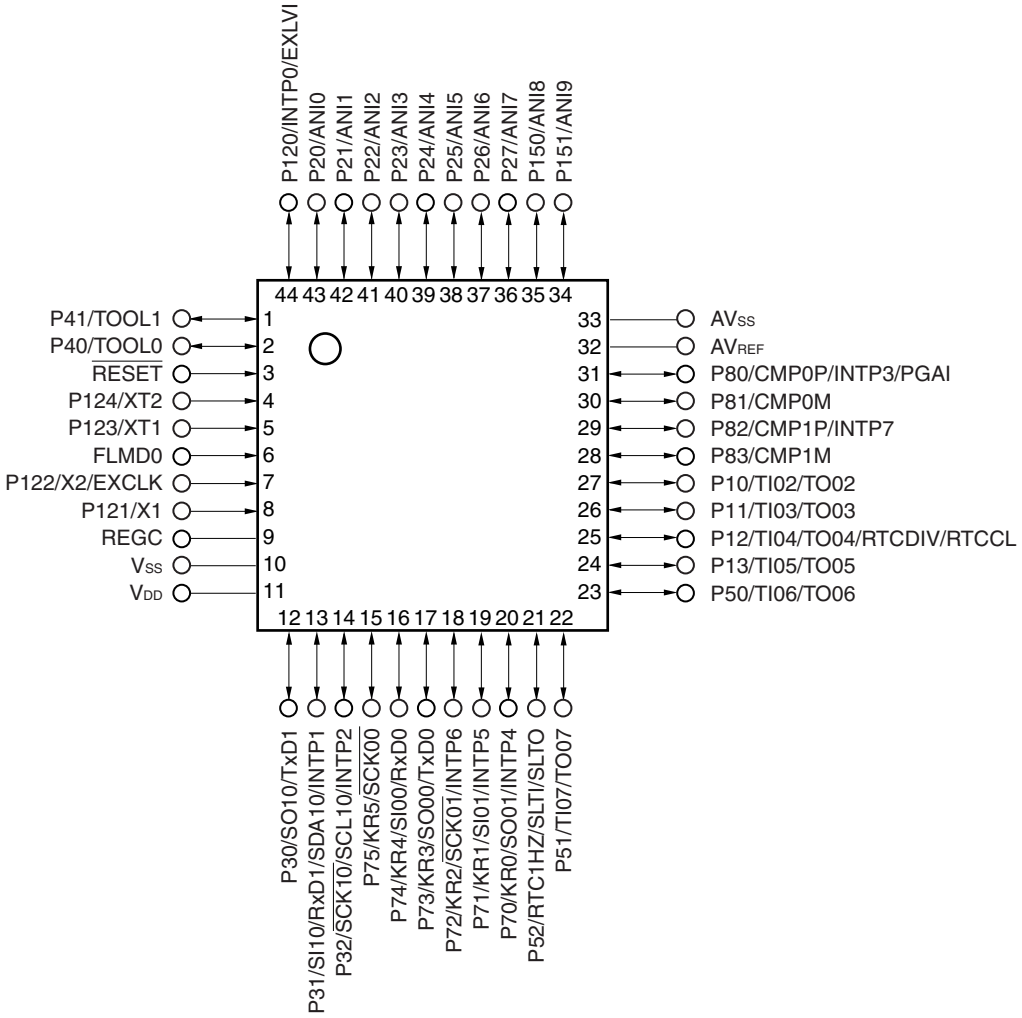
Note Under development

Caution The 78K0R/Kx3-L has an on-chip debug function, which is provided for development and evaluation. Do not use the on-chip debug function in products designated for mass production, because the guaranteed number of rewritable times of the flash memory may be exceeded when this function is used, and product reliability therefore cannot be guaranteed. NEC Electronics is not liable for problems occurring when the on-chip debug function is used.

1.4 Pin Configuration (Top View)

1.4.1 78K0R/KC3-L

- 44-pin plastic LQFP (10 × 10)

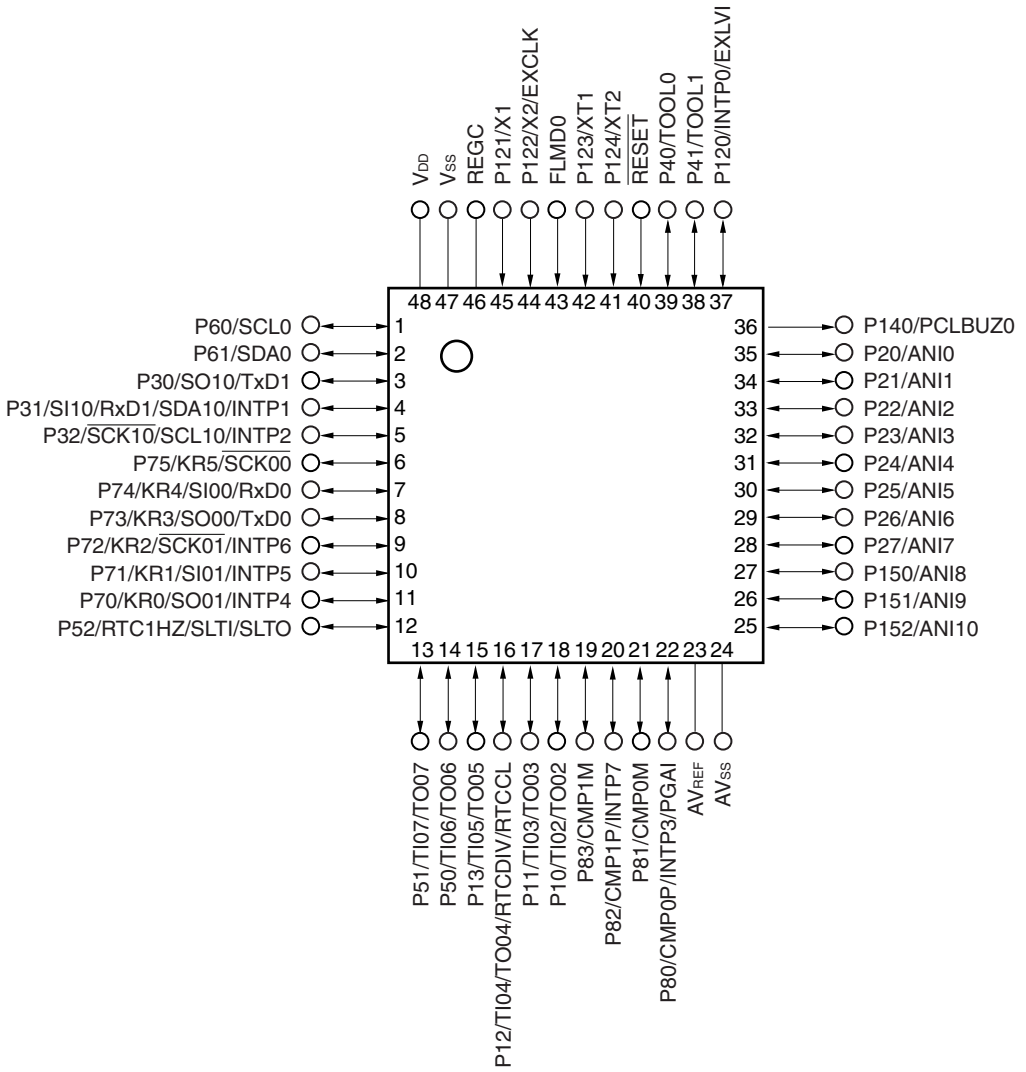


Cautions 1. Make AVSS the same potential as VSS.

2. Connect the REGC pin to Vss via a capacitor (0.47 to 1 μF: target).

Remark For pin identification, see **1.5 Pin Identification**.

- 48-pin plastic TQFP (fine pitch) (7 × 7)



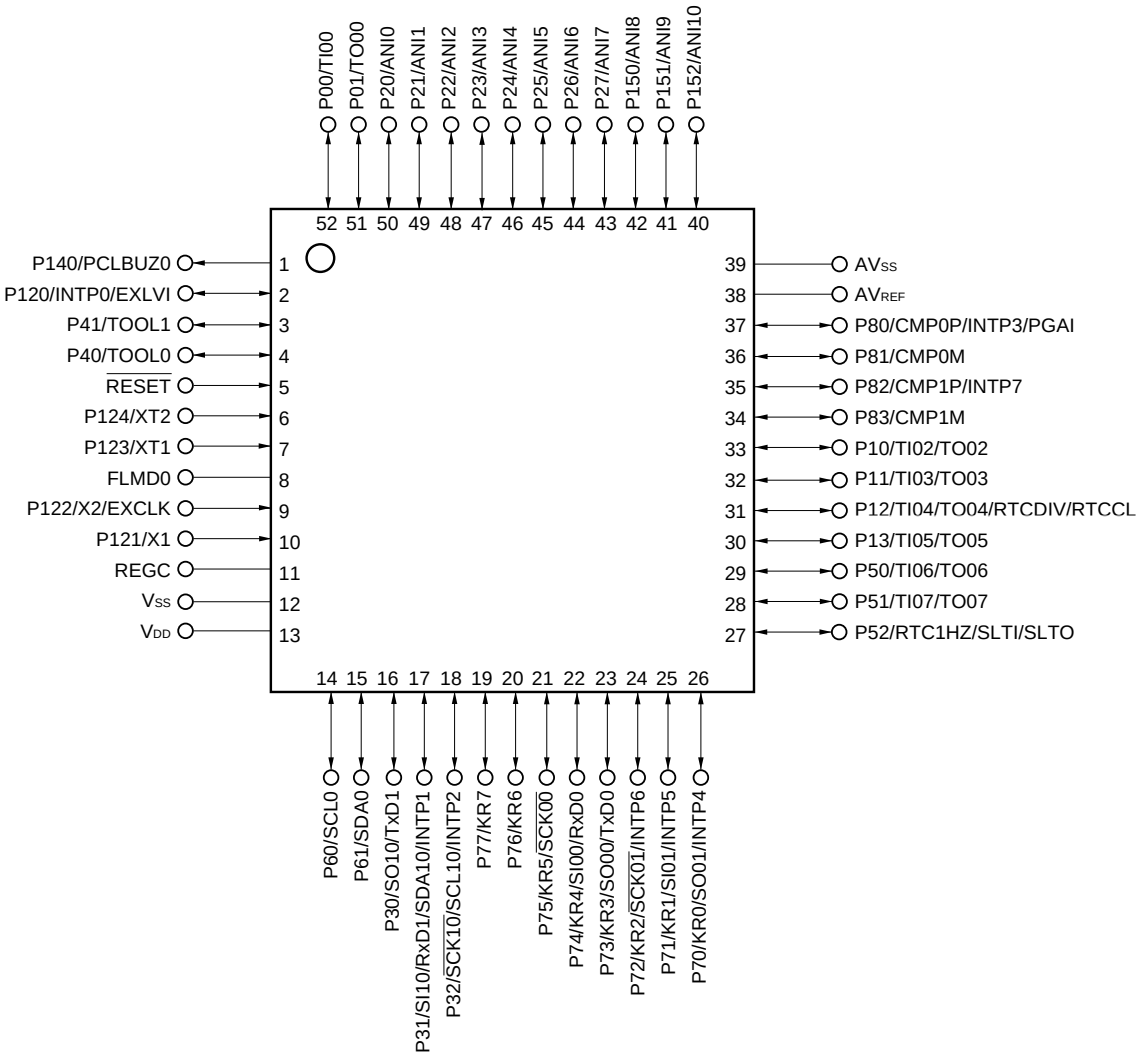
Cautions 1. Make AVSS the same potential as VSS.

2. Connect the REGC pin to Vss via a capacitor (0.47 to 1 μF: target).

Remark For pin identification, see **1.5 Pin Identification**.

1.4.2 78K0R/KD3-L

- 52-pin plastic LQFP (10 × 10)



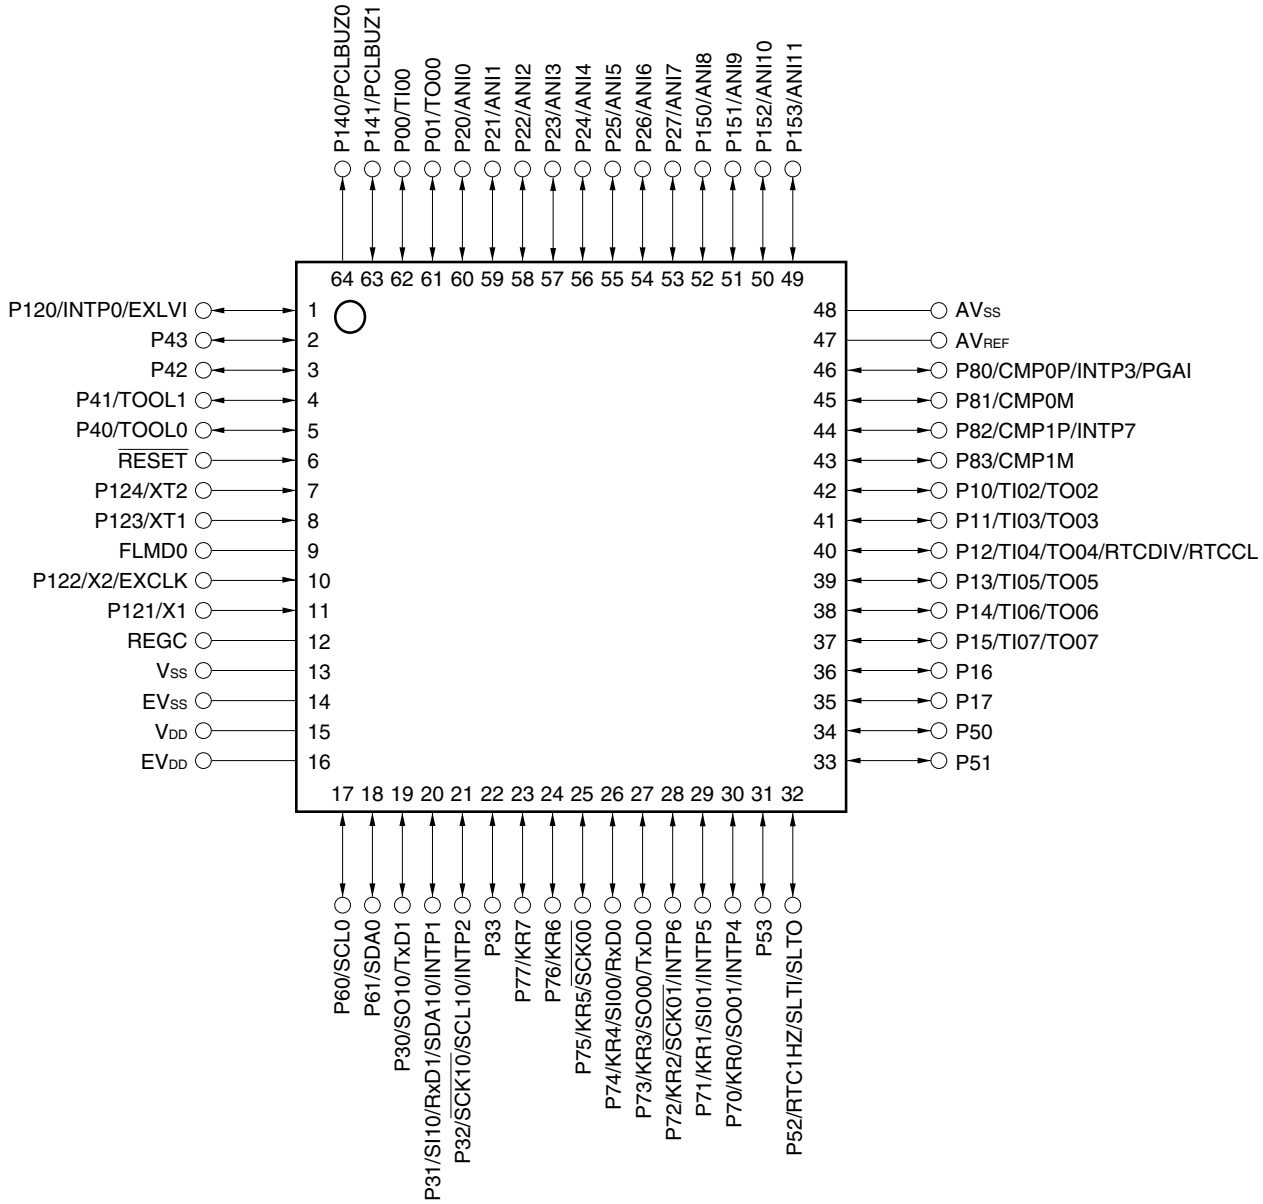
Cautions 1. Make AVSS the same potential as VSS.

2. Connect the REGC pin to Vss via a capacitor (0.47 to 1 μF: target).

Remark For pin identification, see **1.5 Pin Identification**.

1.4.3 78K0R/KE3-L

- 64-pin plastic LQFP (12 × 12)
- 64-pin plastic LQFP (fine pitch) (10 × 10)
- 64-pin plastic TQFP (fine pitch) (7 × 7)



Cautions 1. Make AV_{SS} and EV_{SS} the same potential as V_{SS}.

2. Make EV_{DD} the same potential as V_{DD}.

3. Connect the REGC pin to Vss via a capacitor (0.47 to 1 μF: target).

Remark For pin identification, see **1.5 Pin Identification**.

Reset		• Reset by $\overline{\text{RESET}}$ pin • Internal reset by watchdog timer • Internal reset by power-on-clear • Internal reset by low-voltage detector • Internal reset by illegal instruction execution [Note 2]			
Power-on-clear circuit		• Power-on-reset: 1.61 ±0.09 V • Power-down-reset: 1.59 ±0.09 V			
Low-voltage detector		1.91 V to 4.22 V (16 stages)			
On-chip debug function		Provided			
Power supply voltage		V_{DD} = 1.8 to 5.5 V			
Operating ambient temperature		T_A = –40 to +85 °C			

Notes 1. Under development

2. The illegal instruction is generated when instruction code FFH is executed.
Reset by the illegal instruction execution not issued by emulation with the in-circuit emulator or on-chip debug emulator.

CHAPTER 2 PIN FUNCTIONS

2.1 Pin Function List

Pin I/O buffer power supplies depend on the product. The relationship between these power supplies and the pins is shown below.

Table 2-1. Pin I/O Buffer Power Supplies (AV_{REF}, V_{DD})

- 78K0R/KC3-L: 44-pin plastic LQFP (10x10)
  48-pin plastic TQFP (fine pitch) (7x7)
- 78K0R/KD3-L: 52-pin plastic LQFP (10x10)

Power Supply	Corresponding Pins
AV_{REF}	P20 to P27, P150 to P152[Note], P80 to P83
EV_{DD}	• Port pins other than P20 to P27, P150 to P152[Note], P80 to P83 • Pins other than port pins

Note 44-pin products of the 78K0R/KC3-L do not have a P152 pin.

Table 2-2. Pin I/O Buffer Power Supplies (AV_{REF}, EV_{DD}, V_{DD})

- 78K0R/KE3-L: 64-pin plastic FBGA (5x5)
  64-pin plastic TQFP (fine pitch) (7x7)
  64-pin plastic LQFP (fine pitch) (10x10)
  64-pin plastic LQFP (12x12)

Power Supply	Corresponding Pins
AV_{REF}	P20 to P27, P150 to P153, P80 to P83
EV_{DD}	• Port pins other than P20 to P27, P150 to P153, P80 to P83, and P121 to P124 • $\overline{\text{RESET}}$ pin and FLMD0 pin
V_{DD}	• P121 to P124 • Pins other than port pins (other than the $\overline{\text{RESET}}$ pin and FLMD0 pin)

2.1.1 78K0R/KC3-L

(1) Port functions (1/2): 78K0R/KC3-L

Function Name	I/O	Function	After Reset	Alternate Function
P10	I/O	Port 1. 4-bit I/O port. Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	TI02/TO02
P11				TI03/TO03
P12				TI04/TO04/ RTCDIV/RTCCL
P13				TI05/TO05
P20 to P27	I/O	Port 2. 8-bit I/O port. Input/output can be specified in 1-bit units.	Digital input port	ANI0 to ANI7
P30	I/O	Port 3. 3-bit I/O port. Input of P31 and P32 can be set to TTL buffer. Output of P30 to P32 can be set to N-ch open-drain output (V_{DD} tolerance). Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	SO10/TxD1
P31				SI10/RxD1/SDA10/ INTP1
P32				$\overline{\text{SCK10}}$/SCL10/ INTP2
P40 [Note 1]	I/O	Port 4. 2-bit I/O port. Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	TOOL0
P41				TOOL1
P50	I/O	Port 5. 3-bit I/O port. Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	TI06/TO06
P51				TI07/TO07
P52				RTC1HZ/SLTI/ SLTO
P60 [Note 2]	I/O	Port 6. 2-bit I/O port. Output of P60 and P61 is N-ch open-drain output (6 V tolerance). Input/output can be specified in 1-bit units.	Input port	SCL0 [Note 2]
P61 [Note 2]				SDA0 [Note 2]
P70	I/O	Port 7. 6-bit I/O port. Input of P71, P72, P74, and P75 can be set to TTL buffer. Output of P70, P72, P73, and P75 can be set to N-ch open-drain output (V_{DD} tolerance). Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	KR0/SO01/INTP4
P71				KR1/SI01/INTP5
P72				KR2/$\overline{\text{SCK01}}$/INTP6
P73				KR3/SO00/TxD0
P74				KR4/SI00/RxD0
P75				KR5/$\overline{\text{SCK00}}$

Notes 1. If on-chip debugging is enabled by using an option byte, be sure to pull up the P40/TOOL0 pin externally.

2. 48-pin products only.

(1) Port functions (2/2): 78K0R/KC3-L

Function Name	I/O	Function	After Reset	Alternate Function
P80	I/O	Port 8. 4-bit I/O port. Inputs/output can be specified in 1-bit units. Inputs of P80 to P83 can be set as comparator inputs or programmable gain amplifier inputs.	Analog input	CMP0P/INTP3/ PGAI
P81				CMP0M
P82				CMP1P/INTP7
P83				CMP1M
P120	I/O	Port 12. 1-bit I/O port and 4-bit input port. For only P120, input/output can be specified in 1-bit units. For only P120, use of an on-chip pull-up resistor can be specified by a software setting.	Input port	INTP0/EXLVI
P121	Input			X1
P122				X2/EXCLK
P123				XT1
P124				XT2
P140 Note	Output	Port 14. 1-bit output port.	Output port	PCLBUZ0 Note
P150, P151, P152 Note	I/O	Port 15. 3-bit I/O port. Input/output can be specified in 1-bit units.	Digital input port	ANI8, ANI9, ANI10 Note

Note 48-pin products only.

(2) Non-port functions (1/3): 78K0R/KC3-L

Function Name	I/O	Function	After Reset	Alternate Function
ANI0 to ANI7	Input	A/D converter analog input	Digital input port	P20 to P27
ANI8, ANI9, ANI10 Note	Input			P150, P151, P152 Note
CMP0M	Input	Input voltage on the (–) side of comparator 0	Analog input	P81
CMP0P	Input	Input voltage on the (+) side of comparator 0		P80/INTP3/PGAI
CMP1M	Input	Input voltage on the (–) side of comparator 1		P83
CMP1P	Input	Input voltage on the (+) side of comparator 1		P82/INTP7
EXLVI	Input	Potential input for external low-voltage detection	Input port	P120/INTP0
INTP0	Input	External interrupt request input for which the valid edge (rising edge, falling edge, or both rising and falling edges) can be specified	Input port	P120/EXLVI
INTP1				P31/SI10/RxD1/SDA10
INTP2				P32/$\overline{\text{SCK10}}$/SCL10
INTP3			Analog input	P80/CMP0P/PGAI
INTP4			Input port	P70/KR0/SO01
INTP5				P71/KR1/SI01
INTP6				P72/KR2/$\overline{\text{SCK01}}$
INTP7			Analog input	P82/CMP1P
KR0	Input	Key interrupt input	Input port	P70/SO01/INTP4
KR1				P71/SI01/INTP5
KR2				P72/$\overline{\text{SCK01}}$/INTP6
KR3				P73/SO00/TxD0
KR4				P74/SI00/RxD0
KR5				P75/$\overline{\text{SCK00}}$
PCLBUZ0 Note	Output	Clock output/buzzer output	Output port	P140 Note
PGAI	Input	Programmable gain amplifier input	Analog input	P80/CMP0P/INTP3
REGC	–	Connecting regulator output (2.4 V) stabilization capacitance for internal operation. Connect to V_{SS} via a capacitor (0.47 to 1 μF: target).	–	–
RTCDIV	Output	Real-time counter clock (32 kHz division) output	Input port	P12/TI04/TO04/RTCCL
RTCCL	Output	Real-time counter clock (32 kHz original oscillation) output	Input port	P12/TI04/TO04/RTCDIV
RTC1HZ	Output	Real-time counter correction clock (1 Hz) output	Input port	P52/SLTI/SLTO
$\overline{\text{RESET}}$	Input	System reset input	–	–
RxD0	Input	Serial data input to UART0	Input port	P74/KR4/SI00
RxD1		Serial data input to UART1		P31/SI10/SDA10/INTP1
$\overline{\text{SCK00}}$	I/O	Clock input/output for CSI00	Input port	P75/KR5
$\overline{\text{SCK01}}$		Clock input/output for CSI01		P72/KR2/INTP6
$\overline{\text{SCK10}}$		Clock input/output for CSI10		P32/SCL10/INTP2

Note 48-pin products only.

(2) Non-port functions (2/3): 78K0R/KC3-L

Function Name	I/O	Function	After Reset	Alternate Function
SCL0 Note	I/O	Clock input/output for I^2C	Input port	P60 Note
SCL10	I/O	Clock input/output for simplified I^2C	Input port	P32/$\overline{SCK10}$/INTP2
SDA0 Note	I/O	Serial data I/O for I^2C	Input port	P61 Note
SDA10	I/O	Serial data I/O for simplified I^2C	Input port	P31/SI10/RxD1/ INTP1
SI00	Input	Serial data input to CSI00	Input port	P74/KR4/RxD0
SI01		Serial data input to CSI01		P71/KR1/INTP5
SI10		Serial data input to CSI10		P31/RxD1/SDA10/ INTP1
SLTI	Input	16-bit timer 00, 01 input	Input port	P52/RTC1HZ/SLTO
SLTO	Output	16-bit timer 00, 01 output	Input port	P52/RTC1HZ/SLTI
SO00	Output	Serial data output from CSI00	Input port	P73/KR3/TxD0
SO01		Serial data output from CSI01		P70/KR0/INTP4
SO10		Serial data output from CSI10		P30/TxD1
TI02	Input	External count clock input to 16-bit timer 02	Input port	P10/TO02
TI03		External count clock input to 16-bit timer 03		P11/TO03
TI04		External count clock input to 16-bit timer 04		P12/TO04/ RTCDIV/RTCCL
TI05		External count clock input to 16-bit timer 05		P13/TO05
TI06		External count clock input to 16-bit timer 06		P50/TO06
TI07		External count clock input to 16-bit timer 07		P51/TO07
TO02	Output	16-bit timer 02 output	Input port	P10/TI02
TO03		16-bit timer 03 output		P11/TI03
TO04		16-bit timer 04 output		P12/TI04/ RTCDIV/RTCCL
TO05		16-bit timer 05 output		P13/TI05
TO06		16-bit timer 06 output		P50/TI06
TO07		16-bit timer 07 output		P51/TI07
TxD0	Output	Serial data output from UART0	Input port	P73/KR3/SO00
TxD1		Serial data output from UART1		P30/SO10
X1	–	Resonator connection for main system clock	Input port	P121
X2	–		Input port	P122/EXCLK
XT1	–	Resonator connection for subsystem clock	Input port	P123
XT2	–		Input port	P124
EXCLK	Input	External clock input for main system clock	Input port	P122/X2
V_{DD}	–	Positive power supply (Port pins other than P20 to P27, P80 to P83, P150, P151, P152 Note, and other than ports)	–	–
AV_{REF}	–	• A/D converter and comparator reference voltage input • Positive power supply for P20 to P27, P150, P151, P152 Note, P80 to P83, A/D converter, programmable gain amplifier, and comparator	–	–
V_{SS}	–	Ground potential (Port pins other than P20 to P27, P80 to P83, P150, P151, P152 Note, and other than ports)	–	–

2.1.2 78K0R/KD3-L

(1) Port functions (1/2): 78K0R/KD3-L

Function Name	I/O	Function	After Reset	Alternate Function
P00	I/O	Port 0. 2-bit I/O port. Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	TI00
P01				TO00
P10	I/O	Port 1. 4-bit I/O port. Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	TI02/TO02
P11				TI03/TO03
P12				TI04/TO04/ RTCDIV/RTCCL
P13				TI05/TO05
P20 to P27	I/O	Port 2. 8-bit I/O port. Input/output can be specified in 1-bit units.	Digital input port	ANI0 to ANI7
P30	I/O	Port 3. 3-bit I/O port. Input of P31 and P32 can be set to TTL buffer. Output of P30 to P32 can be set to N-ch open-drain output (V_{DD} tolerance). Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	SO10/TxD1
P31				SI10/RxD1/SDA10/ INTP1
P32				$\overline{\text{SCK10}}$/SCL10/ INTP2
P40[Note]	I/O	Port 4. 2-bit I/O port. Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	TOOL0
P41				TOOL1
P50	I/O	Port 5. 3-bit I/O port. Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	TI06/TO06
P51				TI07/TO07
P52				RTC1HZ/SLTI/ SLTO
P60	I/O	Port 6. 2-bit I/O port. Output of P60 and P61 is N-ch open-drain output (6 V tolerance). Input/output can be specified in 1-bit units.	Input port	SCL0
P61				SDA0

Note If on-chip debugging is enabled by using an option byte, be sure to pull up the P40/TOOL0 pin externally.

(1) Port functions (2/2): 78K0R/KD3-L

Function Name	I/O	Function	After Reset	Alternate Function
P70	I/O	Port 7. 8-bit I/O port. Input of P71, P72, P74, and P75 can be set to TTL buffer. Output of P70, P72, P73, and P75 can be set to N-ch open-drain output (V_{DD} tolerance). Input/output can be specified in 1-bit units. Use of an on-chip pull-up resistor can be specified by a software setting.	Input port	KR0/SO01/INTP4

P80	I/O	Port 8. 4-bit I/O port. Inputs/output can be specified in 1-bit units. Inputs of P80 to P83 can be set as comparator inputs or programmable gain amplifier inputs.	Analog input	CMP0P/INTP3/ PGAI
P81				CMP0M
P82				CMP1P/INTP7
P83				CMP1M
P120	I/O	Port 12. 1-bit I/O port and 4-bit input port. For only P120, input/output can be specified in 1-bit units. For only P120, use of an on-chip pull-up resistor can be specified by a software setting.	Input port	INTP0/EXLVI
P121	Input			X1
P122				X2/EXCLK
P123				XT1
P124				XT2
P140	Output	Port 14. 1-bit output port.	Output port	PCLBUZ0
P150 to P152	I/O	Port 15. 3-bit I/O port. Input/output can be specified in 1-bit units.	Digital input port	ANI8 to ANI10

(2) Non-port functions (1/3): 78K0R/KD3-L

Function Name	I/O	Function	After Reset	Alternate Function
ANI0 to ANI7	Input	A/D converter analog input	Digital input port	P20 to P27
ANI8 to ANI10	Input			P150 to P152
CMP0M	Input	Input voltage on the (–) side of comparator 0	Analog input	P81
CMP0P	Input	Input voltage on the (+) side of comparator 0		P80/INTP3/PGAI
CMP1M	Input	Input voltage on the (–) side of comparator 1		P83
CMP1P	Input	Input voltage on the (+) side of comparator 1		P82/INTP7
EXLVI	Input	Potential input for external low-voltage detection	Input port	P120/INTP0
INTP0	Input	External interrupt request input for which the valid edge (rising edge, falling edge, or both rising and falling edges) can be specified	Input port	P120/EXLVI
INTP1				P31/SI10/RxD1/SDA10
INTP2				P32/$\overline{\text{SCK10}}$/SCL10

2.2 Description of Pin Functions

Remark The pins mounted depend on the product. See **1.4 Pin Configuration (Top View)** and **2.1 Pin Function List**.

2.2.1 P00, P01 (port 0)

P00 and P01 function as an I/O port. These pins also function as timer I/O.

P11/TO00	–	–	√	√

Remark √: Mounted

The following operation modes can be specified in 1-bit units.

(1) Port mode

P00 and P01 function as an I/O port. P00 and P01 can be set to input or output port in 1-bit units using port mode register 0 (PM0). Use of an on-chip pull-up resistor can be specified by pull-up resistor option register 0 (PU0).

(2) Control mode

P00 and P01 function as timer I/O.

(a) TI00

This is the pin for inputting an external count clock/capture trigger to 16-bit timer 00.

(b) TO00

This is the timer output pin of 16-bit timer 00.

2.2.2 P10 to P17 (port 1)

P10 to P17 function as an I/O port. These pins also function as timer I/O and real-time counter clock output.

Remark √: Mounted

The following operation modes can be specified in 1-bit units.

(1) Port mode

P10 to P17 function as an I/O port. P10 to P17 can be set to input or output port in 1-bit units using port mode register 1 (PM1). Use of an on-chip pull-up resistor can be specified by pull-up resistor option register 1 (PU1).

(2) Control mode

P10 to P17 function as timer I/O and real-time counter clock output.

(a) TI02 to TI07

These are the pins for inputting an external count clock/capture trigger to 16-bit timers 02 to 07.

(b) TO02 to TO07

These are the timer output pins of 16-bit timers 02 to 07.

(c) RTCDIV

This is the real-time counter clock (32 kHz division) output pin.

(d) RTCCL

This is the real-time counter clock (32 kHz original oscillation) output pin.

2.2.3 P20 to P27 (port 2)

P20 to P27 function as an I/O port. These pins also function as A/D converter analog input.

	78K0R/KC3-L (44-pin) (μPD78F100y: y = 0 to 3)	78K0R/KC3-L (48-pin) (μPD78F100y: y = 1 to 3)	78K0R/KD3-L (μPD78F100y: y = 4 to 6)	78K0R/KE3-L (μPD78F100y: y = 7 to 9)

P26/ANI6	√	√	√	√
P27/ANI7	√	√	√	√

Remark √: Mounted

The following operation modes can be specified in 1-bit units.

(1) Port mode

P20 to P27 function as an I/O port. P20 to P27 can be set to input or output port in 1-bit units using port mode register 2 (PM2).

(2) Control mode

P20 to P27 function as A/D converter analog input pins (ANI0 to ANI7). When using these pins as analog input pins, see **11.6 (5) ANI0/P20 to ANI7/P27, ANI8/P150 to ANI11/P153**.

Caution ANI0/P20 to ANI7/P27 are set in the digital input (general-purpose port) mode after release of reset.

2.2.4 P30 to P33 (port 3)

P30 to P33 function as an I/O port. These pins also function as serial interface data I/O, clock I/O, and external interrupt request input.

Input to the P30 and P31 pins can be specified through a normal input buffer or a TTL input buffer in 1-bit units, using port input mode register 3 (PIM3).

Output from the P30 to P32 pins can be specified as normal CMOS output or N-ch open-drain output (V_{DD} tolerance) in 1-bit units, using port output mode register 3 (POM3).

	78K0R/KC3-L (44-pin) (μPD78F100y: y = 0 to 3)	78K0R/KC3-L (48-pin) (μPD78F100y: y = 1 to 3)	78K0R/KD3-L (μPD78F100y: y = 4 to 6)	78K0R/KE3-L (μPD78F100y: y = 7 to 9)

Remark √: Mounted

The following operation modes can be specified in 1-bit units.

(1) Port mode

P30 to P33 function as an I/O port. P30 to P33 can be set to input or output port in 1-bit units using port mode register 3 (PM3). Use of an on-chip pull-up resistor can be specified by pull-up resistor option register 3 (PU3).

(2) Control mode

P30 to P33 function as serial interface data I/O, clock I/O, and external interrupt request input.

(a) SI10

This is a serial data input pin of serial interface CSI10.

(b) SO10

This is a serial data output pin of serial interface CSI10.

(c) $\overline{\text{SCK10}}$

This is a serial clock I/O pin of serial interface CSI10.

(d) TxD1

This is a serial data output pin of serial interface UART1.

(e) RxD1

This is a serial data input pin of serial interface UART1.

(f) SDA10

This is a serial data I/O pin of serial interface for simplified I^2C.

(g) SCL10

This is a serial clock I/O pin of serial interface for simplified I^2C.

(h) INTP1, INTP2

These are the external interrupt request input pins for which the valid edge (rising edge, falling edge, or both rising and falling edges) can be specified.

Caution To use P30/SO10/TxD1 and P32/$\overline{\text{SCK10}}$/SCL10/INTP2 as general-purpose ports, set serial communication operation setting register 02 (SCR02) to the default status (0087H). In addition, clear port output mode register 3 (POM3) to 00H.

2.2.5 P40 to P43 (port 4)

P40 to P43 function as an I/O port. These pins also function as data I/O for a flash memory programmer/debugger and clock output.

	78K0R/KC3-L (44-pin) (μPD78F100y: y = 0 to 3)	78K0R/KC3-L (48-pin) (μPD78F100y: y = 1 to 3)	78K0R/KD3-L (μPD78F100y: y = 4 to 6)	78K0R/KE3-L (μPD78F100y: y = 7 to 9)
P40/TOOL0	√	√	√	√
P41/TOOL1	√	√	√	√
P42	–	–	–	√
P43	–	–	–	√

Remark √: Mounted

The following operation modes can be specified in 1-bit units.

(1) Port mode

P40 to P43 function as an I/O port. P40 to P43 can be set to input or output port in 1-bit units using port mode register 4 (PM4). Use of an on-chip pull-up resistor can be specified by pull-up resistor option register 4 (PU4).

Be sure to connect an external pull-up resistor to P40 when on-chip debugging is enabled (by using an option byte).

(2) Control mode

P40 to P43 function as data I/O for a flash memory programmer/debugger and clock output.

(a) TOOL0

This is a data I/O pin for a flash memory programmer/debugger.

Be sure to pull up this pin externally when on-chip debugging is enabled (pulling it down is prohibited).

(b) TOOL1

This is a clock output pin for a debugger.

When the on-chip debug function is used, P41/TOOL1 pin can be used as follows by the mode setting on the debugger.

1-line mode: can be used as a port (P41).

2-line mode: used as a TOOL1 pin and cannot be used as a port (P41).

Caution The function of the P40/TOOL0 pin varies as described in (a) to (c) below. In the case of (b) or (c), make the specified connection.

(a) In normal operation mode and when on-chip debugging is disabled (OCDENSET = 0) by an option byte (000C3H)
=> Use this pin as a port pin (P40).

(b) In normal operation mode and when on-chip debugging is enabled (OCDENSET = 1) by an option byte (000C3H)
=> Connect this pin to V_{DD} via an external resistor, and always input a high level to the pin before reset release.

(c) When on-chip debug function is used, or in write mode of flash memory programmer
=> Use this pin as TOOL0.
Directly connect this pin to the on-chip debug emulator or a flash memory programmer, or pull it up by connecting it to V_{DD} via an external resistor.

2.2.6 P50 to P53 (port 5)

P50 to P53 function as an I/O port. These pins also function as real-time counter correction clock output and timer I/O.

	78K0R/KC3-L (44-pin) (μPD78F100y: y = 0 to 3)	78K0R/KC3-L (48-pin) (μPD78F100y: y = 1 to 3)	78K0R/KD3-L (μPD78F100y: y = 4 to 6)	78K0R/KE3-L (μPD78F100y: y = 7 to 9)

P51/TI07/TO07	√	√	√	P51[Note]
P52/RTC1HZ/ SLTI/SLTO	√	√	√	√
P53	–	–	–	√

Note TI06/TO06 and TI07/TO07 are shared only in the 78K0R/KC3-L and 78K0R/KD3-L. The 78K0R/KE3-L does not have a sharing function.

Remark √: Mounted

The following operation modes can be specified in 1-bit units.

(1) Port mode

P50 to P53 function as an I/O port. P50 to P53 can be set to input or output port in 1-bit units using port mode register 5 (PM5). Use of an on-chip pull-up resistor can be specified by pull-up resistor option register 5 (PU5).

(2) Control mode

P50 to P53 function as real-time counter correction clock output and timer I/O.

(a) RTC1HZ

This is the real-time counter correction clock (1 Hz) output pin.

(b) SLTI

This is used as a pin for inputting an external count clock or a capture trigger to 16-bit timers 00 and 01, by setting the input switching control register (ISC).

(c) SLTO

This is used as a timer output pin of 16-bit timers 00 and 01, by setting the input switching control register (ISC).

(d) TI06, TI07

These are the pins for inputting an external count clock/capture trigger to 16-bit timers 06 and 07.

(e) TO06, TO07

These are the timer output pins of 16-bit timers 06 and 07.

2.2.7 P60 and P61 (port 6)

P60 and P61 function as an I/O port. These pins also function as serial interface IICA data I/O and clock I/O.

	78K0R/KC3-L (44-pin) (μPD78F100y: y = 0 to 3)	78K0R/KC3-L (48-pin) (μPD78F100y: y = 1 to 3)	78K0R/KD3-L (μPD78F100y: y = 4 to 6)	78K0R/KE3-L (μPD78F100y: y = 7 to 9)
P60/SCL0	–	√	√	√
P61/SDA0	–	√	√	√

Remark √: Mounted

The following operation modes can be specified in 1-bit units.

(1) Port mode

P60 and P61 function as an I/O port. P60 and P61 can be set to input port or output port in 1-bit units using port mode register 6 (PM6).

Output of P60 and P61 is N-ch open-drain output (6 V tolerance).

(2) Control mode

P60 and P61 function as serial interface IICA data I/O and clock I/O.

(a) SDA0

This is a serial data I/O pin of serial interface IICA.

(b) SCL0

This is a serial clock I/O pin of serial interface IICA.

2.2.8 P70 to P77 (port 7)

P70 to P77 function as an I/O port. These pins also function as key interrupt input, serial interface data I/O, clock I/O, and external interrupt request input.

Input to the P71, P72, P74, and P75 pins can be specified through a normal input buffer or a TTL input buffer in 1-bit units, using port input mode register 7 (PIM7).

Output from the P70, P72, P73, and P75 pins can be specified as normal CMOS output or N-ch open-drain output (V_{DD} tolerance) in 1-bit units, using port output mode register 7 (POM7).

The following operation modes can be specified in 1-bit units.

(1) Port mode

P70 to P77 function as an I/O port. P70 to P77 can be set to input or output port in 1-bit units using port mode register 7 (PM7). Use of an on-chip pull-up resistor can be specified by pull-up resistor option register 7 (PU7).

(2) Control mode

P70 to P77 function as key interrupt input, serial interface data I/O, clock I/O, and external interrupt request input.

(a) KR0 to KR7

These are key interrupt input pins.

(b) SI00, SI01

These are the serial data input pin of serial interface CSI00 and CSI01.

(c) SO00, SO01

These are the serial data output pin of serial interface CSI00 and CSI01.

(d) $\overline{\text{SCK00}}$, $\overline{\text{SCK01}}$

These are the serial clock I/O pins of serial interface CSI00 and CSI01.

(e) RxD0

This is a serial data input pin of serial interface UART0.

(f) TxD0

This is a serial data output pin of serial interface UART0.

(g) INTP4 to INTP6

These are the external interrupt request input pin for which the valid edge (rising edge, falling edge, or both rising and falling edges) can be specified.

Caution To use P70/KR0/SO01/INTP4, P72/KR2/$\overline{\text{SCK01}}$/INTP6, P73/KR3/SO00/TxD0, and P75/KR5/$\overline{\text{SCK00}}$ as general-purpose ports, set serial communication operation setting registers 00 and 01 (SCR00 and SCR01) to the default status (0087H). In addition, clear port output mode register 7 (POM7) to 00H.

2.2.9 P80 to P83 (port 8)

P80 to P83 function as an I/O port. These pins also function as input voltages on the (+) side of comparators 0 and 1, input voltages on the (−) side of comparators 0 and 1, external interrupt request inputs, and programmable gain amplifier inputs.

Inputs to the P80 to P83 pins must be enabled or disabled in 1-bit units using port input mode register 8 (PIM8).

The following operation modes can be specified in 1-bit units.

(1) Port mode

P80 to P83 function as an I/O port. P80 to P83 can be set to input port or output port in 1-bit units using port mode register 8 (PM8).

(2) Control mode

P80 to P83 function as input voltages on the (+) side of comparators 0 and 1, input voltages on the (−) side of comparators 0 and 1, external interrupt request inputs, and programmable gain amplifier inputs.

(a) CMP0P, CMP1P

These are the input voltage pins on the (+) sides of comparators 0 and 1.

(b) CMP0M, CMP1M

These are the input voltage pins on the (−) sides of comparators 0 and 1.

(c) INTP3, INTP7

These are the external interrupt request input pin for which the valid edge (rising edge, falling edge, or both rising and falling edges) can be specified.

(d) PGAI

This is a programmable gain amplifier input pin.

2.2.10 P120 to P124 (port 12)

P120 functions as an I/O port. P121 to P124 function as ant input port. These pins also function as external interrupt request input, potential input for external low-voltage detection, connecting resonator for main system clock, connecting resonator for subsystem clock, and external clock input for main system clock.

Remark √: Mounted

The following operation modes can be specified in 1-bit units.

(1) Port mode

P120 functions as an I/O port. P120 can be set to input or output port using port mode register 12 (PM12). Use of an on-chip pull-up resistor can be specified by pull-up resistor option register 12 (PU12).

P121 to P124 function as an input port.

(2) Control mode

P120 to P124 function as external interrupt request input, potential input for external low-voltage detection, connecting resonator for main system clock, connecting resonator for subsystem clock, and external clock input for main system clock.

(a) INTP0

This is an external interrupt request input pin for which the valid edge (rising edge, falling edge, or both rising and falling edges) can be specified.

(b) EXLVI

This is a potential input pin for external low-voltage detection.

(c) X1, X2

These are the pins for connecting a resonator for main system clock.

(d) EXCLK

This is an external clock input pin for main system clock.

(e) XT1, XT2

These are the pins for connecting a resonator for subsystem clock.

2.2.11 P140, P141 (port 14)

P140 functions as a 1-bit output port. P141 functions as a 1-bit I/O port. These pins also function as clock/buzzer output.

	78K0R/KC3-L (44-pin) (μPD78F100y: y = 0 to 3)	78K0R/KC3-L (48-pin) (μPD78F100y: y = 1 to 3)	78K0R/KD3-L (μPD78F100y: y = 4 to 6)	78K0R/KE3-L (μPD78F100y: y = 7 to 9)

Remark √: Mounted

The following operation modes can be specified in 1-bit units.

(1) Port mode

P140 functions as a 1-bit output port.

P141 functions as a 1-bit I/O port. P141 can be set to input or output port in 1-bit units using port mode register 14 (PM14). Use of an on-chip pull-up resistor can be specified by pull-up resistor option register 14 (PU14).

(2) Control mode

P140 and P141 function as clock/buzzer output.

(a) PCLBUZ0, PCLBUZ1

These are clock/buzzer output pins.

2.2.12 P150 to P153 (port 15)

P150 to P153 function as an I/O port. These pins also function as A/D converter analog input.

	78K0R/KC3-L (44-pin) (μPD78F100y: y = 0 to 3)	78K0R/KC3-L (48-pin) (μPD78F100y: y = 1 to 3)	78K0R/KD3-L (μPD78F100y: y = 4 to 6)	78K0R/KE3-L (μPD78F100y: y = 7 to 9)

Remark √: Mounted

The following operation modes can be specified in 1-bit units.

(1) Port mode

P150 to P153 function as an I/O port. P150 to P153 can be set to input or output port in 1-bit units using port mode register 15 (PM15).

(2) Control mode

P150 to P153 function as A/D converter analog input pins (ANI8 to ANI11). When using these pins as analog input pins, see **11.6 (5) ANI0/P20 to ANI7/P27 and ANI8/P150 to ANI11/P153**.

Caution ANI8/P150 to ANI11/P153 are set in the digital input (general-purpose port) mode after release of reset.

2.2.13 AV_{REF}, AV_{SS}, V_{DD}, EV_{DD}, V_{SS}, EV_{SS}

	78K0R/KC3-L (44-pin) (μPD78F100y: y = 0 to 3)	78K0R/KC3-L (48-pin) (μPD78F100y: y = 1 to 3)	78K0R/KD3-L (μPD78F100y: y = 4 to 6)	78K0R/KE3-L (μPD78F100y: y = 7 to 9)
AV_{REF}	√	√	√	√
AV_{SS}	√	√	√	√
V_{DD}	√	√	√	√
EV_{DD}	–	–	–	√
V_{SS}	√	√	√	√
EV_{SS}	–	–	–	√

(1) AV_{REF}

This is the A/D converter and comparator reference voltage input pin and the positive power supply pin of P20 to P27, P150 to P153, P80 to P83, A/D converter, programmable gain amplifier, and comparator.

When all pins of port 2, port 15, and port 8 are used as the analog port pins, make the potential of AV_{REF} be such that 1.8 V ≤ AV_{REF} ≤ V_{DD}. When one or more of the pins of port 2, port 15, and port 8 are used as the digital port pins or when the A/D converter, programmable gain amplifier, and comparator are not used, make AV_{REF} the same potential as EV_{DD} or V_{DD}.

(2) AV_{SS}

This is the ground potential pin of A/D converter, programmable gain amplifier, comparator, P20 to P27, P150 to P153, and P80 to P83. Even when the A/D converter, programmable gain amplifier, and comparator are not used, always use this pin with the same potential as EV_{SS} or V_{SS}.

(3) V_{DD}, EV_{DD}

V_{DD} is the positive power supply pin for P121 to P124 and other than ports (other than the $\overline{\text{RESET}}$ pin and FLMD0 pin) [Note].

EV_{DD} is the positive power supply pin for ports other than those of P20 to P27, P150 to P153, P80 to P83, and P121 to P124, as well as for the $\overline{\text{RESET}}$ pin and FLMD0 pin.

Note With products not provided with an EV_{DD} pin, use V_{DD} as the positive power supply pin for port pins other than P20 to P27, P150 to P153, and P80 to P83, as well as for pins other than those of ports.

(4) V_{SS}, EV_{SS}

V_{SS} is the ground potential pin for P121 to P124 and other than ports (other than the $\overline{\text{RESET}}$ pin and FLMD0 pin) [Note].

EV_{SS} is the ground potential pin for ports other than those of P20 to P27, P150 to P153, P80 to P83, and P121 to P124, as well as for the $\overline{\text{RESET}}$ pin and FLMD0 pin.

Note With products not provided with an EV_{SS} pin, use V_{SS} as the ground potential pin for port pins other than P20 to P27, P150 to P153, P80 to P83, as well as for pins other than those of ports.

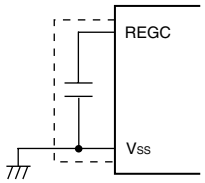
2.2.14 $\overline{\text{RESET}}$

This is the active-low system reset input pin.

2.2.15 REGC

This is the pin for connecting regulator output (2.4 V) stabilization capacitance for internal operation. Connect this pin to V_{SS} via a capacitor (0.47 to 1 μF: target). However, when using the STOP mode that has been entered since operation of the internal high-speed oscillation clock and external main system clock, 0.47 μF is recommended.

Also, use a capacitor with good characteristics, since it is used to stabilize internal voltage.



Caution Keep the wiring length as short as possible for the broken-line part in the above figure.

2.2.16 FLMD0

This is a pin for setting flash memory programming mode.

Perform either of the following processing.

(a) In normal operation mode

It is recommended to leave this pin open during normal operation.

The FLMD0 pin must always be kept at the V_{SS} level before reset release but does not have to be pulled down externally because it is internally pulled down by reset. However, pulling it down must be kept selected (i.e., FLMDPUP = "0", default value) by using bit 7 (FLMDPUP) of the background event control register (BECTL) (see **24.5 (1) Back ground event control register**). To pull it down externally, use a resistor of 200 kΩ or smaller.

Self programming and the rewriting of flash memory with the programmer can be prohibited using hardware, by directly connecting this pin to the V_{SS} pin.

(b) In self programming mode

It is recommended to leave this pin open when using the self programming function. To pull it down externally, use a resistor of 100 kΩ to 200 kΩ.

In the self programming mode, the setting is switched to pull up in the self programming library.

(c) In flash memory programming mode

Directly connect this pin to a flash memory programmer when data is written by the flash memory programmer. This supplies a writing voltage of the V_{DD} level to the FLMD0 pin.

The FLMD0 pin does not have to be pulled down externally because it is internally pulled down by reset. To pull it down externally, use a resistor of 1 kΩ to 200 kΩ.

2.3 Pin I/O Circuits and Recommended Connection of Unused Pins

Table 2-3 shows the types of pin I/O circuits and the recommended connections of unused pins.

3.1.1 Internal program memory space

The internal program memory space stores the program and table data.

78K0R/Kx3-L products incorporate internal ROM (flash memory), as shown below.

Table 3-2. Internal ROM Capacity

Part Number	Internal ROM	
	Structure	Capacity
μPD78F1000	Flash memory	16384 × 8 bits (00000H to 03FFFH)
μPD78F1001, 78F1004, 78F1007		32768 × 8 bits (00000H to 07FFFH)
μPD78F1002, 78F1005, 78F1008		49152 × 8 bits (00000H to 0BFFFH)
μPD78F1003, 78F1006, 78F1009		65536 × 8 bits (00000H to 0FFFFH)

The internal program memory space is divided into the following areas.

(1) Vector table area

The 128-byte area 00000H to 0007FH is reserved as a vector table area. The program start addresses for branch upon reset or generation of each interrupt request are stored in the vector table area.

Of the 16-bit address, the lower 8 bits are stored at even addresses and the higher 8 bits are stored at odd addresses.

Table 3-3. Vector Table

00024H	INTST1/INTCSI10/INTIIC10	0004CH	INTP7

Note This is not mounted onto 44-pin products of the 78K0R/KC3-L.

(2) CALLT instruction table area

The 64-byte area 00080H to 000BFH can store the subroutine entry address of a 2-byte call instruction (CALLT). Set the subroutine entry address to a value in a range of 00000H to 0FFFFH (because an address code is of 2 bytes).

To use the boot swap function, set a CALLT instruction table also at 01080H to 010BFH.

(3) Option byte area

A 4-byte area of 000C0H to 000C3H can be used as an option byte area. Set the option byte at 010C0H to 010C3H when the boot swap is used. For details, see **CHAPTER 23 OPTION BYTE**.

(4) On-chip debug security ID setting area

A 10-byte area of 000C4H to 000CDH and 010C4H to 010CDH can be used as an on-chip debug security ID setting area. Set the on-chip debug security ID of 10 bytes at 000C4H to 000CDH when the boot swap is not used and at 000C4H to 000CDH and 010C4H to 010CDH when the boot swap is used. For details, see **CHAPTER 25 ON-CHIP DEBUG FUNCTION**.

3.1.2 Mirror area

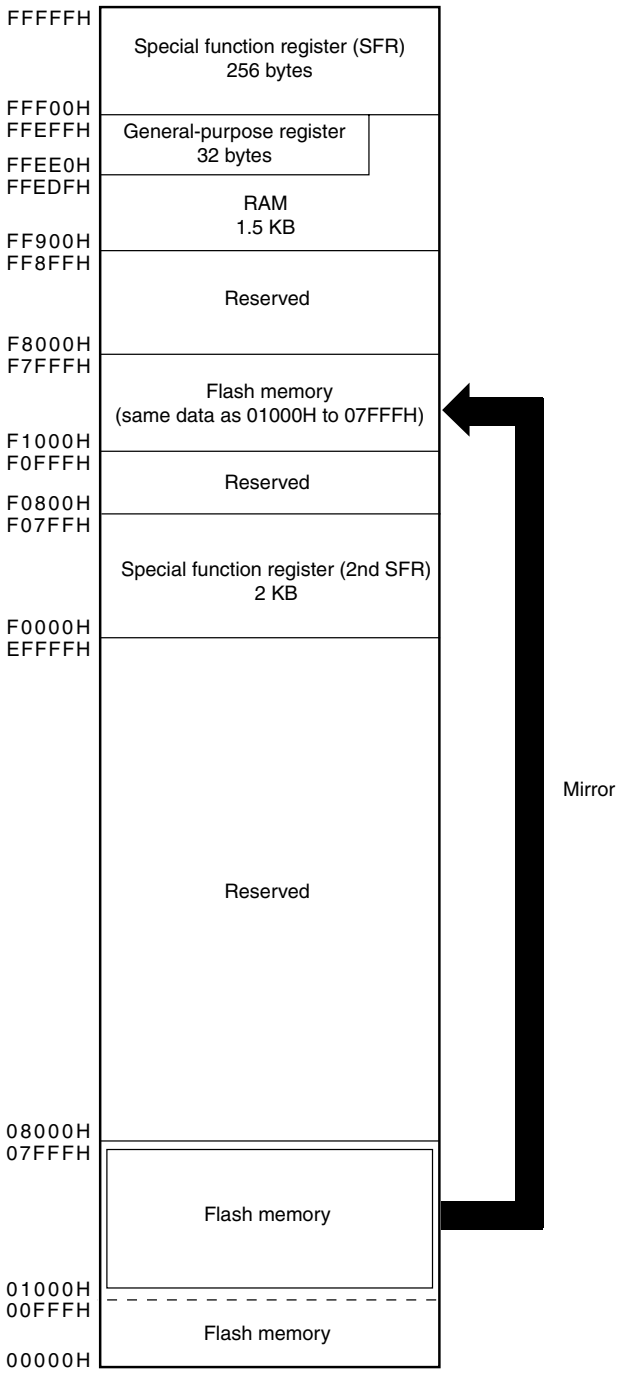
The 78K0R/Kx3-L mirrors the data flash area of 00000H to 0FFFFH, to F0000H to FFFFFH.

By reading data from F0000H to FFFFFH, the contents of the data flash can be read with the shorter code. However, the data flash area is not mirrored to the SFR, extended SFR, RAM, and use prohibited areas.

The mirror area can only be read and no instruction can be fetched from this area.

The following show examples.

Example μPD78F1001, 78F1004, 78F1007 (Flash memory: 32 KB, RAM: 1.5 KB)



3.1.3 Internal data memory space

78K0R/Kx3-L products incorporate the following RAMs.

Table 3-4. Internal RAM Capacity

Part Number	Internal RAM
μPD78F1000	1024 × 8 bits (FFB00H to FFEFFH)
μPD78F1001, 78F1004, 78F1007	1536 × 8 bits (FF900H to FFEFFH)
μPD78F1002, 78F1005, 78F1008	2048 × 8 bits (FF700H to FFEFFH)
μPD78F1003, 78F1006, 78F1009	3072 × 8 bits (FF300H to FFEFFH)

The 32-byte area FFEE0H to FFEFFH is assigned to four general-purpose register banks consisting of eight 8-bit registers per bank.

This area can be used as a program area where instructions are written and executed. However, executing instructions is disabled in the general-purpose register.

The internal high-speed RAM can also be used as a stack memory.

Cautions 1. It is prohibited to use the general-purpose register (FFEE0H to FFEFFH) space for fetching instructions or as a stack area.

2. While using the self-programming function, the area FFE20H to FFEFFH cannot be used as stack memory. Furthermore, the area FF300H to FF6FFH also cannot be used as stack memory with the μPD78F1003, 78F1006, and 78F1009.

3.1.4 Special function register (SFR) area

On-chip peripheral hardware special function registers (SFRs) are allocated in the area FFF00H to FFFFFH (see **Table 3-5** in **3.2.4 Special function registers (SFRs)**).

Caution Do not access addresses to which SFRs are not assigned.

3.1.5 Extended special function register (2nd SFR: 2nd Special Function Register) area

On-chip peripheral hardware special function registers (2nd SFRs) are allocated in the area F0000H to F07FFH (see **Table 3-6** in **3.2.5 Extended Special function registers (2nd SFRs: 2nd Special Function Registers)**).

SFRs other than those in the SFR area (FFF00H to FFFFFH) are allocated to this area. An instruction that accesses the extended SFR area, however, is 1 byte longer than an instruction that accesses the SFR area.

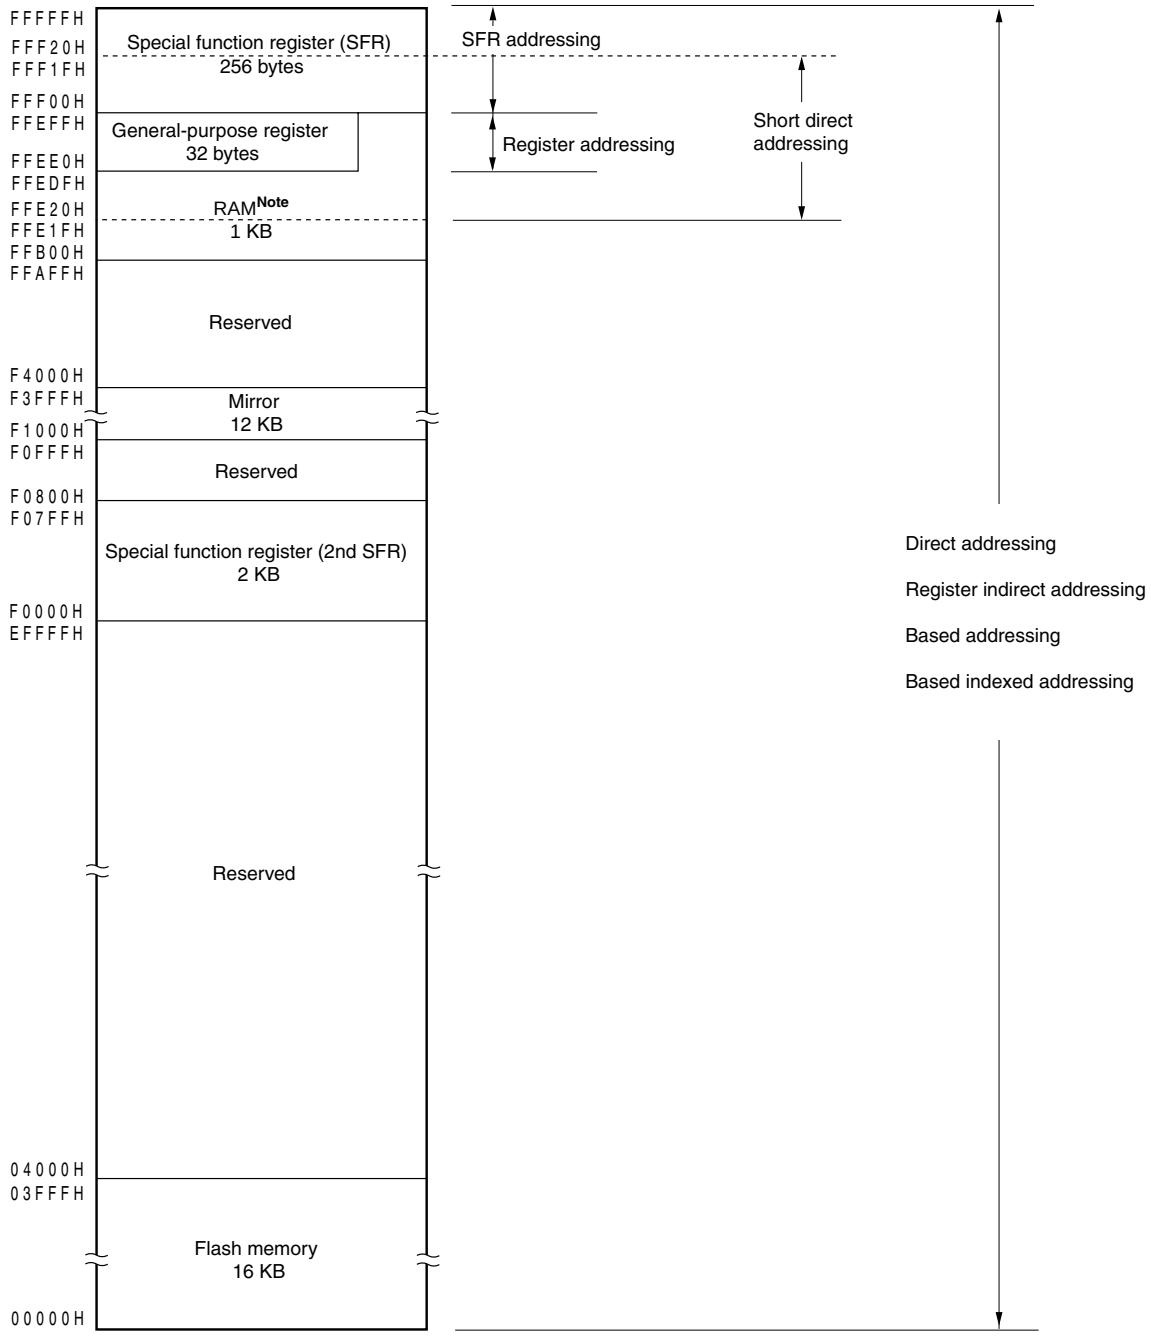
Caution Do not access addresses to which extended SFRs are not assigned.

3.1.6 Data memory addressing

Addressing refers to the method of specifying the address of the instruction to be executed next or the address of the register or memory relevant to the execution of instructions.

Several addressing modes are provided for addressing the memory relevant to the execution of instructions for the 78K0R/Kx3-L, based on operability and other considerations. For areas containing data memory in particular, special addressing methods designed for the functions of special function registers (SFR) and general-purpose registers are available for use. Figures 3-5 to 3-8 show correspondence between data memory and addressing.

Figure 3-5. Correspondence Between Data Memory and Addressing (μPD78F1000)



Note Use of the area FFE20H to FFEDFH is prohibited when using the self-programming function. Since this area is used for self-programming library.

3.2 Processor Registers

The 78K0R/Kx3-L products incorporate the following processor registers.

3.2.1 Control registers

The control registers control the program sequence, statuses and stack memory. The control registers consist of a program counter (PC), a program status word (PSW) and a stack pointer (SP).

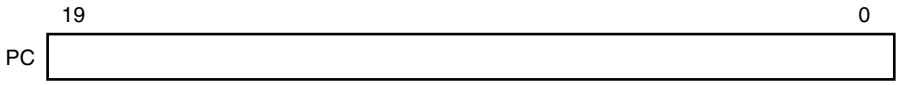
(1) Program counter (PC)

The program counter is a 20-bit register that holds the address information of the next program to be executed.

In normal operation, PC is automatically incremented according to the number of bytes of the instruction to be fetched. When a branch instruction is executed, immediate data and register contents are set.

Reset signal generation sets the reset vector table values at addresses 0000H and 0001H to the program counter.

Figure 3-9. Format of Program Counter



(2) Program status word (PSW)

The program status word is an 8-bit register consisting of various flags set/reset by instruction execution.

Program status word contents are stored in the stack area upon vectored interrupt request is acknowledged or PUSH PSW instruction execution and are restored upon execution of the RETB, RETI and POP PSW instructions.

Reset signal generation sets PSW to 06H.

Figure 3-10. Format of Program Status Word

	7							0
PSW	IE	Z	RBS1	AC	RBS0	ISP1	ISP0	CY

(a) Interrupt enable flag (IE)

This flag controls the interrupt request acknowledge operations of the CPU.

When 0, the IE flag is set to the interrupt disabled (DI) state, and all maskable interrupt requests are disabled.

When 1, the IE flag is set to the interrupt enabled (EI) state and interrupt request acknowledgment is controlled with an in-service priority flag (ISP1, ISP0), an interrupt mask flag for various interrupt sources, and a priority specification flag.

The IE flag is reset (0) upon DI instruction execution or interrupt acknowledgment and is set (1) upon EI instruction execution.

(b) Zero flag (Z)

When the operation result is zero, this flag is set (1). It is reset (0) in all other cases.

(c) Register bank select flags (RBS0, RBS1)

These are 2-bit flags to select one of the four register banks.

In these flags, the 2-bit information that indicates the register bank selected by SEL RBn instruction execution is stored.

(d) Auxiliary carry flag (AC)

If the operation result has a carry from bit 3 or a borrow at bit 3, this flag is set (1). It is reset (0) in all other cases.

(e) In-service priority flags (ISP1, ISP0)

This flag manages the priority of acknowledgeable maskable vectored interrupts. Vectored interrupt requests specified lower than the value of ISP0 and ISP1 by a priority specification flag register (PRn0L, PRn0H, PRn1L, PRn1H, PRn2L, PRn2H) (see **16.3 (3)**) can not be acknowledged. Actual request acknowledgment is controlled by the interrupt enable flag (IE).

Remark n = 0, 1

(f) Carry flag (CY)

This flag stores overflow and underflow upon add/subtract instruction execution. It stores the shift-out value upon rotate instruction execution and functions as a bit accumulator during bit operation instruction execution.

(3) Stack pointer (SP)

This is a 16-bit register to hold the start address of the memory stack area. Only the internal RAM area can be set as the stack area.

Figure 3-11. Format of Stack Pointer

	15															0
SP	SP15	SP14	SP13	SP12	SP11	SP10	SP9	SP8	SP7	SP6	SP5	SP4	SP3	SP2	SP1	SP0

The SP is decremented ahead of write (save) to the stack memory and is incremented after read (restored) from the stack memory.

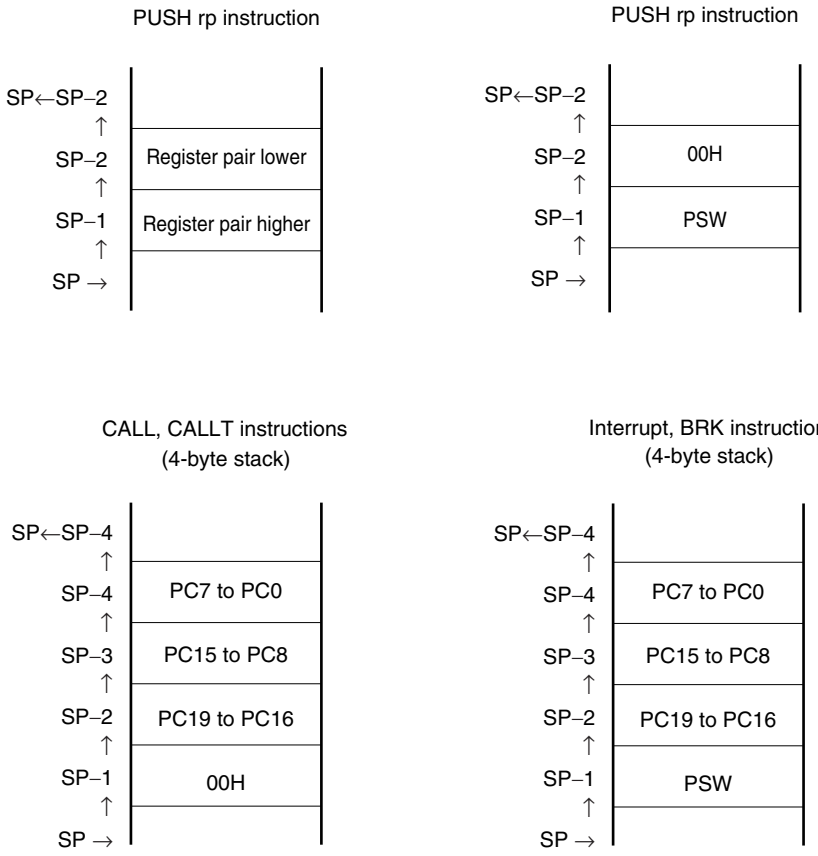
Each stack operation saves data as shown in Figure 3-12.

Caution 1. Since reset signal generation makes the SP contents undefined, be sure to initialize the SP before using the stack.

2. It is prohibited to use the general-purpose register (FFEE0H to FFEFFH) space as a stack area.

3. While using the self-programming function, the area FFE20H to FFEFFH cannot be used as stack memory. Furthermore, the area FF300H to FF6FFH also cannot be used as stack memory with the μPD78F1003, 78F1006, and 78F1009.

Figure 3-12. Data to Be Saved to Stack Memory



3.2.2 General-purpose registers

General-purpose registers are mapped at particular addresses (FFEE0H to FFEFFH) of the data memory. The general-purpose registers consists of 4 banks, each bank consisting of eight 8-bit registers (X, A, C, B, E, D, L, and H).

Each register can be used as an 8-bit register, and two 8-bit registers can also be used in a pair as a 16-bit register (AX, BC, DE, and HL).

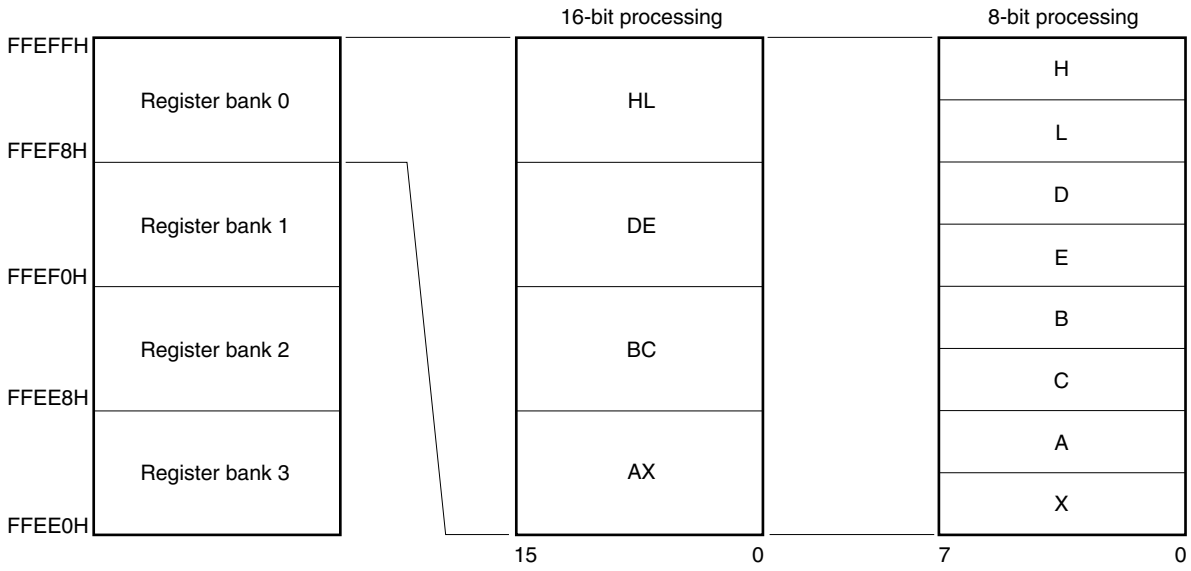
These registers can be described in terms of function names (X, A, C, B, E, D, L, H, AX, BC, DE, and HL) and absolute names (R0 to R7 and RP0 to RP3).

Register banks to be used for instruction execution are set by the CPU control instruction (SEL RBn). Because of the 4-register bank configuration, an efficient program can be created by switching between a register for normal processing and a register for interrupts for each bank.

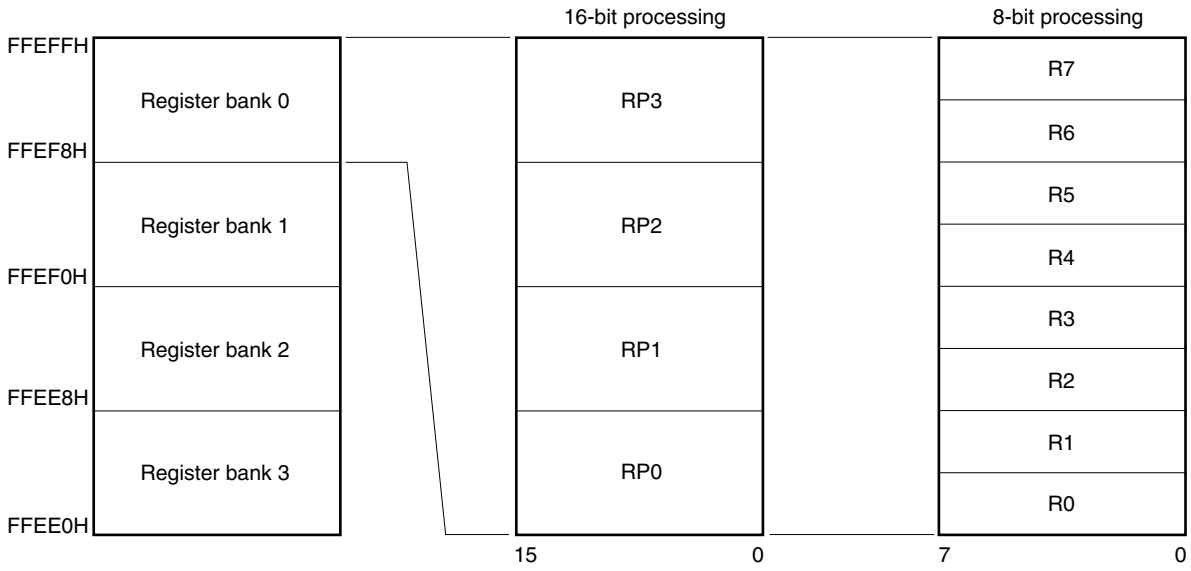
Caution It is prohibited to use the general-purpose register (FFEE0H to FFEFFH) space for fetching instructions or as a stack area.

Figure 3-13. Configuration of General-Purpose Registers

(a) Function name



(b) Absolute name



3.2.3 ES and CS registers

The ES register is used for data access and the CS register is used to specify the higher address when a branch instruction is executed.

The default value of the ES register after reset is 0FH, and that of the CS register is 00H.

Figure 3-14. Configuration of ES and CS Registers

	7	6	5	4	3	2	1	0
ES	0	0	0	0	ES3	ES2	ES1	ES0

	7	6	5	4	3	2	1	0
CS	0	0	0	0	CS3	CP2	CP1	CP0

3.2.4 Special function registers (SFRs)

Unlike a general-purpose register, each SFR has a special function.

SFRs are allocated to the FFF00H to FFFFFH area.

SFRs can be manipulated like general-purpose registers, using operation, transfer, and bit manipulation instructions. The manipulable bit units, 1, 8, and 16, depend on the SFR type.

Each manipulation bit unit can be specified as follows.

- 1-bit manipulation
  Describe the symbol reserved by the assembler for the 1-bit manipulation instruction operand (sfr.bit). This manipulation can also be specified with an address.
- 8-bit manipulation
  Describe the symbol reserved by the assembler for the 8-bit manipulation instruction operand (sfr). This manipulation can also be specified with an address.
- 16-bit manipulation
  Describe the symbol reserved by the assembler for the 16-bit manipulation instruction operand (sfrp). When specifying an address, describe an even address.

Table 3-5 gives a list of the SFRs. The meanings of items in the table are as follows.

- Symbol
  Symbol indicating the address of a special function register. It is a reserved word in the RA78K0R, and is defined as an sfr variable using the #pragma sfr directive in the CC78K0R. When using the RA78K0R, ID78K0R-QB, and SM+ for 78K0R, symbols can be written as an instruction operand.
- R/W
  Indicates whether the corresponding SFR can be read or written.
  R/W: Read/write enable
  R: Read only
  W: Write only
- Manipulable bit units
  "√" indicates the manipulable bit unit (1, 8, or 16). "–" indicates a bit unit for which manipulation is not possible.
- After reset
  Indicates each register status upon reset signal generation.

Caution Do not access addresses to which extended SFRs are not assigned.

Remark For extended SFRs (2nd SFRs), see **3.2.5 Extended special function registers (2nd SFRs: 2nd Special Function Registers)**.

Notes 1. The reset value of RESF varies depending on the reset source.

2. The reset value of LVIM varies depending on the reset source and the setting of the option byte.

3. The reset value of LVIS varies depending on the reset source.

4. The reset value of WDTE is determined by the setting of the option byte.

Note Do not directly operate this SFR, because it is to be used in the self programming library.

Remark For extended SFRs (2nd SFRs), see **Table 3-6 Extended SFR (2nd SFR) List**.

3.2.5 Extended special function registers (2nd SFRs: 2nd Special Function Registers)

Unlike a general-purpose register, each extended SFR (2nd SFR) has a special function.

Extended SFRs are allocated to the F0000H to F07FFH area. SFRs other than those in the SFR area (FFF00H to FFFFFH) are allocated to this area. An instruction that accesses the extended SFR area, however, is 1 byte longer than an instruction that accesses the SFR area.

Extended SFRs can be manipulated like general-purpose registers, using operation, transfer, and bit manipulation instructions. The manipulable bit units, 1, 8, and 16, depend on the SFR type.

Each manipulation bit unit can be specified as follows.

- 1-bit manipulation
  Describe the symbol reserved by the assembler for the 1-bit manipulation instruction operand (!addr16.bit). This manipulation can also be specified with an address.
- 8-bit manipulation
  Describe the symbol reserved by the assembler for the 8-bit manipulation instruction operand (!addr16). This manipulation can also be specified with an address.
- 16-bit manipulation
  Describe the symbol reserved by the assembler for the 16-bit manipulation instruction operand (!addr16). When specifying an address, describe an even address.

Table 3-6 gives a list of the extended SFRs. The meanings of items in the table are as follows.

- Symbol
  Symbol indicating the address of an extended SFR. It is a reserved word in the RA78K0R, and is defined as an sfr variable using the #pragma sfr directive in the CC78K0R. When using the RA78K0R, ID78K0R-QB, and SM+ for 78K0R, symbols can be written as an instruction operand.
- R/W
  Indicates whether the corresponding extended SFR can be read or written.
  R/W: Read/write enable
  R: Read only
  W: Write only
- Manipulable bit units
  "√" indicates the manipulable bit unit (1, 8, or 16). "–" indicates a bit unit for which manipulation is not possible.
- After reset
  Indicates each register status upon reset signal generation.

Caution Do not access addresses to which extended SFRs are not assigned.

Remark For SFRs in the SFR area, see **3.2.4 Special function registers (SFRs)**.

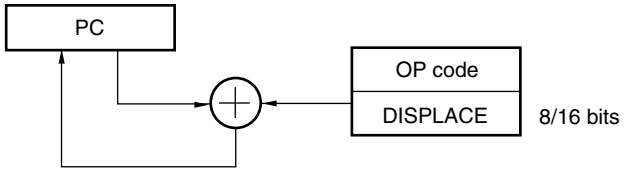
3.3 Instruction Address Addressing

3.3.1 Relative addressing

[Function]

Relative addressing stores in the program counter (PC) the result of adding a displacement value included in the instruction word (signed complement data: −128 to +127 or −32768 to +32767) to the program counter (PC)'s value (the start address of the next instruction), and specifies the program address to be used as the branch destination. Relative addressing is applied only to branch instructions.

Figure 3-15. Outline of Relative Addressing



3.3.2 Immediate addressing

[Function]

Immediate addressing stores immediate data of the instruction word in the program counter, and specifies the program address to be used as the branch destination.

For immediate addressing, CALL !!addr20 or BR !!addr20 is used to specify 20-bit addresses and CALL !addr16 or BR !addr16 is used to specify 16-bit addresses. 0000 is set to the higher 4 bits when specifying 16-bit addresses.

Figure 3-16. Example of CALL !!addr20/BR !!addr20

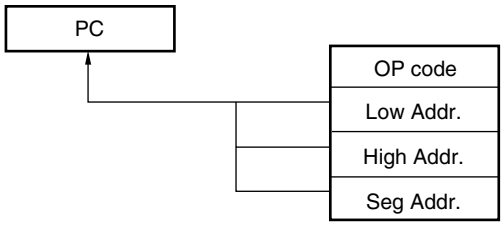


Figure 3-17. Example of CALL !addr16/BR !addr16

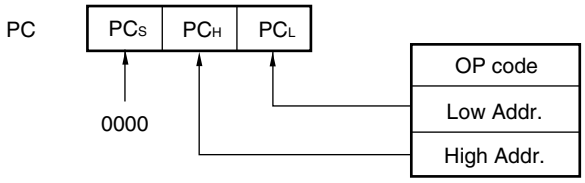


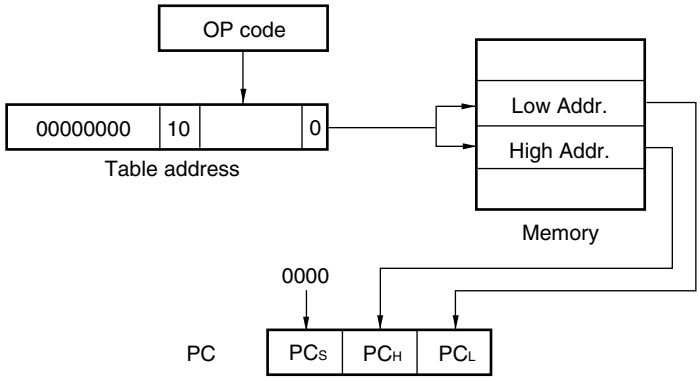
3.3.3 Table indirect addressing

[Function]

Table indirect addressing specifies a table address in the CALLT table area (0080H to 00BFH) with the 5-bit immediate data in the instruction word, stores the contents at that table address and the next address in the program counter (PC) as 16-bit data, and specifies the program address. Table indirect addressing is applied only for CALLT instructions.

In the 78K0R microcontrollers, branching is enabled only to the 64 KB space from 00000H to 0FFFFH.

Figure 3-18. Outline of Table Indirect Addressing

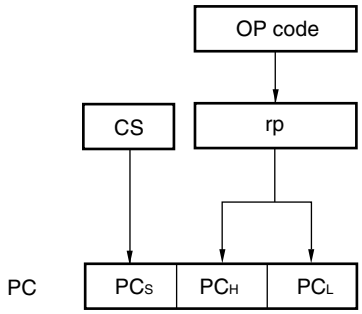


3.3.4 Register direct addressing

[Function]

Register direct addressing stores in the program counter (PC) the contents of a general-purpose register pair (AX/BC/DE/HL) and CS register of the current register bank specified with the instruction word as 20-bit data, and specifies the program address. Register direct addressing can be applied only to the CALL AX, BC, DE, HL, and BR AX instructions.

Figure 3-19. Outline of Register Direct Addressing



3.4 Addressing for Processing Data Addresses

3.4.1 Implied addressing

[Function]

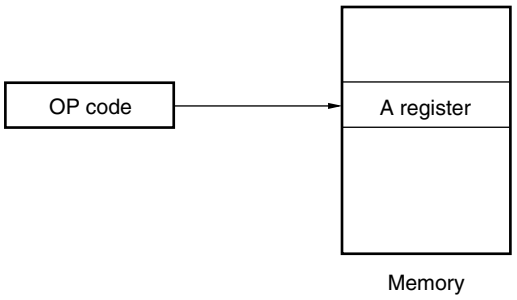
Instructions for accessing registers (such as accumulators) that have special functions are directly specified with the instruction word, without using any register specification field in the instruction word.

[Operand format]

Because implied addressing can be automatically employed with an instruction, no particular operand format is necessary.

Implied addressing can be applied only to MULU X.

Figure 3-20. Outline of Implied Addressing



3.4.2 Register addressing

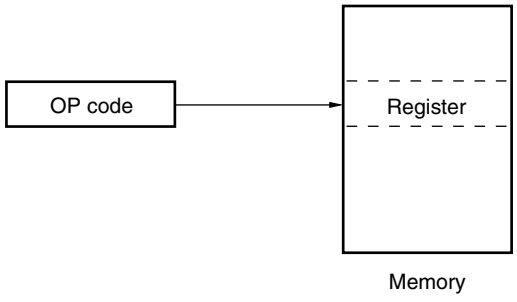
[Function]

Register addressing accesses a general-purpose register as an operand. The instruction word of 3-bit long is used to select an 8-bit register and the instruction word of 2-bit long is used to select a 16-bit register.

[Operand format]

Identifier	Description
r	X, A, C, B, E, D, L, H
rp	AX, BC, DE, HL

Figure 3-21. Outline of Register Addressing



3.4.3 Direct addressing

[Function]

Direct addressing uses immediate data in the instruction word as an operand address to directly specify the target address.

[Operand format]

Identifier	Description
ADDR16	Label or 16-bit immediate data (only the space from F0000H to FFFFFH is specifiable)
ES: ADDR16	Label or 16-bit immediate data (higher 4-bit addresses are specified by the ES register)

Figure 3-22. Example of ADDR16

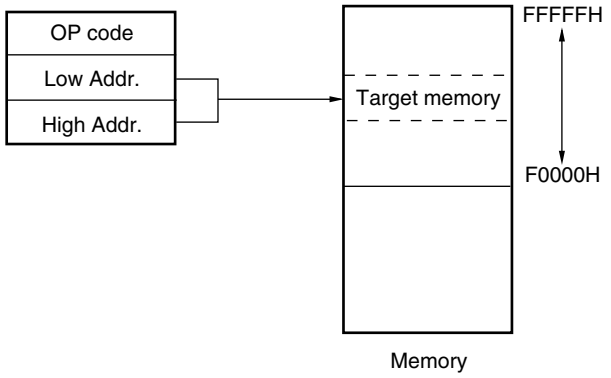


Figure 3-23. Example of ES:ADDR16

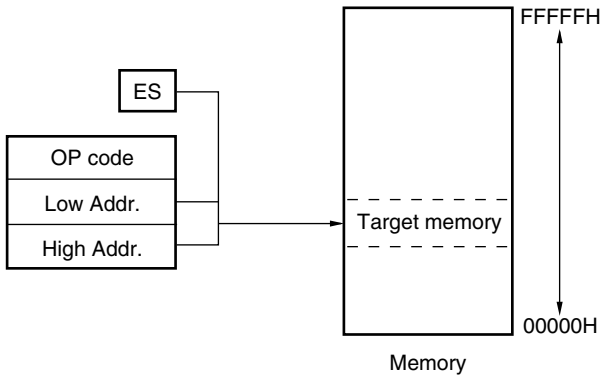


3.4.4 Short direct addressing

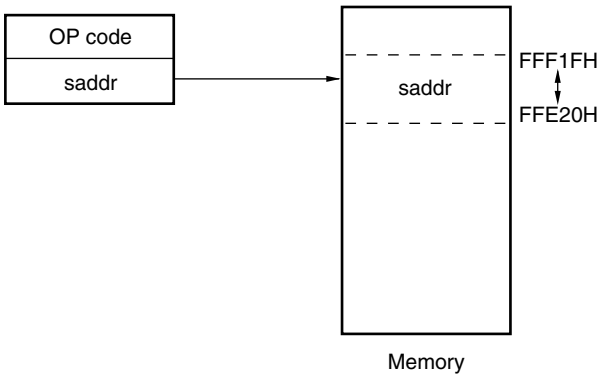
[Function]

Short direct addressing directly specifies the target addresses using 8-bit data in the instruction word. This type of addressing is applied only to the space from FFE20H to FFF1FH.

[Operand format]

Identifier	Description
SADDR	Label, FFE20H to FFF1FH immediate data, or 0FE20H to 0FF1FH immediate data (only the space from FFE20H to FFF1FH is specifiable)
SADDRP	Label, FFE20H to FFF1FH immediate data, or 0FE20H to 0FF1FH immediate data (even address only) (only the space from FFE20H to FFF1FH is specifiable)

Figure 3-24. Outline of Short Direct Addressing



Remark SADDR and SADDRP are used to describe the values of addresses FE20H to FF1FH with 16-bit immediate data (higher 4 bits of actual address are omitted), and the values of addresses FFE20H to FFF1FH with 20-bit immediate data.

Regardless of whether SADDR or SADDRP is used, addresses within the space from FFE20H to FFF1FH are specified for the memory.

3.4.5 SFR addressing

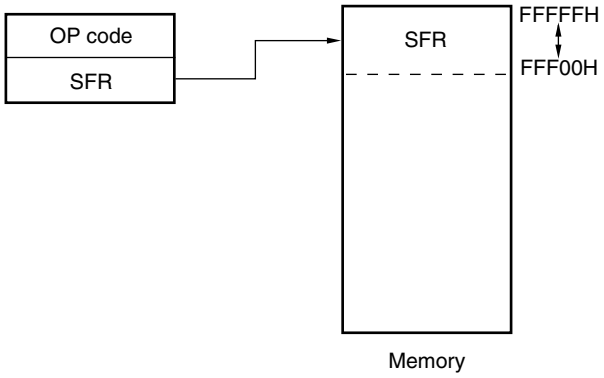
[Function]

SFR addressing directly specifies the target SFR addresses using 8-bit data in the instruction word. This type of addressing is applied only to the space from FFF00H to FFFFFH.

[Operand format]

Identifier	Description
SFR	SFR name
SFRP	16-bit-manipulatable SFR name (even address only)

Figure 3-25. Outline of SFR Addressing



3.4.6 Register indirect addressing

[Function]

Register indirect addressing directly specifies the target addresses using the contents of the register pair specified with the instruction word as an operand address.

[Operand format]

Identifier	Description
–	[DE], [HL] (only the space from F0000H to FFFFFH is specifiable)
–	ES:[DE], ES:[HL] (higher 4-bit addresses are specified by the ES register)

Figure 3-26. Example of [DE], [HL]

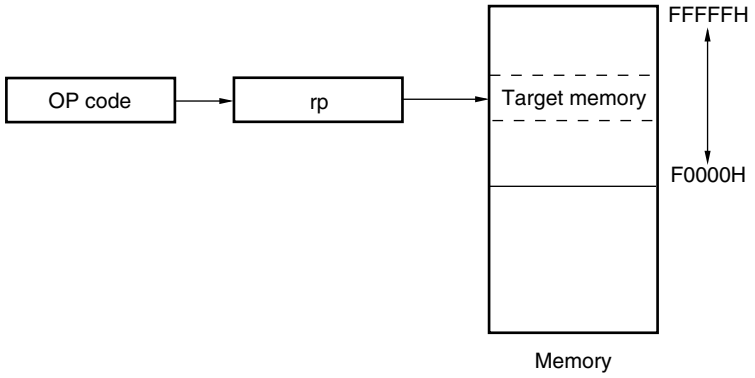


Figure 3-27. Example of ES:[DE], ES:[HL]

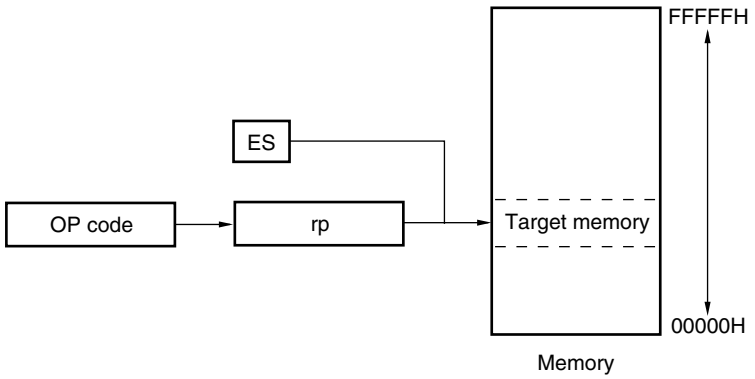

3.4.7 Based addressing

[Function]

Based addressing uses the contents of a register pair specified with the instruction word as a base address, and 8-bit immediate data or 16-bit immediate data as offset data. The sum of these values is used to specify the target address.

[Operand format]

Identifier	Description
–	[HL + byte], [DE + byte], [SP + byte] (only the space from F0000H to FFFFFH is specifiable)
–	word[B], word[C] (only the space from F0000H to FFFFFH is specifiable)
–	word[BC] (only the space from F0000H to FFFFFH is specifiable)
–	ES:[HL + byte], ES:[DE + byte] (higher 4-bit addresses are specified by the ES register)
–	ES:word[B], ES:word[C] (higher 4-bit addresses are specified by the ES register)
–	ES:word[BC] (higher 4-bit addresses are specified by the ES register)

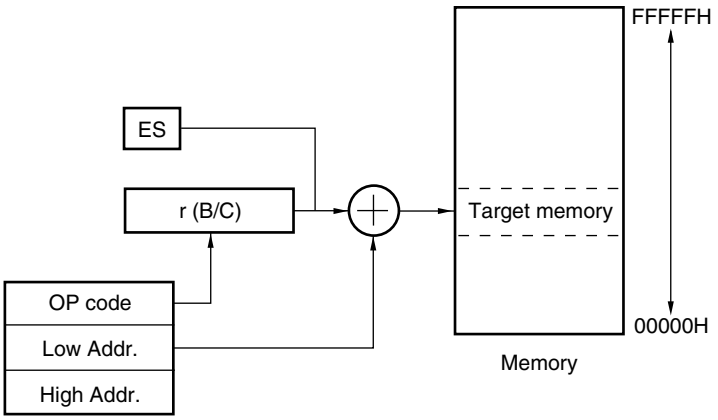

Figure 3-34. Example of ES:word[BC]

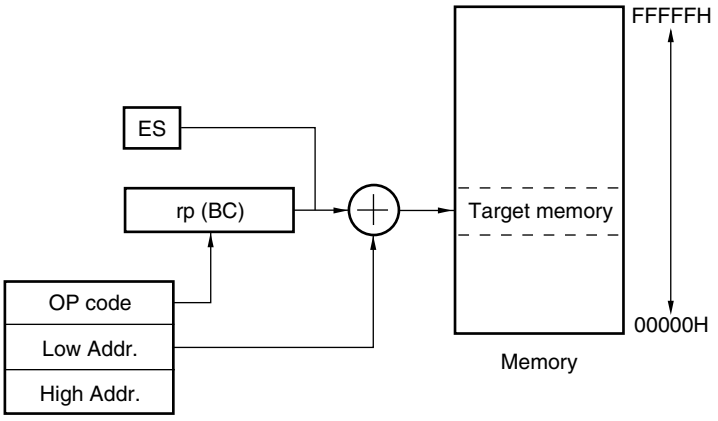

3.4.8 Based indexed addressing

[Function]

Based indexed addressing uses the contents of a register pair specified with the instruction word as the base address, and the content of the B register or C register similarly specified with the instruction word as offset address. The sum of these values is used to specify the target address.

[Operand format]

Identifier	Description
–	[HL+B], [HL+C] (only the space from F0000H to FFFFFH is specifiable)
–	ES:[HL+B], ES:[HL+C] (higher 4-bit addresses are specified by the ES register)

Figure 3-35. Example of [HL+B], [HL+C]

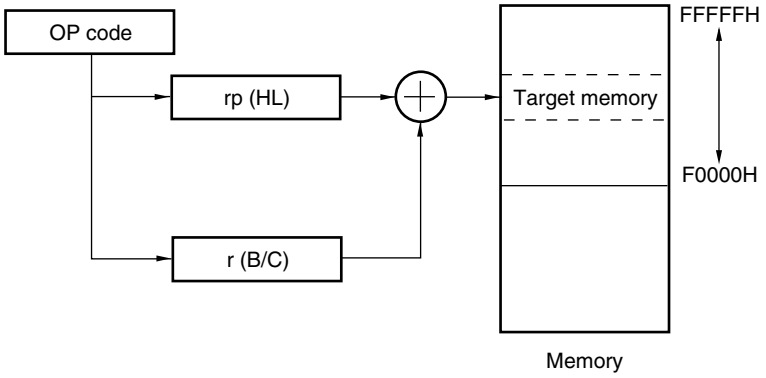

Figure 3-36. Example of ES:[HL+B], ES:[HL+C]

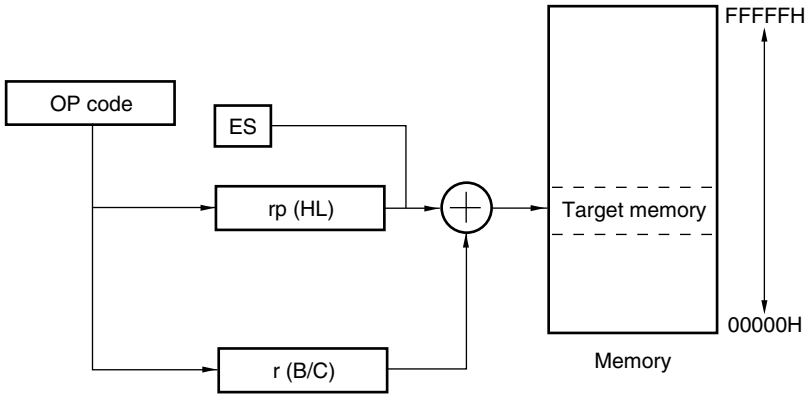

3.4.9 Stack addressing

[Function]

The stack area is indirectly addressed with the stack pointer (SP) contents. This addressing is automatically employed when the PUSH, POP, subroutine call, and return instructions are executed or the register is saved/restored upon generation of an interrupt request.

Stack addressing is applied only to the internal RAM area.

[Operand format]

Identifier	Description
–	PUSH AX/BC/DE/HL POP AX/BC/DE/HL CALL/CALLT RET BRK RETB (Interrupt request generated) RETI

CHAPTER 4 PORT FUNCTIONS

4.1 Port Functions

Pin I/O buffer power supplies depend on the product. The relationship between these power supplies and the pins is shown below.

Table 4-1. Pin I/O Buffer Power Supplies (AV_{REF}, V_{DD})

- 78K0R/KC3-L: 44-pin plastic LQFP (10x10)
  48-pin plastic TQFP (fine pitch) (7x7)
- 78K0R/KD3-L: 52-pin plastic LQFP (10x10)

Power Supply	Corresponding Pins
AV_{REF}	P20 to P27, P150 to P152[Note], P80 to P83
V_{DD}	• Port pins other than P20 to P27, P150 to P152[Note], P80 to P83 • Pins other than port pins

Note 44-pin products of the 78K0R/KC3-L do not have a P152 pin.

  64-pin plastic TQFP (fine pitch) (7x7)
  64-pin plastic LQFP (fine pitch) (10x10)
  64-pin plastic LQFP (12x12)

Power Supply	Corresponding Pins
AV_{REF}	P20 to P27, P150 to P153, P80 to P83
EV_{DD}	• Port pins other than P20 to P27, P150 to P153, P80 to P83, and P121 to P124 • $\overline{\text{RESET}}$ pin and FLMD0 pin
V_{DD}	• P121 to P124 • Pins other than port pins (other than the $\overline{\text{RESET}}$ pin and FLMD0 pin)

78K0R/Kx3-L microcontrollers are provided with digital I/O ports, which enable variety of control operations. The functions of each port are shown in Table 4-3.

In addition to the function as digital I/O ports, these ports have several alternate functions. For details of the alternate functions, see **CHAPTER 2 PIN FUNCTIONS**.

P00/TI00	–	–	√	√
P11/TO00	–	–	√	√

Port 0 is an I/O port with an output latch. Port 0 can be set to the input mode or output mode in 1-bit units using port mode register 0 (PM0). When the P00 and P01 pins are used as an input port, use of an on-chip pull-up resistor can be specified in 1-bit units by pull-up resistor option register 0 (PU0).

This port can also be used for timer I/O.

Reset signal generation sets port 0 to input mode.

Figures 4-1 and 4-2 show block diagrams of port 0.

Caution To use P01/TO00 as a general-purpose port, set bit 0 (TO00) of timer output register 0 (TO0) and bit 0 (TOE00) of timer output enable register 0 (TOE0) to "0", which is the same as their default status setting.

Remark √: Mounted

Port 1 is an I/O port with an output latch. Port 1 can be set to the input mode or output mode in 1-bit units using port mode register 1 (PM1). When the P10 to P17 pins are used as an input port, use of an on-chip pull-up resistor can be specified in 1-bit units by pull-up resistor option register 1 (PU1).

This port can also be used for timer I/O and real-time counter clock output.

Reset signal generation sets port 1 to input mode.

Figures 4-3 and 4-4 show block diagrams of port 1.

Caution To use P10/TI02/TO02, P11/TI03/TO03, P12/TI04/TO04/RTCDIV/RTCCL, P13/TI05/TO05, P14/TI06/TO06, or P15/TI07/TO07 as a general-purpose port, set bits 2 to 7 (TO02 to TO07) of timer output register 0 (TO0) and bits 2 to 7 (TOE02 to TOE07) of timer output enable register 0 (TOE0) to "0", which is the same as their default status setting.

Remark √: Mounted

Port 2 is an I/O port with an output latch. Port 2 can be set to the input mode or output mode in 1-bit units using port mode register 2 (PM2).

This port can also be used for A/D converter analog input.

To use P20/ANI0 to P27/ANI7 as digital input pins, set them in the digital I/O mode by using the A/D port configuration register (ADPC) and in the input mode by using PM2. Use these pins starting from the lower bit.

To use P20/ANI0 to P27/ANI7 as digital output pins, set them in the digital I/O mode by using ADPC and in the output mode by using PM2.

To use P20/ANI0 to P27/ANI7 as analog input pins, set them in the analog input mode by using the A/D port configuration register (ADPC) and in the input mode by using PM2. Use these pins starting from the upper bit.

Table 4-5. Setting Functions of P20/ANI0 to P27/ANI7 Pins

ADPC	PM2	ADS	P20/ANI0 to P27/ANI7 Pins
Digital I/O selection	Input mode	–	Digital input

Remark √: Mounted

Port 3 is an I/O port with an output latch. Port 3 can be set to the input mode or output mode in 1-bit units using port mode register 3 (PM3). When the P30 to P33 pins are used as an input port, use of an on-chip pull-up resistor can be specified in 1-bit units by pull-up resistor option register 3 (PU3).

Input to the P31 and P32 pins can be specified through a normal input buffer or a TTL input buffer in 1-bit units using port input mode register 3 (PIM3).

Output from the P30 to P32 pins can be specified as N-ch open-drain output (V_{DD} tolerance) in 1-bit units using port output mode register 3 (POM3).

This port can also be used for serial interface data I/O, clock I/O, and external interrupt request input.

Reset signal generation sets port 3 to input mode.

Figures 4-6 to 4-8 show block diagrams of port 3.

Caution To use P30/SO10/TxD1, P31/SI10/RxD1/SDA10/INTP1, P32/$\overline{\text{SCK10}}$/SCL10/INTP2 as a general-purpose port, note the serial array unit setting. Port 4 is an I/O port with an output latch. Port 4 can be set to the input mode or output mode in 1-bit units using port mode register 4 (PM4). When the P40 to P43 pins are used as an input port, use of an on-chip pull-up resistor can be specified in 1-bit units by pull-up resistor option register 4 (PU4)[Note].

This port can also be used for flash memory programmer/debugger data I/O and clock output.

Reset signal generation sets port 4 to input mode.

Figures 4-9 and 4-10 show block diagrams of port 4.

Note When a tool is connected, the P40 and P41 pins cannot be connected to a pull-up resistor.

Caution When a tool is connected, the P40 pin cannot be used as a port pin.
When the on-chip debug function is used, P41 pin can be used as follows by the mode setting on the debugger.

1-line mode: can be used as a port (P41).
2-line mode: used as a TOOL1 pin and cannot be used as a port (P41).

Remark √: Mounted

Port 5 is an I/O port with an output latch. Port 5 can be set to the input mode or output mode in 1-bit units using port mode register 5 (PM5). When the P50 to P53 pins are used as an input port, use of an on-chip pull-up resistor can be specified in 1-bit units by pull-up resistor option register 5 (PU5).

This port can also be used for real-time counter correction clock output and timer I/O.

Reset signal generation sets port 5 to input mode.

Figures 4-11 to 4-13 show block diagrams of port 5.

Caution 1. To use P50/TI06/TO06 and P51/TI07/TO07 as a general-purpose port, set bits 6 and 7 (TO06 and TO07) of timer output register 0 (TO0) and bits 6 and 7 (TOE06 and TOE07) of timer output enable register 0 (TOE0) to "0", which is the same as their default status setting.

2. To use P52/RTC1HZ/SLTI/SLTO as a general-purpose port, check which timer I/O pin of which channel n is selected in the input switching control register (ISC) setting. Also, set bit n (TO0n) of timer output register 0 (TO0) and bit n (TOE0n) of timer output enable register 0 (TOE0) to "0", which is the same setting as in the initial state of each.

P120 is an I/O port with an output latch. Port 12 can be set to the input mode or output mode in 1-bit units using port mode register 12 (PM12). When used as an input port, use of an on-chip pull-up resistor can be specified by pull-up resistor option register 12 (PU12).

P121 to P124 are input ports.

This port can also be used for external interrupt request input, potential input for external low-voltage detection, connecting resonator for main system clock, connecting resonator for subsystem clock, and external clock input for main system clock.

Reset signal generation sets port 12 to input mode.

Figures 4-22 to 4-24 show block diagrams of port 12.

Caution The function setting on P121 to P124 is available only once after the reset release. The port once set for connection to an oscillator cannot be used as an input port unless the reset is performed.

P140 is a port dedicated to output and is provided with an output latch.

P141 is an I/O port with an output latch. P141 can be set to the input mode or output mode in 1-bit units using port mode register 14 (PM14). When the P141 pin is used as an input port, use of an on-chip pull-up resistor can be specified in 1-bit units by pull-up resistor option register 14 (PU14).

This port can also be used for clock/buzzer output.

Reset signal generation sets P141 to input mode.

Figures 4-25 and 4-26 show block diagrams of port 14.

Caution To use P140/PCLBUZ0 and P141/PCLBUZ1 as general-purpose ports, set bit 7 of clock output select registers 0 and 1 (CKS0, CKS1) to "0", which is the same as their default status setting.

Port 15 is an I/O port with an output latch. Port 15 can be set to the input mode or output mode in 1-bit units using port mode register 15 (PM15).

This port can also be used for A/D converter analog input.

To use P150/ANI8 to P153/ANI11 as digital input pins, set them in the digital I/O mode by using the A/D port configuration register (ADPC) and in the input mode by using PM15. Use these pins starting from the lower bit.

To use P150/ANI8 to P153/ANI11 as digital output pins, set them in the digital I/O mode by using ADPC and in the output mode by using PM15.

Table 4-6. Setting Functions of P150/ANI8 to P153/ANI11 Pins

4.3 Registers Controlling Port Function

Port functions are controlled by the following six types of registers.

- Port mode registers (PMxx)
- Port registers (Pxx)
- Pull-up resistor option registers (PUxx)
- Port input mode registers (PIM3, PIM7, PIM8)
- Port output mode registers (POM3, POM7)
- A/D port configuration register (ADPC)

(1) Port mode registers (PMxx)

These registers specify input or output mode for the port in 1-bit units.

These registers can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation sets these registers to FFH (PM13 is set to FEH).

When port pins are used as alternate-function pins, set the port mode register by referencing **4.5 Settings of Port Mode Register and Output Latch When Using Alternate Function**.

(2) Port registers (Pxx)

These registers set the output latch value of a port.

If the data is read in the input mode, the pin level is read. If it is read in the output mode, the output latch value is read[Note].

These registers can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears these registers to 00H.

Note It is always 0 and never a pin level that is read out if a port is read during the input mode when P2 and P15 are set to function as an analog input for a A/D converter.

(3) Pull-up resistor option registers (PUxx)

These registers specify whether the on-chip pull-up resistors are to be used or not. On-chip pull-up resistors can be used in 1-bit units only for the bits set to input mode of the pins to which the use of an on-chip pull-up resistor has been specified in these registers. On-chip pull-up resistors cannot be connected to bits set to output mode and bits used as alternate-function output pins, regardless of the settings of these registers.

These registers can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears these registers to 00H.

(4) Port input mode registers (PIM3, PIM7, PIM8)

PIM3 and PIM7 registers set the input buffer of P31, P32, P71, P72, P74, or P75 in 1-bit units.

TTL input buffer can be selected during serial communication with an external device of the different potential.

PIM8 is used to enable or disable the digital inputs to P80 to P83 in 1-bit units. When using a comparator or a programmable gain amplifier, the digital inputs are disabled (used as analog input) by software processing. To use port functions and alternative functions, the digital inputs must be enabled, because they are disabled (used as analog input) by default.

These registers can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears these registers to 00H.

(5) Port output mode registers (POM3, POM7)

These registers set the output mode of P30 to P32, P70, P72, P73, or P75 in 1-bit units.

N-ch open drain output (V_{DD} tolerance) mode can be selected during serial communication with an external device of the different potential, and for the SDA10 pin during simplified I^2C communication with an external device of the same potential.

These registers can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears these registers to 00H.

This register switches the ANI0/P20 to ANI7/P27 and ANI8/P150 to ANI11/P153 pins to digital I/O of port or analog input of A/D converter.

ADPC can be set by an 8-bit memory manipulation instruction.

Reset signal generation sets this register to 10H.

4.4 Port Function Operations

Port operations differ depending on whether the input or output mode is set, as shown below.

4.4.1 Writing to I/O port

(1) Output mode

A value is written to the output latch by a transfer instruction, and the output latch contents are output from the pin.
Once data is written to the output latch, it is retained until data is written to the output latch again.
The data of the output latch is cleared when a reset signal is generated.

(2) Input mode

A value is written to the output latch by a transfer instruction, but since the output buffer is off, the pin status does not change.
Once data is written to the output latch, it is retained until data is written to the output latch again.
The data of the output latch is cleared when a reset signal is generated.

4.4.2 Reading from I/O port

(1) Output mode

The output latch contents are read by a transfer instruction. The output latch contents do not change.

(2) Input mode

The pin status is read by a transfer instruction. The output latch contents do not change.

4.4.3 Operations on I/O port

(1) Output mode

An operation is performed on the output latch contents, and the result is written to the output latch. The output latch contents are output from the pins.
Once data is written to the output latch, it is retained until data is written to the output latch again.
The data of the output latch is cleared when a reset signal is generated.

(2) Input mode

The pin level is read and an operation is performed on its contents. The result of the operation is written to the output latch, but since the output buffer is off, the pin status does not change.
The data of the output latch is cleared when a reset signal is generated.

4.4.4 Connecting to external device with different power potential (2.5 V, 3 V)

When ports 3 and 7 operate with V_{DD} = 4.0 V to 5.5 V, I/O connections with an external device that operates on a 2.5V or 3 V power supply voltage are possible.

Regarding inputs, normal input (CMOS)/TTL switching is possible on a bit-by-bit basis by port input mode registers 3 and 7 (PIM3 and PIM7).

Moreover, regarding outputs, different power potentials can be supported by switching the output buffer to the N-ch open drain (V_{DD} withstand voltage) by the port output mode registers 3 and 7 (POM3 and POM7).

(1) Setting procedure when using I/O pins of UART0, UART1 CSI00, CSI01, and CSI10 functions

(a) Use as 2.5V or 3 V input port

<1> After reset release, the port mode is the input mode (Hi-Z).

<2> If pull-up is needed, externally pull up the pin to be used (on-chip pull-up resistor cannot be used).

In case of UART0:	P74
In case of UART1:	P31
In case of CSI00:	P74, P75
In case of CSI01:	P71, P72
In case of CSI10:	P31, P32

<3> Set the corresponding bit of the PIM3 and PIM7 registers to 1 to switch to the TTL input buffer.

<4> V_{IH}/V_{IL} operates on a 2.5V or 3 V operating voltage.

(b) Use as 2.5V or 3 V output port

<1> After reset release, the port mode changes to the input mode (Hi-Z).

<2> Pull up externally the pin to be used (on-chip pull-up resistor cannot be used).

In case of UART0:	P73
In case of UART1:	P30
In case of CSI00:	P73, P75
In case of CSI01:	P70, P72
In case of CSI10:	P30, P32

<3> Set the output latch of the corresponding port to 1.

<4> Set the corresponding bit of the POM3 and POM7 registers to 1 to set the N-ch open drain output (V_{DD} withstand voltage) mode.

<5> Set the output mode by manipulating the PM3 and PM7 registers.
At this time, the output data is high level, so the pin is in the Hi-Z state.

<6> Communication is started by setting the serial array unit.

(2) Setting procedure when using I/O pins of simplified IIC10 functions

<1> After reset release, the port mode is the input mode (Hi-Z).

<2> Externally pull up the pin to be used (on-chip pull-up resistor cannot be used).

In case of simplified IIC10: P31, P32

<3> Set the output latch of the corresponding port to 1.

<4> Set the corresponding bit of the POM3 register to 1 to set the N-ch open drain output (V_{DD} withstand voltage) mode.

<5> Set the corresponding bit of the PM3 register to the output mode (data I/O is possible in the output mode).

At this time, the output data is high level, so the pin is in the Hi-Z state.

<6> Enable the operation of the serial array unit and set the mode to the simplified I^2C mode.

4.5 Settings of Port Mode Register and Output Latch When Using Alternate Function

To use the alternate function of a port pin, set the port mode register and output latch as shown in Table 4-7.

4.6 Cautions on 1-bit Manipulation Instruction for Port Register n (Pn)

When a 1-bit manipulation instruction is executed on a port that provides both input and output functions, the output latch value of an input port that is not subject to manipulation may be written in addition to the targeted bit.

Therefore, it is recommended to rewrite the output latch when switching a port from input mode to output mode.

<Example> When P10 is an output port, P11 to P17 are input ports (all pin statuses are high level), and the port latch value of port 1 is 00H, if the output of output port P10 is changed from low level to high level via a 1-bit manipulation instruction, the output latch value of port 1 is FFH.

Explanation: The targets of writing to and reading from the Pn register of a port whose PMnm bit is 1 are the output latch and pin status, respectively.

A 1-bit manipulation instruction is executed in the following order in the 78K0R/Kx3-L.

<1> The Pn register is read in 8-bit units.
<2> The targeted one bit is manipulated.
<3> The Pn register is written in 8-bit units.

In step <1>, the output latch value (0) of P10, which is an output port, is read, while the pin statuses of P11 to P17, which are input ports, are read. If the pin statuses of P11 to P17 are high level at this time, the read value is FEH.

The value is changed to FFH by the manipulation in <2>.

FFH is written to the output latch by the manipulation in <3>.

CHAPTER 5 CLOCK GENERATOR

5.1 Functions of Clock Generator

The clock generator generates the clock to be supplied to the CPU and peripheral hardware.
The following three kinds of system clocks and clock oscillators are selectable.

(1) Main system clock

<1> X1 oscillator

This circuit oscillates a clock of f_X = 2 to 20 MHz by connecting a resonator to X1 and X2.
Oscillation can be stopped by executing the STOP instruction or setting of MSTOP (bit 7 of the clock operation status control register (CSC)).

<2> Internal high-speed oscillator[Note]

This circuit oscillates clocks of f_{IH} = 1 and 8 MHz (TYP.). After a reset release, the CPU always starts operating with this internal high-speed oscillation clock. Oscillation can be stopped by executing the STOP instruction or setting HIOSTOP (bit 0 of CSC).

<3> 20 MHz internal high-speed oscillation clock oscillator[Note]

This circuit oscillates a clock of f_{IH20} = 20 MHz (TYP.). Oscillation can be started by setting bit 0 (DSCON) of the 20 MHz internal high-speed oscillation control register (DSCCTL) to 1 with $V_{DD} \geq 2.7$ V. Oscillation can be stopped by setting DSCON to 0.

Note To use the 1, 8, or 20 MHz internal high-speed oscillation clock, use the option byte to set the frequency in advance (for details, see **CHAPTER 23 OPTION BYTE**). Also, the internal high-speed oscillator automatically starts oscillating after reset release. To use the 20 MHz internal high-speed oscillator to operate the microcontroller, oscillation is started by setting bit 0 (DSCON) of the 20 MHz internal high-speed oscillation control register (DSCCTL) to 1.

An external main system clock (f_{EX} = 2 to 20 MHz) can also be supplied from the EXCLK/X2/P122 pin. An external main system clock input can be disabled by executing the STOP instruction or setting of MSTOP.
As the main system clock, a high-speed system clock (X1 clock or external main system clock) or internal high-speed oscillation clock can be selected by setting of MCM0 (bit 4 of the system clock control register (CKC)).

(2) Subsystem clock

- **XT1 clock oscillator**

This circuit oscillates a clock of f_{SUB} = 32.768 kHz by connecting a 32.768 kHz resonator to XT1 and XT2.
Oscillation can be stopped by setting XTSTOP (bit 6 of CSC).

Remark f_X: X1 clock oscillation frequency
f_{IH}: Internal high-speed oscillation clock frequency
f_{IH20}: 20 MHz internal high-speed oscillation clock frequency
f_{EX}: External main system clock frequency
f_{SUB}: Subsystem clock frequency

(3) Internal low-speed oscillation clock (clock dedicated to watchdog timer)

- **Internal low-speed oscillator**

  This circuit oscillates a clock of f_{IL} = 30 kHz (TYP.).

  The internal low-speed oscillation clock cannot be used as the CPU clock. The only hardware that operates with the internal low-speed oscillation clock is the watchdog timer.

  Oscillation is stopped when the watchdog timer stops.

Remarks 1. f_{IL}: Internal low-speed oscillation clock frequency

2. The watchdog timer stops in the following cases.

- When bit 4 (WDTON) of an option byte (000C0H) = 0
- If the HALT or STOP instruction is executed when bit 4 (WDTON) of an option byte (000C0H) = 1 and bit 0 (WDSTBYON) = 0

5.2 Configuration of Clock Generator

The clock generator includes the following hardware.

5.3 Registers Controlling Clock Generator

The following eight registers are used to control the clock generator.

- Clock operation mode control register (CMC)
- Clock operation status control register (CSC)
- Oscillation stabilization time counter status register (OSTC)
- Oscillation stabilization time select register (OSTS)
- System clock control register (CKC)
- 20 MHz internal high-speed oscillation control register (DSCCTL)
- Peripheral enable registers 0, 1, 2 (PER0, PER1, PER2)
- Operation speed mode control register (OSMC)

(1) Clock operation mode control register (CMC)

This register is used to set the operation mode of the X1/P121, X2/EXCLK/P122, XT1/P123, and XT2/P124 pins, and to select a gain of the oscillator.

CMC can be written only once by an 8-bit memory manipulation instruction after reset release. This register can be read by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Figure 5-2. Format of Clock Operation Mode Control Register (CMC)

Address: FFFA0H After reset: 00H R/W

OSCSELS	Subsystem clock pin operation mode	XT1/P123 pin	XT2/P124 pin
0	Input port mode	Input port	
1	XT1 oscillation mode	Crystal resonator connection	

AMPHS1	AMPHS0	XT1 oscillator oscillation mode selection
0	0	Low power consumption oscillation (default)
0	1	Normal oscillation
1	0	Ultra-low power consumption oscillation
1	1	

AMPH	Control of high-speed system clock oscillation frequency
0	2 MHz ≤ f_{MX} ≤ 10 MHz
1	10 MHz < f_{MX} ≤ 20 MHz

Cautions 1. CMC can be written only once after reset release, by an 8-bit memory manipulation instruction.

2. After reset release, set CMC before X1 or XT1 oscillation is started as set by the clock operation status control register (CSC).

3. Be sure to set AMPH to 1 if the X1 clock oscillation frequency exceeds 10 MHz.

4. When CMC is used at the default value (00H), be sure to set 00H to this register after reset release in order to prevent malfunctioning during a program loop.

5. The XT1 oscillator is a circuit with low amplification in order to achieve low-power consumption. Note the following points when designing the circuit.

- **Pins and circuit boards include parasitic capacitance. Therefore, perform oscillation evaluation using a circuit board to be actually used and confirm that there are no problems.**
- **When using the ultra-low power consumption oscillation (AMPHS1 = 1) as the mode of the XT1 oscillator, use the recommended resonators described in CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET).**
- **Make the wiring between the XT1 and XT2 pins and the resonators as short as possible, and minimize the parasitic capacitance and wiring resistance. Note this particularly when the ultra-low power consumption oscillation (AMPHS1 = 1) is selected.**

(Cautions and Remark are given on the next page.)

- **Configure the circuit of the circuit board, using material with little wiring resistance.**
- **Place a ground pattern that has the same potential as V_{SS} as much as possible near the XT1 oscillator.**
- **Be sure that the signal lines between the XT1 and XT2 pins, and the resonators do not cross with the other signal lines. Do not route the wiring near a signal line through which a high fluctuating current flows.**
- **The impedance between the XT1 and XT2 pins may drop and oscillation may be disturbed due to moisture absorption of the circuit board in a high-humidity environment or dew condensation on the board. When using the circuit board in such an environment, take measures to damp-proof the circuit board, such as by coating.**
- **When coating the circuit board, use material that does not cause capacitance or leakage between the XT1 and XT2 pins.**

Remark f_{MX}: High-speed system clock frequency

(2) Clock operation status control register (CSC)

This register is used to control the operations of the high-speed system clock, internal high-speed oscillation clock, and subsystem clock (except the 20 MHz internal high-speed oscillation clock and internal low-speed oscillation clock).

CSC can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation sets this register to C0H.

Figure 5-3. Format of Clock Operation Status Control Register (CSC)

Address: FFFA1H After reset: C0H R/W

Symbol	<7>	<6>	5	4	3	2	1	<0>
CSC	MSTOP	XTSTOP	0	0	0	0	0	HIOSTOP

MSTOP	High-speed system clock operation control		
	X1 oscillation mode	External clock input mode	Input port mode
0	X1 oscillator operating	External clock from EXCLK pin is valid	Input port
1	X1 oscillator stopped	External clock from EXCLK pin is invalid	

XTSTOP	Subsystem clock operation control	
	XT1 oscillation mode	Input port mode
0	XT1 oscillator operating	Input port
1	XT1 oscillator stopped	

HIOSTOP	Internal high-speed oscillation clock operation control
0	Internal high-speed oscillator operating
1	Internal high-speed oscillator stopped

(**Cautions** are listed on the next page.)

Cautions 1. After reset release, set the clock operation mode control register (CMC) before setting CSC.

2. To start X1 oscillation as set by MSTOP, check the oscillation stabilization time of the X1 clock by using the oscillation stabilization time counter status register (OSTC).

3. Do not stop the clock selected for the CPU peripheral hardware clock (f_{CLK}) with the OSC register.

4. The setting of the flags of the register to stop clock oscillation (invalidate the external clock input) and the condition before clock oscillation is to be stopped are as follows.

Table 5-2. Condition Before Stopping Clock Oscillation and Flag Setting

Clock	Condition Before Stopping Clock (Invalidating External Clock Input)	Setting of CSC Register Flags
X1 clock External main system clock	CPU and peripheral hardware clocks operate with a clock other than the high-speed system clock. (CLS = 0 and MCS = 0, or CLS = 1)	MSTOP = 1
Subsystem clock	CPU and peripheral hardware clocks operate with a clock other than the subsystem clock. (CLS = 0)	XTSTOP = 1
Internal high-speed oscillation clock	CPU and peripheral hardware clocks operate with a clock other than the internal high-speed oscillator clock. (CLS = 0 and MCS = 1, or CLS = 1)	HIOSTOP = 1

(3) Oscillation stabilization time counter status register (OSTC)

This is the register that indicates the count status of the X1 clock oscillation stabilization time counter.
The X1 clock oscillation stabilization time can be checked in the following case,

- If the X1 clock starts oscillation while the internal high-speed oscillation clock or subsystem clock is being used as the CPU clock.
- If the STOP mode is entered and then released while the internal high-speed oscillation clock is being used as the CPU clock with the X1 clock oscillating.

OSTC can be read by a 1-bit or 8-bit memory manipulation instruction.
When reset signal is generated, the STOP instruction and MSTOP (bit 7 of CSC register) = 1 clear OSTC to 00H.

Remark The oscillation stabilization time counter starts counting in the following cases.

- When oscillation of the X1 clock starts (EXCLK, OSCSEL = 0, 1 → MSTOP = 0)
- When the STOP mode is released

1	1	1	1	1	1	1	1	$2^{18}/f_X$ min.	26.21 ms min.	13.11 ms min.

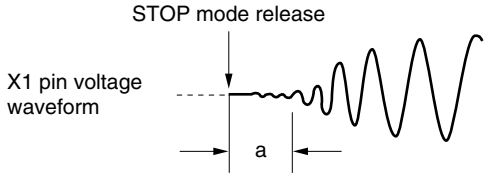
Cautions 1. After the above time has elapsed, the bits are set to 1 in order from MOST8 and remain 1.

2. The oscillation stabilization time counter counts up to the oscillation stabilization time set by OSTS.

In the following cases, set the oscillation stabilization time of OSTS to the value greater than the count value which is to be checked by the OSTC register after the oscillation starts.

- **If the X1 clock starts oscillation while the internal high-speed oscillation clock or subsystem clock is being used as the CPU clock.**
- **If the STOP mode is entered and then released while the internal high-speed oscillation clock is being used as the CPU clock with the X1 clock oscillating. (Note, therefore, that only the status up to the oscillation stabilization time set by OSTS is set to OSTC after the STOP mode is released.)**

3. The X1 clock oscillation stabilization wait time does not include the time until clock oscillation starts (“a” below).



Remark f_X: X1 clock oscillation frequency

(4) Oscillation stabilization time select register (OSTS)

This register is used to select the X1 clock oscillation stabilization wait time when the STOP mode is released.

When the X1 clock is selected as the CPU clock, the operation automatically waits for the time set using OSTS after the STOP mode is released.

When the internal high-speed oscillation clock is selected as the CPU clock, confirm with OSTC that the desired oscillation stabilization time has elapsed after the STOP mode is released. The oscillation stabilization time can be checked up to the time set using OSTC.

OSTS can be set by an 8-bit memory manipulation instruction.

Reset signal generation sets OSTS to 07H.

1	0	1	2^{15}/fx	3.27 ms	1.64 ms
1	1	0	2^{17}/fx	13.11 ms	6.55 ms
1	1	1	2^{18}/fx	26.21 ms	13.11 ms

Cautions 1. To set the STOP mode when the X1 clock is used as the CPU clock, set the OSTS register before executing the STOP instruction.

2. Setting the oscillation stabilization time to 20 μs or less is prohibited.

3. To change the setting of the OSTS register, be sure to confirm that the counting operation of the OSTC register has been completed.

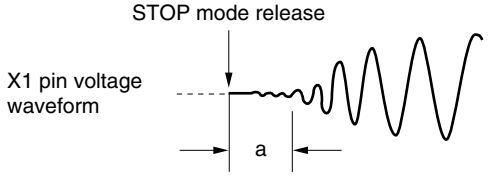
4. Do not change the value of the OSTS register during the X1 clock oscillation stabilization time.

5. The oscillation stabilization time counter counts up to the oscillation stabilization time set by OSTS.

In the following cases, set the oscillation stabilization time of OSTS to the value greater than the count value which is to be checked by the OSTC register after the oscillation starts.

- **If the X1 clock starts oscillation while the internal high-speed oscillation clock or subsystem clock is being used as the CPU clock.**
- **If the STOP mode is entered and then released while the internal high-speed oscillation clock is being used as the CPU clock with the X1 clock oscillating. (Note, therefore, that only the status up to the oscillation stabilization time set by OSTS is set to OSTC after the STOP mode is released.)**

6. The X1 clock oscillation stabilization wait time does not include the time until clock oscillation starts ("a" below).



Remark fx: X1 clock oscillation frequency

(5) System clock control register (CKC)

This register is used to select a CPU/peripheral hardware clock and a division ratio.

CKC can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation sets this register to 09H.

Notes 1. Bits 7 and 5 are read-only.

2. Setting is prohibited when f_{MX} < 4 MHz.

3. Changing the value of the MCM0 bit is prohibited while CSS is set to 1.

Remarks 1. f_{IH}: Internal high-speed oscillation clock frequency

f_{MX}: High-speed system clock frequency

f_{SUB}: Subsystem clock frequency

2. ×: don't care

(**Cautions 1** to **3** are listed on the next page.)

Cautions 1. Be sure to set bit 3 to 1.

2. The clock set by CSS, MCM0, and MDIV2 to MDIV0 is supplied to the CPU and peripheral hardware. If the CPU clock is changed, therefore, the clock supplied to peripheral hardware (except the real-time counter, clock output/buzzer output, and watchdog timer) is also changed at the same time. Consequently, stop each peripheral function when changing the CPU/peripheral hardware clock.

3. If the peripheral hardware clock is used as the subsystem clock, the operations of the A/D converter and IICA are not guaranteed. For the operating characteristics of the peripheral hardware, refer to the chapters describing the various peripheral hardware as well as CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET).

The fastest instruction can be executed in 1 clock of the CPU clock in the 78K0R/Kx3-L. Therefore, the relationship between the CPU clock (f_{CLK}) and the minimum instruction execution time is as shown in Table 5-3.

Table 5-3. Relationship Between CPU Clock and Minimum Instruction Execution Time

(6) 20 MHz internal high-speed oscillation control register (DSCCTL)

This register controls the 20 MHz internal high-speed oscillation clock (DSC) function.

It can be used to select whether to use the 20 MHz internal high-speed oscillation clock (f_{IH20}) as a peripheral hardware clock that supports 20 MHz.

DSCCTL can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

0	Does not select 20 MHz internal high-speed oscillation (clock selected by CKC register is supplied to f_{CLK})
1	Selects 20 MHz internal high-speed oscillation (20 MHz internal high-speed oscillation is supplied to f_{CLK})

DSCON	20 MHz internal high-speed oscillation clock (f_{IH20}) operation enable/disable
0	Disables operation.
1	Enables operation.

Note Bit 3 is read-only.

Caution Set SELDSC when 100 μs have elapsed after having set DSCON with $V_{DD} \geq 2.7$ V.

(7) Peripheral enable registers 0, 1, 2 (PER0, PER1, PER2)

These registers are used to enable or disable use of each peripheral hardware macro. Clock supply to the hardware that is not used is also stopped so as to decrease the power consumption and noise.

PER0, PER1, PER2 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears theses registers to 00H.

(8) Operation speed mode control register (OSMC)

FLPC and FSEL can be used to control the step-up circuit of the flash memory for high-speed operation.

If the microcontroller operates at a low speed with a system clock of 10 MHz or less, the power consumption can be lowered by setting this register to the default value, 00H. Furthermore, when operating the system clock at 1 MHz, the power consumption can be further reduced by setting FLPC to 1.

RTCLPC can be used to set the operation in subsystem clock HALT mode.

OSMC can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Figure 5-9. Format of Operation Speed Mode Control Register (OSMC)

Address: F00F3H After reset: 00H R/W

Symbol	7	6	5	4	3	2	1	0
OSMC	RTCLPC	0	0	0	0	0	FLPC	FSEL

FLPC	FSEL	f_{CLK} frequency selection
0	0	Operates at a frequency of 10 MHz or less (default).
0	1	Operates at a frequency higher than 10 MHz.
1	0	Operates at a frequency of 1 MHz.
1	1	Setting prohibited

RTCLPC	Setting in subsystem clock HALT mode
0	Enables supply of subsystem clock to peripheral functions (See Table 18-1 for peripheral functions whose operations are enabled.)
1	Stops supply of subsystem clock to peripheral functions other than real-time counter

Cautions 1. Write "1" to FSEL before the following two operations.

- **Changing the clock prior to dividing f_{CLK} to a clock other than f_{IH}.**
- **Operating the DMA controller.**

2. The CPU waits when "1" is written to the FSEL flag.
The wait time is 15 μs to 20 μs (target) when $f_{CLK} = f_{IH}$, and 30 μs to 40 μs (target) when $f_{CLK} = f_{IH}/2$.
However, counting the oscillation stabilization time of f_X can continue even while the CPU is waiting.

3. To increase f_{CLK} to 10 MHz or higher, set FSEL to "1", then change f_{CLK} after two or more clocks have elapsed.

4. Even when set to FSEL = 1, the system clock can be operated at a frequency of 10 MHz or less.
When setting FSEL to "1", however, do so while $V_{DD} \geq 2.25$ V.
When set to FSEL = 1, make sure that $V_{DD} \geq 2.25$ V at the following timings, even if f_{CLK} is divided.

- **When releasing f_{IH} or f_{EX} from the STOP mode selected for f_{CLK}**
- **When switching f_{CLK} from f_{SUB} to f_{MAIN}**

(Cautions are given on the next page.)

5. The HALT mode current when the subsystem clock is used can be reduced by setting RTCLPC to 1. However, no clock can be supplied to the peripheral functions other than the real-time counter during subsystem clock HALT mode. Set bit 7 (RTCEN) of PER0 to 1, and all of bits 0 to 6 of PER0, bits 0 to 7 of PER1, and bits 0 to 7 of PER2 to 0 before setting subsystem clock HALT mode.

6 If FLPC is once set from 0 to 1, it is prohibited to set it back from 1 to 0, other than by a reset.

5.4 System Clock Oscillator

5.4.1 X1 oscillator

The X1 oscillator oscillates with a crystal resonator or ceramic resonator (2 to 20 MHz) connected to the X1 and X2 pins.

An external clock can also be input. In this case, input the clock signal to the EXCLK pin.

To use the X1 oscillator, set bits 7 and 6 (EXCLK, OSCSEL) of the clock operation mode control register (CMC) as follows.

- Crystal or ceramic oscillation: EXCLK, OSCSEL = 0, 1
- External clock input: EXCLK, OSCSEL = 1, 1

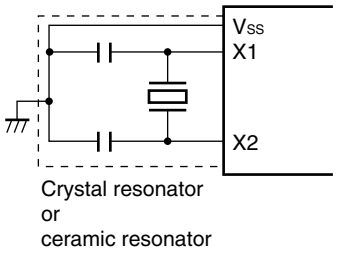
When the X1 oscillator is not used, set the input port mode (EXCLK, OSCSEL = 0, 0).

When the pins are not used as input port pins, either, see **Table 2-2 Connection of Unused Pins**.

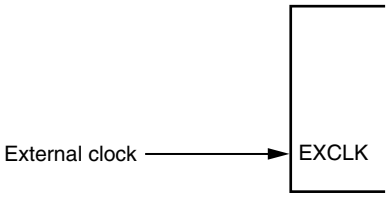
Figure 5-10 shows an example of the external circuit of the X1 oscillator.

Figure 5-10. Example of External Circuit of X1 Oscillator

(a) Crystal or ceramic oscillation



(b) External clock



Cautions are listed on the next page.

5.4.2 XT1 oscillator

The XT1 oscillator oscillates with a crystal resonator (standard: 32.768 kHz) connected to the XT1 and XT2 pins.

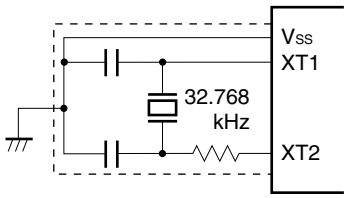
To use the XT1 oscillator, set bit 4 (OSCSELS) of the clock operation mode control register (CMC) to 1.

When the XT1 oscillator is not used, set the input port mode (OSCSELS = 0).

When the pins are not used as input port pins, either, see **Table 2-2 Connection of Unused Pins**.

Figure 5-11 shows an example of the external circuit of the XT1 oscillator.

Figure 5-11. Example of External Circuit of XT1 Oscillator (Crystal Oscillation)



Cautions are listed on the next page.

Caution 1. When using the X1 oscillator and XT1 oscillator, wire as follows in the area enclosed by the broken lines in the Figures 5-10 and 5-11 to avoid an adverse effect from wiring capacitance.

- **Keep the wiring length as short as possible.**
- **Do not cross the wiring with the other signal lines. Do not route the wiring near a signal line through which a high fluctuating current flows.**
- **Always make the ground point of the oscillator capacitor the same potential as V_{SS}. Do not ground the capacitor to a ground pattern through which a high current flows.**
- **Do not fetch signals from the oscillator.**

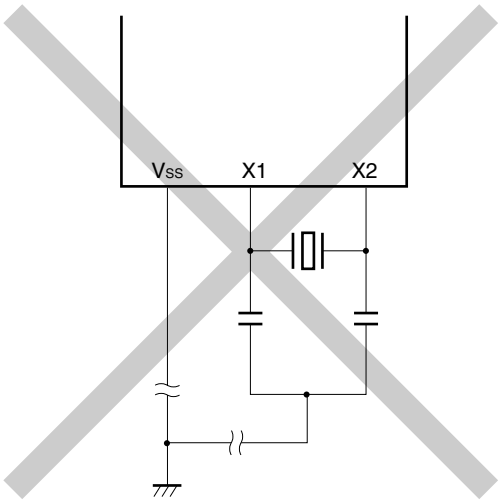
The XT1 oscillator is a circuit with low amplification in order to achieve low-power consumption. Note the following points when designing the circuit.

- **Pins and circuit boards include parasitic capacitance. Therefore, perform oscillation evaluation using a circuit board to be actually used and confirm that there are no problems.**
- **When using the ultra-low power consumption oscillation (AMPHS1 = 1) as the mode of the XT1 oscillator, use the recommended resonators described in CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET).**
- **Make the wiring between the XT1 and XT2 pins and the resonators as short as possible, and minimize the parasitic capacitance and wiring resistance. Note this particularly when the ultra-low power consumption oscillation (AMPHS1 = 1) is selected.**
- **Configure the circuit of the circuit board, using material with little wiring resistance.**
- **Place a ground pattern that has the same potential as V_{SS} as much as possible near the XT1 oscillator.**
- **Be sure that the signal lines between the XT1 and XT2 pins, and the resonators do not cross with the other signal lines. Do not route the wiring near a signal line through which a high fluctuating current flows.**
- **The impedance between the XT1 and XT2 pins may drop and oscillation may be disturbed due to moisture absorption of the circuit board in a high-humidity environment or dew condensation on the board. When using the circuit board in such an environment, take measures to damp-proof the circuit board, such as by coating.**
- **When coating the circuit board, use material that does not cause capacitance or leakage between the XT1 and XT2 pins.**

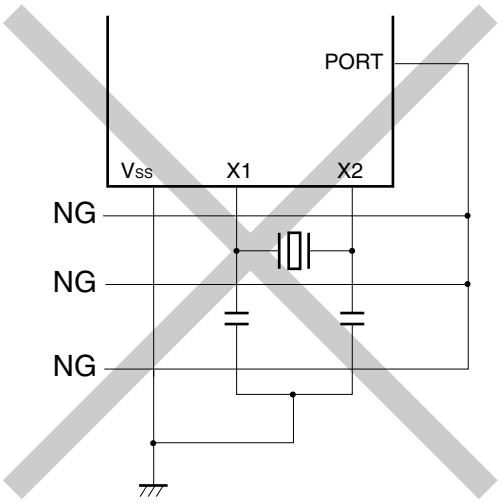
Figure 5-12 shows examples of incorrect resonator connection.

Figure 5-12. Examples of Incorrect Resonator Connection (1/2)

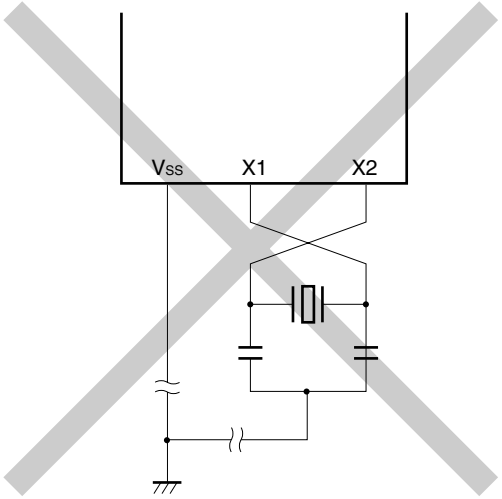
(a) Too long wiring



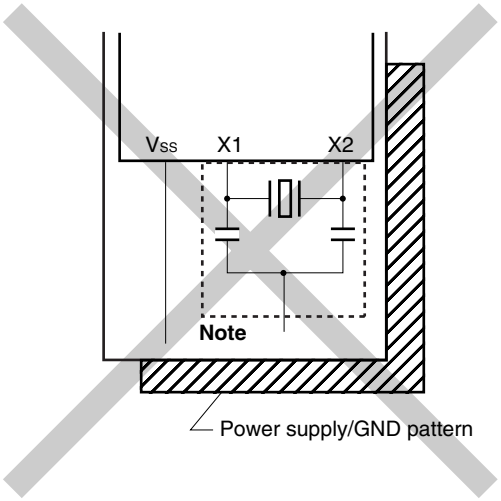
(b) Crossed signal line



(c) The X1 and X2 signal line wires cross.



(d) A power supply/GND pattern exists under the X1 and X2 wires.

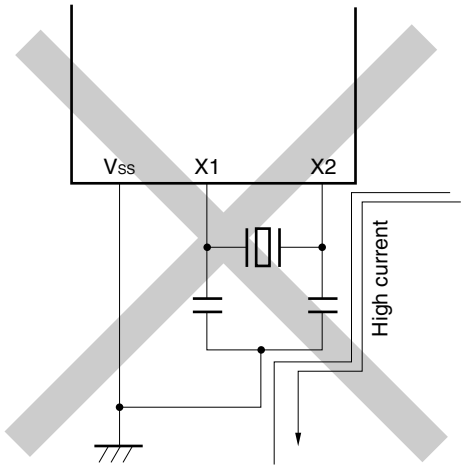


Note Do not place a power supply/GND pattern under the wiring section (section indicated by a broken line in the figure) of the X1 and X2 pins and the resonators in a multi-layer board or double-sided board.
Do not configure a layout that will cause capacitance elements and affect the oscillation characteristics.

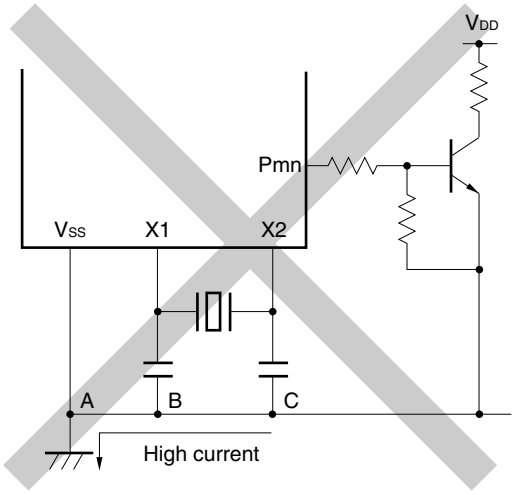
Remark When using the subsystem clock, replace X1 and X2 with XT1 and XT2, respectively. Also, insert resistors in series on the XT2 side.

Figure 5-12. Examples of Incorrect Resonator Connection (2/2)

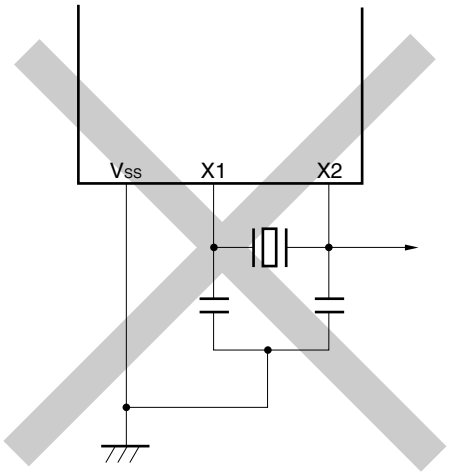
(e) Wiring near high alternating current



(f) Current flowing through ground line of oscillator (potential at points A, B, and C fluctuates)



(g) Signals are fetched



Remark When using the subsystem clock, replace X1 and X2 with XT1 and XT2, respectively. Also, insert resistors in series on the XT2 side.

Caution 2. When X2 and XT1 are wired in parallel, the crosstalk noise of X2 may increase with XT1, resulting in malfunctioning.

5.4.3 Internal high-speed oscillator[Note]

The internal high-speed oscillator is incorporated in the 78K0R/Kx3-L (1, 8 MHz (TYP.)). Oscillation can be controlled by bit 0 (HIOSTOP) of the clock operation status control register (CSC).

5.4.4 20 MHz internal high-speed oscillator[Note]

The 20 MHz internal high-speed oscillator is incorporated in the 78K0R/Kx3-L (20 MHz (TYP.)). Oscillation can be controlled by bit 0 (DSCON) of the 20 MHz internal high-speed oscillation control register (DSCCTL) with $V_{DD} \geq 2.7$ V.

After a reset release, the 20 MHz internal high-speed oscillator starts oscillating by setting bit 0 (DSCON) of the DSCCTL register to 1.

Note To use the 1, 8, or 20 MHz internal high-speed oscillation clock, use the option byte to set the frequency in advance (for details, see **CHAPTER 23 OPTION BYTE**). Also, the internal high-speed oscillator automatically starts oscillating after reset release. To use the 20 MHz internal high-speed oscillator to operate the microcontroller, oscillation is started by setting bit 0 (DSCON) of the 20 MHz internal high-speed oscillation control register (DSCCTL) to 1 with $V_{DD} \geq 2.7$ V.

5.4.5 Internal low-speed oscillator

The internal low-speed oscillator is incorporated in the 78K0R/Kx3-L.

The internal low-speed oscillation clock is used only as the watchdog timer clock. The internal low-speed oscillation clock cannot be used as the CPU clock.

After a reset release, the internal low-speed oscillator automatically starts oscillation, and the watchdog timer is driven (30 kHz (TYP.)) if the watchdog timer operation is enabled by the option byte.

The internal low-speed oscillator continues oscillation except when the watchdog timer stops. When the watchdog timer operates, the internal low-speed oscillation clock does not stop, even in case of a program loop.

5.4.6 Prescaler

The prescaler generates a CPU/peripheral hardware clock by dividing the main system clock and subsystem clock.

5.5 Clock Generator Operation

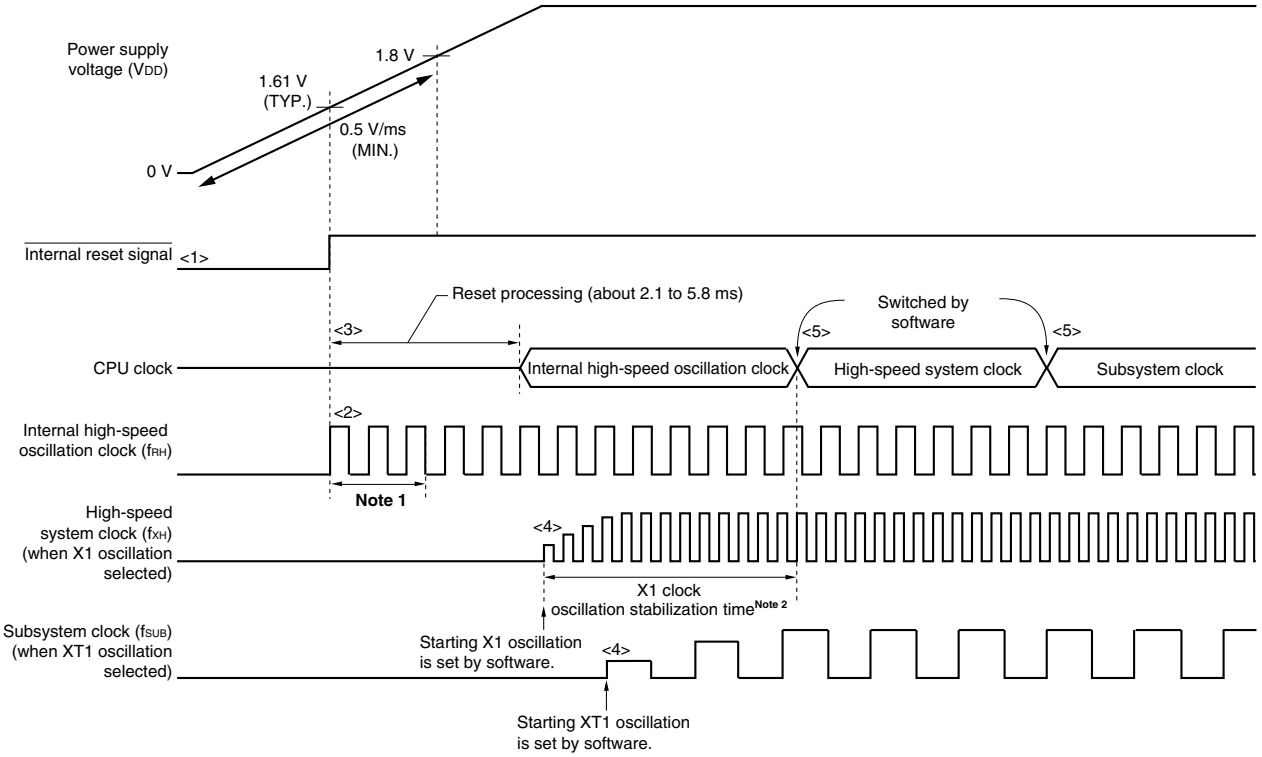
The clock generator generates the following clocks and controls the operation modes of the CPU, such as standby mode (see **Figure 5-1**).

- Main system clock f_{MAIN}
  - High-speed system clock f_{MX}
    X1 clock f_X
    External main system clock f_{EX}
  - Internal high-speed oscillation clock f_{IH}
  - 20 MHz internal high-speed oscillation clock f_{IH20}
- Subsystem clock f_{SUB}
- Internal low-speed oscillation clock f_{IL}
- CPU/peripheral hardware clock f_{CLK}

The CPU starts operation when the internal high-speed oscillator starts outputting after a reset release in the 78K0R/Kx3-L.

When the power supply voltage is turned on, the clock generator operation is shown in Figure 5-13 to Figure 5-16.

Figure 5-13. Clock Generator Operation When Power Supply Voltage Is Turned On (When LVI Default Start Function Stopped Is Set (Option Byte: LVIOFF = 1))



<1> When the power is turned on, an internal reset signal is generated by the power-on-clear (POC) circuit.

<2> When the power supply voltage exceeds 1.61 V (TYP.), the reset is released and the internal high-speed oscillator automatically starts oscillation.

<3> When the power supply voltage rises with a slope of 0.5 V/ms (MIN.), the CPU starts operation on the internal high-speed oscillation clock after a reset processing such as waiting for the voltage of the power supply or regulator to stabilize has been performed after reset release.

<4> Set the start of oscillation of the X1 or XT1 clock via software (see **(1)** in **5.6.1 Example of controlling high-speed system clock** and **(1)** in **5.6.3 Example of controlling subsystem clock)**.

<5> When switching the CPU clock to the X1 or XT1 clock, wait for the clock oscillation to stabilize, and then set switching via software (see **(3)** in **5.6.1 Example of controlling high-speed system clock** and **(2)** in **5.6.3 Example of controlling subsystem clock**).

Notes 1. The internal reset processing time includes the oscillation accuracy stabilization time of the internal high-speed oscillation clock.

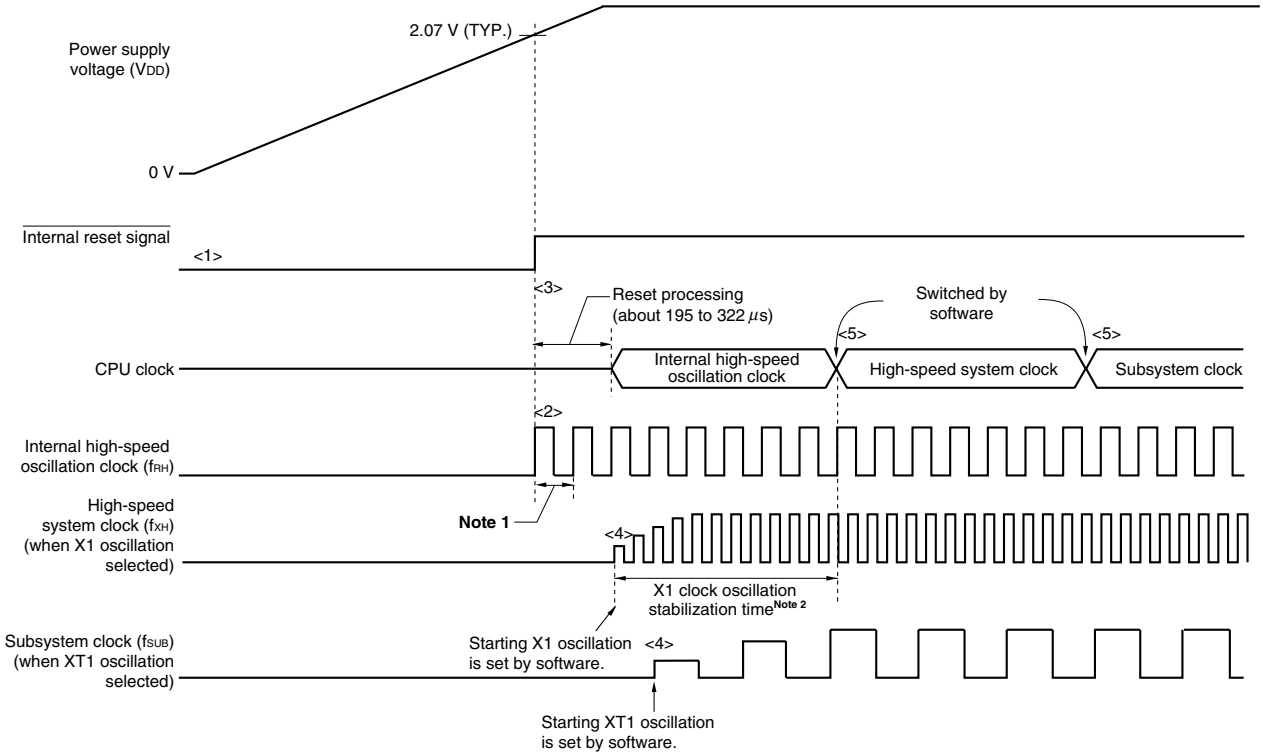
2. When releasing a reset (above figure) or releasing STOP mode while the CPU is operating on the internal high-speed oscillation clock, confirm the oscillation stabilization time for the X1 clock using the oscillation stabilization time counter status register (OSTC). If the CPU operates on the high-speed system clock (X1 oscillation), set the oscillation stabilization time when releasing STOP mode using the oscillation stabilization time select register (OSTS).

Cautions 1. If the voltage rises with a slope of less than 0.5 V/ms (MIN.) from power application until the voltage reaches 1.8 V, input a low level to the $\overline{\text{RESET}}$ pin from power application until the voltage reaches 1.8 V, or set the LVI default start function stopped by using the option byte (LVIOFF = 0) (see Figure 5-14). By doing so, the CPU operates with the same timing as <2> and thereafter in Figure 5-13 after reset release by the $\overline{\text{RESET}}$ pin.

2. It is not necessary to wait for the oscillation stabilization time when an external clock input from the EXCLK pin is used.

Remark While the microcontroller is operating, a clock that is not used as the CPU clock can be stopped via software settings. The internal high-speed oscillation clock and high-speed system clock can be stopped by executing the STOP instruction (see **(4)** in **5.6.1 Example of controlling high-speed system clock**, **(3)** in **5.6.2 Example of controlling internal high-speed oscillation clock**, and **(3)** in **5.6.3 Example of controlling subsystem clock**).

Figure 5-14. Clock Generator Operation When Power Supply Voltage Is Turned On (When LVI Default Start Function Enabled Is Set (Option Byte: LVIOFF = 0))



<1> When the power is turned on, an internal reset signal is generated by the power-on-clear (POC) circuit.

<2> When the power supply voltage exceeds 2.07 V (TYP.), the reset is released and the internal high-speed oscillator automatically starts oscillation.

<3> After the reset is released and reset processing is performed, the CPU starts operation on the internal high-speed oscillation clock.

<4> Set the start of oscillation of the X1 or XT1 clock via software (see **(1)** in **5.6.1 Example of controlling high-speed system clock** and **(1)** in **5.6.3 Example of controlling subsystem clock**).

<5> When switching the CPU clock to the X1 or XT1 clock, wait for the clock oscillation to stabilize, and then set switching via software (see **(3)** in **5.6.1 Example of controlling high-speed system clock** and **(2)** in **5.6.3 Example of controlling subsystem clock**).

Notes 1. The internal reset processing time includes the oscillation accuracy stabilization time of the internal high-speed oscillation clock.

2. When releasing a reset (above figure) or releasing STOP mode while the CPU is operating on the internal high-speed oscillation clock, confirm the oscillation stabilization time for the X1 clock using the oscillation stabilization time counter status register (OSTC). If the CPU operates on the high-speed system clock (X1 oscillation), set the oscillation stabilization time when releasing STOP mode using the oscillation stabilization time select register (OSTS).

Cautions 1. A voltage stabilization time (about 2.0 to 5.8 ms) is required after the supply voltage reaches 1.61 V (TYP.). If the time for the supply voltage to rise from 1.61 V (TYP.) to 2.07 V (TYP.) is shorter than the voltage stabilization time, reset processing is entered after the voltage stabilization time elapses.

2. It is not necessary to wait for the oscillation stabilization time when an external clock input from the EXCLK pin is used.

Remark While the microcontroller is operating, a clock that is not used as the CPU clock can be stopped via software settings. The internal high-speed oscillation clock and high-speed system clock can be stopped by executing the STOP instruction (see **(4)** in **5.6.1 Example of controlling high-speed system clock, (3)** in **5.6.2 Example of controlling internal high-speed oscillation clock**, and **(3)** in **5.6.3 Example of controlling subsystem clock**).

<2> When the power supply voltage exceeds 1.61 V (TYP.), the reset is released and the internal high-speed oscillator automatically starts oscillation.

<3> When the power supply voltage rises with a slope of 0.5 V/ms (MIN.), the CPU starts operation on the internal high-speed oscillation clock after a reset processing such as waiting for the voltage of the power supply or regulator to stabilize has been performed after reset release.

<4> Check that the power supply voltage is 2.7 V or more and set DSCON = 1 by software.

<5> Switch the clock by setting SELDSC = 1 by software after waiting for 100 μs.

Note The internal reset processing time includes the oscillation accuracy stabilization time of the internal high-speed oscillation clock.

Cautions 1. To use the 20 MHz internal high-speed oscillation clock, use bits 2 and 1 (FRQSEL2 and FRQSEL1) of the option byte (000C1H) to set the frequency to 20 MHz in advance (for details, see CHAPTER 23 OPTION BYTE).

2. If the voltage rises with a slope of less than 0.5 V/ms (MIN.) from power application until the voltage reaches 1.8 V, input a low level to the $\overline{\text{RESET}}$ pin from power application until the voltage reaches 1.8 V, or set the LVI default start function stopped by using the option byte (LVIOFF = 0) (see Figure 5-16). By doing so, the CPU operates with the same timing as <2> and thereafter in Figure 5-15 after reset release by the $\overline{\text{RESET}}$ pin.

<2> When the power supply voltage exceeds 2.07 V (TYP.), the reset is released and the internal high-speed oscillator automatically starts oscillation.

<3> After the reset is released and reset processing is performed, the CPU starts operation on the internal high-speed oscillation clock.

<5> Switch the clock by setting SELDSC = 1 by software after waiting for 100 μs.

Note The internal reset processing time includes the oscillation accuracy stabilization time of the internal high-speed oscillation clock.

Cautions 1. To use the 20 MHz internal high-speed oscillation clock, use bits 2 and 1 (FRQSEL2 and FRQSEL1) of the option byte (000C1H) to set the frequency to 20 MHz in advance (for details, see CHAPTER 23 OPTION BYTE).

2. A voltage stabilization time (about 2.0 to 5.8 ms) is required after the supply voltage reaches 1.61 V (TYP.). If the time for the supply voltage to rise from 1.61 V (TYP.) to 2.07 V (TYP.) is shorter than the voltage stabilization time, reset processing is entered after the voltage stabilization time elapses.

5.6 Controlling Clock

5.6.1 Example of controlling high-speed system clock

The following two types of high-speed system clocks are available.

- X1 clock: Crystal/ceramic resonator is connected to the X1 and X2 pins.
- External main system clock: External clock is input to the EXCLK pin.

When the high-speed system clock is not used, the X1/P121 and X2/EXCLK/P122 pins can be used as input port pins.

Caution The X1/P121 and X2/EXCLK/P122 pins are in the input port mode after a reset release.

The following describes examples of setting procedures for the following cases.

(1) When oscillating X1 clock
(2) When using external main system clock
(3) When using high-speed system clock as CPU/peripheral hardware clock
(4) When stopping high-speed system clock

(1) Example of setting procedure when oscillating the X1 clock

<1> Setting P121/X1 and P122/X2/EXCLK pins and setting oscillation frequency (CMC register)

- 2 MHz ≤ fx ≤ 10 MHz

EXCLK	OSCSEL	0	OSCSELS	0	AMPHS1	AMPHS0	AMPH
0	1	0	0/1	0	0/1	0/1	0

- 10 MHz < fx ≤ 20 MHz

EXCLK	OSCSEL	0	OSCSELS	0	AMPHS1	AMPHS0	AMPH
0	1	0	0/1	0	0/1	0/1	1

Remarks 1. fx: X1 clock oscillation frequency

2. For setting of the P123/XT1 and P124/XT2 pins, see **5.6.3 Example of controlling subsystem clock**.

<2> Controlling oscillation of X1 clock (CSC register)
If MSTOP is cleared to 0, the X1 oscillator starts oscillating.

<3> Waiting for the stabilization of the oscillation of X1 clock
Check the OSTC register and wait for the necessary time.
During the wait time, other software processing can be executed with the internal high-speed oscillation clock.

Cautions 1. The CMC register can be written only once after reset release, by an 8-bit memory manipulation instruction.
Therefore, it is necessary to also set the value of the OSCSELS bit at the same time. For OSCSELS bit, see 5.6.3 Example of controlling subsystem clock.

2. Set the X1 clock after the supply voltage has reached the operable voltage of the clock to be used (see CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET)).

(2) Example of setting procedure when using the external main system clock

<1> Setting P121/X1 and P122/X2/EXCLK pins (CMC register)

EXCLK	OSCSEL	0	OSCSELS	0	AMPHS1	AMPHS0	AMPH
1	1	0	0/1	0	0/1	0/1	0/1

Remark For setting of the P123/XT1 and P124/XT2 pins, see **5.6.3 (1) Example of setting procedure when oscillating the subsystem clock**.

<2> Controlling external main system clock input (CSC register)
When MSTOP is cleared to 0, the input of the external main system clock is enabled.

Cautions 1. The CMC register can be written only once after reset release, by an 8-bit memory manipulation instruction.
Therefore, it is necessary to also set the value of the OSCSELS bits at the same time. For OSCSELS bits, see 5.6.3 Example of controlling subsystem clock.
2. Set the external main system clock after the supply voltage has reached the operable voltage of the clock to be used (see CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET)).

(3) Example of setting procedure when using high-speed system clock as CPU/peripheral hardware clock

<1> Setting high-speed system clock oscillation[Note]
(See **5.6.1 (1) Example of setting procedure when oscillating the X1 clock** and **(2) Example of setting procedure when using the external main system clock.**)

Note The setting of <1> is not necessary when high-speed system clock is already operating.

<2> Setting the high-speed system clock as the source clock of the CPU/peripheral hardware clock and setting the division ratio of the set clock (CKC register)

MCM0	MDIV2	MDIV1	MDIV0	Selection of CPU/Peripheral Hardware Clock (f_{CLK})
1	0	0	0	f_{MX}
	0	0	1	$f_{MX}/2$
	0	1	0	$f_{MX}/2^2$
	0	1	1	$f_{MX}/2^3$
	1	0	0	$f_{MX}/2^4$
	1	0	1	$f_{MX}/2^5$ [Note]

Note Setting is prohibited when f_{MX} < 4 MHz.

<3> If some peripheral hardware macros are not used, supply of the input clock to each hardware macro can be stopped.

(4) Example of setting procedure when stopping the high-speed system clock

The high-speed system clock can be stopped (disabling clock input if the external clock is used) in the following two ways.

- Executing the STOP instruction
- Setting MSTOP to 1

(a) To execute a STOP instruction

<1> Setting to stop peripheral hardware
Stop peripheral hardware that cannot be used in the STOP mode (for peripheral hardware that cannot be used in STOP mode, see **CHAPTER 18 STANDBY FUNCTION**).

<2> Setting the X1 clock oscillation stabilization time after STOP mode is released
If the X1 clock oscillates before the STOP mode is entered, set the value of the OSTS register before executing the STOP instruction.

<3> Executing the STOP instruction
When the STOP instruction is executed, the system is placed in the STOP mode and X1 oscillation is stopped (the input of the external clock is disabled).

(b) To stop X1 oscillation (disabling external clock input) by setting MSTOP to 1

<1> Confirming the CPU clock status (CKC register)

Confirm with CLS and MCS that the CPU is operating on a clock other than the high-speed system clock.

When CLS = 0 and MCS = 1, the high-speed system clock is supplied to the CPU, so change the CPU clock to the subsystem clock or internal high-speed oscillation clock.

CLS	MCS	CPU Clock Status
0	0	Internal high-speed oscillation clock or 20 MHz internal high-speed oscillation clock
0	1	High-speed system clock
1	×	Subsystem clock

<2> Setting of X1 clock oscillation stabilization time after restart of X1 clock oscillation[Note]

Prior to setting "1" to MSTOP, set the OSTS register to a value greater than the count value to be confirmed with the OSTS register after X1 clock oscillation is restarted.

<3> Stopping the high-speed system clock (CSC register)

When MSTOP is set to 1, X1 oscillation is stopped (the input of the external clock is disabled).

Note This setting is required to resume the X1 clock oscillation when the high-speed system clock is in the X1 oscillation mode.

This setting is not required in the external clock input mode.

Caution Be sure to confirm that MCS = 0 or CLS = 1 when setting MSTOP to 1. In addition, stop peripheral hardware that is operating on the high-speed system clock.

5.6.2 Example of controlling internal high-speed oscillation clock

The following describes examples of clock setting procedures for the following cases.

(1) When restarting oscillation of the internal high-speed oscillation clock
(2) When using internal high-speed oscillation clock as CPU/peripheral hardware clock
(3) When stopping the internal high-speed oscillation clock

(1) Example of setting procedure when restarting oscillation of the internal high-speed oscillation clock[Note]

<1> Setting restart of oscillation of the internal high-speed oscillation clock (CSC register)

When HIOSTOP is cleared to 0, the internal high-speed oscillation clock restarts oscillation.

Note After a reset release, the internal high-speed oscillator automatically starts oscillating and the internal high-speed oscillation clock is selected as the CPU/peripheral hardware clock.

(2) Example of setting procedure when using internal high-speed oscillation clock as CPU/peripheral hardware clock

<1> Restarting oscillation of the internal high-speed oscillation clock[Note]

(See **5.6.2 (1) Example of setting procedure when restarting internal high-speed oscillation clock**).

Note The setting of <1> is not necessary when the internal high-speed oscillation clock is operating.

<2> Setting the internal high-speed oscillation clock as the source clock of the CPU/peripheral hardware clock and setting the division ratio of the set clock (CKC register)

MCM0	MDIV2	MDIV1	MDIV0	Selection of CPU/Peripheral Hardware Clock (f_{CLK})
0	0	0	0	f_{IH}
	0	0	1	$f_{IH}/2$
	0	1	0	$f_{IH}/2^2$
	0	1	1	$f_{IH}/2^3$
	1	0	0	$f_{IH}/2^4$
	1	0	1	$f_{IH}/2^5$

Caution If switching the CPU/peripheral hardware clock from the high-speed system clock to the internal high-speed oscillation clock after restarting the internal high-speed oscillation clock, do so after 10 μs or more have elapsed.

If the switching is made immediately after the internal high-speed oscillation clock is restarted, the accuracy of the internal high-speed oscillation cannot be guaranteed for 10 μs.

(3) Example of setting procedure when stopping the internal high-speed oscillation clock

The internal high-speed oscillation clock can be stopped in the following two ways.

- Executing the STOP instruction
- Setting HIOSTOP to 1

(a) To execute a STOP instruction

<1> Setting of peripheral hardware

Stop peripheral hardware that cannot be used in the STOP mode (for peripheral hardware that cannot be used in STOP mode, see **CHAPTER 18 STANDBY FUNCTION**).

<2> Setting the X1 clock oscillation stabilization time after STOP mode is released

If the X1 clock oscillates before the STOP mode is entered, set the value of the OSTS register before executing the STOP instruction.

<3> Executing the STOP instruction

When the STOP instruction is executed, the system is placed in the STOP mode and internal high-speed oscillation clock is stopped.

(b) To stop internal high-speed oscillation clock by setting HIOSTOP to 1

<1> Confirming the CPU clock status (CKC register)

Confirm with CLS and MCS that the CPU is operating on a clock other than the internal high-speed oscillation clock.

When CLS = 0 and MCS = 0, the internal high-speed oscillation clock is supplied to the CPU, so change the CPU clock to the high-speed system clock or subsystem clock.

CLS	MCS	CPU Clock Status
0	0	Internal high-speed oscillation clock or 20 MHz internal high-speed oscillation clock
0	1	High-speed system clock
1	×	Subsystem clock

<2> Stopping the internal high-speed oscillation clock (CSC register)
When HIOSTOP is set to 1, internal high-speed oscillation clock is stopped.

Caution Be sure to confirm that MCS = 1 or CLS = 1 when setting HIOSTOP to 1. In addition, stop peripheral hardware that is operating on the internal high-speed oscillation clock.

5.6.3 Example of controlling subsystem clock

The subsystem clock can be oscillated by connecting a crystal resonator to the XT1 and XT2 pins.
When the subsystem clock is not used, the XT1/P123 and XT2/P124 pins can be used as input port pins.

Caution The XT1/P123 and XT2/P124 pins are in the input port mode after a reset release.

The following describes examples of setting procedures for the following cases.
(1) When oscillating subsystem clock
(2) When using subsystem clock as CPU clock
(3) When stopping subsystem clock

Caution When the subsystem clock is used as the CPU clock, the subsystem clock is also supplied to the peripheral hardware (except the real-time counter, clock output/buzzer output, and watchdog timer). At this time, the operations of the A/D converter and IICA are not guaranteed. For the operating characteristics of the peripheral hardware, refer to the chapters describing the various peripheral hardware as well as CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET).

(1) Example of setting procedure when oscillating the subsystem clock

<1> Setting P123/XT1 and P124/XT2 pins (CMC register)

EXCLK	OSCSEL	0	OSCSELS	0	AMPHS1	AMPHS0	AMPH
0/1	0/1	0	1	0	0/1	0/1	0/1

Remark For setting of the P121/X1 and P122/X2 pins, see **5.6.1 Example of controlling high-speed system clock**.

<2> Controlling oscillation of subsystem clock (CSC register)
If XTSTOP is cleared to 0, the XT1 oscillator starts oscillating.

<3> Waiting for the stabilization of the subsystem clock oscillation
Wait for the oscillation stabilization time of the subsystem clock by software, using a timer function.

Caution The CMC register can be written only once after reset release, by an 8-bit memory manipulation instruction.
Therefore, it is necessary to also set the value of the EXCLK and OSCSEL bits at the same time. For EXCLK and OSCSEL bits, see 5.6.1 (1) Example of setting procedure when oscillating the X1 clock or 5.6.1 (2) Example of setting procedure when using the external main system clock.

(2) Example of setting procedure when using the subsystem clock as the CPU clock

<1> Setting subsystem clock oscillation[Note]

(See **5.6.3 (1) Example of setting procedure when oscillating the subsystem clock**.)

Note The setting of <1> is not necessary when while the subsystem clock is operating.

<2> Setting the subsystem clock as the source clock of the CPU clock (CKC register)

CSS	Selection of CPU/Peripheral Hardware Clock (f_{CLK})
1	$f_{SUB}/2$

Caution When the subsystem clock is used as the CPU clock, the subsystem clock is also supplied to the peripheral hardware (except the real-time counter, clock output/buzzer output, and watchdog timer). At this time, the operations of the A/D converter and IICA are not guaranteed. For the operating characteristics of the peripheral hardware, refer to the chapters describing the various peripheral hardware as well as CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET).

(3) Example of setting procedure when stopping the subsystem clock

<1> Confirming the CPU clock status (CKC register)

Confirm with CLS and MCS that the CPU is operating on a clock other than the subsystem clock.

When CLS = 1, the subsystem clock is supplied to the CPU, so change the CPU clock to the internal high-speed oscillation clock or high-speed system clock.

CLS	MCS	CPU Clock Status
0	0	Internal high-speed oscillation clock or 20 MHz internal high-speed oscillation clock
0	1	High-speed system clock
1	×	Subsystem clock

<2> Stopping the subsystem clock (CSC register)

When XTSTOP is set to 1, subsystem clock is stopped.

Cautions 1. Be sure to confirm that CLS = 0 when setting XTSTOP to 1. In addition, stop the peripheral hardware if it is operating on the subsystem clock.

2. The subsystem clock oscillation cannot be stopped using the STOP instruction.

5.6.4 Example of controlling internal low-speed oscillation clock

The internal low-speed oscillation clock cannot be used as the CPU clock. Used only as the watchdog timer clock.

The internal low-speed oscillator automatically starts oscillation after a reset release, and the watchdog timer is driven (30 kHz (TYP.)) if the watchdog timer operation is enabled by the option byte.

The internal low-speed oscillator continues oscillation except when the watchdog timer stops. When the watchdog timer operates, the internal low-speed oscillation clock does not stop even in case of a program loop.

(1) Example of setting procedure when stopping the internal low-speed oscillation clock

The internal low-speed oscillation clock can be stopped in the following two ways.

- Stop the watchdog timer in the HALT/STOP mode by the option byte (bit 0 (WDSTBYON) of 000C0H = 0), and execute the HALT or STOP instruction.
- Stop the watchdog timer by the option byte (bit 4 (WDTON) of 000C0H = 0).

(2) Example of setting procedure when restarting oscillation of the internal low-speed oscillation clock

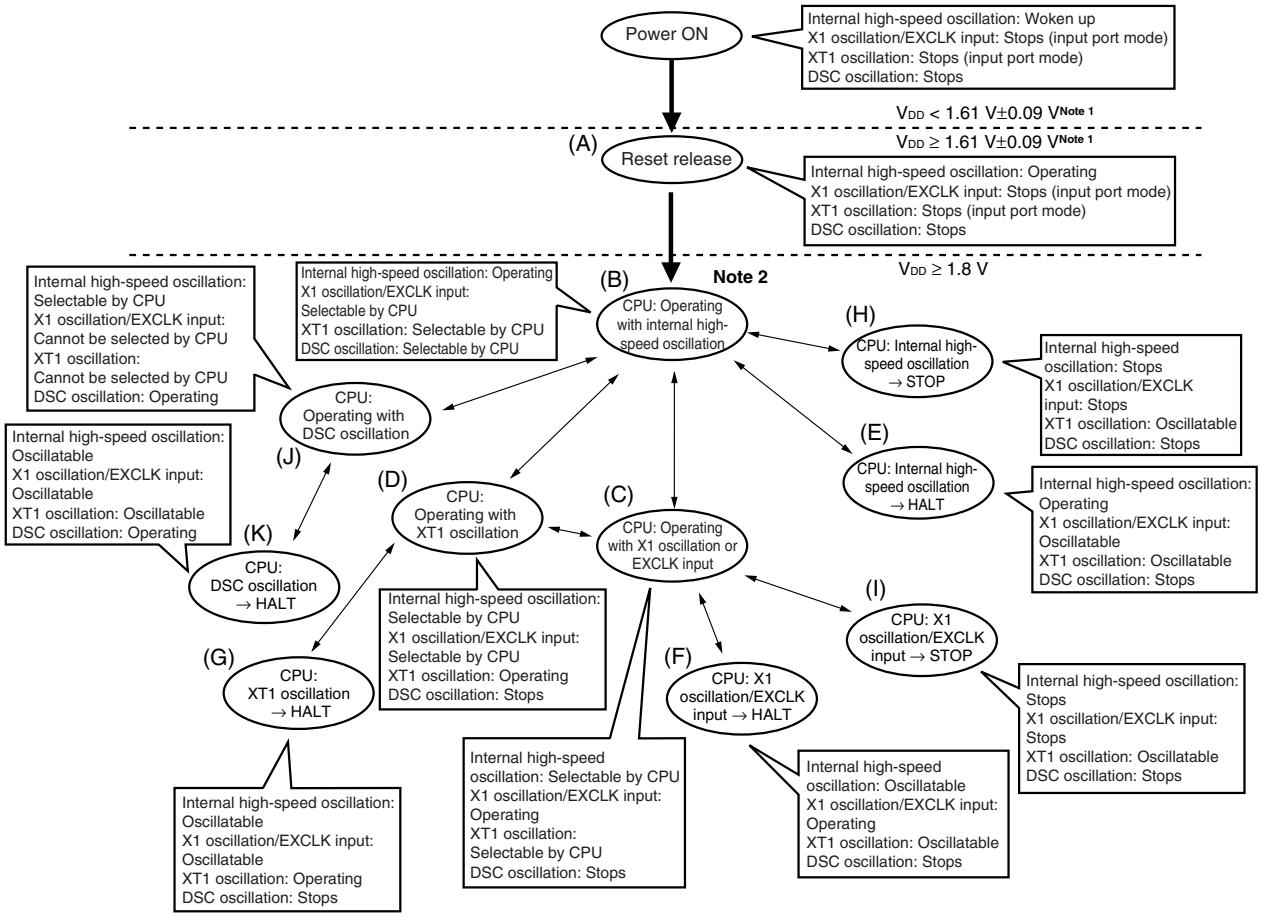
The internal low-speed oscillation clock can be restarted as follows.

- Release the HALT or STOP mode
  (only when the watchdog timer is stopped in the HALT/STOP mode by the option byte (bit 0 (WDSTBYON) of 000C0H) = 0) and when the watchdog timer is stopped as a result of execution of the HALT or STOP instruction).

5.6.5 CPU clock status transition diagram

Figure 5-17 shows the CPU clock status transition diagram of this product.

Figure 5-17. CPU Clock Status Transition Diagram



Notes 1. Preliminary value and subject to change.

2. After reset release, an operation at one of the following operating frequencies is started, because $f_{CLK} = f_{IH}/2$ has been selected by setting the system clock control register (CKC) to 09H.

- When 1 MHz has been selected by using the option byte: 500 kHz (1 MHz/2)
- When 8 MHz or 20 MHz has been selected by using the option byte: 4 MHz (8 MHz/2)

Remarks 1. If the low-power-supply detector (LVI) is set to ON by default by the option bytes, the reset will not be released until the power supply voltage (V_{DD}) exceeds 2.07 V±0.2 V Note.
After the reset operation, the status will shift to (B) in the above figure.

5.6.7 Time required for switchover of CPU clock and main system clock

By setting bits 0 to 2, 4, and 6 (MDIV0 to MDIV2, MCM0, CSS) of the system clock control register (CKC), the CPU clock can be switched (between the main system clock and the subsystem clock), main system clock can be switched (between the internal high-speed oscillation clock and the high-speed system clock), and the division ratio of the main system clock can be changed.

The actual switchover operation is not performed immediately after rewriting to CKC; operation continues on the pre-switchover clock for several clocks (see Table 5-6 to Table 5-9).

Whether the CPU is operating on the main system clock or the subsystem clock can be ascertained using bit 7 (CLS) of CKC. Whether the main system clock is operating on the high-speed system clock or internal high-speed oscillation clock can be ascertained using bit 5 (MCS) of CKC.

When the CPU clock is switched, the peripheral hardware clock is also switched.

Table 5-6. Maximum Time Required for Main System Clock Switchover

Clock A	Switching directions	Clock B	Remark
f_{MAIN}	◀⟶ (changing the division ratio)	f_{MAIN}	See Table 5-7
f_{IH}	◀⟶	f_{MX}	See Table 5-8

		0 ($f_{MAIN} = f_{IH}$)	1 ($f_{MAIN} = f_{MX}$)
0 ($f_{MAIN} = f_{IH}$)	$f_{MX} > f_{IH}$		1 + f_{MX}/f_{IH} clock
	$f_{MX} < f_{IH}$		$2f_{IH}/f_{MX}$ clock
1 ($f_{MAIN} = f_{MX}$)	$f_{MX} > f_{IH}$	$2f_{MX}/f_{IH}$ clock	
	$f_{MX} < f_{IH}$	1 + f_{MX}/f_{IH} clock	

(**Remarks 1 and 2** are listed on the next page.)

Table 5-9. Maximum Number of Clocks Required for $f_{MAIN} \leftrightarrow f_{SUB}$

Set Value Before Switchover		Set Value After Switchover	
CSS		CSS	
		0 ($f_{CLK} = f_{MAIN}$)	1 ($f_{CLK} = f_{SUB}$)
0 ($f_{CLK} = f_{MAIN}$)	$f_{MAIN} < f_{SUB}$		2 + f_{MAIN}/f_{SUB} clock
	$f_{MAIN} > f_{SUB}$		1 + 2f_{MAIN}/f_{SUB} clock
1 ($f_{CLK} = f_{SUB}$)	$f_{MAIN} < f_{SUB}$	1 + 2f_{SUB}/f_{MAIN} clock	
	$f_{MAIN} > f_{SUB}$	2 + f_{SUB}/f_{MAIN} clock	

Remarks 1. The number of clocks listed in Table 5-7 to Table 5-9 is the number of CPU clocks before switchover.

2. Calculate the number of clocks in Table 5-7 to Table 5-9 by removing the decimal portion.

Example When switching the main system clock from the internal high-speed oscillation clock to the high-speed system clock (@ oscillation with f_{IH} = 8 MHz, f_{MX} = 10 MHz)

$1 + f_{IH}/f_{MX} = 1 + 8/10 = 1 + 0.8 = 1.8 \rightarrow 2$ clocks

5.6.8 Conditions before clock oscillation is stopped

The following lists the register flag settings for stopping the clock oscillation (disabling external clock input) and conditions before the clock oscillation is stopped.

CHAPTER 6 TIMER ARRAY UNIT TAUS

Timer array unit TAUS has eight 16-bit timers per unit. Each 16-bit timer is called a channel and can be used as an independent timer. In addition, two or more “channels” can be used to create a high-accuracy timer.

Single-operation Function	Combination-operation Function
• Interval timer • Square wave output • External event counter • Divider function (channel 0 of 78K0R/KD3-L and 78K0R/KE3-L only) • Input pulse interval measurement • Measurement of high-/low-level width of input signal	• PWM output • One-shot pulse output • Multiple PWM output

Channel 7 can be used to realize LIN-bus reception processing in combination with UART0 of the serial array unit.

The presence or absence of timer I/O pins in each timer array unit channel depends on the product.

Timer array unit channels	I/O Pins of Each Product			
	KC3-L (44-pin)	KC3-L (48-pin)	KD3-L	KE3-L
Channel 0	–	–	P00/TI00, P01/TO00	
Channel 1	–	–	–	–
Channel 2	P10/TI02/TO02			
Channel 3	P11/TI03/TO03			
Channel 4	P12/TI04/TO04			
Channel 5	P13/TI05/TO05			
Channel 6	P50/TI06/TO06			P14/TI06/TO06
Channel 7	P51/TI07/TO07			P15/TI07/TO07

Remark The P52/SLTI/SLTO pin can be assigned to the timer I/Os of channels 0 and 1 by setting the input switch control register (ISC). See “• Timer I/O pin configuration” in **6.2 Configuration of Timer Array Unit TAUS**.

6.1 Functions of Timer Array Unit TAUS

Timer array unit TAUS has the following functions.

6.1.1 Functions of each channel when it operates independently

Single-operation functions are those functions that can be used for any channel regardless of the operation mode of the other channel (for details, refer to **6.6.1 Overview of single-operation function and combination-operation function**).

(1) Interval timer

Each timer of a unit can be used as a reference timer that generates an interrupt (INTTM0n) at fixed intervals.

(2) Square wave output

A toggle operation is performed each time INTTM0n is generated and a square wave with a duty factor of 50% is output from a timer output pin (TO0n, SLTO).

(3) External event counter

Each timer of a unit can be used as an event counter that generates an interrupt when the number of the valid edges of a signal input to the timer input pin (TI0n, SLTI) has reached a specific value.

(4) Divider function (channel 0 only) [Note]

A clock input from a timer input pin (TI00) is divided and output from an output pin (TO00).

(5) Input pulse interval measurement

Counting is started by the valid edge of a pulse signal input to a timer input pin (TI0n, SLTI). The count value of the timer is captured at the valid edge of the next pulse. In this way, the interval of the input pulse can be measured.

(6) Measurement of high-/low-level width of input signal

Counting is started by a single edge of the signal input to the timer input pin (TI0n, SLTI), and the count value is captured at the other edge. In this way, the high-level or low-level width of the input signal can be measured.

Note 78K0R/KD3-L and 78K0R/KE3-L only

Remark n: Channel number (n = 0 to 7)

6.1.2 Functions of each channel when it operates with another channel

Combination-operation functions are those functions that are attained by using the master channel (mostly the reference timer that controls cycles) and the slave channels (timers that operate following the master channel) in combination (for details, refer to **6.6.1 Overview of single-operation function and combination-operation function**).

(1) PWM (Pulse Width Modulation) output

Two channels are used as a set to generate a pulse with a specified period and a specified duty factor.

(2) One-shot pulse output

Two channels are used as a set to generate a one-shot pulse with a specified delay time and a specified pulse width.

(3) Multiple PWM (Pulse Width Modulation) output

By extending the PWM function and using one master channel and two or more slave channels, up to seven types of PWM signals that have a specific period and a specified duty factor can be generated.

6.1.3 LIN-bus supporting function (channel 7 only)

(1) Detection of wakeup signal

The timer starts counting at the falling edge of a signal input to the serial data input pin (RxD0) of UART0 and the count value of the timer is captured at the rising edge. In this way, a low-level width can be measured. If the low-level width is greater than a specific value, it is recognized as a wakeup signal.

(2) Detection of sync break field

The timer starts counting at the falling edge of a signal input to the serial data input pin (RxD0) of UART0 after a wakeup signal is detected, and the count value of the timer is captured at the rising edge. In this way, a low-level width is measured. If the low-level width is greater than a specific value, it is recognized as a sync break field.

(3) Measurement of pulse width of sync field

After a sync break field is detected, the low-level width and high-level width of the signal input to the serial data input pin (RxD0) of UART0 are measured. From the bit interval of the sync field measured in this way, a baud rate is calculated.

6.2 Configuration of Timer Array Unit TAUS

Timer array unit TAUS includes the following hardware.

Table 6-1. Configuration of Timer Array Unit TAUS

Item	Configuration
Timer/counter	Timer counter register 0n (TCR0n)
Register	Timer data register 0n (TDR0n)
Timer input	TI00 to TI07, SLTI pins, RxD0 pin (for LIN-bus)
Timer output	TO00 to TO07, SLTO pins, output controller
Control registers	<Registers of unit setting block> • Peripheral enable register 2 (PER2) • Timer clock select register 0 (TPS0) • Timer channel enable status register 0 (TE0) • Timer channel start register 0 (TS0) • Timer channel stop register 0 (TT0) • Timer input select register 0 (TIS0) • Timer output enable register 0 (TOE0) • Timer output register 0 (TO0) • Timer output level register 0 (TOL0) • Timer output mode register 0 (TOM0)
	<Registers of each channel> • Timer mode register 0n (TMR0n) • Timer status register 0n (TSR0n) • Input switch control register (ISC) • Noise filter enable registers 1, 2 (NFEN1, NFEN2) • Port mode registers 0, 1, 5 (PM0, PM1, PM5) • Port registers 0, 1, 5 (P0, P1, P5)

Remark n: Channel number (n = 0 to 7)

• Timer I/O pin configuration

The P52/SLTI/SLTO pin can be assigned to the timer I/Os of channels 0 and 1 by setting the input switch control register (ISC). (For details of the input switch control register (ISC), see **6.3 (13) Input switch control register (ISC)**.)

The following I/O pins can be selected for channels 0 and 1.

Table 6-2. I/O Pins That Can Be Selected for Channels 0 and 1

Channel for Which I/O Pin Can Be Selected	Input Pin	Output Pin
Channel 0	• P00/TI00 pin Note • P52/SLTI/SLTO pin	• P01/TO00 pin Note • P52/SLTI/SLTO pin
Channel 1	P52/SLTI/SLTO pin	P52/SLTI/SLTO pin

Note 78K0R/KD3-L and 78K0R/KE3-L only. Only the P52/SLTI/SLTO pin can be assigned to channels 0 and 1 in the 78K0R/KC3-L.

Caution Hereinafter, timer I/O pins are described as TIn and TOn (n = xx), which also includes the selection of the SLTI and SLTO pins.

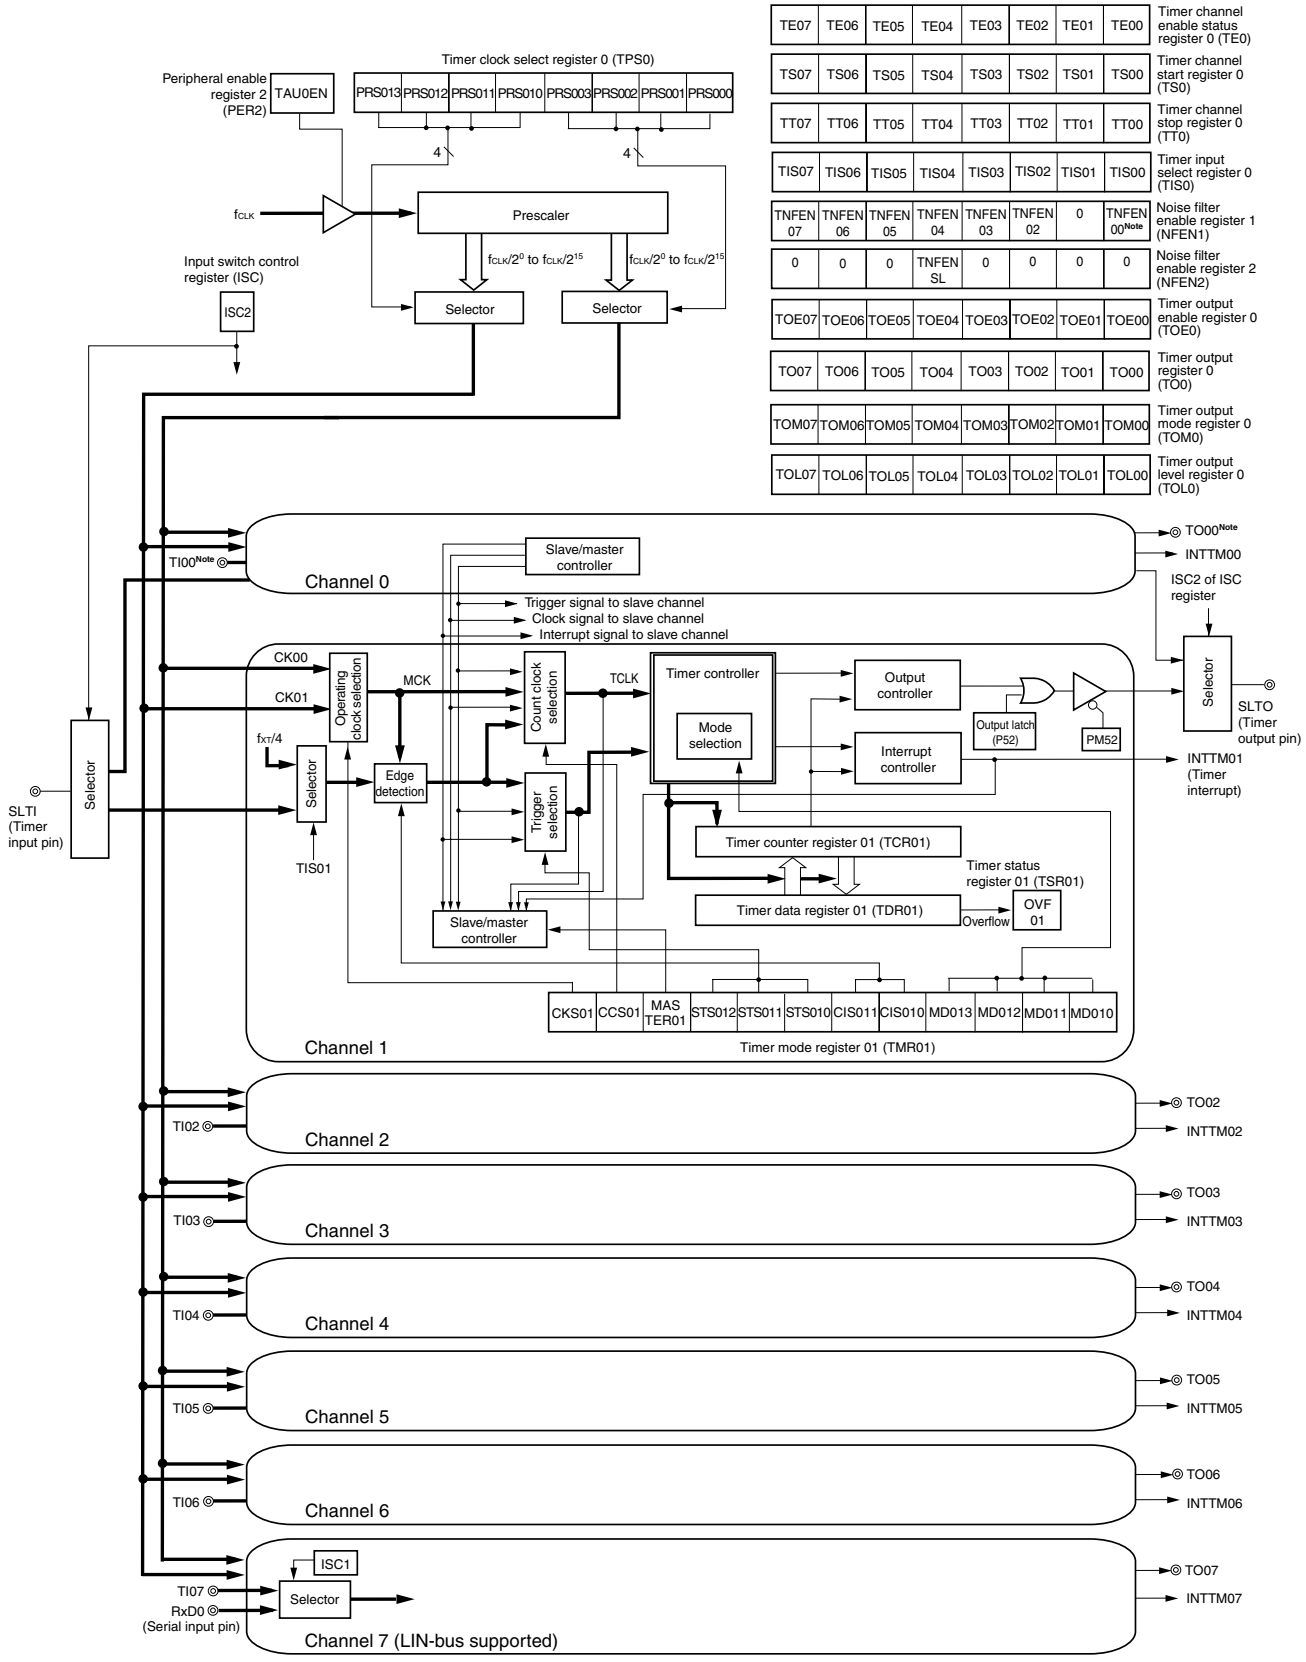
Remarks 1. When timer input and timer output are shared by the same pin, either only timer input or only timer output can be used.

2. Only one of the above-mentioned channels can be assigned as the timer I/O pin for the P52/SLTI/SLTO pin.

3. The SLTI and SLTO pins cannot be selected as timer I/Os for channels other than those mentioned above (channels 2 to 7).

Figure 6-1 shows the block diagram.

Figure 6-1. Block Diagram of Timer Array Unit



Note 78K0R/KD3-L and 78K0R/KE3-L only

(1) Timer/counter register 0n (TCR0n)

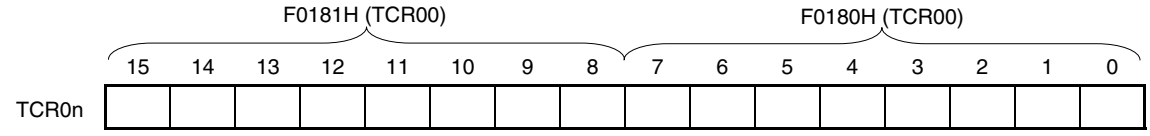
TCR0n is a 16-bit read-only register and is used to count clocks.

The value of this counter is incremented or decremented in synchronization with the rising edge of a count clock.

Whether the counter is incremented or decremented depends on the operation mode that is selected by the MD0n3 to MD0n0 bits of TMR0n.

Figure 6-2. Format of Timer/Counter Register 0n (TCR0n)

Address: F0180H, F0181H (TCR00) to F018EH, F018FH (TCR07) After reset: FFFFH R



(n = 0 to 7)

The count value can be read by reading TCR0n.

The count value is set to FFFFH in the following cases.

- When the reset signal is generated
- When the TAU0EN bit of peripheral enable register 2 (PER2) is cleared
- When counting of the slave channel has been completed in the PWM output mode
- When counting of the master/slave channel has been completed in the one-shot pulse output mode
- When counting of the slave channel has been completed in the multiple PWM output mode

The count value is cleared to 0000H in the following cases.

- When the start trigger is input in the capture mode
- When capturing has been completed in the capture mode

Caution The count value is not captured to TDR0n even when TCR0n is read.

The TCR0n register read value differs as follows according to operation mode changes and the operating status.

Table 6-3. TCR0n Register Read Value in Various Operation Modes

Operation Mode	Count Mode	TCR0n Register Read Value[Note]			
		Operation mode change after reset	Operation mode change after count operation paused (TT0n = 1)	Operation restart after count operation paused (TT0n = 1)	During start trigger wait status after one count
Interval timer mode	Count down	FFFFH	Undefined	Stop value	–
Capture mode	Count up	0000H	Undefined	Stop value	–
Event counter mode	Count down	FFFFH	Undefined	Stop value	–
One-count mode	Count down	FFFFH	Undefined	Stop value	FFFFH
Capture & one-count mode	Count up	0000H	Undefined	Stop value	Capture value of TDR0n register + 1

Note The read values of the TCR0n register when TS0n has been set to "1" while TE0n = 0 are shown. The read value is held in the TCR0n register until the count operation starts.

Remark n = 0 to 7

(2) Timer data register 0n (TDR0n)

This is a 16-bit register from which a capture function and a compare function can be selected.

The capture or compare function can be switched by selecting an operation mode by using the MD0n3 to MD0n0 bits of TMR0n.

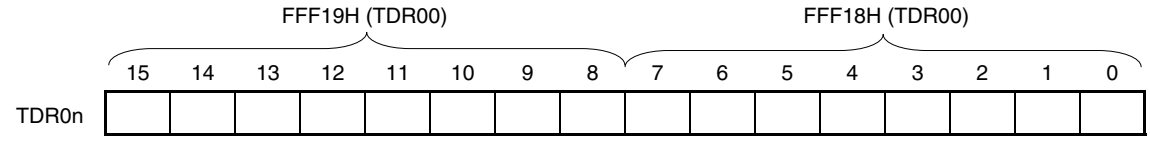
The value of TDR0n can be changed at any time.

This register can be read or written in 16-bit units.

Reset signal generation clears this register to 0000H.

Figure 6-3. Format of Timer Data Register 0n (TDR0n)

Address: FFF18H, FFF19H (TDR00), FFF1AH, FFF1BH (TDR01), FFF64H, FFF65H (TDR02) to FFF6EH, FFF6FH (TDR07) After reset: 0000H R/W



(n = 0 to 7)

(i) When TDR0n is used as compare register

Counting down is started from the value set to TDR0n. When the count value reaches 0000H, an interrupt signal (INTTM0n) is generated. TDR0n holds its value until it is rewritten.

Caution TDR0n does not perform a capture operation even if a capture trigger is input, when it is set to the compare function.

(ii) When TDR0n is used as capture register

The count value of TCR0n is captured to TDR0n when the capture trigger is input.

A valid edge of the TI0n pin can be selected as the capture trigger. This selection is made by TMR0n.

Remark n = 0 to 7

6.3 Registers Controlling Timer Array Unit

Timer array unit is controlled by the following registers.

- Peripheral enable register 2 (PER2)
- Timer clock select register 0 (TPS0)
- Timer mode register 0n (TMR0n)
- Timer status register 0n (TSR0n)
- Timer channel enable status register 0 (TE0)
- Timer channel start register 0 (TS0)
- Timer channel stop register 0 (TT0)
- Timer input select register 0 (TIS0)
- Timer output enable register 0 (TOE0)
- Timer output register 0 (TO0)
- Timer output level register 0 (TOL0)
- Timer output mode register 0 (TOM0)
- Input switch control register (ISC)
- Noise filter enable registers 1, 2 (NFEN1, NFEN2)
- Port mode registers 0, 1, 5 (PM0, PM1, PM5)
- Port registers 0, 1, 5 (P0, P1, P5)

Remark n = 0 to 7

(1) Peripheral enable register 2 (PER2)

PER2 is used to enable or disable use of each peripheral hardware macro. Clock supply to a hardware macro that is not used is stopped in order to reduce the power consumption and noise.

When timer array unit TAUS is used, be sure to set bit 0 (TAU0EN) of this register to 1.

PER2 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Cautions 1. When setting timer array unit TAUS, be sure to set TAU0EN to 1 first. If TAU0EN = 0, writing to a control register of timer array unit TAUS is ignored, and all read values are default values.

2. Be sure to clear bit 1 to 7 of the PER2 register to 0.

1	Supplies input clock. • SFR used by timer array unit TAUS can be read/written.

(2) Timer clock select register 0 (TPS0)

TPS0 is a 16-bit register that is used to select two types of operation clocks (CK00, CK01) that are commonly supplied to each channel. CK01 is selected by bits 7 to 4 of TPS0, and CK00 is selected by bits 3 to 0.

Rewriting of TPS0 during timer operation is possible only in the following cases.

Rewriting of PRS000 to PRS003 bits: Possible only when all the channels set to CKS0n = 0 are in the operation stopped state (TE0n = 0)

Rewriting of PRS010 to PRS013 bits: Possible only when all the channels set to CKS0n = 1 are in the operation stopped state (TE0n = 0)

TPS0 can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

Note When changing the clock selected for f_{CLK} (by changing the system clock control register (CKC) value), stop timer array unit TAUS (TT0 = 00FFH).

Caution Be sure to clear bits 15 to 8 to "0".

Remarks 1. f_{CLK}: CPU/peripheral hardware clock frequency

2. m = 0, 1 n = 0 to 7

(3) Timer mode register 0n (TMR0n)

TMR0n sets an operation mode of channel n. It is used to select an operation clock (MCK), a count clock, whether the timer operates as the master or a slave, a start trigger and a capture trigger, the valid edge of the timer input, and an operation mode (interval, capture, event counter, one-count, or capture & one-count).

Rewriting TMR0n is prohibited when the register is in operation (when TE0 = 1). However, bits 7 and 6 (CIS0n1, CIS0n0) can be rewritten even while the register is operating with some functions (when TE0 = 1) (for details, see **6.7 Operation of Timer Array Unit TAUS as Independent Channel** and **6.8 Operation of Plural Channels of Timer Array Unit TAUS**).

TMR0n can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

Notes 1. In one-count mode, interrupt output (INTTM0n) when starting a count operation and TOn output are not controlled.

2. If the start trigger (TS0n = 1) is issued during operation, the counter is cleared, an interrupt is generated, and recounting is started.

Remark n = 0 to 7

(4) Timer status register 0n (TSR0n)

TSR0n indicates the overflow status of the counter of channel n.

TSR0n is valid only in the capture mode (MD0n3 to MD0n1 = 010B) and capture & one-count mode (MD0n3 to MD0n1 = 110B). It will not be set in any other mode. See Table 6-4 for the operation of the OVF bit in each operation mode and set/clear conditions.

TSR0n can be read by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

(5) Timer channel enable status register 0 (TE0)

TE0 is used to enable or stop the timer operation of each channel.

When a bit of timer channel start register 0 (TS0) is set to 1, the corresponding bit of this register is set to 1.

When a bit of timer channel stop register 0 (TT0) is set to 1, the corresponding bit of this register is cleared to 0.

TE0 can be read by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

(6) Timer channel start register 0 (TS0)

TS0 is a trigger register that is used to clear a timer counter (TCR0n) and start the counting operation of each channel.

When a bit (TS0n) of this register is set to 1, the corresponding bit (TE0n) of timer channel enable status register 0 (TE0) is set to 1. TS0n is a trigger bit and cleared immediately when TE0n = 1.

TS0 can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

1	TE0n is set to 1 and the count operation becomes enabled. The TCR0n count operation start in the count operation enabled state varies depending on each operation mode (see Table 6-5).

Caution Be sure to clear bits 15 to 8 to "0".

Remarks 1. When the TS0 register is read, 0 is always read.

2. n = 0 to 7

Table 6-5. Operations from Count Operation Enabled State to TCR0n Count Start (1/2)

Timer operation mode	Operation when TS0n = 1 is set
• Interval timer mode	No operation is carried out from start trigger detection (TS0n=1) until count clock generation. The first count clock loads the value of TDR0n to TCR0n and the subsequent count clock performs count down operation (see **6.3 (6) (a) Start timing in interval timer mode**).
• Event counter mode	Writing 1 to TS0n bit loads the value of TDR0n to TCR0n. The subsequent count clock performs count down operation. The external trigger detection selected by STS0n2 to STS0n0 bits in the TMR0n register does not start count operation (see **6.3 (6) (b) Start timing in event counter mode**).
• Capture mode	No operation is carried out from start trigger detection until count clock generation. The first count clock loads 0000H to TCR0n and the subsequent count clock performs count up operation (see **6.3 (6) (c) Start timing in capture mode**).

Table 6-5. Operations from Count Operation Enabled State to TCR0n Count Start (2/2)

Timer operation mode	Operation when TS0n = 1 is set
• One-count mode	When TS0n = 0, writing 1 to TS0n bit sets the start trigger wait state. No operation is carried out from start trigger detection until count clock generation. The first count clock loads the value of TDR0n to TCR0n and the subsequent count clock performs count down operation (see **6.3 (6) (d) Start timing in one-count mode**).
• Capture & one-count mode	When TS0n = 0, writing 1 to TS0n bit sets the start trigger wait state. No operation is carried out from start trigger detection until count clock generation. The first count clock loads 0000H to TCR0n and the subsequent count clock performs count up operation (see **6.3 (6) (e) Start timing in capture & one-count mode**).

(a) Start timing in interval timer mode

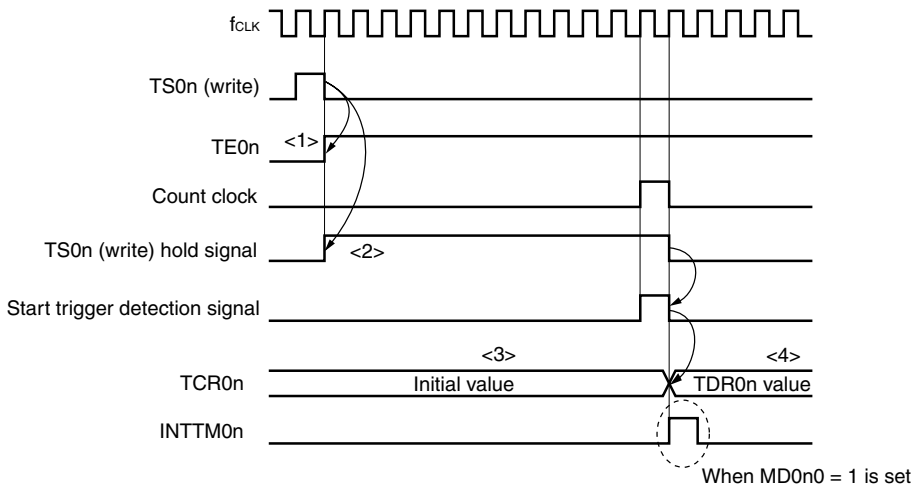
<1> Writing 1 to TS0n sets TE0n = 1

<2> The write data to TS0n is held until count clock generation.

<3> TCR0n holds the initial value until count clock generation.

<4> On generation of count clock, the “TDR0n value” is loaded to TCR0n and count starts.

Figure 6-10. Start Timing (In Interval Timer Mode)

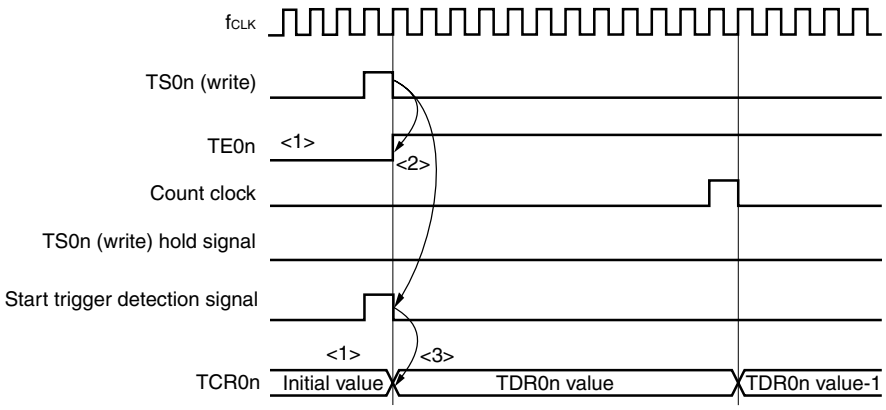


Caution In the first cycle operation of count clock after writing TS0n, an error at a maximum of one clock is generated since count start delays until count clock has been generated. When the information on count start timing is necessary, an interrupt can be generated at count start by setting MD0n0 = 1.

(b) Start timing in event counter mode

<1> While TE0n is set to 0, TCR0n holds the initial value.
<2> Writing 1 to TS0n sets 1 to TE0n.
<3> As soon as 1 has been written to TS0n and 1 has been set to TE0n, the "TDR0n value" is loaded to TCR0n to start counting.
<4> After that, the TCR0n value is counted down according to the count clock.

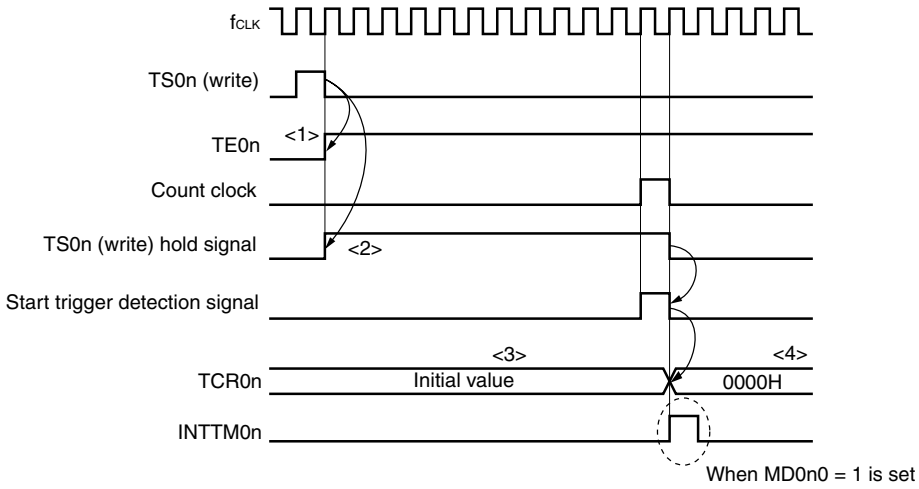
Figure 6-11. Start Timing (In Event Counter Mode)



(c) Start timing in capture mode

<1> Writing 1 to TS0n sets TE0n = 1
<2> The write data to TS0n is held until count clock generation.
<3> TCR0n holds the initial value until count clock generation.
<4> On generation of count clock, 0000H is loaded to TCR0n and count starts.

Figure 6-12. Start Timing (In Capture Mode)



Caution In the first cycle operation of count clock after writing TS0n, an error at a maximum of one clock is generated since count start delays until count clock has been generated. When the information on count start timing is necessary, an interrupt can be generated at count start by setting MD0n0 = 1.

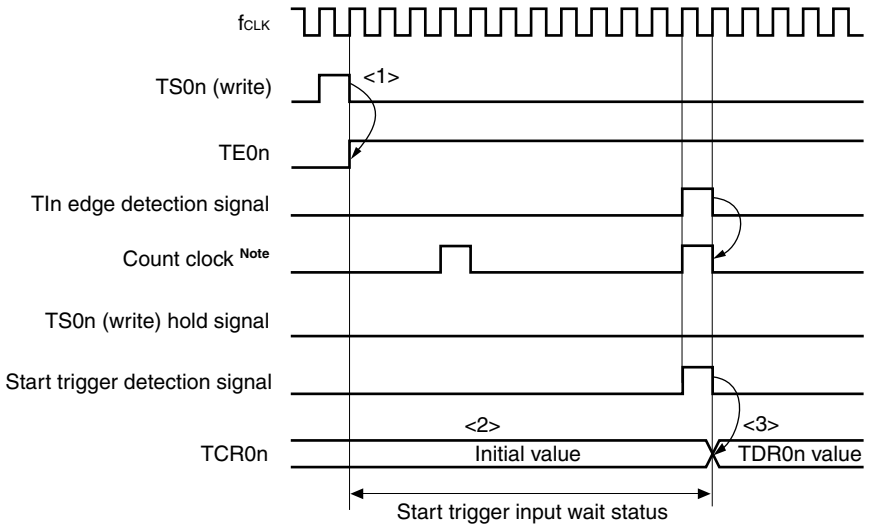
(d) Start timing in one-count mode

<1> Writing 1 to TS0n sets TE0n = 1

<2> Enters the start trigger input wait status, and TCR0n holds the initial value.

<3> On start trigger detection, the “TDR0n value” is loaded to TCR0n and count starts.

Figure 6-13. Start Timing (In One-count Mode)



Note When the one-count mode is set, the operation clock (MCK) is selected as count clock (CCS0n = 0).

Caution An input signal sampling error is generated since operation starts upon start trigger detection (The error is one count clock when TI0n is used).

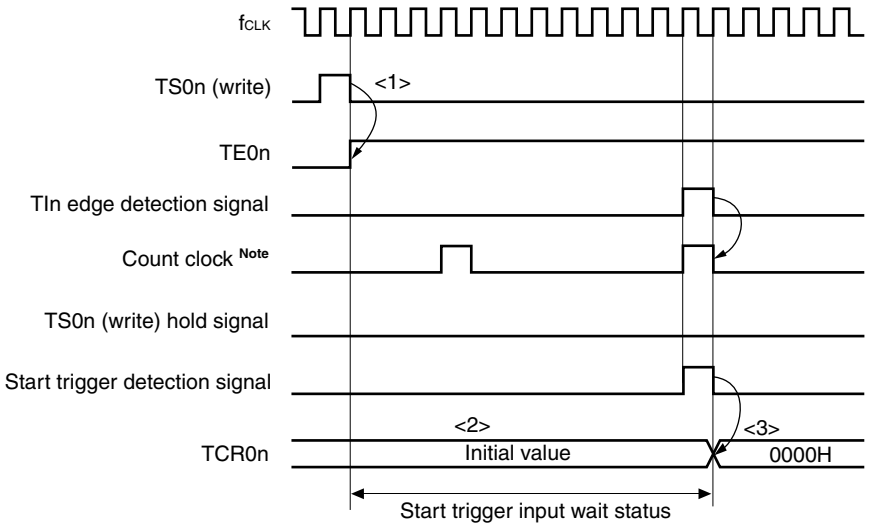
(e) Start timing in capture & one-count mode

<1> Writing 1 to TS0n sets TE0n = 1

<2> Enters the start trigger input wait status, and TCR0n holds the initial value.

<3> On start trigger detection, 0000H is loaded to TCR0n and count starts.

Figure 6-14. Start Timing (In Capture & One-count Mode)



Note When the capture & one-count mode is set, the operation clock (MCK) is selected as count clock (CCS0n = 0).

Caution An input signal sampling error is generated since operation starts upon start trigger detection (The error is one count clock when TI0n is used).

(7) Timer channel stop register 0 (TT0)

TT0 is a trigger register that is used to clear a timer counter (TCR0n) and start the counting operation of each channel.

When a bit (TT0n) of this register is set to 1, the corresponding bit (TE0n) of timer channel enable status register 0 (TE0) is cleared to 0. TT0n is a trigger bit and cleared to 0 immediately when TE0n = 0.

TT0 can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

Remarks 1. When the TT0 register is read, 0 is always read.

2. n = 0 to 7

(8) Timer input select register 0 (TIS0)

TIS0 is used to select whether a signal input to the timer input pin (TI0n) or the subsystem clock divided by four ($f_{XT}/4$) is valid for each channel.

TIS0 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

1	Subsystem clock divided by 4 ($f_{XT}/4$)

(9) Timer output enable register 0 (TOE0)

TOE0 is used to enable or disable timer output of each channel.

Channel n for which timer output has been enabled becomes unable to rewrite the value of the TO0n bit of the timer output register (TO0) described later by software, and the value reflecting the setting of the timer output function through the count operation is output from the timer output pin (TO0n).

TOE0 can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

TOE0n	Timer output enable/disable of channel n
0	The TO0n operation stopped by count operation (timer channel output bit). Writing to the TO0n bit is enabled. The TO0n pin functions as data output, and it outputs the level set to the TO0n bit. The output level of the TO0n pin can be manipulated by software.
1	The TO0n operation enabled by count operation (timer channel output bit). Writing to the TO0n bit is disabled (writing is ignored). The TO0n pin functions as timer output, and the TOE0n is set or reset depending on the timer operation. The TO0n pin outputs the square-wave or PWM depending on the timer operation.

Caution Be sure to clear bits 15 to 8 to “0”.

Remark n = 0 to 7

(10) Timer output register 0 (TO0)

TO0 is a buffer register of timer output of each channel.

The value of each bit in this register is output from the timer output pin (TO0n) of each channel.

This register can be rewritten by software only when timer output is disabled (TOE0n = 0). When timer output is enabled (TOE0n = 1), rewriting this register by software is ignored, and the value is changed only by the timer operation.

To use the P01/TO00, P10/TO02, P11/TO03, P12/TO04, P13/TO05, P14/TO06 Note, P15/TO07 Note, or P52/SLTO pin as a port function pin, set the corresponding TO0n bit to "0".

TO0 can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

Note TO06 and TO07 are shared with P50 and P51 (P50/TO06, P51/TO07), respectively, in products other than the 78K0R/KE3-L.

Remark n = 0 to 7

(11) Timer output level register 0 (TOL0)

TOL0 is a register that controls the timer output level of each channel.

The setting of the inverted output of channel n by this register is reflected at the timing of set or reset of the timer output signal while the timer output is enabled (TOE0n = 1) in the combination-operation mode (TOM0n = 1). In the toggle mode (TOM0n = 0), this register setting is invalid.

TOL0 can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

0	Positive logic output (active-high)
1	Inverted output (active-low)

Caution Be sure to clear bits 15 to 8 to "0".

Remarks 1. If the value of this register is rewritten during timer operation, the timer output is inverted when the timer output signal changes next, instead of immediately after the register value is rewritten.

2. n = 0 to 7

(12) Timer output mode register 0 (TOM0)

TOM0 is used to control the timer output mode of each channel.

When a channel is used for the single-operation function, set the corresponding bit of the channel to be used to 0.

When a channel is used for the combination-operation function (PWM output, one-shot pulse output, or multiple PWM output), set the corresponding bit of the master channel to 0 and the corresponding bit of the slave channel to 1.

The setting of each channel n by this register is reflected at the timing when the timer output signal is set or reset while the timer output is enabled (TOE0n = 1).

TOM0 can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

Caution Be sure to clear bits 15 to 8 to "0".

Remark n: Channel number, m: Slave channel number
n = 0 to 7 (n = 0, 2, 4, 6 for master channel)
n < m ≤ 7 (where m is a consecutive integer greater than n)

(13) Input switch control register (ISC)

The ISC1 and ISC0 bits of the ISC register are used to implement LIN-bus communication operation by using channel 7 in association with the serial array unit. When the ISC1 bit is set to 1, the input signal of the serial data input pin (RxD0) is selected as a timer input signal.

The ISC2 bit is set when selecting the P52/SLTI/SLTO pin as the timer I/O pin of timer channels 0 and 1.

ISC can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

1	Uses the input signal of the RxD0 pin as an external interrupt (to measure the pulse widths of the sync break field and sync field).

Note 78K0R/KD3-L and 78KR/KE3-L only. Only the P52/SLTI/SLTO pin can be assigned to channels 0 and 1 in the 78K0R/KC3-L.

Caution Be sure to clear bits 7 to 3 to "0".

Remark When the LIN-bus communication function is used, select the input signal of the RxD0 pin by setting ISC1 to 1.

(14) Noise filter enable registers 1, 2 (NFEN1, NFEN2)

NFEN1 and NFEN2 are used to set whether the noise filter can be used for the timer input signal to each channel.

Enable the noise filter by setting the corresponding bits to 1 on the pins in need of noise removal.

When the noise filter is ON, match detection and synchronization of the 2 clocks is performed with the CPU/peripheral hardware clock (f_{CLK}). When the noise filter is OFF, only synchronization is performed with the CPU/peripheral hardware clock (f_{CLK}).

NFEN1 and NFEN2 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

2. TI06/TO06 and TI07/TO07 are shared with P50 and P51, respectively, in products other than the 78K0R/KE3-L.

3. The applicable pin can be switched by setting ISC1 of the ISC register.

ISC1 = 0: Whether or not to use the noise filter of TI07 pin can be selected.

ISC1 = 1: Whether or not to use the noise filter of RxD0 pin can be selected.

(15) Port mode registers 0 [Note], 1, 5 (PM0 [Note], PM1, PM5)

These registers set input/output of ports 0[Note], 1, and 5 in 1-bit units.

When using the ports (such as P01/TO00 and P10/TO02/TI02) to be shared with the timer output pin for timer output, set the port mode register (PMxx) bit and port register (Pxx) bit corresponding to each port to 0.

Example: When using P10/TO02/TI02 for timer output
Set the PM10 bit of port mode register 1 to 0.
Set the P10 bit of port register 1 to 0.

When using the ports (such as P00/TI00 and P10/TO02/TI02) to be shared with the timer output pin for timer input, set the port mode register (PMxx) bit corresponding to each port to 1. At this time, the port register (Pxx) bit may be 0 or 1.

Example: When using P10/TO02/TI02 for timer input
Set the PM10 bit of port mode register 1 to 1.
Set the P10 bit of port register 1 to 0 or 1.

PM0 [Note], PM1, and PM5 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation sets these registers to FFH.

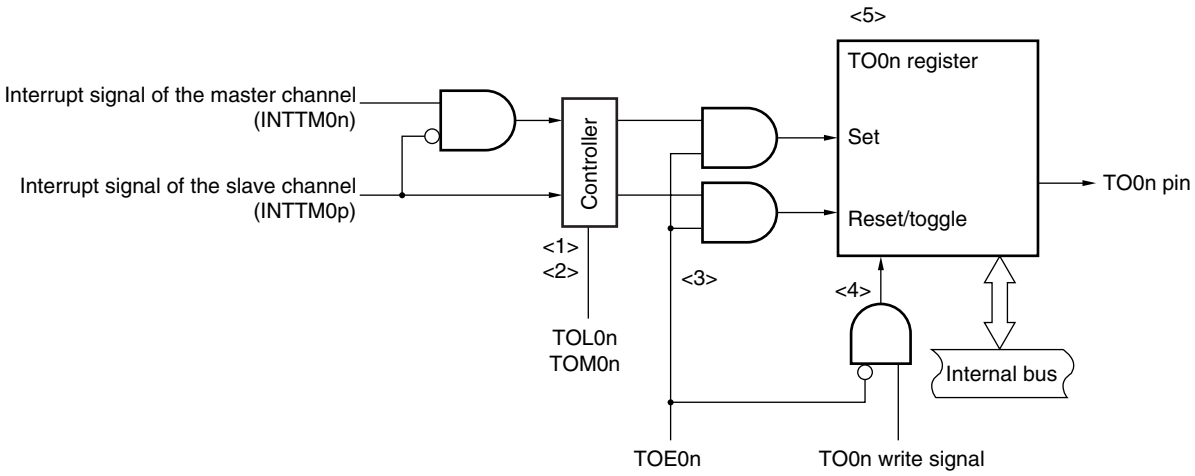
6.4 Channel Output (TO0n pin) Control

6.4.1 TO0n pin output circuit configuration

Figure 6-24. Output Circuit Configuration



The following describes the TO0n pin output circuit.

<1> When TOM0n = 0 (toggle mode), the set value of the TOL0n register is ignored and only INTTM0p (slave channel timer interrupt) is transmitted to the TO0n register.

<2> When TOM0n = 1 (combination-operation mode), both INTTM0n (master channel timer interrupt) and INTTM0p (slave channel timer interrupt) are transmitted to the TO0n register.
At this time, the TOL0n register becomes valid and the signals are controlled as follows:

When TOL0n = 0: Forward operation (INTTM0 → set, INTTM0p → reset)
When TOL0n = 1: Reverse operation (INTTM0 → reset, INTTM0p → set)

When INTTM0n and INTTM0p are simultaneously generated, (0% output of PWM), INTTM0p (reset signal) takes priority, and INTTM0n (set signal) is masked.

<3> When TOE0n = 1, INTTM0n (master channel timer interrupt) and INTTM0p (slave channel timer interrupt) are transmitted to the TO0n register. Writing to the TO0n register (TO0n write signal) becomes invalid.
When TOE0n = 1, the TO0n pin output never changes with signals other than interrupt signals.
To initialize the TO0n pin output level, it is necessary to set TOE0n = 0 and to write a value to TO0n.

<4> When TOE0n = 0, writing to TO0n bit to the target channel (TO0n write signal) becomes valid. When TOE0n = 0, neither INTTM0n (master channel timer interrupt) nor INTTM0p (slave channel timer interrupt) is transmitted to TO0n register.

<5> The TO0n register can always be read, and the TO0n pin output level can be checked.

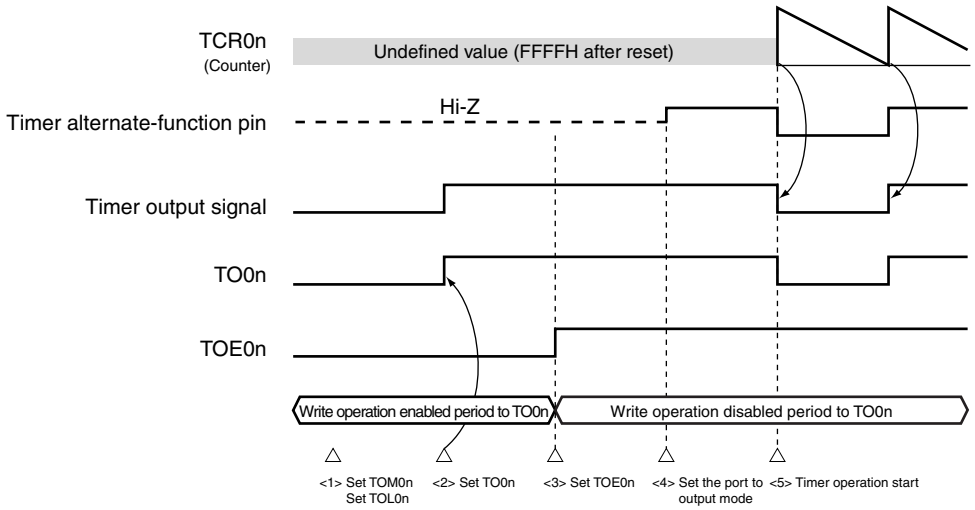
Remarks 1. n = 0 to 7 (n = 0, 2, 4, or 6 for master channel)

2. p = n + 1, n + 2, n + 3 ... (where p ≤ 7)

6.4.2 TO0n Pin Output Setting

The following figure shows the procedure and status transition of TO0n out put pin from initial setting to timer operation start.

Figure 6-25. Status Transition from Timer Output Setting to Operation Start



<1> The operation mode of timer output is set.

- TOM0n bit (0: Toggle mode, 1: Combination-operation mode)
- TOL0n bit (0: Forward output, 1: Reverse output)

<2> The timer output signal is set to the initial status by setting TO0n.
<3> The timer output operation is enabled by writing 1 to TOE0n (writing to TO0n is disabled).
<4> The port I/O setting is set to output (see **6.3 (15) Port mode registers 0, 1, 5**).
<5> The timer operation is enabled (TS0n = 1).

Remark n = 0 to 7

6.4.3 Cautions on Channel Output Operation

(1) Changing values set in registers TO0, TOE0, and TOL0 during timer operation

Since the timer operations (operations of TCR0n and TDR0n) are independent of the TO0n output circuit and changing the values set in TO0, TOE0, and TOL0 does not affect the timer operation, the values can be changed during timer operation.
When the values set in TOE0, TOL0, and TOM0 (except for TO0) are changed close to the timer interrupt (INTTM0n), the waveform output to the TO0n pin may be different depending on whether the values are changed immediately before or immediately after the timer interrupt (INTTM0n) signal generation timing.

Remark n = 0 to 7

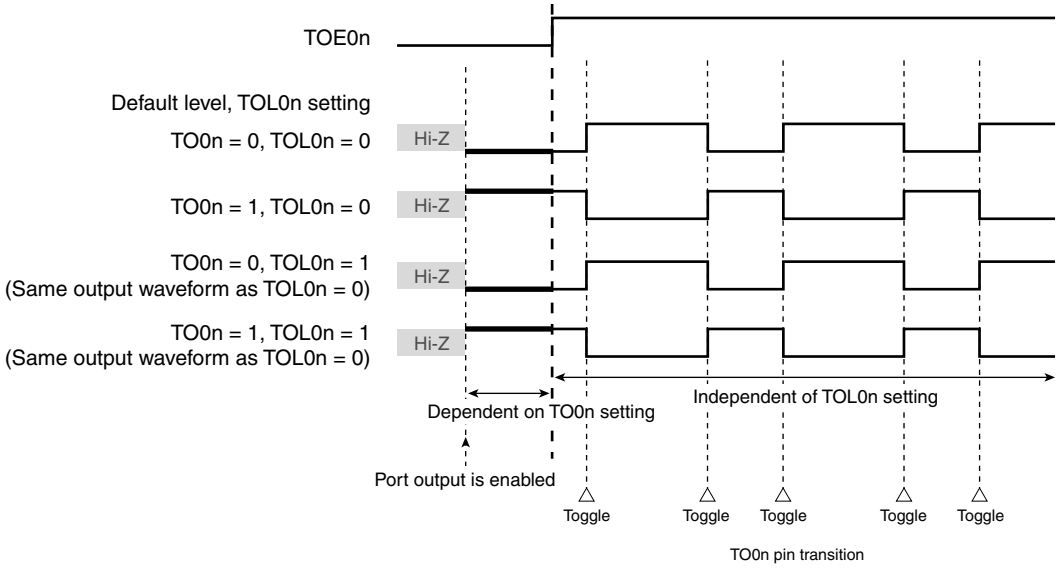
(2) Default level of TO0n pin and output level after timer operation start

The following figure shows the TO0n pin output level transition when writing has been done in the state of TOE0n = 0 before port output is enabled and TOE0n = 1 is set after changing the default level.

(a) When operation starts with TOM0n = 0 setting (toggle output)

The setting of TOL0n is invalid when TOM0n = 0. When the timer operation starts after setting the default level, the toggle signal is generated and the output level of TO0n pin is reversed.

Figure 6-26. TO0n Pin Output Status at Toggle Output (TOM0n = 0)



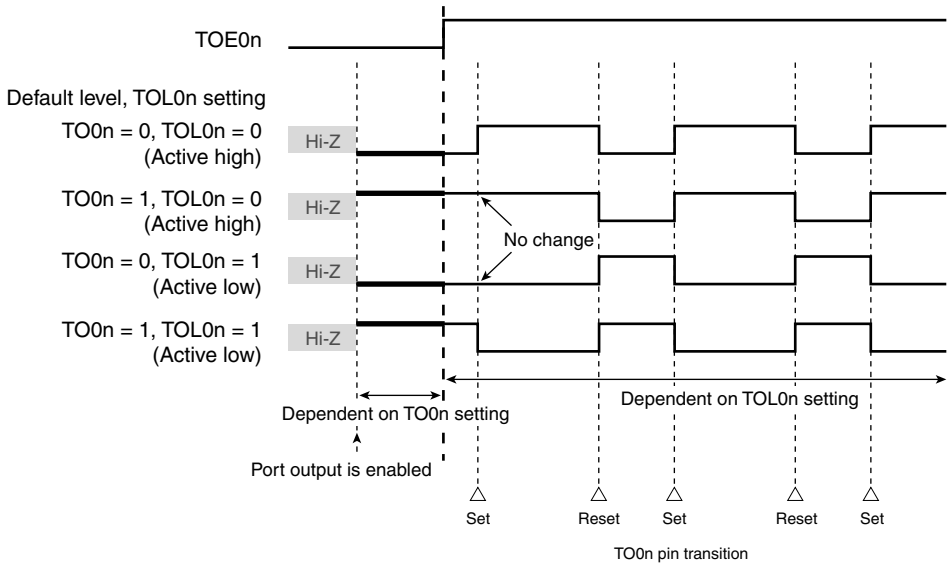
Remarks 1. Toggle: Reverse TO0n pin output status

2. n = 0 to 7

(b) When operation starts with TOM0n = 1 setting (Combination-operation mode (PWM output))

When TOM0n = 1, the active level is determined by TOL0n setting.

Figure 6-27. TO0n Pin Output Status at PWM Output (TOM0n = 1)



Remarks 1. Set: The output signal of TO0n pin changes from inactive level to active level.
Reset: The output signal of TO0n pin changes from active level to inactive level.

2. n = 0 to 7

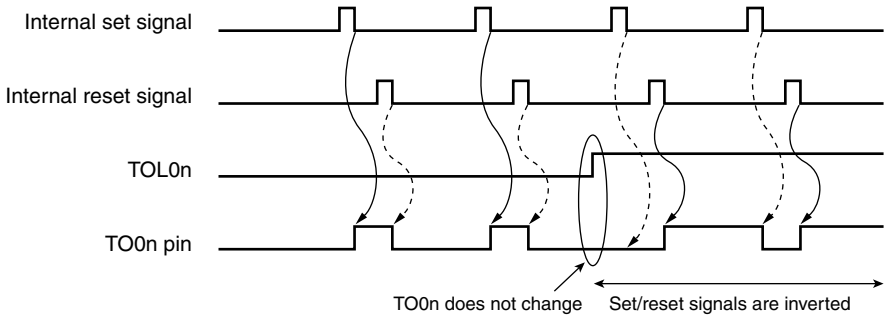
(3) Operation of TO0n pin in combination-operation mode (TOM0n = 1)

(a) When TOL0n setting has been changed during timer operation

When the TOL0n setting has been changed during timer operation, the setting becomes valid at the generation timing of TO0n change condition. Rewriting TOL0n does not change the output level of TO0n.

The following figure shows the operation when the value of TOL0n has been changed during timer operation (TOM0n = 1).

Figure 6-28. Operation when TOL0n Has Been Changed during Timer Operation



Remarks 1. Set: The output signal of TO0n pin changes from inactive level to active level.
Reset: The output signal of TO0n pin changes from active level to inactive level.

2. n = 0 to 7

(b) Set/reset timing

To realize 0%/100% output at PWM output, the TO0n pin/TO0n set timing at master channel timer interrupt (INTTM0n) generation is delayed by 1 count clock by the slave channel.

If the set condition and reset condition are generated at the same time, a higher priority is given to the latter.

Figure 6-29 shows the set/reset operating statuses where the master/slave channels are set as follows.

Master channel: TOE0n = 1, TOM0n = 0, TOL0n = 0
Slave channel: TOE0p = 1, TOM0p = 1, TOL0p = 0

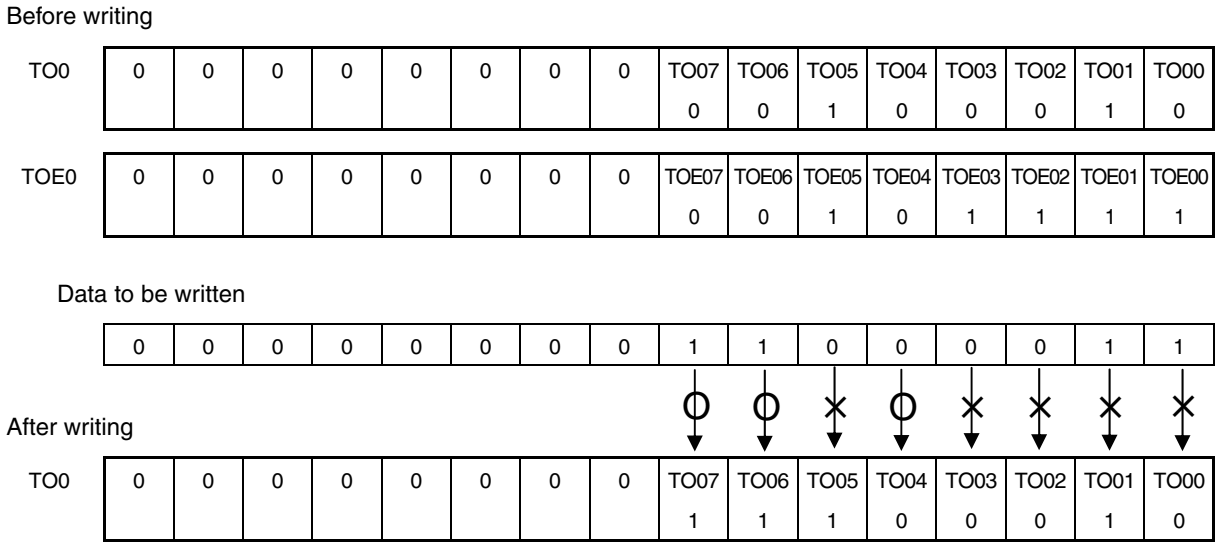
3. p = n+1, n+2, n+3 ... (where p ≤ 7)

6.4.4 Collective manipulation of TO0n bit

In the TO0 register, the setting bits for all the channels are located in one register in the same way as the TS0 register (channel start trigger). Therefore, TO0n of all the channels can be manipulated collectively. Only specific bits can also be manipulated by setting the corresponding TOE0n = 0 to a target TO0n (channel output).

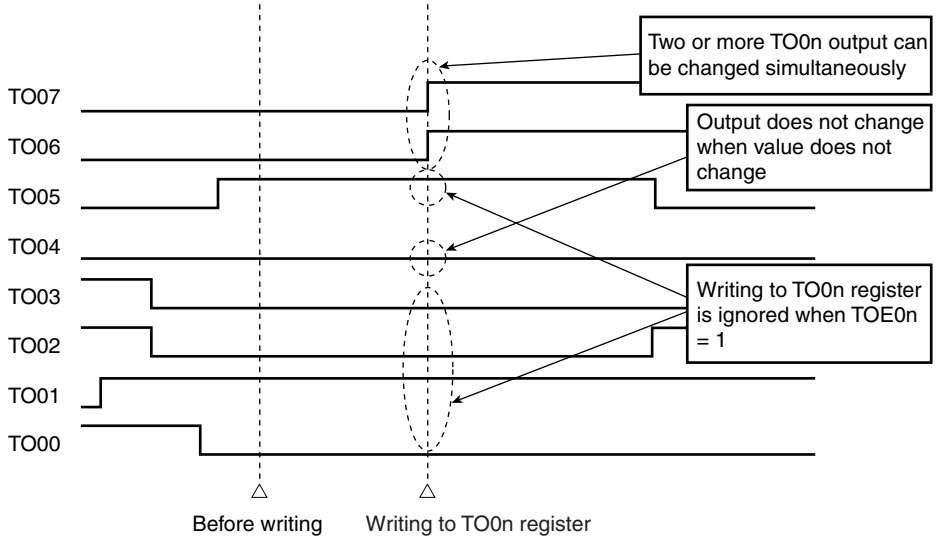
Figure 6-30. Example of TO0n Bit Collective Manipulation



Writing is done only to TO0n bit with TOE0n = 0, and writing to TO0n bit with TOE0n = 1 is ignored.

TO0n (channel output) to which TOE0n = 1 is set is not affected by the write operation. Even if the write operation is done to TO0n, it is ignored and the output change by timer operation is normally done.

Figure 6-31. TO0n Pin Statuses by Collective Manipulation of TO0n Bit



(Caution and Remark are given on the next page.)

Caution When TOE0n = 1, even if the output by timer interrupt of each timer (INTTM0n) contends with writing to TO0n, output is normally done to TO0n pin.

Remark n = 0 to 7

6.4.5 Timer Interrupt and TO0n Pin Output at Operation Start

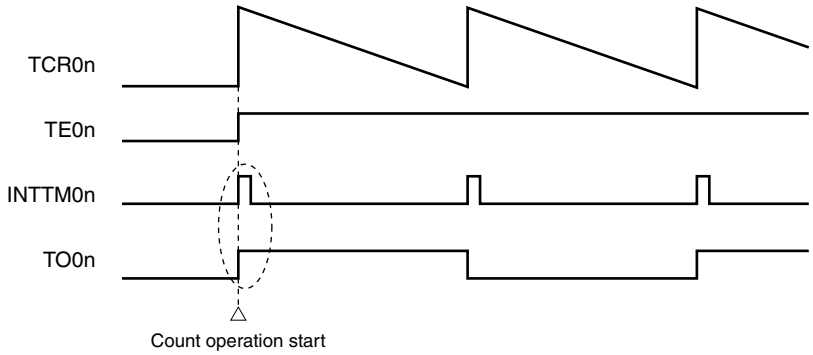
In the interval timer mode or capture mode, the MD0n0 bit in the TMR0n register sets whether or not to generate a timer interrupt at count start.

When MD0n0 is set to 1, the count operation start timing can be known by the timer interrupt (INTTM0n) generation.

In the other modes, neither timer interrupt at count operation start nor TO0n output is controlled.

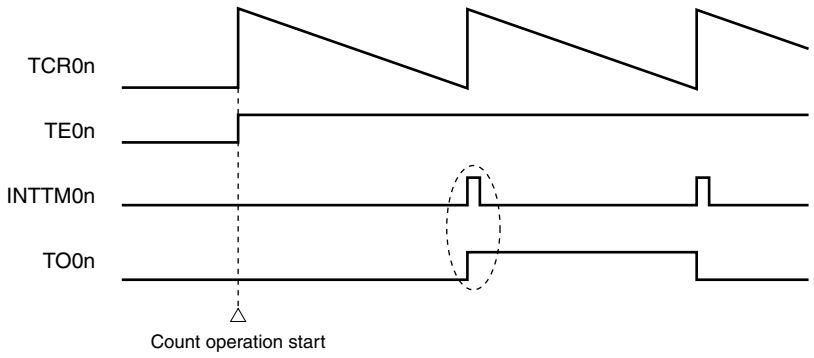
Figures 6-32 and 6-33 show operation examples when the interval timer mode (TOE0n = 1, TOM0n = 0) is set.

Figure 6-32. When MD0n0 is set to 1



When MD0n0 is set to 1, a timer interrupt (INTTM0n) is output at count operation start, and TO0n performs a toggle operation.

Figure 6-33. When MD0n0 is set to 0



When MD0n0 is set to 0, a timer interrupt (INTTM0n) is not output at count operation start, and TO0n does not change either. After counting one cycle, INTTM0n is output and TO0n performs a toggle operation.

6.6 Basic Function of Timer Array Unit TAUS

6.6.1 Overview of single-operation function and combination-operation function

Timer array unit TAUS consists of several channels and has a single-operation function that allows each channel to operate independently, and a combination-operation function that uses two or more channels in combination.

The single-operation function can be used for any channel, regardless of the operation mode of the other channels.

The combination-operation function is realized by combining a master channel (reference timer that mainly counts periods) and a slave channel (timer that operates in accordance with the master channel), and several rules must be observed when using this function.

6.6.2 Basic rules of combination-operation function

The basic rules of using the combination-operation function are as follows.

(1) Only an even channel (channel 0, 2, 4, etc.) can be set as a master channel.
(2) Any channel, except channel 0, can be set as a slave channel.
(3) The slave channel must be lower than the master channel.
Example: If channel 2 is set as a master channel, channel 3 or those that follow (channels 3, 4, 5, etc.) can be set as a slave channel.

(4) Two or more slave channels can be set for one master channel.
(5) When two or more master channels are to be used, slave channels with a master channel between them may not be set.
Example: If channels 0 and 4 are set as master channels, channels 1 to 3 can be set as the slave channels of master channel 0. Channels 5 to 7 cannot be set as the slave channels of master channel 0.

(6) The operating clock for a slave channel in combination with a master channel must be the same as that of the master channel. The CKS bit (bit 15 of the TMR0n register) of the slave channel that operates in combination with the master channel must be the same value as that of the master channel.
(7) A master channel can transmit INTTM0n (interrupt), start software trigger, and count clock to the lower channels.
(8) A slave channel can use the INTTM0n (interrupt), start software trigger, and count clock of the master channel, but it cannot transmit its own INTTM0n (interrupt), start software trigger, and count clock to the lower channel.
(9) A master channel cannot use the INTTM0n (interrupt), start software trigger, and count clock from the other higher master channel.
(10) To simultaneously start channels that operate in combination, the TS0n bit of the channels in combination must be set at the same time.
(11) To stop the channels in combination simultaneously, the TT0n bit of the channels in combination must be set at the same time.

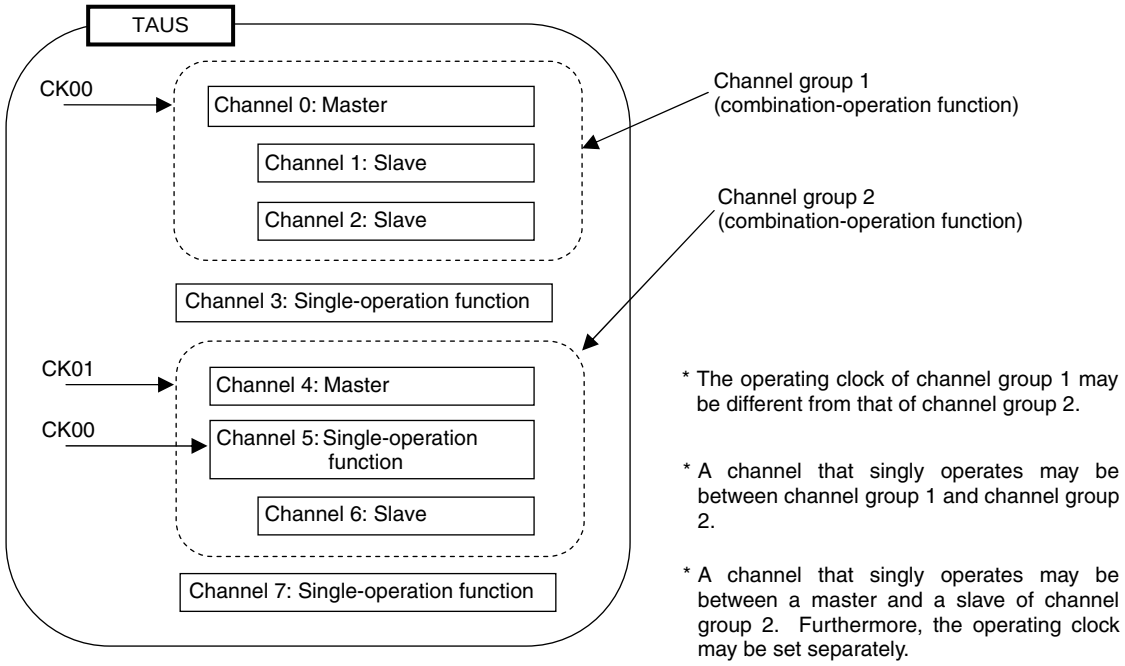
Remark n = 0 to 7

6.6.3 Applicable range of basic rules of combination-operation function

The rules of the combination-operation function are applied in a channel group (a master channel and slave channels forming one combination-operation function).

If two or more channel groups that do not operate in combination are specified, the basic rules of the combination-operation function in **6.6.2 Basic rules of combination-operation function** do not apply to the channel groups.

Example



6.7 Operation of Timer Array Unit TAUS as Independent Channel

6.7.1 Operation as interval timer/square wave output

(1) Interval timer

The timer array unit can be used as a reference timer that generates INTTM0n (timer interrupt) at fixed intervals.

The interrupt generation period can be calculated by the following expression.

Generation period of INTTM0n (timer interrupt) = Period of count clock × (Set value of TDR0n + 1)

(2) Operation as square wave output

TO0n performs a toggle operation as soon as INTTM0n has been generated, and outputs a square wave with a duty factor of 50%.

The period and frequency for outputting a square wave from TO0n can be calculated by the following expressions.

- Period of square wave output from TO0n = Period of count clock × (Set value of TDR0n + 1) × 2
- Frequency of square wave output from TO0n = Frequency of count clock/{(Set value of TDR0n + 1) × 2}

TCR0n operates as a down counter in the interval timer mode.

TCR0n loads the value of TDR0n at the first count clock after the channel start trigger bit (TS0n) is set to 1. If MD0n0 of TMR0n = 0 at this time, INTTM0n is not output and TO0n is not toggled. If MD0n0 of TMR0n = 1, INTTM0n is output and TO0n is toggled.

After that, TCR0n count down in synchronization with the count clock.

When TCR0n = 0000H, INTTM0n is output and TO0n is toggled at the next count clock. At the same time, TCR0n loads the value of TDR0n again. After that, the same operation is repeated.

TDR0n can be rewritten at any time. The new value of TDR0n becomes valid from the next period.

The TO0n pin output level goes into Hi-Z output state.
	The TAU0EN bit of the PER2 register is cleared to 0. →	Power-off status All circuits are initialized and SFR of each channel is also initialized. (The TO0n bit is cleared to 0 and the TO0n pin is set to port mode.)

Operation is resumed.

Remark n = 0 to 7

6.7.2 Operation as external event counter

The timer array unit can be used as an external event counter that counts the number of times the valid input edge (external event) is detected in the TI0n pin. When a specified count value is reached, the event counter generates an interrupt. The specified number of counts can be calculated by the following expression.

Specified number of counts = Set value of TDR0n + 1

TCR0n operates as a down counter in the event counter mode.

When the channel start trigger bit (TS0n) is set to 1, TCR0n loads the value of TDR0n.

TCR0n counts down each time the valid input edge of the TI0n pin has been detected. When TCR0n = 0000H, TCR0n loads the value of TDR0n again, and outputs INTTM0n.

After that, the above operation is repeated.

TO0n must not be used because its waveform depends on the external event and irregular.

TDR0n can be rewritten at any time. The new value of TDR0n becomes valid during the next count period.

Remark n = 0 to 7

6.7.3 Operation as frequency divider (channel 0 of 78K0R/KD3-L and 78K0R/KE3-L only)

The timer array unit can be used as a frequency divider that divides a clock input to the TI00 pin and outputs the result from TO00.

The divided clock frequency output from TO00 can be calculated by the following expression.

- When rising edge/falling edge is selected:
  Divided clock frequency = Input clock frequency/{(Set value of TDR00 + 1) × 2}
- When both edges are selected:
  Divided clock frequency ≅ Input clock frequency/(Set value of TDR00 + 1)

TCR00 operates as a down counter in the interval timer mode.

After the channel start trigger bit (TS00) is set to 1, TCR00 loads the value of TDR00 when the TI00 valid edge is detected. If MD000 of TMR00 = 0 at this time, INTTM00 is not output and TO00 is not toggled. If MD000 of TMR00 = 1, INTTM00 is output and TO00 is toggled.

After that, TCR00 counts down at the valid edge of TI00. When TCR00 = 0000H, it toggles TO00. At the same time, TCR00 loads the value of TDR00 again, and continues counting.

If detection of both the edges of TI00 is selected, the duty factor error of the input clock affects the divided clock period of the TO00 output.

The period of the TO00 output clock includes a sampling error of one period of the operation clock.

Clock period of TO00 output = Ideal TO00 output clock period ± Operation clock period (error)

TDR00 can be rewritten at any time. The new value of TDR00 becomes valid during the next count period.

Operation is resumed.

6.7.4 Operation as input pulse interval measurement

The count value can be captured at the TI0n valid edge and the interval of the pulse input to TI0n can be measured. The pulse interval can be calculated by the following expression.

TI0n input pulse interval = Period of count clock × ((10000H × TSR0n: OVF) + (Capture value of TDR0n + 1))

Caution The TI0n pin input is sampled using the operating clock selected with the CKS0n bit of the TMR0n register, so an error equivalent to one operation clock occurs.

TCR0n operates as an up counter in the capture mode.

When the channel start trigger (TS0n) is set to 1, TCR0n counts up from 0000H in synchronization with the count clock.

When the TI0n pin input valid edge is detected, the count value is transferred (captured) to TDR0n and, at the same time, the counter (TCR0n) is cleared to 0000H, and the INTTM0n is output. If the counter overflows at this time, the OVF bit of the TSR0n register is set to 1. If the counter does not overflow, the OVF bit is cleared. After that, the above operation is repeated.

As soon as the count value has been captured to the TDR0n register, the OVF bit of the TSR0n register is updated depending on whether the counter overflows during the measurement period. Therefore, the overflow status of the captured value can be checked.

If the counter reaches a full count for two or more periods, it is judged to be an overflow occurrence, and the OVF bit of the TSR0n register is set to 1. However, a normal interval value cannot be measured for the OVF bit, if two or more overflows occur.

Set STS0n2 to STS0n0 of the TMR0n register to 001B to use the valid edges of TI0n as a start trigger and a capture trigger.

When TE0n = 1, instead of the TI0n pin input, a software operation (TS0n = 1) can be used as a capture trigger.

Remark n = 0 to 7

6.7.5 Operation as input signal high-/low-level width measurement

By starting counting at one edge of TI0n and capturing the number of counts at another edge, the signal width (high-level width/low-level width) of TI0n can be measured. The signal width of TI0n can be calculated by the following expression.

Signal width of TI0n input = Period of count clock × ((10000H × TSR0n: OVF) + (Capture value of TDR0n + 1))

Caution The TI0n pin input is sampled using the operating clock selected with the CKS0n bit of the TMR0n register, so an error equivalent to one operation clock occurs.

TCR0n operates as an up counter in the capture & one-count mode.

When the channel start trigger (TS0n) is set to 1, TE0n is set to 1 and the TI0n pin start edge detection wait status is set.

When the TI0n start valid edge (rising edge of TI0n when the high-level width is to be measured) is detected, the counter counts up in synchronization with the count clock. When the valid capture edge (falling edge of TI0n when the high-level width is to be measured) is detected later, the count value is transferred to TDR0n and, at the same time, INTTM0n is output. If the counter overflows at this time, the OVF bit of the TSR0n register is set to 1. If the counter does not overflow, the OVF bit is cleared. TCR0n stops at the value “value transferred to TDR0n + 1”, and the TI0n pin start edge detection wait status is set. After that, the above operation is repeated.

As soon as the count value has been captured to the TDR0n register, the OVF bit of the TSR0n register is updated depending on whether the counter overflows during the measurement period. Therefore, the overflow status of the captured value can be checked.

If the counter reaches a full count for two or more periods, it is judged to be an overflow occurrence, and the OVF bit of the TSR0n register is set to 1. However, a normal interval value cannot be measured for the OVF bit, if two or more overflows occur.

Whether the high-level width or low-level width of the TI0n pin is to be measured can be selected by using the CIS0n1 and CIS0n0 bits of the TMR0n register.

Because this function is used to measure the signal width of the TI0n pin input, TS0n cannot be set to 1 while TE0n is 1.

CIS0n1, CIS0n0 of TMR0n = 10B: Low-level width is measured.

CIS0n1, CIS0n0 of TMR0n = 11B: High-level width is measured.

During operation	Set value of the TDR0n register can be changed. The TCR0n register can always be read. The TSR0n register is not used. Set values of TMR0n, TOM0, TOL0, TO0, and TOE0 registers cannot be changed.	When the TI0n pin start edge is detected, the counter (TCR0n) counts up from 0000H. If a capture edge of the TI0n pin is detected, the count value is transferred to TDR0n and INTTM0n is generated. If an overflow occurs at this time, the OVF bit of the TSR0n register is set; if an overflow does not occur, the OVF bit is cleared. TCR0n stops the count operation until the next TI0n pin start edge is detected.
Operation stop	The TT0n bit is set to 1. → TT0n bit automatically returns to 0 because it is a trigger bit.	TE0n = 0, and count operation stops. TCR0n holds count value and stops. The OVF bit of the TSR0n register is also held.
TAUS stop	The TAU0EN bit of PER2 register is cleared to 0. →	Power-off status All circuits are initialized and SFR of each channel is also initialized.

6.8 Operation of Plural Channels of Timer Array Unit TAUS

6.8.1 Operation as PWM function

Two channels can be used as a set to generate a pulse of any period and duty factor.

The period and duty factor of the output pulse can be calculated by the following expressions.

Pulse period = {Set value of TDR0n (master) + 1} × Count clock period
Duty factor [%] = {Set value of TDR0m (slave)}/{Set value of TDR0n (master) + 1} × 100
0% output: Set value of TDR0m (slave) = 0000H
100% output: Set value of TDR0m (slave) ≥ {Set value of TDR0n (master) + 1}

Remark The duty factor exceeds 100% if the set value of TDR0m (slave) > (set value of TDR0n (master) + 1), it summarizes to 100% output.

The master channel operates in the interval timer mode and counts the periods. When the channel start trigger (TS0n) is set to 1, INTTM0n is output. TCR0n counts down starting from the loaded value of TDR0n, in synchronization with the count clock. When TCR0n = 0000H, INTTM0n is output. TCR0n loads the value of TDR0n again. After that, it continues the similar operation.

TCR0m of a slave channel operates in one-count mode, counts the duty factor, and outputs a PWM waveform from the TO0m pin. TCR0m of the slave channel loads the value of TDR0m, using INTTM0n of the master channel as a start trigger, and stops counting until the next start trigger (INTTM0n of the master channel) is input.

The output level of TO0m becomes active one count clock after generation of INTTM0n from the master channel, and inactive when TCR0m = 0000H.

Caution To rewrite both TDR0n of the master channel and TDR0m of the slave channel, a write access is necessary two times. The timing at which the values of TDR0n and TDR0m are loaded to TCR0n and TRC0m is upon occurrence of INTTM0n of the master channel. Thus, when rewriting is performed split before and after occurrence of INTTM0n of the master channel, the TO0m pin cannot output the expected waveform. To rewrite both TDR0n of the master and TDR0m of the slave, therefore, be sure to rewrite both the registers immediately after INTTM0n is generated from the master channel.

6.8.2 Operation as one-shot pulse output function

By using two channels as a set, a one-shot pulse having any delay pulse width can be generated from the signal input to the TI0n pin.

The delay time and pulse width can be calculated by the following expressions.

Delay time = {Set value of TDR0n (master) + 2} × Count clock period
Pulse width = {Set value of TDR0m (slave)} × Count clock period

The Master channel operates in the one-count mode and counts the delays. TCR0n of the master channel starts operating upon start trigger detection and TCR0n loads the value of TDR0n. TCR0n counts down from the value of TDR0n it has loaded, in synchronization with the count clock. When TCR0n = 0000H, it outputs INTTM0n and stops counting until the next start trigger is detected.

The slave channel operates in the one-count mode and counts the pulse width. TCR0m of the slave channel starts operation using INTTM0n of the master channel as a start trigger, and loads the TDR0m value. TCR0m counts down from the value of TDR0m it has loaded, in synchronization with the count value. When TCR0m = 0000H, it outputs INTTM0m and stops counting until the next start trigger (INTTM0n of the master channel) is detected. The output level of TO0m becomes active one count clock after generation of INTTM0n from the master channel, and inactive when TCR0m = 0000H.

Instead of using the TI0n pin input, a one-shot pulse can also be output using the software operation (TS0n = 1) as a start trigger.

Caution The timing of loading of TDR0n of the master channel is different from that of TDR0m of the slave channel. If TDR0n and TDR0m are rewritten during operation, therefore, an illegal waveform is output. Be sure to rewrite TDR0n and TDR0m after INTTM0n of the channel to be rewritten is generated.

Remark n = 0, 2, 4, 6

6.8.3 Operation as multiple PWM output function

By extending the PWM function and using two or more slave channels, many PWM output signals can be produced.

For example, when using two slave channels, the period and duty factor of an output pulse can be calculated by the following expressions.

Pulse period = {Set value of TDR0n (master) + 1} × Count clock period
Duty factor 1 [%] = {Set value of TDR0p (slave 1)}/{Set value of TDR0n (master) + 1} × 100
Duty factor 2 [%] = {Set value of TDR0q (slave 2)}/{Set value of TDR0n (master) + 1} × 100

Remark Although the duty factor exceeds 100% if the set value of TDR0p (slave 1) > {set value of TDR0n (master) + 1} or if the {set value of TDR0q (slave 2)} > {set value of TDR0n (master) + 1}, it is summarized into 100% output.

TCR0n of the master channel operates in the interval timer mode and counts the periods.

TCR0p of the slave channel 1 operates in one-count mode, counts the duty factor, and outputs a PWM waveform from the TO0p pin. TCR0p loads the value of TDR0p to TCR0p, using INTTM0n of the master channel as a start trigger, and start counting down. When TCR0p = 0000H, TCR0p outputs INTTM0p and stops counting until the next start trigger (INTTM0n of the master channel) has been input. The output level of TO0p becomes active one count clock after generation of INTTM0n from the master channel, and inactive when TCR0p = 0000H.

In the same way as TCR0p of the slave channel 1, TCR0q of the slave channel 2 operates in one-count mode, counts the duty factor, and outputs a PWM waveform from the TO0q pin. TCR0q loads the value of TDR0q to TCR0q, using INTTM0n of the master channel as a start trigger, and starts counting down. When TCR0q = 0000H, TCR0q outputs INTTM0q and stops counting until the next start trigger (INTTM0n of the master channel) has been input. The output level of TO0q becomes active one count clock after generation of INTTM0n from the master channel, and inactive when TCR0q = 0000H.

When channel 0 is used as the master channel as above, up to seven types of PWM signals can be output at the same time.

Caution To rewrite both TDR0n of the master channel and TDR0p of the slave channel 1, write access is necessary at least twice. Since the values of TDR0n and TDR0p are loaded to TCR0n and TCR0p after INTTM0n is generated from the master channel, if rewriting is performed separately before and after generation of INTTM0n from the master channel, the TO0p pin cannot output the expected waveform. To rewrite both TDR0n of the master and TDR0p of the slave, be sure to rewrite both the registers immediately after INTTM0n is generated from the master channel (This applies also to TDR0q of the slave channel 2) .

	Sets the TPS0 register. Determines clock frequencies of CK00 and CK01.	
Channel default setting	Sets the TMR0n, TMR0p, and TMR0q registers of each channel to be used (determines operation mode of channels). An interval (period) value is set to the TDR0n register of the master channel, and a duty factor is set to the TDR0p and TDR0q registers of the slave channel.	Channel stops operating. (Clock is supplied and some power is consumed.)
	Sets slave channel. The TOM0p and TOM0q bits of the TOM0 register are set to 1 (combination-operation mode). Clears the TOL0p and TOL0q bits to 0. Sets the TO0p and TO0q bits and determines default level of the TO0p and TO0q outputs. →	The TO0p and TO0q pins go into Hi-Z output state. The TO0p and TO0q default setting levels are output when the port mode register is in output mode and the port register is 0.
	Sets TOE0p or TOE0q to 1 and enables operation of TO0p and TO0q. →	TO0p or TO0q does not change because channel stops operating.
	Clears the port register and port mode register to 0. →	The TO0p and TO0q pins output the TO0p and TO0q set levels.

Remarks 1. n = 0, 2, 4

2. p = n + 1; q = n + 2

Figure 6-69. Operation Procedure When Multiple PWM Output Function Is Used (2/2)

Operation is resumed.

	Software Operation	Hardware Status
Operation start	Sets TOE0p and TOE0q (slave) to 1 (only when operation is resumed). The TS0n bit (master), and TS0p and TS0q (slave) bits of the TS0 register are set to 1 at the same time. →	TE0n = 1, TE0p, TE0q = 1 When the master channel starts counting, INTTM0n is generated. Triggered by this interrupt, the slave channel also starts counting.
	The TS0n, TS0p, and TS0q bits automatically return to 0 because they are trigger bits.	
During operation	Set values of the TMR0n, TMR0p, TMR0q, TOM0, and TOE0 registers cannot be changed. Set values of the TDR0n, TDR0p, and TDR0q registers can be changed after INTTM0n of the master channel is generated. The TCR0n, TCR0p, and TCR0q registers can always be read. The TSR0n, TSR0p, and TSR0q registers are not used. Set values of the TOM0, TOL0, TO0, and TOE0 registers can be changed.	The counter of the master channel loads the TDR0n value to TCR0n and counts down. When the count value reaches TCR0n = 0000H, INTTM0n output is generated. At the same time, the value of the TDR0n register is loaded to TCR0n, and the counter starts counting down again. At the slave channel 1, the values of TDR0p are transferred to TCR0p, triggered by INTTM0n of the master channel, and the counter starts counting down. The output levels of TO0p become active one count clock after generation of the INTTM0n output from the master channel. It becomes inactive when TCR0p = 0000H, and the counting operation is stopped. At the slave channel 2, the values of TDR0q are transferred to TDR0q, triggered by INTTM0n of the master channel, and the counter starts counting down. The output levels of TO0q become active one count clock after generation of the INTTM0n output from the master channel. It becomes inactive when TCR0q = 0000H, and the counting operation is stopped. After that, the above operation is repeated.
Operation stop	The TT0n bit (master), TT0p, and TT0q (slave) bits are set to 1 at the same time. →	TE0n, TE0p, TE0q = 0, and count operation stops. TCR0n, TCR0p, and TCR0q hold count value and stops. The TO0p and TO0q output is not initialized but holds current status.
	The TT0n, TT0p, and TT0q bits automatically return to 0 because they are trigger bits.	
	TOE0p or TOE0q of slave channel is cleared to 0 and value is set to the TO0p and TO0q bits. →	The TO0p and TO0q pins output the TO0p and TO0q set levels.
TAUS stop	To hold the TO0p and TO0q pin output levels Clears TO0p and TO0q bits to 0 after the value to be held is set to the port register. →	The TO0p and TO0q pin output levels are held by port function.
	When holding the TO0p and TO0q pin output levels is not necessary Switches the port mode register to input mode. →	The TO0p and TO0q pin output levels go into Hi-Z output state.
	The TAU0EN bit of the PER2 register is cleared to 0. →	Power-off status All circuits are initialized and SFR of each channel is also initialized. (The TO0p and TO0q bits are cleared to 0 and the TO0p and TO0q pins are set to port mode.)

Remarks 1. n = 0, 2, 4

2. p = n + 1; q = n + 2

CHAPTER 7 REAL-TIME COUNTER

7.1 Functions of Real-Time Counter

The real-time counter has the following features.

- Having counters of year, month, week, day, hour, minute, and second, and can count up to 99 years.
- Constant-period interrupt function (period: 1 month to 0.5 seconds)
- Alarm interrupt function (alarm: week, hour, minute)
- Interval interrupt function
- Pin output function of 1 Hz
- Pin output function of 512 Hz or 16.384 kHz or 32.768 kHz

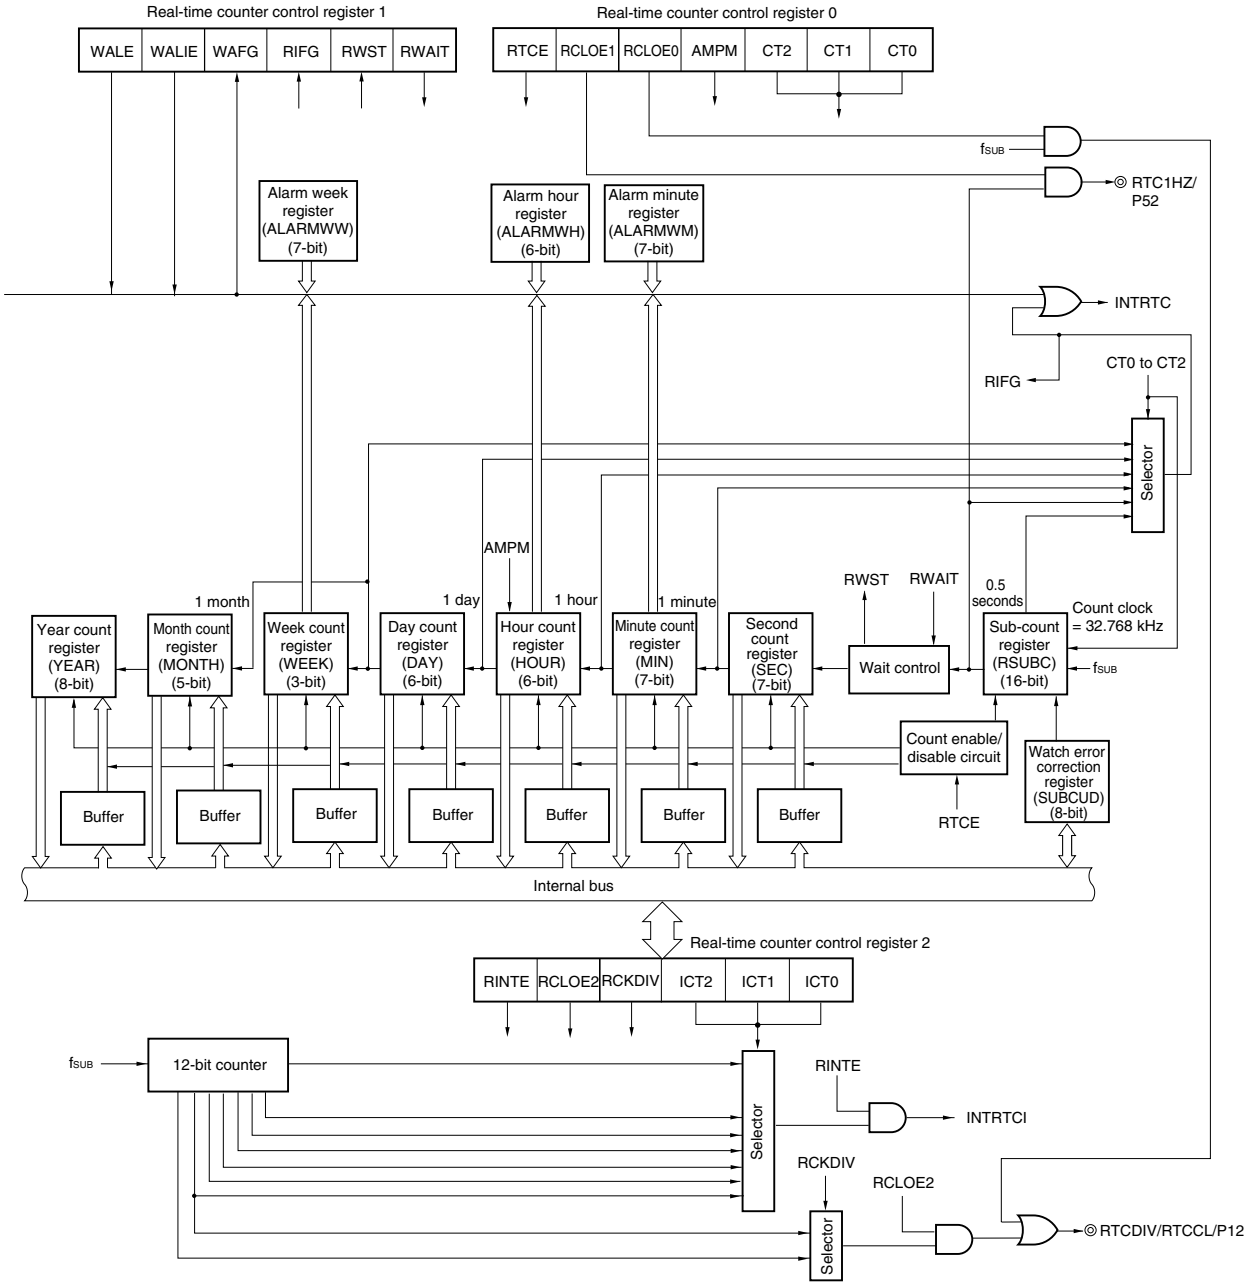
7.2 Configuration of Real-Time Counter

The real-time counter includes the following hardware.

Table 7-1. Configuration of Real-Time Counter

Item	Configuration
Control registers	Peripheral enable register 0 (PER0)
	Real-time counter control register 0 (RTCC0)
	Real-time counter control register 1 (RTCC1)
	Real-time counter control register 2 (RTCC2)
	Sub-count register (RSUBC)
	Second count register (SEC)
	Minute count register (MIN)
	Hour count register (HOUR)
	Day count register (DAY)
	Week count register (WEEK)
	Month count register (MONTH)
	Year count register (YEAR)
	Watch error correction register (SUBCUD)
	Alarm minute register (ALARMWM)
	Alarm hour register (ALARMWH)
	Alarm week register (ALARMWW)

Figure 7-1. Block Diagram of Real-Time Counter



7.3 Registers Controlling Real-Time Counter

The real-time counter is controlled by the following 16 registers.

- Peripheral enable register 0 (PER0)
- Real-time counter control register 0 (RTCC0)
- Real-time counter control register 1 (RTCC1)
- Real-time counter control register 2 (RTCC2)
- Sub-count register (RSUBC)
- Second count register (SEC)
- Minute count register (MIN)
- Hour count register (HOUR)
- Day count register (DAY)
- Week count register (WEEK)
- Month count register (MONTH)
- Year count register (YEAR)
- Watch error correction register (SUBCUD)
- Alarm minute register (ALARMWM)
- Alarm hour register (ALARMWH)
- Alarm week register (ALARMWW)

(1) Peripheral enable register 0 (PER0)

PER0 is used to enable or disable use of each peripheral hardware macro. Clock supply to a hardware macro that is not used is stopped in order to reduce the power consumption and noise.

When the real-time counter is used, be sure to set bit 7 (RTCEN) of this register to 1.

PER0 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Figure 7-2. Format of Peripheral Enable Register 0 (PER0)

Address: F00F0H After reset: 00H R/W

Symbol	<7>	6	<5>	<4>	3	<2>	1	0
PER0	RTCEN	0	ADCEN	IICAEN	0	SAU0EN	0	0

RTCEN	Control of real-time counter (RTC) input clock supply [Note]
0	Stops supply of input clock. • SFR used by the real-time counter (RTC) cannot be written. • The real-time counter (RTC) is in the reset status.
1	Supplies input clock. • SFR used by the real-time counter (RTC) can be read/written.

Note The input clock that can be controlled by RTCEN is used when the register that is used by the real-time counter (RTC) is accessed from the CPU. RTCEN cannot control supply of the operating clock (f_{SUB}) to RTC.

Cautions 1. When using the real-time counter, first set RTCEN to 1, while oscillation of the subsystem clock (f_{SUB}) is stable. If RTCEN = 0, writing to a control register of the real-time counter is ignored, and, even if the register is read, only the default value is read.

2. Clock supply to peripheral functions other than the real-time counter can be stopped in HALT mode when the subsystem clock is used, by setting RTCLPC of the operation speed mode control register (OSMC) to 1. In that case, set RTCEN to 1 and bits 0 to 6 of PER0 to 0. Furthermore, set bits 0 to 7 of the PER1 and PER2 registers also to 0.

3. Be sure to clear bits 0, 1, 3, and 6 (44-pin products: bits 0, 1, 3, 4, and 6) of the PER0 register to 0.

(2) Real-time counter control register 0 (RTCC0)

The RTCC0 register is an 8-bit register that is used to start or stop the real-time counter operation, control the RTCCL and RTC1HZ pins, and set a 12- or 24-hour system and the constant-period interrupt function.

RTCC0 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

0	Stops counter operation.
1	Starts counter operation.

RCLOE1	RTC1HZ pin output control
0	Disables output of RTC1HZ pin (1 Hz).
1	Enables output of RTC1HZ pin (1 Hz).

RCLOE0[Note]	RTCCL pin output control
0	Disables output of RTCCL pin (32.768 kHz).
1	Enables output of RTCCL pin (32.768 kHz).

AMPM	Selection of 12-/24-hour system
0	12-hour system (a.m. and p.m. are displayed.)
1	24-hour system
• To change the value of AMPM, set RWAIT (bit 0 of RTCC1) to 1, and re-set the hour count register (HOUR). • Table 7-2 shows the displayed time digits that are displayed.	

CT2	CT1	CT0	Constant-period interrupt (INTRTC) selection
0	0	0	Does not use constant-period interrupt function.
0	0	1	Once per 0.5 s (synchronized with second count up)
0	1	0	Once per 1 s (same time as second count up)
0	1	1	Once per 1 m (second 00 of every minute)
1	0	0	Once per 1 hour (minute 00 and second 00 of every hour)
1	0	1	Once per 1 day (hour 00, minute 00, and second 00 of every day)
1	1	×	Once per 1 month (Day 1, hour 00 a.m., minute 00, and second 00 of every month)
After changing the values of CT2 to CT0, clear the interrupt request flag.			

Note RCLOE0 and RCLOE2 must not be enabled at the same time.

Caution If RCLOE0 and RCLOE1 are changed when RTCE = 1, the last waveform of the 32.768 kHz and 1 Hz output signals may become short.

Remark ×: don't care

(3) Real-time counter control register 1 (RTCC1)

The RTCC1 register is an 8-bit register that is used to control the alarm interrupt function and the wait time of the counter.

RTCC1 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Figure 7-4. Format of Real-Time Counter Control Register 1 (RTCC1) (1/2)

Address: FFF9EH After reset: 00H R/W

Symbol	<7>	<6>	5	<4>	<3>	2	<1>	<0>
RTCC1	WALE	WALIE	0	WAFG	RIFG	0	RWST	RWAIT

WALE	Alarm operation control
0	Match operation is invalid.
1	Match operation is valid.
To set the registers of alarm (WALIE flag of RTCC1, ALARMWM register, ALARMWH register, and ALARMWW register), disable WALE (clear it to “0”).	

WALIE	Control of alarm interrupt (INTRTC) function operation
0	Does not generate interrupt on matching of alarm.
1	Generates interrupt on matching of alarm.

WAFG	Alarm detection status flag
0	Alarm mismatch
1	Detection of matching of alarm
This is a status flag that indicates detection of matching with the alarm. It is valid only when WALE = 1 and is set to “1” one clock (32.768 kHz) after matching of the alarm is detected. This flag is cleared when “0” is written to it. Writing “1” to it is invalid.	

Figure 7-4. Format of Real-Time Counter Control Register 1 (RTCC1) (2/2)

RIFG	Constant-period interrupt status flag
0	Constant-period interrupt is not generated.
1	Constant-period interrupt is generated.
This flag indicates the status of generation of the constant-period interrupt. When the constant-period interrupt is generated, it is set to “1”. This flag is cleared when “0” is written to it. Writing “1” to it is invalid.	

RWST	Wait status flag of real-time counter
0	Counter is operating.
1	Mode to read or write counter value
This status flag indicates whether the setting of RWAIT is valid. Before reading or writing the counter value, confirm that the value of this flag is 1.	

RWAIT	Wait control of real-time counter
0	Sets counter operation.
1	Stops SEC to YEAR counters. Mode to read or write counter value
This bit controls the operation of the counter. Be sure to write “1” to it to read or write the counter value. Because RSUBC continues operation, complete reading or writing of it in 1 second, and clear this bit back to 0. When RWAIT = 1, it takes up to 1 clock (32.768 kHz) until the counter value can be read or written. If RSUBC overflows when RWAIT = 1, it counts up after RWAIT = 0. If the second count register is written, however, it does not count up because RSUBC is cleared.	

Caution If writing is performed to the RTCC1 register with a 1-bit manipulation instruction, the RIFG flag and WAFG flag may be cleared. Therefore, to perform writing to the RTCC1 register, be sure to use an 8-bit manipulation instruction. To prevent the RIFG flag and WAFG flag from being cleared during writing, disable writing by setting 1 to the corresponding bit. If the RIFG flag and WAFG flag are not used and the value may be changed, the RTCC1 register may be written by using a 1-bit manipulation instruction.

Remark Fixed-cycle interrupts and alarm match interrupts use the same interrupt source (INTRTC). When using these two types of interrupts at the same time, which interrupt occurred can be judged by checking the fixed-cycle interrupt status flag (RIFG) and the alarm detection status flag (WAFG) upon INTRTC occurrence.

(4) Real-time counter control register 2 (RTCC2)

The RTCC2 register is an 8-bit register that is used to control the interval interrupt function and the RTCDIV pin.

RTCC2 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

1	1	0	1	$2^{11}/f_{XT}$ (62.5 ms)
1	1	1	×	$2^{12}/f_{XT}$ (125 ms)

RCLOE2[Note]	RTCDIV pin output control
0	Output of RTCDIV pin is disabled.
1	Output of RTCDIV pin is enabled.

RCKDIV	Selection of RTCDIV pin output frequency
0	RTCDIV pin outputs 512 Hz. (1.95 ms)
1	RTCDIV pin outputs 16.384 kHz. (0.061 ms)

Notes RCLOE0 and RCLOE2 must not be enabled at the same time.

Cautions 1. Change ICT2, ICT1, and ICT0 when RINTE = 0.

2. When the output from RTCDIV pin is stopped, the output continues after a maximum of two clocks of f_{XT} and enters the low level. While 512 Hz is output, and when the output is stopped immediately after entering the high level, a pulse of at least one clock width of f_{XT} may be generated.

(5) Sub-count register (RSUBC)

The RSUBC register is a 16-bit register that counts the reference time of 1 second of the real-time counter. Normally, it takes a value of 0000H to 7FFFH and counts 1 second with a clock of 32.768 kHz.

RSUBC can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

Cautions 1. When a correction is made by using the SUBCUD register, the value may become 8000H or more.

2. This register is also cleared by reset effected by writing the second count register.

3. The value read from this register is not guaranteed if it is read during operation, because a value that is changing is read.

(6) Second count register (SEC)

The SEC register is an 8-bit register that takes a value of 0 to 59 (decimal) and indicates the count value of seconds.

It counts up when the sub-counter overflows.

When data is written to this register, it is written to a buffer and then to the counter up to 2 clocks (32.768 kHz) later. Set a decimal value of 00 to 59 to this register in BCD code.

SEC can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

(7) Minute count register (MIN)

The MIN register is an 8-bit register that takes a value of 0 to 59 (decimal) and indicates the count value of minutes.

It counts up when the second counter overflows.

When data is written to this register, it is written to a buffer and then to the counter up to 2 clocks (32.768 kHz) later. Set a decimal value of 00 to 59 to this register in BCD code.

MIN can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

(8) Hour count register (HOUR)

The HOUR register is an 8-bit register that takes a value of 00 to 23 or 01 to 12, 21 to 32 (decimal) and indicates the count value of hours.

It counts up when the minute counter overflows.

When data is written to this register, it is written to a buffer and then to the counter up to 2 clocks (32.768 kHz) later. Set a decimal value of 00 to 23, 01 to 12, or 21 to 32 to this register in BCD code.

HOUR can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 12H.

However, the value of this register is 00H if the AMPM bit (bit 3 of the RTCC0 register) is set to 1 after reset.

The HOUR register value is set to 12-hour display when the AMPM bit is “0” and to 24-hour display when the AMPM bit is “1”.

In 12-hour display, the fifth bit of the HOUR register displays 0 for AM and 1 for PM.

(9) Day count register (DAY)

The DAY register is an 8-bit register that takes a value of 1 to 31 (decimal) and indicates the count value of days.

It counts up when the hour counter overflows.

This counter counts as follows.

- 01 to 31 (January, March, May, July, August, October, December)
- 01 to 30 (April, June, September, November)
- 01 to 29 (February, leap year)
- 01 to 28 (February, normal year)

When data is written to this register, it is written to a buffer and then to the counter up to 2 clocks (32.768 kHz) later. Set a decimal value of 01 to 31 to this register in BCD code.

DAY can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 01H.

(10) Week count register (WEEK)

The WEEK register is an 8-bit register that takes a value of 0 to 6 (decimal) and indicates the count value of weekdays.

It counts up in synchronization with the day counter.

When data is written to this register, it is written to a buffer and then to the counter up to 2 clocks (32.768 kHz) later. Set a decimal value of 00 to 06 to this register in BCD code.

WEEK can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Sunday	00H
Monday	01H
Tuesday	02H
Wednesday	03H
Thursday	04H
Friday	05H
Saturday	06H

(11) Month count register (MONTH)

The MONTH register is an 8-bit register that takes a value of 1 to 12 (decimal) and indicates the count value of months.

It counts up when the day counter overflows.

When data is written to this register, it is written to a buffer and then to the counter up to 2 clocks (32.768 kHz) later. Set a decimal value of 01 to 12 to this register in BCD code.

MONTH can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 01H.

(12) Year count register (YEAR)

The YEAR register is an 8-bit register that takes a value of 0 to 99 (decimal) and indicates the count value of years.

It counts up when the month counter overflows.

Values 00, 04, 08, …, 92, and 96 indicate a leap year.

When data is written to this register, it is written to a buffer and then to the counter up to 2 clocks (32.768 kHz) later. Set a decimal value of 00 to 99 to this register in BCD code.

YEAR can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

(13) Watch error correction register (SUBCUD)

This register is used to correct the watch with high accuracy when it is slow or fast by changing the value that overflows from the sub-count register (RSUBC) to the second count register (reference value: 7FFFH).

SUBCUD can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

0	Increases by {(F5, F4, F3, F2, F1, F0) – 1} × 2.
1	Decreases by {(/F5, /F4, /F3, /F2, /F1, /F0) + 1} × 2.
When (F6, F5, F4, F3, F2, F1, F0) = (*, 0, 0, 0, 0, 0, *), the watch error is not corrected. * is 0 or 1. /F5 to /F0 are the inverted values of the corresponding bits (000011 when 111100). Range of correction value: (when F6 = 0) 2, 4, 6, 8, … , 120, 122, 124 (when F6 = 1) –2, –4, –6, –8, … , –120, –122, –124	

The range of value that can be corrected by using the watch error correction register (SUBCUD) is shown below.

	DEV = 0 (correction every 20 seconds)	DEV = 1 (correction every 60 seconds)
Correctable range	–189.2 ppm to 189.2 ppm	–63.1 ppm to 63.1 ppm
Maximum excludes quantization error	± 1.53 ppm	± 0.51 ppm
Minimum resolution	± 3.05 ppm	± 1.02 ppm

Remark If a correctable range is −63.1 ppm or lower and 63.1 ppm or higher, set 0 to DEV.

(14) Alarm minute register (ALARMWM)

This register is used to set minutes of alarm.

ALARMWM can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Caution Set a decimal value of 00 to 59 to this register in BCD code. If a value outside the range is set, the alarm is not detected.

(15) Alarm hour register (ALARMWH)

This register is used to set hours of alarm.

ALARMWH can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 12H.

However, the value of this register is 00H if the AMPM bit (bit 3 of the RTCC0 register) is set to 1 after reset.

Caution Set a decimal value of 00 to 23, 01 to 12, or 21 to 32 to this register in BCD code. If a value outside the range is set, the alarm is not detected.

(16) Alarm week register (ALARMWW)

This register is used to set date of alarm.

ALARMWW can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

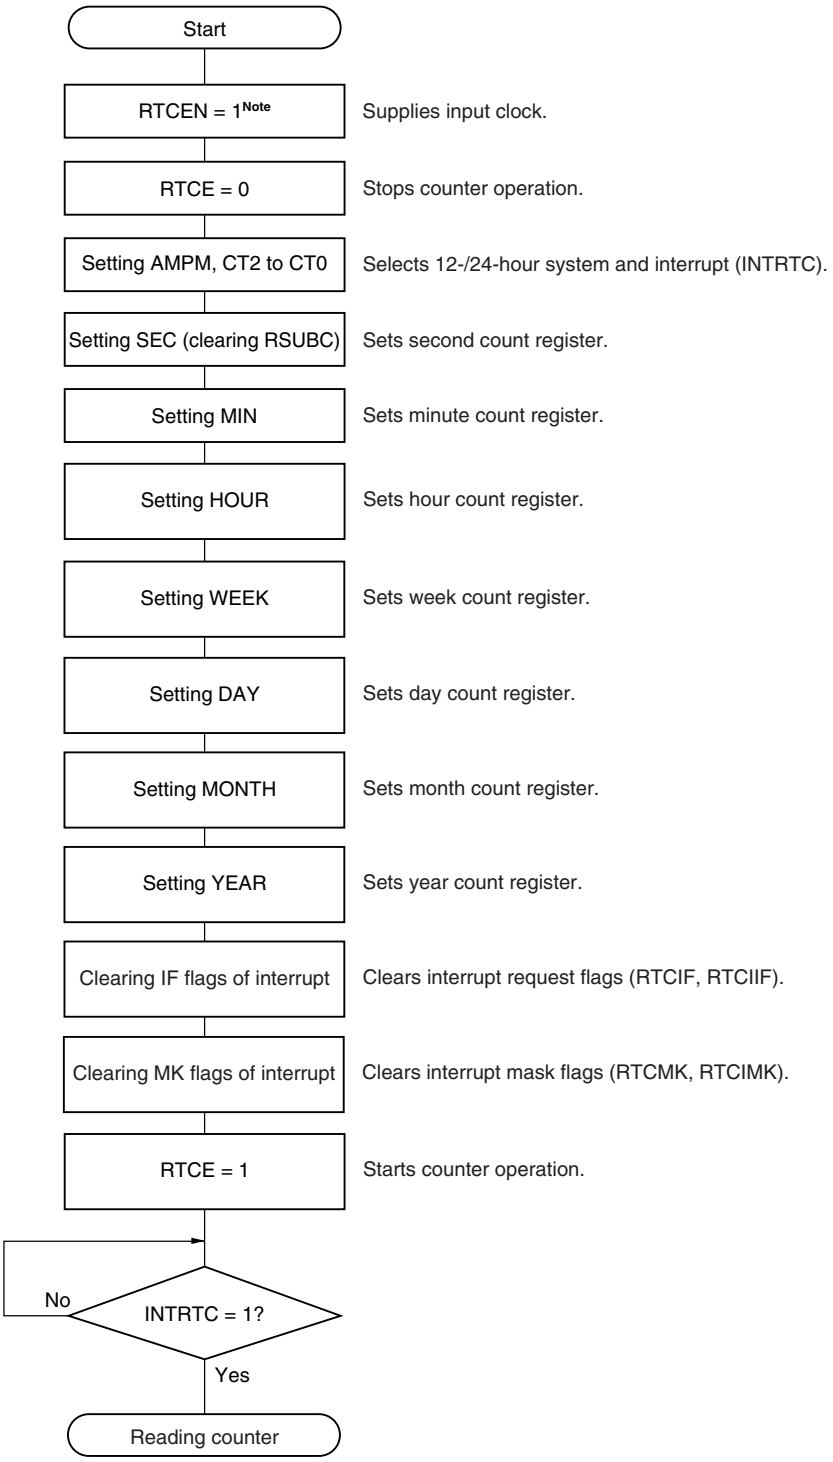
7.4 Real-Time Counter Operation

7.4.1 Starting operation of real-time counter

Figure 7-18. Procedure for Starting Operation of Real-Time Counter



Note First set RTCEN to 1, while oscillation of the subsystem clock (f_{SUB}) is stable.

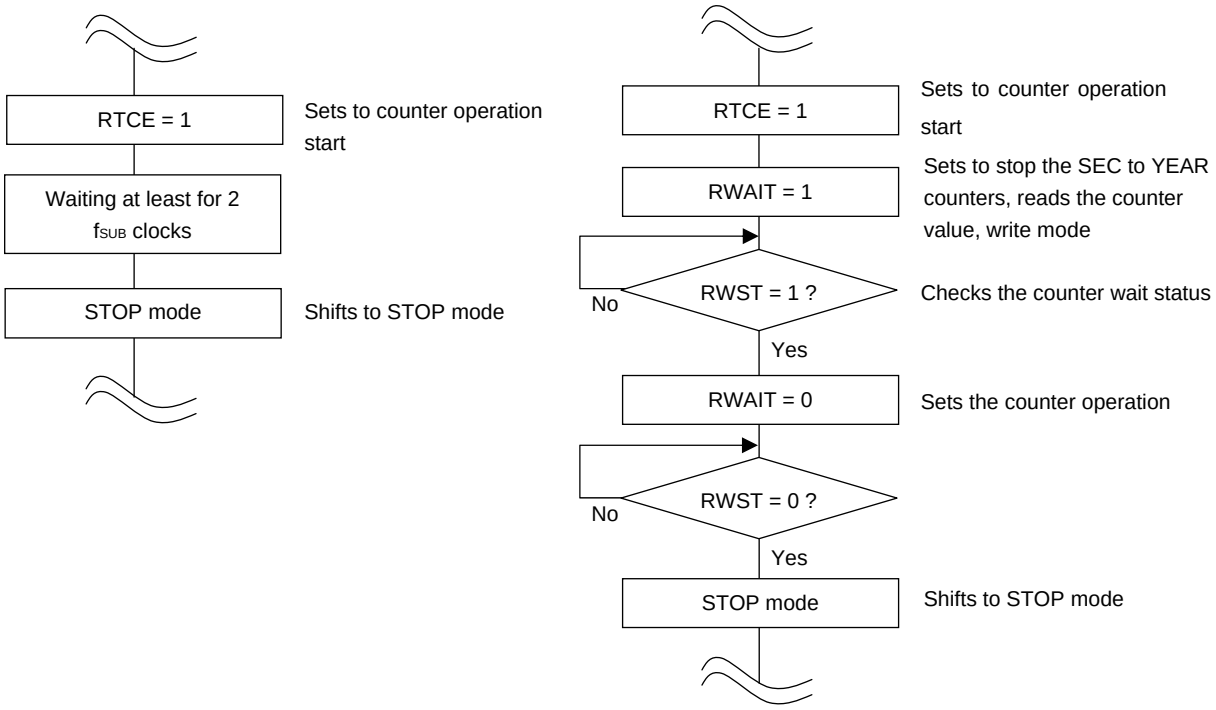
7.4.2 Shifting to STOP mode after starting operation

Perform one of the following processing when shifting to STOP mode immediately after setting RTCE to 1.

However, after setting RTCE to 1, this processing is not required when shifting to STOP mode after the first INTRTC interrupt has occurred.

- Shifting to STOP mode when at least two subsystem clocks (f_{SUB}) (about 62 μs) have elapsed after setting RTCE to 1 (see **Figure 7-19**, **Example 1**).
- Checking by polling RWST to become 1, after setting RTCE to 1 and then setting RWAIT to 1. Afterward, setting RWAIT to 0 and shifting to STOP mode after checking again by polling that RWST has become 0 (see **Figure 7-19**, **Example 2**).

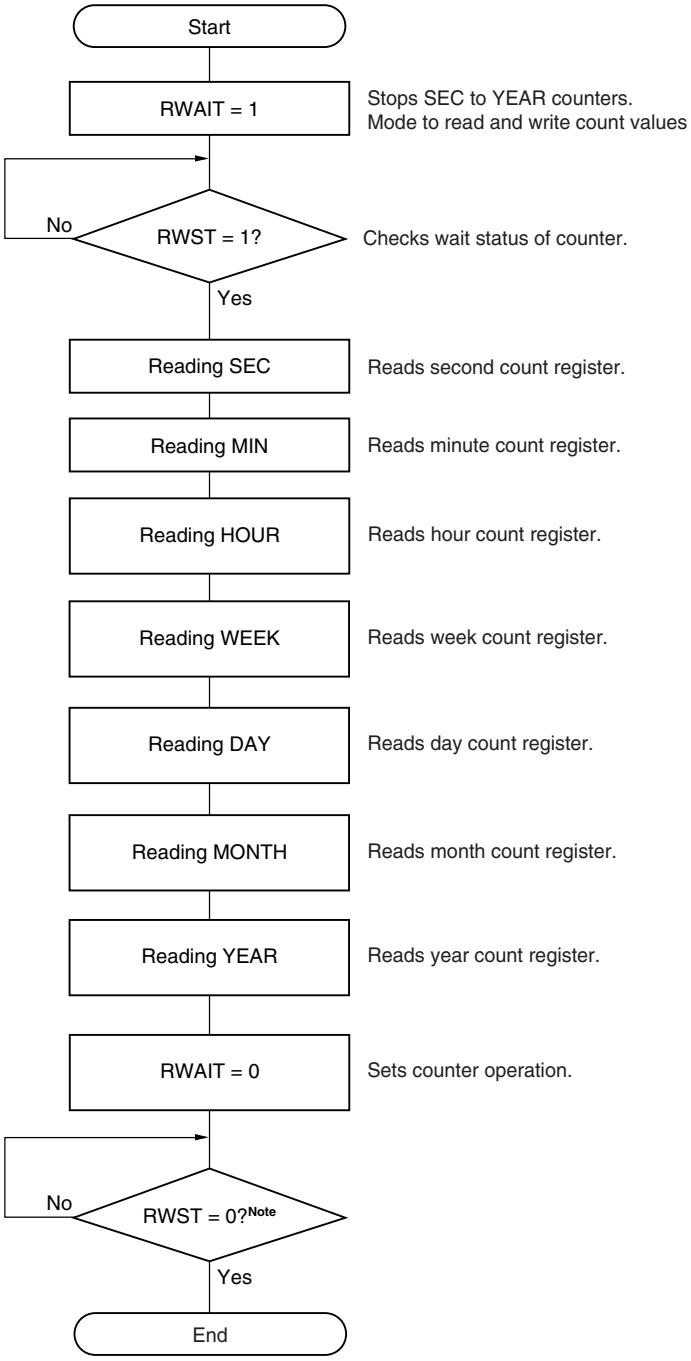
Figure 7-19. Procedure for Shifting to STOP Mode After Setting RTCE to 1



7.4.3 Reading/writing real-time counter

Read or write the counter after setting 1 to RWAIT first.

Figure 7-20. Procedure for Reading Real-Time Counter

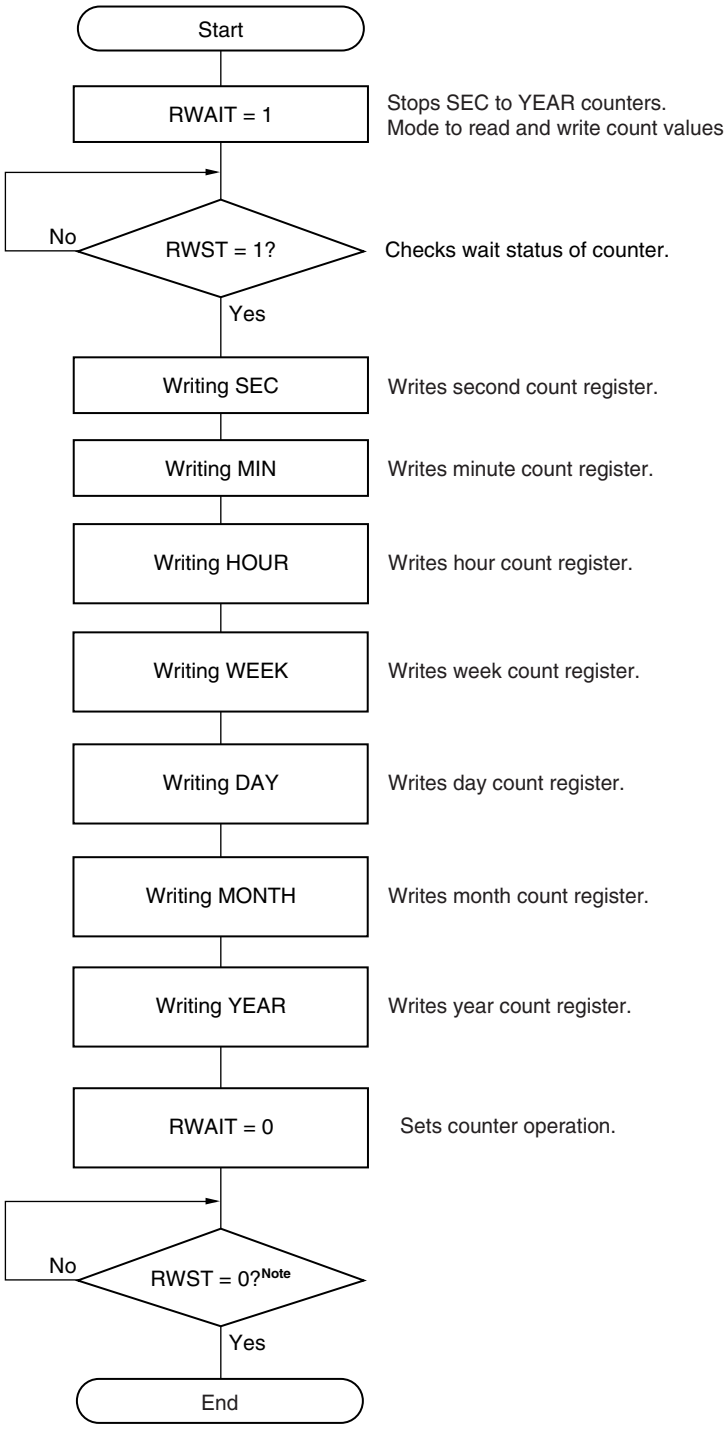


Note Be sure to confirm that RWST = 0 before setting STOP mode.

Caution Complete the series of operations of setting RWAIT to 1 to clearing RWAIT to 0 within 1 second.

Remark SEC, MIN, HOUR, WEEK, DAY, MONTH, and YEAR may be read in any sequence.
All the registers do not have to be set and only some registers may be read.

Figure 7-21. Procedure for Writing Real-Time Counter



Note Be sure to confirm that RWST = 0 before setting STOP mode.

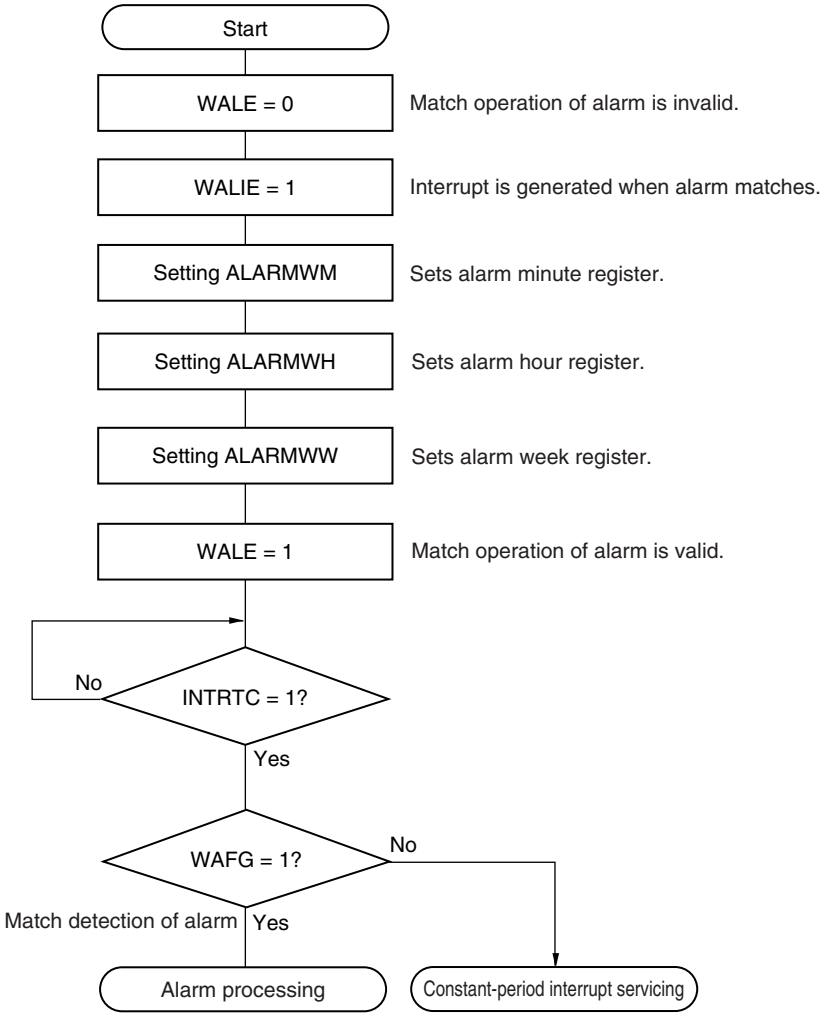
Caution Complete the series of operations of setting RWAIT to 1 to clearing RWAIT to 0 within 1 second.

Remark SEC, MIN, HOUR, WEEK, DAY, MONTH, and YEAR may be written in any sequence.
All the registers do not have to be set and only some registers may be written.

7.4.4 Setting alarm of real-time counter

Set time of alarm after setting 0 to WALE first.

Figure 7-22. Alarm Setting Procedure



Remarks 1. ALARMWM, ALARMWH, and ALARMWW may be written in any sequence.

2. Fixed-cycle interrupts and alarm match interrupts use the same interrupt source (INTRTC). When using these two types of interrupts at the same time, which interrupt occurred can be judged by checking the fixed-cycle interrupt status flag (RIFG) and the alarm detection status flag (WAFG) upon INTRTC occurrence.

7.4.8 Example of watch error correction of real-time counter

The watch can be corrected with high accuracy when it is slow or fast, by setting a value to the watch error correction register.

Example of calculating the correction value

The correction value used when correcting the count value of the sub-count register (RSUBC) is calculated by using the following expression.

Set DEV to 0 when the correction range is −63.1 ppm or less, or 63.1 ppm or more.

(When DEV = 0)

Correction value[Note] = Number of correction counts in 1 minute ÷ 3 = (Oscillation frequency ÷ Target frequency − 1) × 32768 × 60 ÷ 3

(When DEV = 1)

Correction value[Note] = Number of correction counts in 1 minute = (Oscillation frequency ÷ Target frequency − 1) × 32768 × 60

Note The correction value is the watch error correction value calculated by using bits 6 to 0 of the watch error correction register (SUBCUD).

(When F6 = 0) Correction value = {(F5, F4, F3, F2, F1, F0) − 1} × 2

(When F6 = 1) Correction value = − {(/F5, /F4, /F3, /F2, /F1, /F0) + 1} × 2

When (F6, F5, F4, F3, F2, F1, F0) is (*, 0, 0, 0, 0, 0, *), watch error correction is not performed. "*" is 0 or 1.

/F5 to /F0 are bit-inverted values (000011 when 111100).

Remarks 1. The correction value is 2, 4, 6, 8, … 120, 122, 124 or −2, −4, −6, −8, … −120, −122, −124.

2. The oscillation frequency is the subsystem clock (f_{SUB}).
It can be calculated from the 32 kHz output frequency of the RTCCL pin or the output frequency of the RTC1HZ pin × 32768 when the watch error correction register is set to its initial value (00H).

3. The target frequency is the frequency resulting after correction performed by using the watch error correction register.

Correction example <1>

Example of correcting from 32772.3 Hz to 32768 Hz (32772.3 Hz − 131.2 ppm)

[Measuring the oscillation frequency]

The oscillation frequency[Note] of each product is measured by outputting about 32 kHz from the RTCCL pin or outputting about 1 Hz from the RTC1HZ pin when the watch error correction register is set to its initial value (00H).

Note See **7.4.5 1 Hz output of real-time counter** for the setting procedure of outputting about 1 Hz from the RTC1HZ pin, and **7.4.6 32.768 kHz output of real-time counter** for the setting procedure of outputting about 32 kHz from the RTCCL pin.

[Calculating the correction value]

(When the output frequency from the RTCCL pin is 32772.3 Hz)

If the target frequency is assumed to be 32768 Hz (32772.3 Hz − 131.2 ppm), the correction range for −131.2 ppm is −63.1 ppm or less, so assume DEV to be 0.

The expression for calculating the correction value when DEV is 0 is applied.

$$\begin{aligned}\text{Correction value} &= \text{Number of correction counts in 1 minute} \div 3\\ &= (\text{Oscillation frequency} \div \text{Target frequency} - 1) \times 32768 \times 60 \div 3\\ &= (32772.3 \div 32768 - 1) \times 32768 \times 60 \div 3\\ &= 86\end{aligned}$$

[Calculating the values to be set to (F6 to F0)]

(When the correction value is 86)

If the correction value is 0 or more (when delaying), assume F6 to be 0.

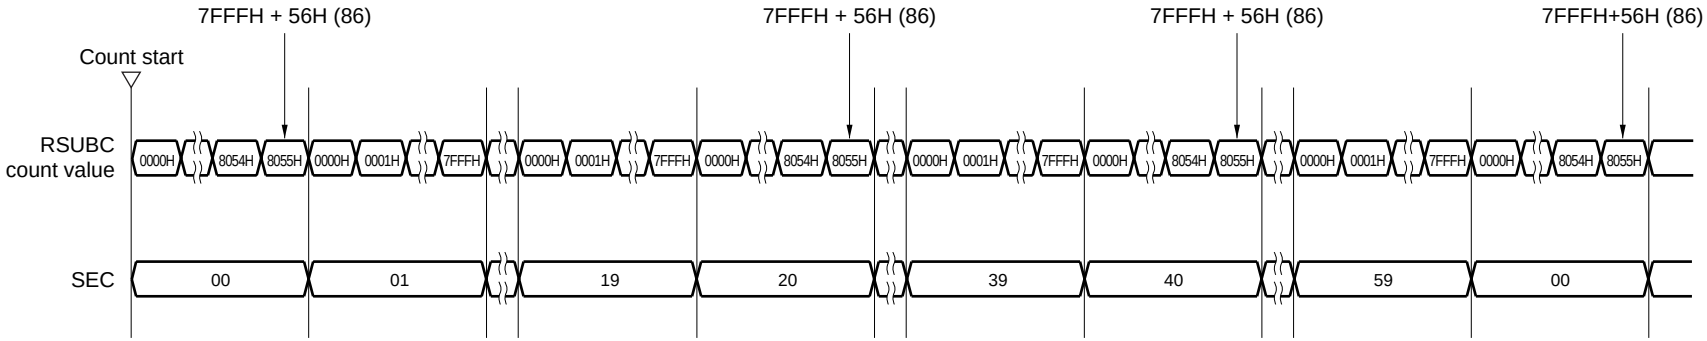
Calculate (F5, F4, F3, F2, F1, F0) from the correction value.

$$\begin{aligned}\{(F5, F4, F3, F2, F1, F0) - 1\} \times 2 &= 86\\ (F5, F4, F3, F2, F1, F0) &= 44\\ (F5, F4, F3, F2, F1, F0) &= (1, 0, 1, 1, 0, 0)\end{aligned}$$

Consequently, when correcting from 32772.3 Hz to 32768 Hz (32772.3 Hz − 131.2 ppm), setting the correction register such that DEV is 0 and the correction value is 86 (bits 6 to 0 of SUBCUD: 0101100) results in 32768 Hz (0 ppm).

Figure 7-26 shows the operation when (DEV, F6, F5, F4, F3, F2, F1, F0) is (0, 0, 1, 0, 1, 1, 0, 0).

Figure 7-26. Operation when (DEV, F6, F5, F4, F3, F2, F1, F0) = (0, 0, 1, 0, 1, 1, 0, 0)



Correction example <2>

Example of correcting from 32767.4 Hz to 32768 Hz (32767.4 Hz + 18.3 ppm)

[Measuring the oscillation frequency]

The oscillation frequency[Note] of each product is measured by outputting about 32 kHz from the RTCCL pin or outputting about 1 Hz from the RTC1HZ pin when the watch error correction register is set to its initial value (00H).

Note See **7.4.5 1 Hz output of real-time counter** for the setting procedure of outputting about 1 Hz from the RTC1HZ pin, and **7.4.6 32.768 kHz output of real-time counter** for the setting procedure of outputting about 32 kHz from the RTCCL pin.

[Calculating the correction value]

(When the output frequency from the RTCCL pin is 0.9999817 Hz)

Oscillation frequency = 32768 × 0.9999817 ≈ 32767.4 Hz

Assume the target frequency to be 32768 Hz (32767.4 Hz + 18.3 ppm) and DEV to be 1.

The expression for calculating the correction value when DEV is 1 is applied.

Correction value = Number of correction counts in 1 minute
= (Oscillation frequency ÷ Target frequency − 1) × 32768 × 60
= (32767.4 ÷ 32768 − 1) × 32768 × 60
= −36

[Calculating the values to be set to (F6 to F0)]

(When the correction value is −36)

If the correction value is 0 or less (when quickening), assume F6 to be 1.

Calculate (F5, F4, F3, F2, F1, F0) from the correction value.

− {(/F5, /F4, /F3, /F2, /F1, /F0) − 1} × 2	= −36
(/F5, /F4, /F3, /F2, /F1, /F0)	= 17
(/F5, /F4, /F3, /F2, /F1, /F0)	= (0, 1, 0, 0, 0, 1)
(F5, F4, F3, F2, F1, F0)	= (1, 0, 1, 1, 1, 0)

Consequently, when correcting from 32767.4 Hz to 32768 Hz (32767.4 Hz + 18.3 ppm), setting the correction register such that DEV is 1 and the correction value is −36 (bits 6 to 0 of SUBCUD: 1101110) results in 32768 Hz (0 ppm).

Figure 7-27 shows the operation when (DEV, F6, F5, F4, F3, F2, F1, F0) is (1, 1, 1, 0, 1, 1, 1, 0).

CHAPTER 8 COMPARATORS/PROGRAMMABLE GAIN AMPLIFIERS

8.1 Features of Comparator and Programmable Gain Amplifier

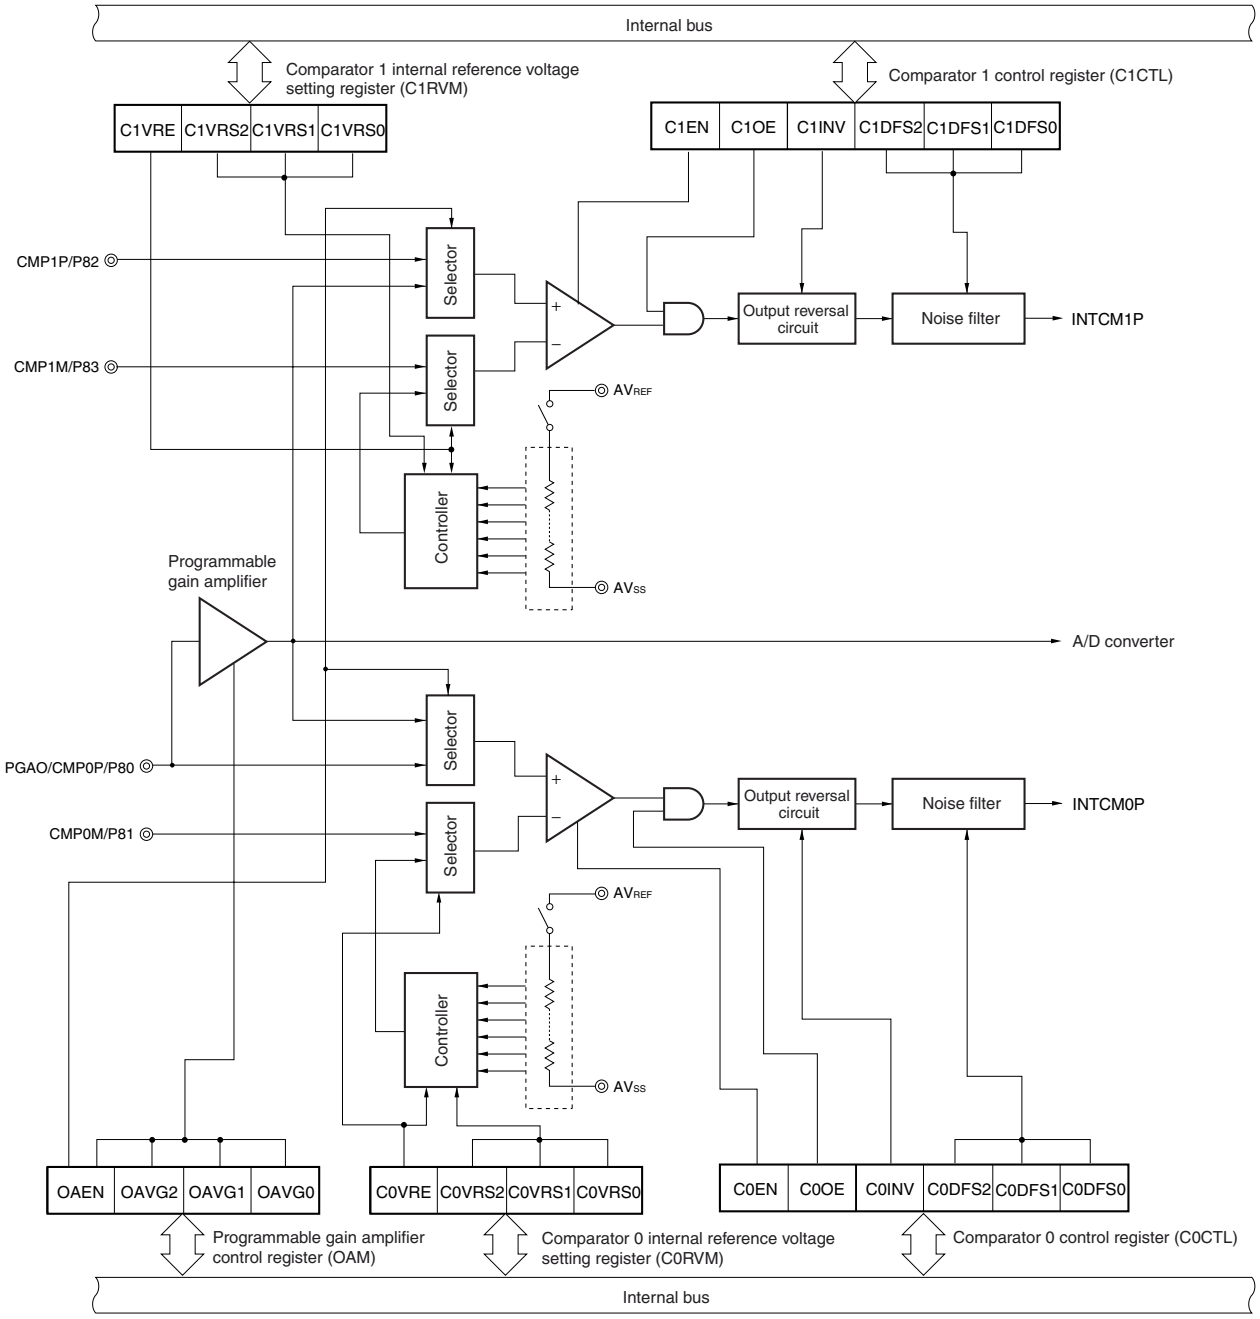
The features of the programmable gain amplifiers and comparators are described below.

○ Comparators
- A comparator is equipped with two channels (CMP0, CMP1).
- Negative-side input pins (CMP0M, CMP1M) and a positive-side input pin (CMP0P, CMP1P) can be connected.
- The output signal of a programmable gain amplifier can be used as the positive-side input signal of a comparator [Note].
- CMP0M and CMP1M pin inputs and the internal generation reference voltage (6 combinations for each comparator) can be selected as the reference voltage.
- The elimination width of the noise elimination digital filter can be selected.
- An interrupt request is generated when the reference voltage is exceeded (INTCMP0, INTCMP1).

○ Programmable gain amplifiers
- A programmable gain amplifier amplifies and outputs an analog voltage that is input. One among five amplification factors can be selected.
- The output signal of a programmable gain amplifier can be used as the positive-side input signal of a comparator [Note].
- The output signal of a programmable gain amplifier can be selected as the analog input of an A/D converter.

Note When using the output signals of the programmable gain amplifiers as the positive-side input signals of the comparators, the output signal is simultaneously input to both channels of comparators 0 and 1.

Figure 8-1. Block Diagram of Comparator/Programmable Gain Amplifier



8.2 Configurations of Comparator and Programmable Gain Amplifier

The comparators and programmable gain amplifiers consist of the following hardware.

Table 8-1. Configurations of Comparator and Programmable Gain Amplifier

Item	Configuration
Control registers	Peripheral enable register 1 (PER1) Programmable gain amplifier control register (OAM) Comparator 0 and 1 control registers (C0CTL, C1CTL) Comparator 0 and 1 internal reference voltage setting registers (C0RVM, C1RVM) Port input mode register 8 (PIM8) Port mode register 8 (PM8)

8.3 Registers Controlling Comparators and Programmable Gain Amplifiers

The comparators and programmable gain amplifiers use the following eight registers.

- Peripheral enable register 1 (PER1)
- Programmable gain amplifier control register (OAM)
- Comparator 0 and 1 control registers (C0CTL, C1CTL)
- Comparator 0 and 1 internal reference voltage setting registers (C0RVM, C1RVM)
- Port input mode register 8 (PIM8)
- Port mode register 8 (PM8)

(1) Peripheral enable register 1 (PER1)

This register is used to set whether each peripheral hardware macro can be used. Power consumption and noise are reduced by stopping the clock supply to unused hardware.

Make sure to set bit 3 (OACMPEN) to 1 to use a comparator or a programmable gain amplifier.

PER1 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Cautions 1. Make sure to set OACMPEN to 1 first, when setting the comparator or programmable gain amplifier. Writing to the control register of the comparator or programmable gain amplifier will be ignored and all values read will be initialized when OACMPEN is set to 0.

2. Make sure to set bits 0 to 2 and bits 4 to 7 of the PER1 register to "0".

Figure 8-2. Format of Peripheral Enable Register 1 (PER1)

1	Supplies input clock. • SFR used by the comparator and programmable gain amplifier can be read and written.

(2) Programmable gain amplifier control register (OAM)

This register is used to enable or disable the operation of a programmable gain amplifier and set the amplification factor.

OAM can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Figure 8-3. Format of Programmable Gain Amplifier Control Register (OAM)

0	1	0	×6
0	1	1	×8
1	0	0	×10
1	0	1	×12
Other than the above			Setting prohibited

Cautions 1. Set the amplification factor before enabling (OAEN = 1) the operation of the programmable gain amplifier. Changing the amplification factor setting in the operation enabled state (OAEN = 1) is prohibited.

2. Set the CnCTL register after setting OAM register.

Remark n = 0, 1

(3) Comparator n control register (CnCTL)

This register is used to control the operation of comparator n, enable or disable comparator output, reverse the output, and set the noise elimination width.

CnCTL can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

0	0	1	250 ns
0	1	0	500 ns
0	1	1	1 μs
1	0	0	2 μs
Other than the above			Setting prohibited

Note If OAEN = 1 (OAM register) and CnEN is set to 1, a programmable gain amplifier output signal will be input to the positive-side input of comparator n.

Cautions 1. Rewrite CnINV and CnDFS2 to CnDFS0 after setting the comparator output to the disabled state (CnOE = 0).

2. With the noise elimination width, an extra CPU clock (f_{CLK}) may be eliminated from the setting value.
(Example: When f_{CLK} = 20 MHz, CnDFS2 to CnDFS0 = 001, noise elimination width = 250 to 300 ns)

3. To operate the comparator in combination with a programmable gain amplifier, set the operation of the comparator after setting the operation of the programmable gain amplifier (see Figure 8-10 and Figure 8-11).

4. The negative-side external pin input of the comparator will be cutoff when CnVRE of the CnRVM register is set (1), regardless of the value that enables or disables the comparator operation (CnEN).

Remarks 1. f_{CLK}: CPU or peripheral hardware clock frequency

2. n = 0, 1

(4) Comparator n internal reference voltage selection register (CnRVM)

This register is used to set the internal reference voltage of comparator n. The internal reference voltage can be selected from six voltages that use AV_{REF}.

CnRVM can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

1	1	0	$12AV_{REF}/16$	$13AV_{REF}/16$
1	1	1	Setting prohibited	

Cautions 1. The operation of the comparator is controlled by CnEN when the operation of the internal reference voltage is stopped (CnVRE = 0).

2. The negative-side external pin input of the comparator will be cutoff when CnVRE is set (1), regardless of the value that enables or disables the comparator operation (CnEN).

3. Set the reference voltage before enabling the operation of the internal reference voltage (CnVRE = 1). Changing the reference voltage setting in the operation enabled state (CnVRE = 1) is prohibited.

Remark n = 0, 1

(5) Port input mode register 8 (PIM8)

This register is used to enable or disable port 8 digital input in 1-bit units.

Set to digital input disable (used as analog input) to use a comparator or a programmable gain amplifier. Set to digital input enable to use the port function or the external interrupt function, because digital input disable (used as analog input) is set by default.

PIM8 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

(6) Port mode register 8 (PM8)

This register is used to set port 8 input or output in 1-bit units.

Set the PM80 to PM83 bits to 1 to use the P80/CMP0P/INTP3/PGAI, P81/CMP0M, P82/CMP1P/INTP7, or P83/CMP1M pin as the positive-side or negative-side input function of the comparator, or the programmable gain amplifier input function.

The output latches of P80 to P83 may be 0 or 1 at this time.

PM80 to PM83 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation sets this register to FFH.

Caution The port function that is alternatively used as the CMP0M, CMP1M pin can be used in the input mode, when the CMP0P, CMP1P pin is selected as the positive-side input of the comparator, and the internal reference voltage is used on the negative side. Using the output mode, however, is prohibited. Furthermore accessing port register 8 (P8) is also prohibited.

8.4 Operations of Comparator and Programmable Gain Amplifier

8.4.1 Starting comparator and programmable gain amplifier operation

The procedures for starting the operation of a comparator and a programmable gain amplifier are described below, separately for each use method.

○ Using only a comparator
  • Using the external pin input for the comparator reference voltage (Figure 8-8)
  • Using the internal reference voltage for the comparator reference voltage (Figure 8-9)
○ Using a comparator and a programmable gain amplifier (using the programmable gain amplifier output voltage as the comparator compare voltage input)
  • Using the external pin input for the comparator reference voltage (Figure 8-10)
  • Using the internal reference voltage for the comparator reference voltage (Figure 8-11)
○ Using the programmable gain amplifier output voltage as the A/D converter analog input (Figure 8-12)

8.4.2 Stopping comparator and programmable gain amplifier operation

The procedures for stopping the operation of a comparator and a programmable gain amplifier are described below, separately for each use method.

- ○ Using only a comparator (Figure 8-13)
- ○ Using the programmable gain amplifier output voltage as the comparator compare voltage input (Figure 8-14)
- ○ Using the programmable gain amplifier output voltage as the A/D converter analog input (Figure 8-15)

CHAPTER 9 CLOCK OUTPUT/BUZZER OUTPUT CONTROLLER

The number of output pins of the clock output and buzzer output controllers differs, depending on the product. Furthermore, 44-pin products of the 78K0R/KC3-L are not provided with clock output and buzzer output controllers.

Output pin	KC3-L (44-pin)	KC3-L (48-pin)	KD3-L	KE3-L
PCLBUZ0	–	√	√	√
PCLBUZ1	–	–	–	√

9.1 Functions of Clock Output/Buzzer Output Controller

The clock output controller is intended for carrier output during remote controlled transmission and clock output for supply to peripheral ICs.

Buzzer output is a function to output a square wave of buzzer frequency.

One pin can be used to output a clock or buzzer sound.

Two output pins, PCLBUZ0 and PCLBUZ1, are available.

PCLBUZn outputs a clock selected by clock output select register n (CKSn).

Figure 9-1 shows the block diagram of clock output/buzzer output controller.

Remark n = 0: 78K0R/KC3-L (48-pin), 78K0R/KD3-L
n = 0, 1: 78K0R/KE3-L

Figure 9-1. Block Diagram of Clock Output/Buzzer Output Controller

- 78K0R/KC3-L (48-pin), 78K0R/KD3-L

Note The PCLBUZ0 and PCLBUZ1 pins can output a clock of up to 10 MHz at 2.7 V ≤ V_{DD}. Setting a clock exceeding 5 MHz at V_{DD} < 2.7 V is prohibited.

9.2 Configuration of Clock Output/Buzzer Output Controller

The clock output/buzzer output controller includes the following hardware.

Table 9-1. Configuration of Clock Output/Buzzer Output Controller

9.3 Registers Controlling Clock Output/Buzzer Output Controller

The following two registers are used to control the clock output/buzzer output controller.

- Clock output select registers n (CKSn)
- Port mode register 14 (PM14) (78K0R/KE3-L only)

(1) Clock output select registers n (CKSn)

These registers set output enable/disable for clock output or for the buzzer frequency output pin (PCLBUZn), and set the output clock.

Select the clock to be output from PCLBUZn by using CKSn.

CKSn are set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears these registers to 00H.

Note Use the output clock within a range of 10 MHz. Furthermore, when using the output clock at $V_{DD} < 2.7$ V, use it within 5 MHz.

Cautions 1. Change the output clock after disabling clock output (PCLOEn = 0).

2. If the selected clock (f_{MAIN} or f_{SUB}) stops during clock output (PCLOEn = 1), the output becomes undefined.

Remarks 1. n = 0: 78K0R/KC3-L (48-pin), 78K0R/KD3-L

3. f_{SUB}: Subsystem clock frequency

(2) Port mode register 14 (PM14) (78K0R/KE3-L only)

This register sets P141 input/output of port 14 in 1-bit units.

When using the P140/PCLBUZ0 and P141/PCLBUZ1 pins for clock output/buzzer output, clear PM141 and the output latches of P140 and P141 to 0.

PM14 is set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation sets this register to FFH.

9.4 Operations of Clock Output/Buzzer Output Controller

One pin can be used to output a clock or buzzer sound.

PCLBUZ0 outputs a clock/buzzer selected by clock output select register 0 (CKS0).

PCLBUZ1 outputs a clock/buzzer selected by clock output select register 1 (CKS1).

9.4.1 Operation as output pin

PCLBUZn is output as the following procedure.

<1> Select the output frequency with bits 0 to 3 (CCSn0 to CCSn2, CSELn) of the clock output select register (CKSn) of the PCLBUZn pin (output in disabled status).

<2> Set bit 7 (PCLOEn) of CKSn to 1 to enable clock/buzzer output.

Remarks 1. The controller is designed not to output a pulse with a narrow width when it is used to output a clock and when clock output is enabled or disabled. As shown in Figure 9-4, be sure to start output from the low period of the clock (marked with * in the figure). When stopping output, do so after the high-level period of the clock.

CHAPTER 10 WATCHDOG TIMER

10.1 Functions of Watchdog Timer

The watchdog timer operates on the internal low-speed oscillation clock.

The watchdog timer is used to detect an inadvertent program loop. If a program loop is detected, an internal reset signal is generated.

Program loop is detected in the following cases.

- If the watchdog timer counter overflows
- If a 1-bit manipulation instruction is executed on the watchdog timer enable register (WDTE)
- If data other than “ACH” is written to WDTE
- If data is written to WDTE during a window close period

When a reset occurs due to the watchdog timer, bit 4 (WDRF) of the reset control flag register (RESF) is set to 1. For details of RESF, see **CHAPTER 19 RESET FUNCTION**.

When 75% of the overflow time is reached, an interval interrupt can be generated.

10.2 Configuration of Watchdog Timer

The watchdog timer includes the following hardware.

Table 10-1. Configuration of Watchdog Timer

Item	Configuration
Control register	Watchdog timer enable register (WDTE)

How the counter operation is controlled, overflow time, window open period, and interval interrupt are set by the option byte.

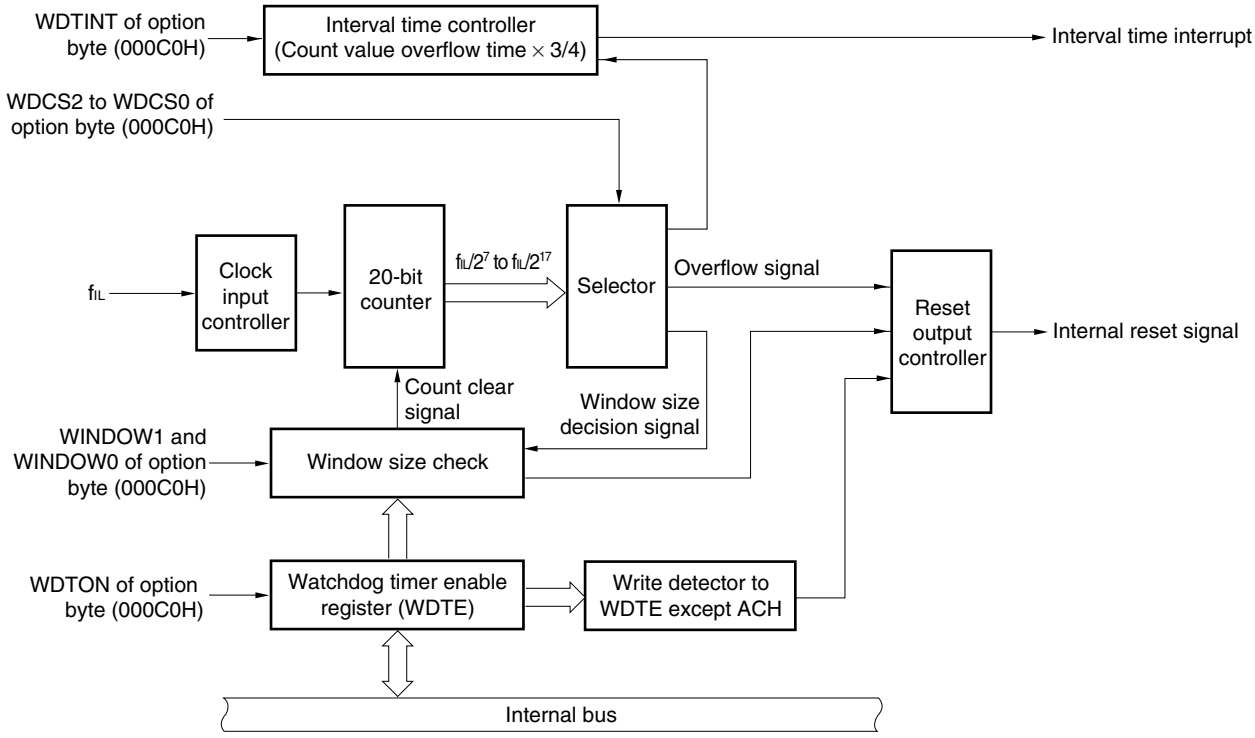
Remark For the option byte, see **CHAPTER 23 OPTION BYTE**.

Figure 10-1. Block Diagram of Watchdog Timer



10.3 Register Controlling Watchdog Timer

The watchdog timer is controlled by the watchdog timer enable register (WDTE).

(1) Watchdog timer enable register (WDTE)

Writing “ACH” to WDTE clears the watchdog timer counter and starts counting again.

This register can be set by an 8-bit memory manipulation instruction.

Reset signal generation sets this register to 9AH or 1AH[Note].

Figure 10-2. Format of Watchdog Timer Enable Register (WDTE)

Address: FFFABH After reset: 9AH/1AH[Note] R/W

Symbol	7	6	5	4	3	2	1	0
WDTE								

Note The WDTE reset value differs depending on the WDTON setting value of the option byte (000C0H). To operate watchdog timer, set WDTON to 1.

WDTON Setting Value	WDTE Reset Value
0 (watchdog timer count operation disabled)	1AH
1 (watchdog timer count operation enabled)	9AH

Cautions 1. If a value other than “ACH” is written to WDTE, an internal reset signal is generated.

2. If a 1-bit memory manipulation instruction is executed for WDTE, an internal reset signal is generated.

3. The value read from WDTE is 9AH/1AH (this differs from the written value (ACH)).

10.4 Operation of Watchdog Timer

10.4.1 Controlling operation of watchdog timer

1. When the watchdog timer is used, its operation is specified by the option byte (000C0H).

   - Enable counting operation of the watchdog timer by setting bit 4 (WDTON) of the option byte (000C0H) to 1 (the counter starts operating after a reset release) (for details, see **CHAPTER 23**).

WDTON	Watchdog Timer Counter
0	Counter operation disabled (counting stopped after reset)
1	Counter operation enabled (counting started after reset)

   - Set an overflow time by using bits 3 to 1 (WDCS2 to WDCS0) of the option byte (000C0H) (for details, see **10.4.2** and **CHAPTER 23**).
   - Set a window open period by using bits 6 and 5 (WINDOW1 and WINDOW0) of the option byte (000C0H) (for details, see **10.4.3** and **CHAPTER 23**).

2. After a reset release, the watchdog timer starts counting.
3. By writing “ACH” to WDTE after the watchdog timer starts counting and before the overflow time set by the option byte, the watchdog timer is cleared and starts counting again.
4. After that, write WDTE the second time or later after a reset release during the window open period. If WDTE is written during a window close period, an internal reset signal is generated.
5. If the overflow time expires without “ACH” written to WDTE, an internal reset signal is generated.
   An internal reset signal is generated in the following cases.

   - If a 1-bit manipulation instruction is executed on the watchdog timer enable register (WDTE)
   - If data other than “ACH” is written to WDTE

Cautions 1. When data is written to WDTE for the first time after reset release, the watchdog timer is cleared in any timing regardless of the window open time, as long as the register is written before the overflow time, and the watchdog timer starts counting again.

2. If the watchdog timer is cleared by writing “ACH” to WDTE, the actual overflow time may be different from the overflow time set by the option byte by up to 2/f_{IL} seconds.

3. The watchdog timer can be cleared immediately before the count value overflows.

Cautions 4. The operation of the watchdog timer in the HALT and STOP modes differs as follows depending on the set value of bit 0 (WDSTBYON) of the option byte (000C0H).

	WDSTBYON = 0	WDSTBYON = 1
In HALT mode	Watchdog timer operation stops.	Watchdog timer operation continues.
In STOP mode		

If WDSTBYON = 0, the watchdog timer resumes counting after the HALT or STOP mode is released. At this time, the counter is cleared to 0 and counting starts.
When operating with the X1 oscillation clock after releasing the STOP mode, the CPU starts operating after the oscillation stabilization time has elapsed.
Therefore, if the period between the STOP mode release and the watchdog timer overflow is short, an overflow occurs during the oscillation stabilization time, causing a reset.
Consequently, set the overflow time in consideration of the oscillation stabilization time when operating with the X1 oscillation clock and when the watchdog timer is to be cleared after the STOP mode release by an interval interrupt.

5. The watchdog timer continues its operation during self-programming of the flash memory and EEPROM™ emulation. During processing, the interrupt acknowledge time is delayed. Set the overflow time and window size taking this delay into consideration.

10.4.2 Setting overflow time of watchdog timer

Set the overflow time of the watchdog timer by using bits 3 to 1 (WDCS2 to WDCS0) of the option byte (000C0H).

If an overflow occurs, an internal reset signal is generated. The present count is cleared and the watchdog timer starts counting again by writing “ACH” to WDTE during the window open period before the overflow time.

The following overflow times can be set.

Table 10-3. Setting of Overflow Time of Watchdog Timer

WDCS2	WDCS1	WDCS0	Overflow Time of Watchdog Timer (f_{IL} = 33 kHz (MAX.))
0	0	0	$2^7/f_{IL}$ (3.88 ms)
0	0	1	$2^8/f_{IL}$ (7.76 ms)
0	1	0	$2^9/f_{IL}$ (15.52 ms)
0	1	1	$2^{10}/f_{IL}$ (31.03 ms)
1	0	0	$2^{12}/f_{IL}$ (124.12 ms)
1	0	1	$2^{14}/f_{IL}$ (496.48 ms)
1	1	0	$2^{15}/f_{IL}$ (992.97 ms)
1	1	1	$2^{17}/f_{IL}$ (3971.88 ms)

Caution The watchdog timer continues its operation during self-programming of the flash memory and EEPROM emulation. During processing, the interrupt acknowledge time is delayed. Set the overflow time and window size taking this delay into consideration.

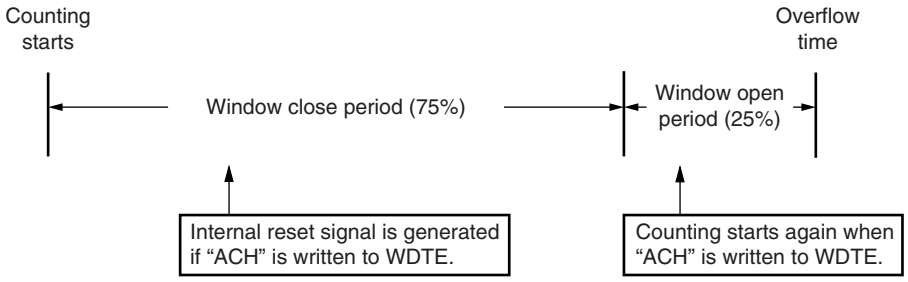
Remark f_{IL}: Internal low-speed oscillation clock frequency

10.4.3 Setting window open period of watchdog timer

Set the window open period of the watchdog timer by using bits 6 and 5 (WINDOW1, WINDOW0) of the option byte (000C0H). The outline of the window is as follows.

- If “ACH” is written to WDTE during the window open period, the watchdog timer is cleared and starts counting again.
- Even if “ACH” is written to WDTE during the window close period, an abnormality is detected and an internal reset signal is generated.

Example: If the window open period is 25%



Caution When data is written to WDTE for the first time after reset release, the watchdog timer is cleared in any timing regardless of the window open time, as long as the register is written before the overflow time, and the watchdog timer starts counting again.

The window open period can be set is as follows.

Table 10-4. Setting Window Open Period of Watchdog Timer

WINDOW1	WINDOW0	Window Open Period of Watchdog Timer
0	0	25%
0	1	50%
1	0	75%
1	1	100%

Cautions 1. The watchdog timer continues its operation during self-programming of the flash memory and EEPROM emulation. During processing, the interrupt acknowledge time is delayed. Set the overflow time and window size taking this delay into consideration.

2. When bit 0 (WDSTBYON) of the option byte (000C0H) = 0, the window open period is 100% regardless of the values of WINDOW1 and WINDOW0.

3. Do not set the window open period to 25% if the watchdog timer corresponds to either of the conditions below.

- **When stopping all main system clocks (internal high-speed oscillation clock, X1 clock, and external main system clock) by use of the STOP mode or software.**

Remark If the overflow time is set to $2^{10}/f_{IL}$, the window close time and open time are as follows.

	Setting of Window Open Period			
	25%	50%	75%	100%
Window close time	0 to 28.44 ms	0 to 18.96 ms	0 to 9.48 ms	None
Window open time	28.44 to 31.03 ms	18.96 to 31.03 ms	9.48 to 31.03 ms	0 to 31.03 ms

<When window open period is 25%>

- Overflow time:
  $2^{10}/f_{IL}$ (MAX.) = 2^{10}/33 kHz (MAX.) = 31.03 ms
- Window close time:
  0 to $2^{10}/f_{IL}$ (MIN.) × (1 − 0.25) = 0 to 2^{10}/27 kHz (MIN.) × 0.75 = 0 to 28.44 ms
- Window open time:
  $2^{10}/f_{IL}$ (MIN.) × (1 − 0.25) to $2^{10}/f_{IL}$ (MAX.) = 2^{10}/27 kHz (MIN.) × 0.75 to 2^{10}/33 kHz (MAX.) = 28.44 to 31.03 ms

10.4.4 Setting watchdog timer interval interrupt

Depending on the setting of bit 7 (WDTINT) of an option byte (000C0H), an interval interrupt (INTWDTI) can be generated when 75% of the overflow time is reached.

Table 10-5. Setting of Watchdog Timer Interval Interrupt

WDTINT	Use of Watchdog Timer Interval Interrupt
0	Interval interrupt is used.
1	Interval interrupt is generated when 75% of overflow time is reached.

Caution When operating with the X1 oscillation clock after releasing the STOP mode, the CPU starts operating after the oscillation stabilization time has elapsed.
Therefore, if the period between the STOP mode release and the watchdog timer overflow is short, an overflow occurs during the oscillation stabilization time, causing a reset.
Consequently, set the overflow time in consideration of the oscillation stabilization time when operating with the X1 oscillation clock and when the watchdog timer is to be cleared after the STOP mode release by an interval interrupt.

Remark The watchdog timer continues counting even after INTWDTI is generated (until ACH is written to the WDTE register). If ACH is not written to the WDTE register before the overflow time, an internal reset signal is generated.

The number of analog input channels of the A/D converter differs, depending on the product.

	78K0R/KC3-L (44-pin)	78K0R/KC3-L (48-pin)	78K0R/KD3-L	78K0R/KE3-L
Analog input channels	10 ch (ANI0 to ANI9)	11 ch (ANI0 to ANI10)	11 ch (ANI0 to ANI10)	12 ch (ANI0 to ANI11)

11.1 Function of A/D Converter

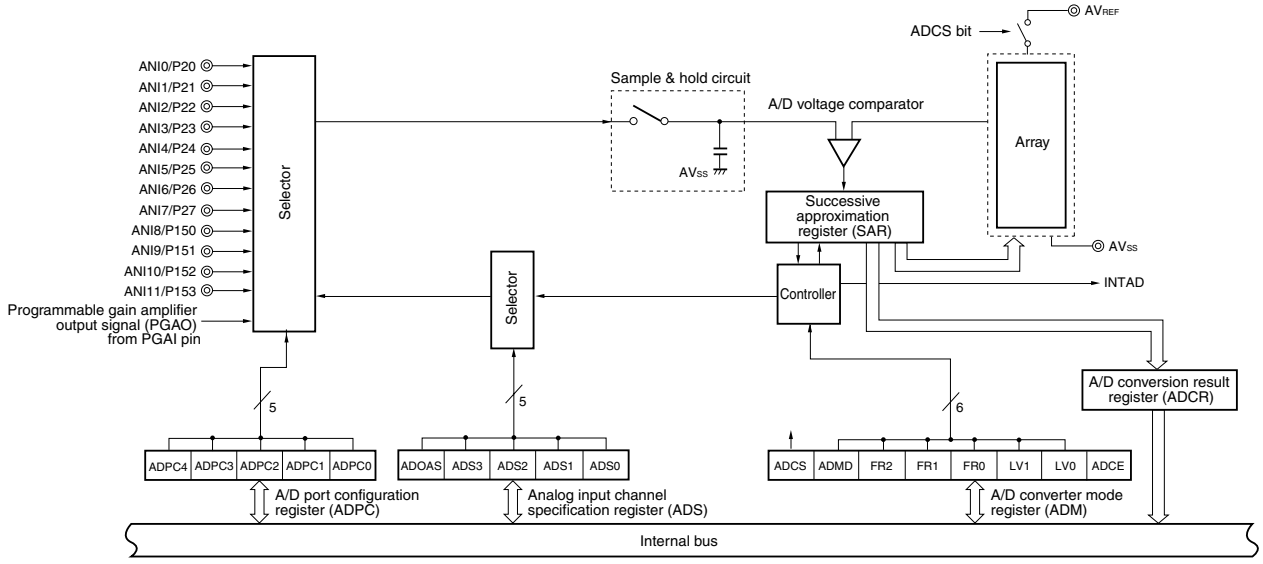
The A/D converter is a 10-bit resolution converter that converts analog input signals into digital values, and is configured to control a total of thirty channels of analog inputs, including up to twelve channels of A/D converter analog inputs (ANI0 to ANI11) and a programmable gain amplifier output (PGAO).

The A/D converter has the following function.

- **10-bit resolution A/D conversion**

  10-bit resolution A/D conversion is carried out repeatedly for one analog input channel selected from ANI0 to ANI11. Each time an A/D conversion operation ends, an interrupt request (INTAD) is generated.

Figure 11-1. Block Diagram of A/D Converter



Remark ANI0 to ANI9: 78K0R/KC3-L (44-pin)
ANI0 to ANI10: 78K0R/KC3-L (48-pin) and 78K0R/KD3-L
ANI0 to ANI11: 78K0R/KE3-L

11.2 Configuration of A/D Converter

The A/D converter includes the following hardware.

(1) ANI0 to ANI11 pins

These are the analog input pins of the twelve channels of the A/D converter. They input analog signals to be converted into digital signals. Pins other than the one selected as the analog input pin can be used as I/O port pins.

Remark ANI0 to ANI9: 78K0R/KC3-L (44-pin)
ANI0 to ANI10: 78K0R/KC3-L (48-pin) and 78K0R/KD3-L
ANI0 to ANI11: 78K0R/KE3-L

(2) PGAO

This is the programmable gain amplifier output signal from PGAI pin. The A/D converter can perform A/D conversion by selecting the output signal of the programmable gain amplifier as the analog input.

(3) Sample & hold circuit

The sample & hold circuit samples each of the analog input voltages sequentially sent from the input circuit, and sends them to the A/D voltage comparator. This circuit also holds the sampled analog input voltage during A/D conversion.

(4) A/D voltage comparator

This A/D voltage comparator compares the voltage generated from the voltage tap of the array with the analog input voltage. If the analog input voltage is found to be greater than the reference voltage (1/2 AV_{REF}) as a result of the comparison, the most significant bit (MSB) of the successive approximation register (SAR) is set. If the analog input voltage is less than the reference voltage (1/2 AV_{REF}), the MSB of the SAR is reset.
After that, bit 10 of the SAR register is automatically set, and the next comparison is made. The voltage tap of the array is selected by the value of bit 11, to which the result has been already set.

Bit 11 = 0: (1/4 AV_{REF})
Bit 11 = 1: (3/4 AV_{REF})

The voltage tap of the array and the analog input voltage are compared and bit 10 of the SAR register is manipulated according to the result of the comparison.

Analog input voltage ≥ Voltage tap of array: Bit 10 = 1
Analog input voltage ≤ Voltage tap of array: Bit 10 = 0

Comparison is continued like this to bit 0 of the SAR register.

(5) Array

The array generates the comparison voltage input from an analog input pin.

(6) Successive approximation register (SAR)

The SAR register is a 12-bit register that sets voltage tap data whose values from the array match the voltage values of the analog input pins, 1 bit at a time starting from the most significant bit (MSB).

If data is set in the SAR register all the way to the least significant bit (LSB) (end of A/D conversion), the contents of the SAR register (conversion results) are held in the A/D conversion result register (ADCR). When all the specified A/D conversion operations have ended, an A/D conversion end interrupt request signal (INTAD) is generated.

(7) 10-bit A/D conversion result register (ADCR)

The A/D conversion result is loaded from the successive approximation register to this register each time A/D conversion is completed, and the ADCR register holds the A/D conversion result in its higher 10 bits (the lower 6 bits are fixed to 0).

(8) 8-bit A/D conversion result register (ADCRH)

The A/D conversion result is loaded from the successive approximation register to this register each time A/D conversion is completed, and the ADCRH register stores the higher 8 bits of the A/D conversion result.

(9) Controller

This circuit controls the conversion time of an input analog signal that is to be converted into a digital signal, as well as starting and stopping of the conversion operation. When A/D conversion has been completed, this controller generates INTAD.

(10) AV_{REF} pin

This pin inputs the reference voltage of the A/D converter, the programmable gain amplifier, the power supply pins and A/D converter of the comparator, and the comparator. When all pins of ports 2, 15, and 8 are used as the analog port pins, make the potential of AV_{REF} be such that $1.8\ V \leq AV_{REF} \leq V_{DD}$. When one or more of the pins of ports 2, 15, and 8 are used as the digital port pins, make AV_{REF} the same potential as V_{DD}.

The analog signal input to ANI0 to ANI11 is converted into a digital signal, based on the voltage applied across AV_{REF} and AV_{SS}.

(11) AV_{SS} pin

This is the ground potential pin of the A/D converter. Always use this pin at the same potential as that of the V_{SS} pin even when the A/D converter is not used.

Remark ANI0 to ANI9: 78K0R/KC3-L (44-pin)
ANI0 to ANI10: 78K0R/KC3-L (48-pin) and 78K0R/KD3-L
ANI0 to ANI11: 78K0R/KE3-L

11.3 Registers Used in A/D Converter

The A/D converter uses the following seven registers.

- Peripheral enable register 0 (PER0)
- A/D converter mode register (ADM)
- A/D port configuration register (ADPC)
- Analog input channel specification register (ADS)
- Port mode registers 2, 15, 8 (PM2, PM15, PM8)
- 10-bit A/D conversion result register (ADCR)
- 8-bit A/D conversion result register (ADCRH)

(1) Peripheral enable register 0 (PER0)

PER0 is used to enable or disable use of each peripheral hardware macro. Clock supply to a hardware macro that is not used is stopped in order to reduce the power consumption and noise.

When the A/D converter is used, be sure to set bit 5 (ADCEN) of this register to 1.

PER0 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

0	Stops supply of input clock. • SFR used by the A/D converter cannot be written. • The A/D converter is in the reset status.
1	Supplies input clock. • SFR used by the A/D converter can be read/written.

Cautions 1. When setting the A/D converter, be sure to set ADCEN to 1 first. If ADCEN = 0, writing to a control register of the A/D converter is ignored, and, even if the register is read, only the default value is read.

2. Be sure to clear bits 0, 1, 3, and 6 (bits 0, 1, 3, 4, and 6 for 44-pin products of 78K0R/KC3-L) of the PER0 register, to 0.

(2) A/D converter mode register (ADM)

This register sets the conversion time for analog input to be A/D converted, and starts/stops conversion.

ADM can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

1	Enables A/D voltage comparator operation (A/D voltage comparator: 1/2AV_{REF} operation)

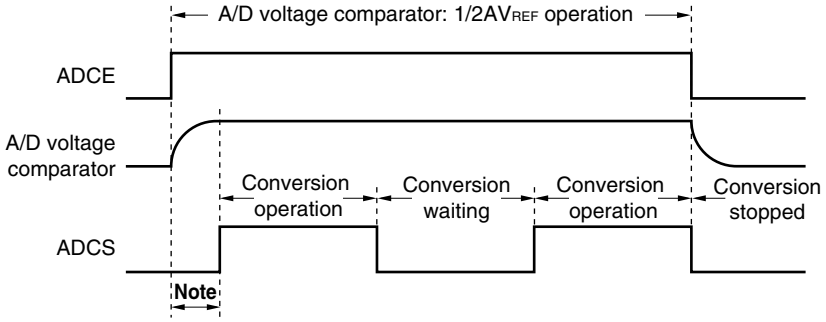
Notes 1. For details of FR2 to FR0, LV1, LV0, and A/D conversion, see **Table 11-2 A/D Conversion Time Selection**.

2. The operation of the A/D voltage comparator is controlled by ADCS and ADCE, and it takes 1 μs from operation start to operation stabilization. Therefore, when ADCS is set to 1 after 1 μs or more has elapsed from the time ADCE is set to 1, the conversion result at that time has priority over the first conversion result. Otherwise, ignore data of the first conversion.

Table 11-1. Settings of ADCS and ADCE

ADCS	ADCE	A/D Conversion Operation
0	0	Stop status (DC power consumption path does not exist)
0	1	Conversion waiting mode (A/D voltage comparator: 1/2AV_{REF} operation, only comparator consumes power)
1	0	Setting prohibited
1	1	Conversion mode (A/D voltage comparator: 1/2AV_{REF} operation)

Figure 11-4. Timing Chart When A/D Voltage Comparator Is Used



Note To stabilize the internal circuit, the time from the rising of the ADCE bit to the falling of the ADCS bit must be 1 μs or longer.

Caution A/D conversion must be stopped before rewriting bits FR0 to FR2, LV1, and LV0 to values other than the identical data.

(3) 10-bit A/D conversion result register (ADCR)

This register is a 16-bit register that stores the A/D conversion result in the select mode. The lower 6 bits are fixed to 0. Each time A/D conversion ends, the conversion result is loaded from the successive approximation register. The higher 8 bits of the conversion result are stored in FFF1FH and the lower 2 bits are stored in the higher 2 bits of FFF1EH.

ADCR can be read by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

Caution When writing to A/D converter mode register (ADM), analog input channel specification register (ADS), and A/D port configuration register (ADPC), the contents of ADCR may become undefined. Read the conversion result following conversion completion before writing to ADM, ADS, and ADPC. Using timing other than the above may cause an incorrect conversion result to be read.

(4) 8-bit A/D conversion result register (ADCRH)

This register is an 8-bit register that stores the A/D conversion result. The higher 8 bits of 10-bit resolution are stored.

ADCRH can be read by an 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

(5) Analog input channel specification register (ADS)

This register specifies the input channel of the analog voltage to be A/D converted.

ADS can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

(7) Port input mode register 8 (PIM8)

This register enables or disables the digital input of port 8 in 1-bit units.

Disable the digital input (used as analog input) to use the PGAI pin as the analog input. Enable the digital input to use the port function, or the external interrupt and timer Hi-Z control functions, because the digital input is disabled (used as analog input) in the initial state.

PIM8 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

(8) Port mode registers 2, 15, and 8 (PM2, PM15, PM8)

When using the ANI0/P20 to ANI7/P27, ANI8/P150 to ANI11/P153, and PGAI/P80 pins for analog input port, set PM20 to PM27, PM150 to PM153, and PM80 to 1. The output latches of P20 to P27, P150 to P153, and P80 at this time may be 0 or 1.

If PM20 to PM27, PM150 to PM153, and PM80 are set to 0, they cannot be used as analog input port pins.

PM2, PM15, and PM8 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation sets these registers to FFH.

Caution If a pin is set as an analog input port, not the pin level but "0" is always read.

11.4 A/D Converter Operations

11.4.1 Basic operations of A/D converter

<1> Set bit 5 (ADCEN) of peripheral enable register 0 (PER0) to 1 to start the supply of the input clock to the A/D converter.

<2> Set the A/D conversion time by using bits 5 to 1 (FR2 to FR0, LV1, and LV0) of ADM, and set the operation mode by using bit 6 (ADMD) of ADM.

<3> Set bit 0 (ADCE) of A/D converter mode register (ADM) to 1 to start the operation of the A/D voltage comparator.

<4> Set the channels for A/D conversion to analog input by using the A/D port configuration register (ADPC) and set to input mode by using port mode registers (PM2, PM15, and PM8).

<5> Set the programmable gain amplifier operation to set the programmable gain amplifier output (PGAI pin) for the analog input channel (refer to **8.4.1 Starting comparator and programmable gain amplifier operation**).

<6> Select one channel for A/D conversion using the analog input channel specification register (ADS).

<7> Start the conversion operation by setting bit 7 (ADCS) of ADM to 1.
(<8> to <14> are operations performed by hardware.)

<8> The voltage input to the selected analog input channel is sampled by the sample & hold circuit.

<9> When sampling has been done for a certain time, the sample & hold circuit is placed in the hold state and the sampled voltage is held until the A/D conversion operation has ended.

<10> Bit 9 of the successive approximation register (SAR) is set. The series resistor string voltage tap is set to (1/2) AV_{REF} by the tap selector.

<11> The voltage difference between the series resistor string voltage tap and sampled voltage is compared by the voltage comparator. If the analog input is greater than (1/2) AV_{REF}, the MSB of SAR remains set to 1. If the analog input is smaller than (1/2) AV_{REF}, the MSB is reset to 0.

<12> Next, bit 8 of SAR is automatically set to 1, and the operation proceeds to the next comparison. The series resistor string voltage tap is selected according to the preset value of bit 9, as described below.

- Bit 9 = 1: (3/4) AV_{REF}
- Bit 9 = 0: (1/4) AV_{REF}

The voltage tap and sampled voltage are compared and bit 8 of SAR is manipulated as follows.

- Sampled voltage ≥ Voltage tap: Bit 8 = 1
- Sampled voltage < Voltage tap: Bit 8 = 0

<13> Comparison is continued in this way up to bit 0 of SAR.

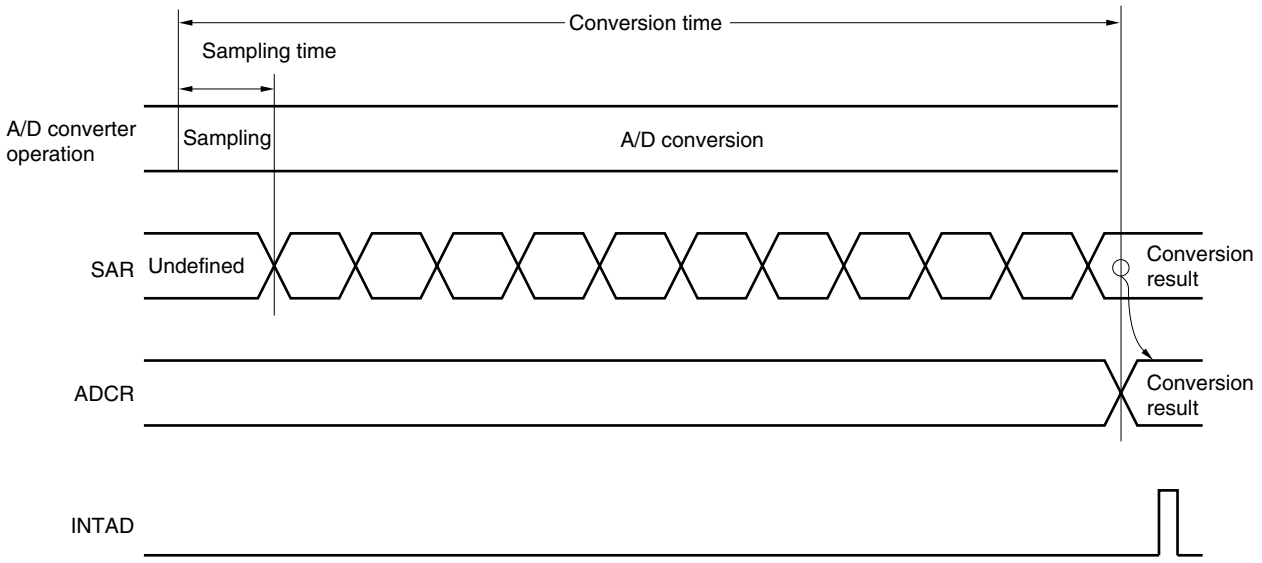
<14> Upon completion of the comparison of 10 bits, an effective digital result value remains in SAR, and the result value is transferred to the A/D conversion result register (ADCR, ADCRH) and then latched.
At the same time, the A/D conversion end interrupt request (INTAD) can also be generated.

<15> Repeat steps <8> to <14>, until ADCS is cleared to 0.
To stop the A/D converter, clear ADCS to 0.
To restart A/D conversion from the status of ADCE = 1, start from <7>. To start A/D conversion again when ADCE = 0, set ADCE to 1, wait for 1 μs or longer, and start <7>. To change a channel of A/D conversion, start from <6>.

Caution Make sure the period of <3> to <7> is 1 μs or more.

Remark Two types of A/D conversion result registers are available.
- ADCR (16 bits): Store 10-bit A/D conversion value
- ADCRH (8 bits): Store 8-bit A/D conversion value

Figure 11-12. Basic Operation of A/D Converter



A/D conversion operations are performed continuously until bit 7 (ADCS) of A/D converter mode register (ADM) is reset (0) by software.

If a write operation is performed to the analog input channel specification register (ADS) during an A/D conversion operation, the conversion operation is initialized, and if the ADCS bit is set (1), conversion starts again from the beginning.

Reset signal generation clears the A/D conversion result register (ADCR, ADCRH) to 0000H or 00H.

11.4.2 Input voltage and conversion results

The relationship between the analog input voltage input to the analog input pins (ANI0 to ANI11, PGAI) and the theoretical A/D conversion result (stored in the 10-bit A/D conversion result register (ADCR)) is shown by the following expression.

$$SAR = INT\left(\frac{V_{AIN}}{AV_{REF}} \times 1024 + 0.5\right)$$

$$ADCR = SAR \times 64$$

or

$$\left(\frac{ADCR}{64} - 0.5\right) \times \frac{AV_{REF}}{1024} \leq V_{AIN} < \left(\frac{ADCR}{64} + 0.5\right) \times \frac{AV_{REF}}{1024}$$

where, INT( ): Function which returns integer part of value in parentheses

V_{AIN}: Analog input voltage

AV_{REF}: AV_{REF} pin voltage

ADCR: A/D conversion result register (ADCR) value

SAR: Successive approximation register

Figure 11-13 shows the relationship between the analog input voltage and the A/D conversion result.

11.4.3 A/D converter operation modes

The select mode and scan mode are provided as the A/D converter operation modes.

(1) Select mode

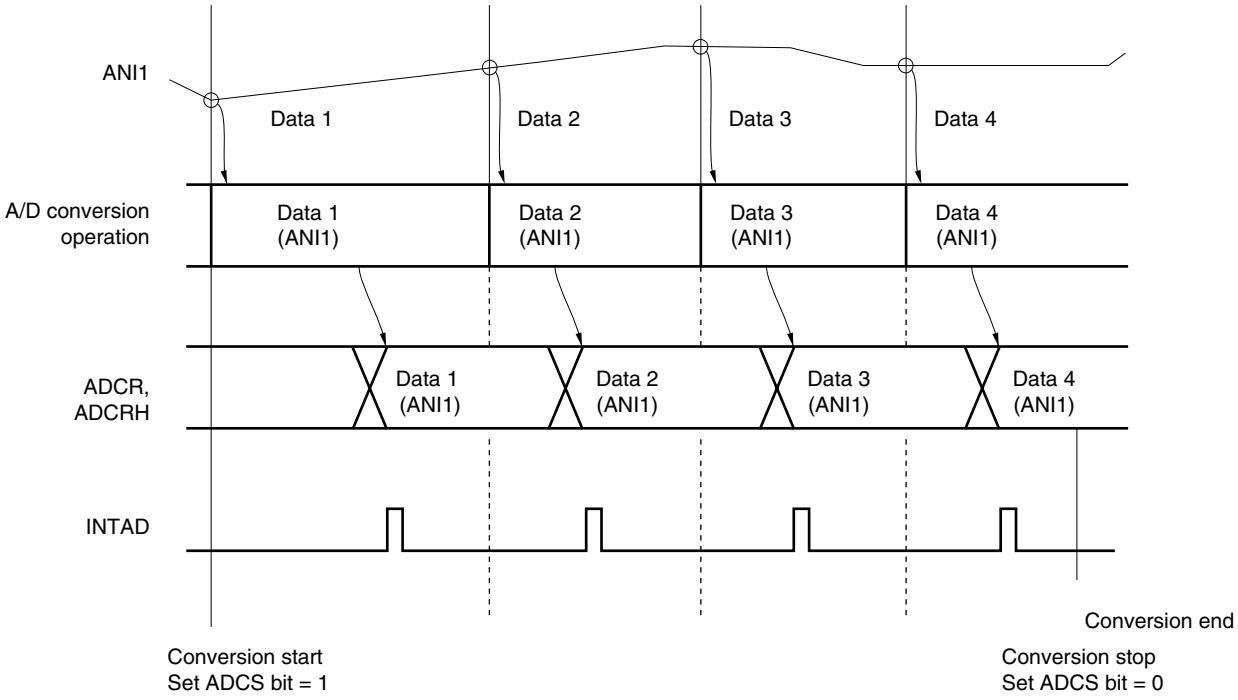
One analog input specified by the analog input channel specification register (ADS), while the ADMD bit of A/D converter mode register (ADM) is 0, is A/D converted.

When A/D conversion is complete, the conversion result is stored in the A/D conversion result register (ADCR) and the A/D conversion end interrupt request signal (INTAD) is generated.

After A/D conversion has been completed, A/D conversion is repeated successively, unless the ADCS bit is set to 0.

If anything is written to ADM or ADS during conversion, A/D conversion is aborted. In this case, A/D conversion is started again from the beginning.

Figure 11-14. Example of Select Mode Operation Timing



(2) Scan mode

The four analog input channels of scans 0 to 3, which are specified by the analog input channel specification register (ADS), while the ADMD bit of A/D converter mode register (ADM) is 1, are A/D converted successively. A/D conversion is performed in sequence, starting from the analog input channel specified by scan 0.

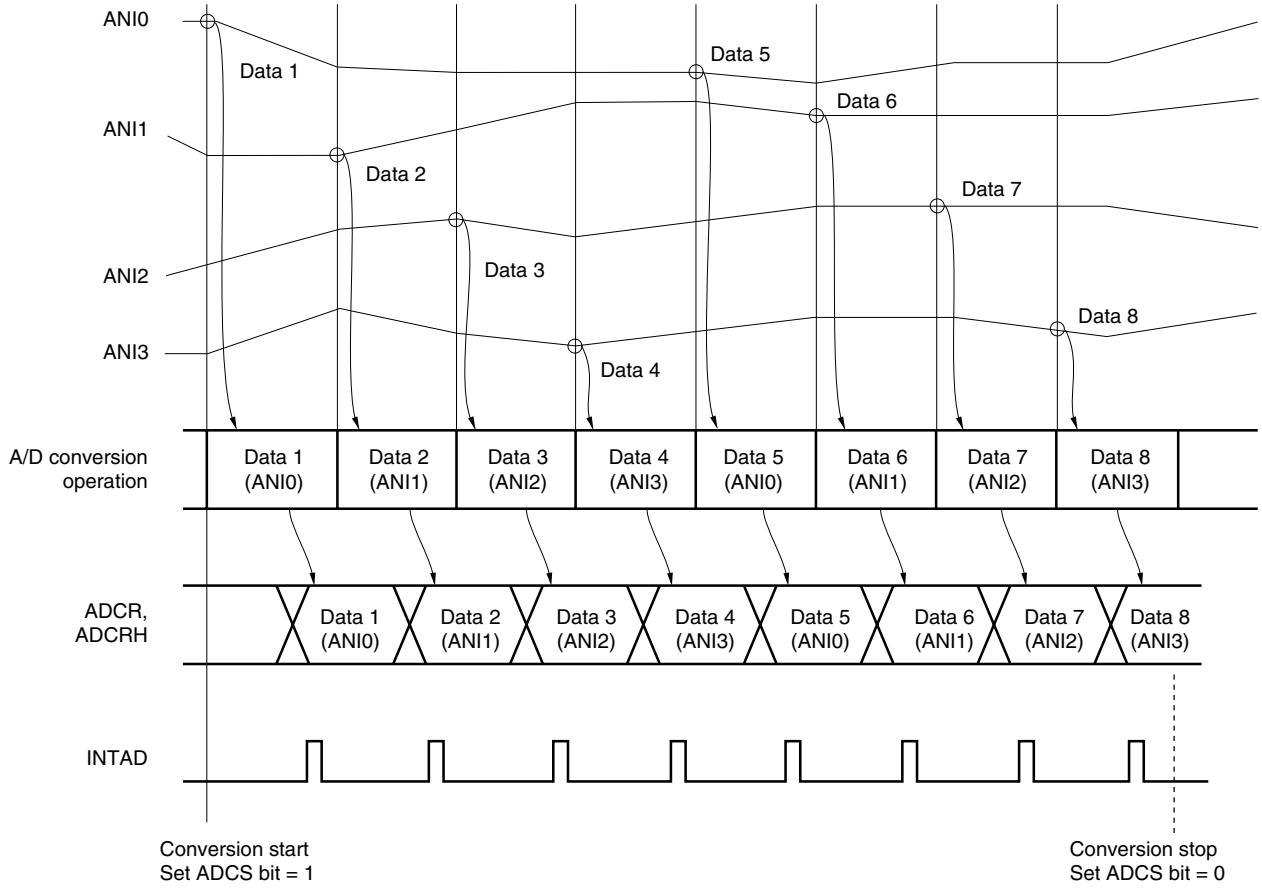
When A/D conversion of one analog input is complete, the conversion result is stored in the A/D conversion result register (ADCR) and the A/D conversion end interrupt request signal (INTAD) is generated.

The A/D conversion results of all the analog input channels are stored in ADCR. It is therefore recommended to save the contents of ADCR to RAM, once A/D conversion of one analog input channel has been completed.

After A/D conversion has been completed, A/D conversion is repeated successively, unless the ADCS bit is set to 0.

If anything is written to ADM or ADS during conversion, A/D conversion is aborted. In this case, A/D conversion is started again from the analog input channel of scan 0.

Figure 11-15. Example of Scan Mode Operation Timing



The setting methods are described below.

<1> Set bit 5 (ADCEN) of peripheral enable register 0 (PER0) to 1.
<2> Select the conversion time by using bits 5 to 1 (FR2 to FR0, LV1, and LV0) of ADM, and select the operation mode by using bit 6 (ADMD) of ADM.
<3> Set bit 0 (ADCE) of A/D converter mode register (ADM) to 1.
<4> Set the channel to be used in the analog input mode by using bits 4 to 0 (ADPC4 to ADPC0) of the A/D port configuration register (ADPC), bits 7 to 0 (PM27 to PM20) of port mode register 2 (PM2), bits 3 to 0 (PM153 to PM150) of port mode register 15 (PM15), and bit 0 (PM80) of port mode register 8 (PM8).
<5> Set the programmable gain amplifier operation to set the programmable gain amplifier output (PGAI pin) for the analog input channel (refer to **8.4.1 Starting comparator and programmable gain amplifier operation**).
<6> Select a channel to be used by using bits 6 and 3 to 0 (ADOAS, ADS3 to ADS0) of the analog input channel specification register (ADS).
<7> Set bit 7 (ADCS) of ADM to 1 to start A/D conversion.
<8> When one A/D conversion has been completed, an interrupt request signal (INTAD) is generated.
<9> Transfer the A/D conversion data to the A/D conversion result register (ADCR, ADCRH).

<Change the channel>

<10> Change the channel using bits 6 and 3 to 0 (ADOAS, ADS3 to ADS0) of ADS to start A/D conversion.
<11> When one A/D conversion has been completed, an interrupt request signal (INTAD) is generated.
<12> Transfer the A/D conversion data to the A/D conversion result register (ADCR, ADCRH).

<Complete A/D conversion>

<13> Clear ADCS to 0.
<14> Clear ADCE to 0.
<15> Clear bit 5 (ADCEN) of peripheral enable register 0 (PER0) to 0.

Cautions 1. Make sure the period of <3> to <7> is 1 μs or more.
2. <3> may be done between <4> and <6>.
3. <3> can be omitted. However, ignore data of the first conversion after <7> in this case.
4. The period from <8> to <11> differs from the conversion time set using bits 5 to 1 (FR2 to FR0, LV1, LV0) of ADM. The period from <10> to <11> is the conversion time set using FR2 to FR0, LV1, and LV0.

11.5 How to Read A/D Converter Characteristics Table

Here, special terms unique to the A/D converter are explained.

(1) Resolution

This is the minimum analog input voltage that can be identified. That is, the percentage of the analog input voltage per bit of digital output is called 1LSB (Least Significant Bit). The percentage of 1LSB with respect to the full scale is expressed by %FSR (Full Scale Range).

1LSB is as follows when the resolution is 10 bits.

$1LSB = 1/2^{10} = 1/1024$
$= 0.098\%FSR$

Accuracy has no relation to resolution, but is determined by overall error.

(2) Overall error

This shows the maximum error value between the actual measured value and the theoretical value.

Zero-scale error, full-scale error, integral linearity error, and differential linearity errors that are combinations of these express the overall error.

Note that the quantization error is not included in the overall error in the characteristics table.

(3) Quantization error

When analog values are converted to digital values, a ±1/2LSB error naturally occurs. In an A/D converter, an analog input voltage in a range of ±1/2LSB is converted to the same digital code, so a quantization error cannot be avoided.

Note that the quantization error is not included in the overall error, zero-scale error, full-scale error, integral linearity error, and differential linearity error in the characteristics table.

Figure 11-16. Overall Error

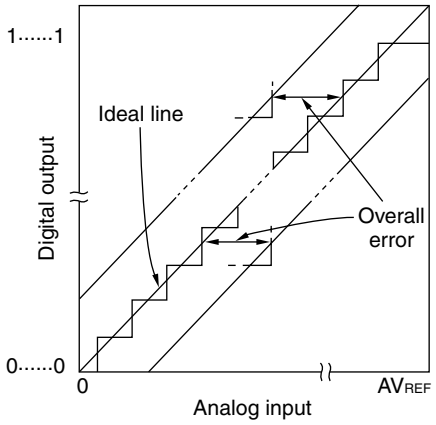


Figure 11-17. Quantization Error

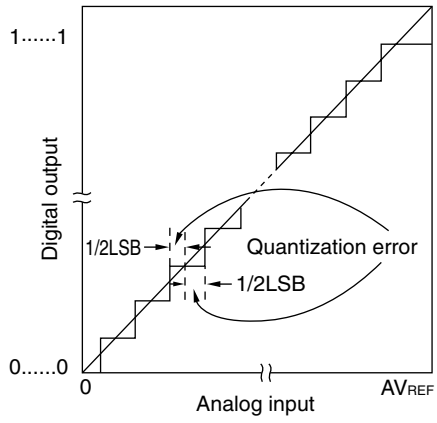

(4) Zero-scale error

This shows the difference between the actual measurement value of the analog input voltage and the theoretical value (1/2LSB) when the digital output changes from 0.....000 to 0.....001.

If the actual measurement value is greater than the theoretical value, it shows the difference between the actual measurement value of the analog input voltage and the theoretical value (3/2LSB) when the digital output changes from 0……001 to 0……010.

(5) Full-scale error

This shows the difference between the actual measurement value of the analog input voltage and the theoretical value (Full-scale − 3/2LSB) when the digital output changes from 1.....110 to 1.....111.

(6) Integral linearity error

This shows the degree to which the conversion characteristics deviate from the ideal linear relationship. It expresses the maximum value of the difference between the actual measurement value and the ideal straight line when the zero-scale error and full-scale error are 0.

(7) Differential linearity error

While the ideal width of code output is 1LSB, this indicates the difference between the actual measurement value and the ideal value.

Figure 11-18. Zero-Scale Error

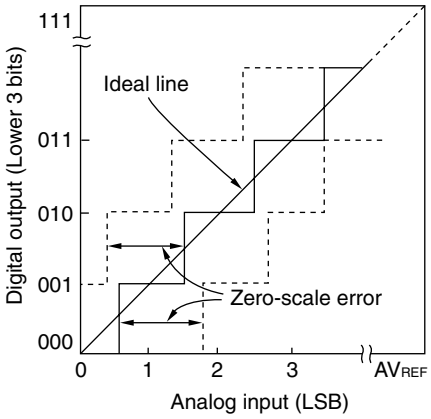

Figure 11-19. Full-Scale Error

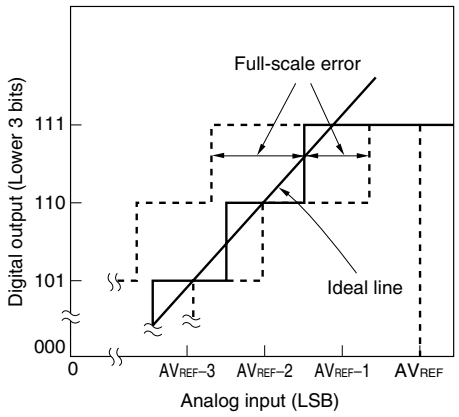

Figure 11-20. Integral Linearity Error

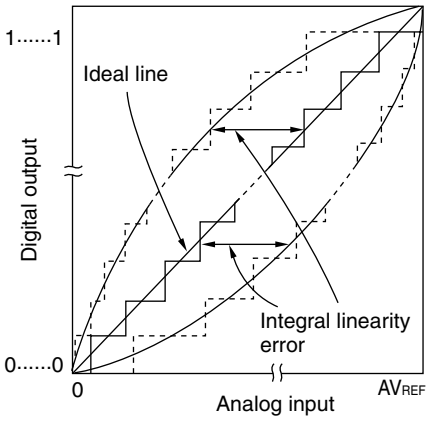

Figure 11-21. Differential Linearity Error

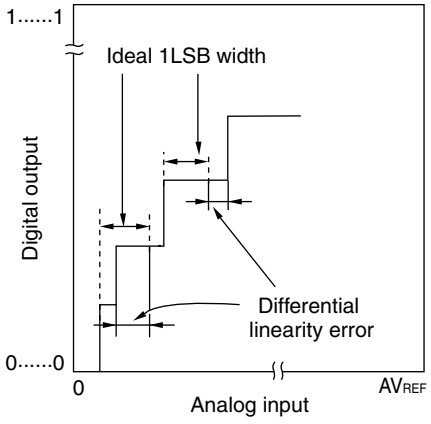


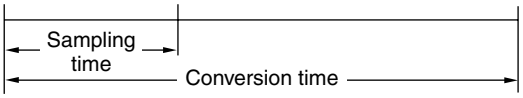
(8) Conversion time

This expresses the time from the start of sampling to when the digital output is obtained.

The sampling time is included in the conversion time in the characteristics table.

(9) Sampling time

This is the time the analog switch is turned on for the analog voltage to be sampled by the sample & hold circuit.



11.6 Cautions for A/D Converter

(1) Operating current in STOP mode

The A/D converter stops operating in the STOP mode. At this time, the operating current can be reduced by clearing bit 7 (ADCS) and bit 0 (ADCE) of A/D converter mode register (ADM) to 0.

To restart from the standby status, clear bit 0 (ADIF) of interrupt request flag register 1L (IF1L) to 0 and start operation.

(2) Input range of ANI0 to ANI11

Observe the rated range of the ANI0 to ANI11 input voltage. If a voltage of AV_{REF} or higher and AV_{SS} or lower (even in the range of absolute maximum ratings) is input to an analog input channel, the converted value of that channel becomes undefined. In addition, the converted values of the other channels may also be affected.

(3) Conflicting operations

<1> Conflict between A/D conversion result register (ADCR, ADCRH) write and ADCR or ADCRH read by instruction upon the end of conversion

ADCR or ADCRH read has priority. After the read operation, the new conversion result is written to ADCR or ADCRH.

<2> Conflict between ADCR or ADCRH write and A/D converter mode register (ADM) write, analog input channel specification register (ADS), or A/D port configuration register (ADPC) write upon the end of conversion

ADM, ADS, or ADPC write has priority. ADCR or ADCRH write is not performed, nor is the conversion end interrupt signal (INTAD) generated.

(4) Noise countermeasures

To maintain the 10-bit resolution, attention must be paid to noise input to the AV_{REF} pin and pins ANI0 to ANI11.

<1> Connect a capacitor with a low equivalent resistance and a good frequency response to the power supply.

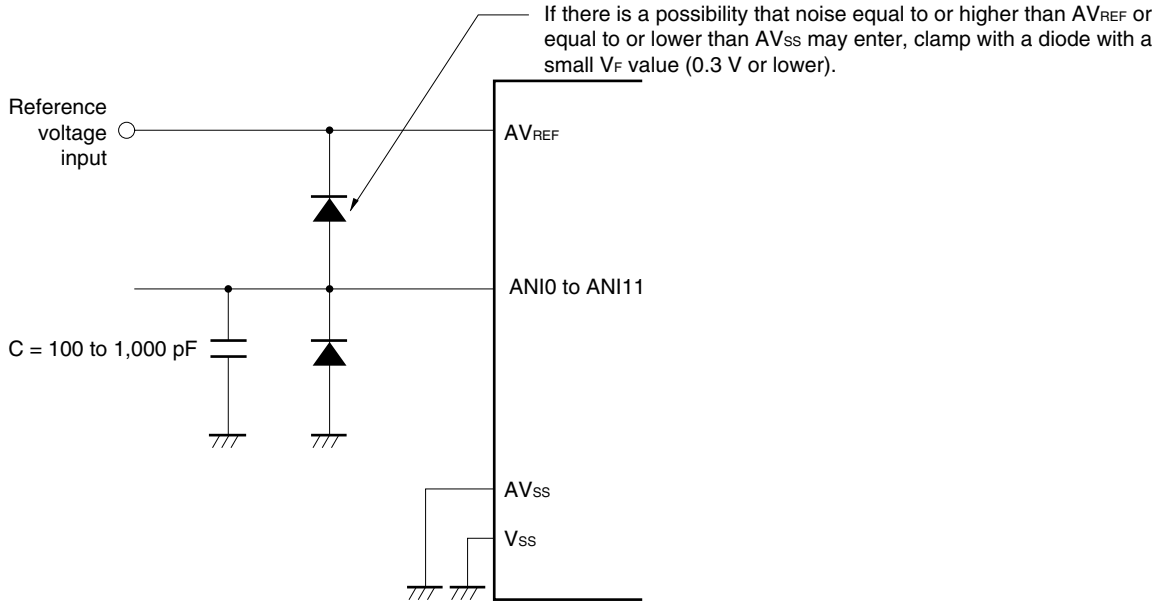
<2> The higher the output impedance of the analog input source, the greater the influence. To reduce the noise, connecting external C as shown in Figure 11-22 is recommended.

<3> Do not switch these pins with other pins during conversion.

<4> The accuracy is improved if the HALT mode is set immediately after the start of conversion.

Remark ANI0 to ANI9: 78K0R/KC3-L (44-pin)
ANI0 to ANI10: 78K0R/KC3-L (48-pin) and 78K0R/KD3-L
ANI0 to ANI11: 78K0R/KE3-L

Figure 11-22. Analog Input Pin Connection



(5) ANI0/P20 to ANI7/P27 and ANI8/P150 to ANI11/P153

<1> The analog input pins (ANI0 to AN11) are also used as input port pins (P20 to P27, P150 to P153). When A/D conversion is performed with any of ANI0 to ANI11 selected, do not access P20 to P27 and P150 to P153 while conversion is in progress; otherwise the conversion resolution may be degraded. It is recommended to select pins used as P20 to P27 and P150 to P153 starting with the ANI0/P20 that is the furthest from AV_{REF}.

<2> If a digital pulse is applied to the pins adjacent to the pins currently used for A/D conversion, the expected value of the A/D conversion may not be obtained due to coupling noise. Therefore, do not apply a pulse to the pins adjacent to the pin undergoing A/D conversion.

(6) Input impedance of ANI0 to ANI11 pins

This A/D converter charges a sampling capacitor for sampling during sampling time.

Therefore, only a leakage current flows when sampling is not in progress, and a current that charges the capacitor flows during sampling. Consequently, the input impedance fluctuates depending on whether sampling is in progress, and on the other states.

To make sure that sampling is effective, however, it is recommended to keep the output impedance of the analog input source to within 1 kΩ, and to connect a capacitor of about 100 pF to the ANI0 to ANI11 pins (see **Figure 11-22**).

(7) AV_{REF} pin input impedance

A series resistor string of several tens of kΩ is connected between the AV_{REF} and AV_{SS} pins.

Therefore, if the output impedance of the reference voltage source is high, this will result in a series connection to the series resistor string between the AV_{REF} and AV_{SS} pins, resulting in a large reference voltage error.

P20/ANI0 to P27/ANI9, P150/ANI8 to P153/ANI11: 78K0R/KE3-L

(8) Interrupt request flag (ADIF)

The interrupt request flag (ADIF) is not cleared even if the analog input channel specification register (ADS) is changed.

Therefore, if an analog input pin is changed during A/D conversion, the A/D conversion result and ADIF for the pre-change analog input may be set just before the ADS rewrite. Caution is therefore required since, at this time, when ADIF is read immediately after the ADS rewrite, ADIF is set despite the fact A/D conversion for the post-change analog input has not ended.

When A/D conversion is stopped and then resumed, clear ADIF before the A/D conversion operation is resumed.

78K0R/KC3-L (48-pin), 78K0R/KD3-L: m = 0 to 10
78K0R/KE3-L: m = 0 to 11

(9) Conversion results just after A/D conversion start

The first A/D conversion value immediately after A/D conversion starts may not fall within the rating range if the ADCS bit is set to 1 within 1 μs after the ADCE bit was set to 1, or if the ADCS bit is set to 1 with the ADCE bit = 0. Take measures such as polling the A/D conversion end interrupt request (INTAD) and removing the first conversion result.

(10) A/D conversion result register (ADCR, ADCRH) read operation

When a write operation is performed to A/D converter mode register (ADM), analog input channel specification register (ADS), and A/D port configuration register (ADPC), the contents of ADCR and ADCRH may become undefined. Read the conversion result following conversion completion before writing to ADM, ADS, or ADPC. Using a timing other than the above may cause an incorrect conversion result to be read.

(11) Internal equivalent circuit

The equivalent circuit of the analog input block is shown below.

CHAPTER 12 SERIAL ARRAY UNIT

The serial array unit has four serial channels per unit and can use two or more of various serial interfaces (3-wire serial (CSI), UART, and simplified I^2C) in combination.

Function assignment of each channel supported by the 78K0R/Kx3-L is as shown below.

Channel	Used as CSI	Used as UART	Used as Simplified I^2C
0	CSI00	UART0 (supporting LIN-bus)	–
1	CSI01		–
2	CSI10	UART1	IIC10
3	–		–

(Example of combination) When “UART0” is used for channels 0 and 1, CSI00 and CSI01 cannot be used, but CSI10, UART1, or IIC10 can be used.

12.1 Functions of Serial Array Unit

Each serial interface supported by the 78K0R/Kx3-L has the following features.

12.1.1 3-wire serial I/O (CSI00, CSI01, CSI10)

This is a clocked communication function that uses three lines: serial clock (SCK) and serial data (SI and SO) lines.

[Data transmission/reception]

- Data length of 7 or 8 bits
- Phase control of transmit/receive data
- MSB/LSB first selectable
- Level setting of transmit/receive data

[Clock control]

- Master/slave selection
- Phase control of I/O clock
- Setting of transfer period by prescaler and internal counter of each channel
- Maximum transfer rate

  During master communication: Max. $f_{CLK}/4$, during slave communication: Max. $f_{MCK}/6$ [Note]

[Interrupt function]

- Transfer end interrupt/buffer empty interrupt

[Error detection flag]

- Overrun error

Note Use the clocks within a range satisfying the $\overline{SCK}$ cycle time (t_{KCY}) characteristics (see **CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET)**).

12.1.2 UART (UART0, UART1)

This is a start-stop synchronization function using two lines: serial data transmission (TxD) and serial data reception (RxD) lines. It transmits or receives data in asynchronization with the party of communication (by using an internal baud rate). Full-duplex UART communication can be realized by using two channels, one dedicated to transmission (even channel) and the other to reception (odd channel).

[Data transmission/reception]

- Data length of 5, 7, or 8 bits
- Select the MSB/LSB first
- Level setting of transmit/receive data and select of reverse
- Parity bit appending and parity check functions
- Stop bit appending

[Interrupt function]

- Transfer end interrupt/buffer empty interrupt
- Error interrupt in case of framing error, parity error, or overrun error

[Error detection flag]

- Framing error, parity error, or overrun error

The LIN-bus is accepted in UART0 (0 and 1 channels)

[LIN-bus functions]

- Wakeup signal detection
- Sync break field (SBF) detection
- Sync field measurement, baud rate calculation

} External interrupt (INTP0) or timer array unit TAUS is used.

12.1.3 Simplified I^2C (IIC10)

This is a clocked communication function to communicate with two or more devices by using two lines: serial clock (SCL) and serial data (SDA). This simplified I^2C is designed for single communication with a device such as EEPROM, flash memory, or A/D converter, and therefore, it functions only as a master and does not have a function to detect wait states.

Make sure by using software, as well as operating the control registers, that the AC specifications of the start and stop conditions are observed.

[Data transmission/reception]

- Master transmission, master reception (only master function with a single master)
- ACK output function[Note] and ACK detection function
- Data length of 8 bits (When an address is transmitted, the address is specified by the higher 7 bits, and the least significant bit is used for R/W control.)
- Manual generation of start condition and stop condition

[Interrupt function]

- Transfer end interrupt

[Error detection flag]

- Parity error (ACK error)

* [Functions not supported by simplified I^2C]

- Slave transmission, slave reception
- Arbitration loss detection function
- Wait detection functions

Note When receiving the last data, ACK will not be output if 0 is written to the SOE02 (SOE0 register) bit and serial communication data output is stopped. See the processing flow in **12.7.3 (2)** for details.

Remark To use an I^2C bus of full function, see **CHAPTER 13 SERIAL INTERFACE IICA**.

12.2 Configuration of Serial Array Unit

The serial array unit includes the following hardware.

Table 12-1. Configuration of Serial Array Unit

Item	Configuration
Shift register	8 bits
Buffer register	Lower 8 bits of serial data register 0n (SDR0n)[Note]
Serial clock I/O	SCK00, SCK01, SCK10 pins (for 3-wire serial I/O), SCL10 pin (for simplified I^2C)
Serial data input	SI00, SI01, SI10 pins (for 3-wire serial I/O), RxD0 pin (for UART supporting LIN-bus), RxD1 pins (for UART)
Serial data output	SO00, SO01, SO10 pins (for 3-wire serial I/O), TxD0 pin (for UART supporting LIN-bus), TxD1 pin (for UART), output controller
Serial data I/O	SDA10 pin (for simplified I^2C)
Control registers	<Registers of unit setting block> • Peripheral enable register 0 (PER0) • Serial clock select register 0 (SPS0) • Serial channel enable status register 0 (SE0) • Serial channel start register 0 (SS0) • Serial channel stop register 0 (ST0) • Serial output enable register 0 (SOE0) • Serial output register 0 (SO0) • Serial output level register 0 (SOL0) • Input switch control register (ISC) • Noise filter enable register 0 (NFEN0)

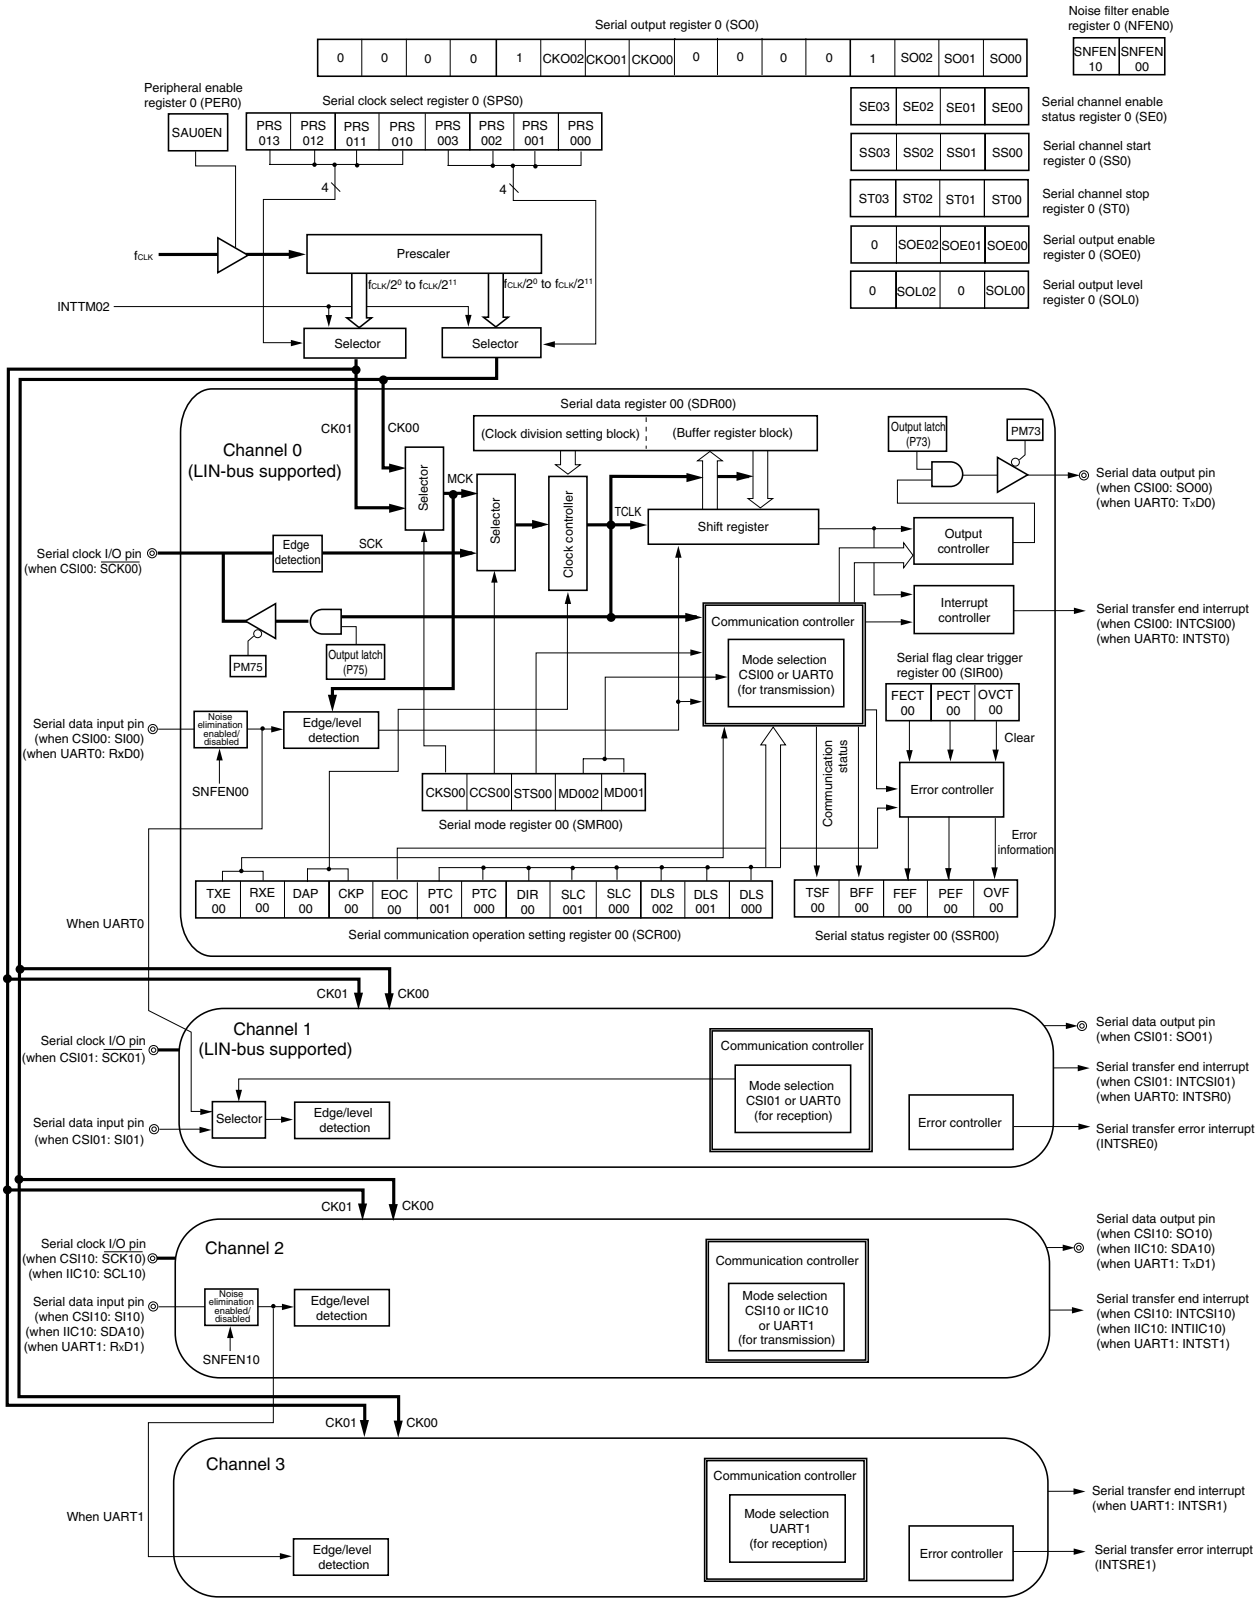
Note The lower 8 bits of the serial data register 0n (SDR0n) can be read or written as the following SFR, depending on the communication mode.

- CSIp communication … SIOp (CSIp data register)
- UARTq reception … RXDq (UARTq receive data register)
- UARTq transmission … TXDq (UARTq transmit data register)
- IIC10 communication … SIO10 (IIC10 data register)

Remark n: Channel number (n = 0 to 3),
p: CSI number (p = 00, 01, 10),
q: UART number (q = 0, 1)

Figure 12-1 shows the block diagram of the serial array unit.

Figure 12-1. Block Diagram of Serial Array Unit



(1) Shift register

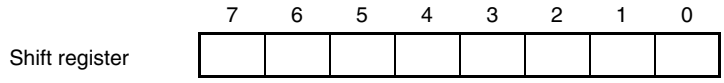
This is an 8-bit register that converts parallel data into serial data or vice versa.

During reception, it converts data input to the serial pin into parallel data.

When data is transmitted, the value set to this register is output as serial data from the serial output pin.

The shift register cannot be directly manipulated by program.

To read or write the shift register, use the lower 8 bits of serial data register 0n (SDR0n).



(2) Lower 8 bits of the serial data register 0n (SDR0n)

SDR0n is the transmit/receive data register (16 bits) of channel n. Bits 7 to 0 function as a transmit/receive buffer register, and bits 15 to 9 are used as a register that sets the division ratio of the operation clock (MCK).

When data is received, parallel data converted by the shift register is stored in the lower 8 bits. When data is to be transmitted, set transmit to be transferred to the shift register to the lower 8 bits.

The data stored in the lower 8 bits of this register is as follows, depending on the setting of bits 0 to 2 (DLS0n0 to DLS0n2) of the SCR0n register, regardless of the output sequence of the data.

- 5-bit data length (stored in bits 0 to 4 of SDR0n register) (settable in UART mode only)
- 7-bit data length (stored in bits 0 to 6 of SDR0n register)
- 8-bit data length (stored in bits 0 to 7 of SDR0n register)

SDR0n can be read or written in 16-bit units.

The lower 8 bits of SDR0n of SDR0n can be read or written[Note] as the following SFR, depending on the communication mode.

- CSIp communication … SIOp (CSIp data register)
- UARTq reception … RXDq (UARTq receive data register)
- UARTq transmission … TXDq (UARTq transmit data register)
- IIC10 communication … SIO10 (IIC10 data register)

Reset signal generation clears this register to 0000H.

Note Writing in 8-bit units is prohibited when the operation is stopped (SE0n = 0).

Remarks 1. After data is received, “0” is stored in bits 0 to 7 in bit portions that exceed the data length.

2. n: Channel number (n = 0 to 3),
p: CSI number (p = 00, 01, 10),
q: UART number (q = 0, 1)

12.3 Registers Controlling Serial Array Unit

Serial array unit is controlled by the following registers.

- Peripheral enable register 0 (PER0)
- Serial clock select register 0 (SPS0)
- Serial mode register 0n (SMR0n)
- Serial communication operation setting register 0n (SCR0n)
- Serial data register 0n (SDR0n)

Remark n: Channel number (n = 0 to 3)

(1) Peripheral enable register 0 (PER0)

PER0 is used to enable or disable use of each peripheral hardware macro. Clock supply to a hardware macro that is not used is stopped in order to reduce the power consumption and noise.

When serial array unit is used, be sure to set bit 2 (SAU0EN) of this register to 1.

PER0 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

SAU0EN	Control of serial array unit input clock supply
0	Stops supply of input clock. • SFR used by serial array unit cannot be written. • Serial array unit is in the reset status.
1	Supplies input clock. • SFR used by serial array unit can be read/written.

Cautions 1. When setting serial array unit, be sure to set SAU0EN to 1 first. If SAU0EN = 0, writing to a control register of serial array unit is ignored, and, even if the register is read, only the default value is read (except for input switch control register (ISC), noise filter enable register (NFEN0), port input mode registers (PIM3, PIM7), port output mode registers (POM3, POM7), port mode registers (PM3, PM7), and port registers (P3, P7)).

2. After setting the PER0 register to 1, be sure to set the SPS0 register after 4 or more clocks have elapsed.

3. Be sure to clear bits 0, 1, 3, and 6 (bits 0, 1, 3, 4, and 6 for 44-pin products of 78K0R/KC3-L) of PER0 register to 0.

(2) Serial clock select register 0 (SPS0)

SPS0 is a 16-bit register that is used to select two types of operation clocks (CK00, CK01) that are commonly supplied to each channel. CK01 is selected by bits 7 to 4 of SPS0, and CK00 is selected by bits 3 to 0.

Rewriting SPS0 is prohibited when the register is in operation (when SE0n = 1).

SPS0 can be set by a 16-bit memory manipulation instruction.

The lower 8 bits of SPS0 can be set with an 8-bit memory manipulation instruction with SPS0L.

Reset signal generation clears this register to 0000H.

Notes 1. When changing the clock selected for f_{CLK} (by changing the system clock control register (CKC) value), do so after having stopped (ST0 = 000FH) the operation of the serial array unit (SAU). When selecting INTTM02 for the operation clock, also stop the timer array unit TAUS (TT0 = 00FFH).

2. SAU can be operated at a fixed division ratio of the subsystem clock, regardless of the f_{CLK} frequency (main system clock, subsystem clock), by setting the TIS02 bit of the TIS0 register of TAUS to 1, selecting $f_{SUB}/4$ for the input clock, and selecting INTTM02 using the SPS0 register. When changing f_{CLK}, however, SAU and TAUS must be stopped as described in Note 1 above.

Cautions 1. Be sure to clear bits 15 to 8 to "0".

2. After setting the PER0 register to 1, be sure to set the SPS0 register after 4 or more clocks have elapsed.

Remarks 1. f_{CLK}: CPU/peripheral hardware clock frequency

2. p = 0, 1

(3) Serial mode register 0n (SMR0n)

SMR0n is a register that sets an operation mode of channel n. It is also used to select an operation clock (MCK), specify whether the serial clock (SCK) may be input or not, set a start trigger, an operation mode (CSI, UART, or I^2C), and an interrupt source. This register is also used to invert the level of the receive data only in the UART mode.

Rewriting SMR0n is prohibited when the register is in operation (when SE0n = 1). However, the MD0n0 bit can be rewritten during operation.

SMR0n can be set by a 16-bit memory manipulation instruction.

Reset signal generation sets this register to 0020H.

Transfer clock TCLK is used for the shift register, communication controller, output controller, interrupt controller, and error controller. When CCS0n = 0, the division ratio of MCK is set by the higher 7 bits of the SDR0n register.	

STS 0n	Selection of start trigger source
0	Only software trigger is valid (selected for CSI, UART transmission, and simplified I^2C).
1	Valid edge of RxD pin (selected for UART reception)
Transfer is started when the above source is satisfied after 1 is set to the SS0 register.	

Caution Be sure to clear bits 13 to 9, 7, 4, and 3 to "0". Be sure to set bit 5 to "1".

(4) Serial communication operation setting register 0n (SCR0n)

SCR0n is a communication operation setting register of channel n. It is used to set a data transmission/reception mode, phase of data and clock, whether an error signal is to be masked or not, parity bit, start bit, stop bit, and data length.

Rewriting SCR0n is prohibited when the register is in operation (when SE0n = 1).

SCR0n can be set by a 16-bit memory manipulation instruction.

Reset signal generation sets this register to 0087H.

Remark n: Channel number (n = 0 to 3)

(5) Higher 7 bits of the serial data register 0n (SDR0n)

SDR0n is the transmit/receive data register (16 bits) of channel n. Bits 7 to 0 function as a transmit/receive buffer register, and bits 15 to 9 are used as a register that sets the division ratio of the operation clock (MCK).

If the CCS0n bit of serial mode register 0n (SMR0n) is cleared to 0, the clock set by dividing the operating clock by the higher 7 bits of SDR0n is used as the transfer clock.

For the function of the lower 8 bits of SDR0n, see **12.2 Configuration of Serial Array Unit**.

SDR0n can be read or written in 16-bit units.

However, the higher 7 bits can be written or read only when the operation is stopped (SE0n = 0). During operation (SE0n = 1), a value is written only to the lower 8 bits of SDR0n. When SDR0n is read during operation, 0 is always read.

Reset signal generation clears this register to 0000H.

Cautions 1. Be sure to clear bit 8 to "0".

2. Setting SDR0n[15:9] = (0000000B, 0000001B) is prohibited when UART is used.

Remarks 1. For the function of the lower 8 bits of SDR0n, see **12.2 Configuration of Serial Array Unit**.

2. n: Channel number (n = 0 to 3)

(6) Serial status register 0n (SSR0n)

SSR0n is a register that indicates the communication status and error occurrence status of channel n. The errors indicated by this register are a framing error, parity error, and overrun error.

SSR0n can be read by a 16-bit memory manipulation instruction.

The lower 8 bits of SSR0n can be set with an 8-bit memory manipulation instruction with SSR0nL.

Reset signal generation clears this register to 0000H.

BFF0n	Buffer register status indication flag of channel n
0	Valid data is not stored in the SDR0n register.
1	Valid data is stored in the SDR0n register.
This is an updating flag. It is automatically cleared when transfer from the SDR0n register to the shift register is completed. During reception, it is automatically cleared when data has been read from the SDR0n register. This flag is cleared also when the ST0n/SS0n bit is set to 1. This flag is automatically set if transmit data is written to the SDR0n register when the TXE0n bit of the SCR0n register = 1 (transmission or reception mode in each communication mode). It is automatically set if receive data is stored in the SDR0n register when the RXE0n bit of the SCR0n register = 1 (transmission or reception mode in each communication mode). It is also set in case of a reception error. If data is written to the SDR0n register when BFF0n = 1, the transmit/receive data stored in the register is discarded and an overrun error (OVF0n = 1) is detected.

PEF 0n	Parity error detection flag of channel n
0	Error does not occur.
1	A parity error occurs during UART reception or ACK is not detected during I^2C transmission. <Parity error cause> • A parity error occurs if the parity of transmit data does not match the parity bit on completion of UART reception. • ACK is not detected if the ACK signal is not returned from the slave in the timing of ACK reception during I^2C transmission.
This is a cumulative flag and is not cleared until 1 is written to the PECT0n bit of the SIR0n register.	

OVF 0n	Overrun error detection flag of channel n
0	No error occurs.
1	An overrun error occurs. <Causes of overrun error> • Receive data stored in the SDR0n register is not read and transmit data is written or the next receive data is written. • Transmit data is not ready for slave transmission or reception in the CSI mode.
This is a cumulative flag and is not cleared until 1 is written to the OVCT0n bit of the SIR0n register.	

Remark n: Channel number (n = 0 to 3)

(7) Serial flag clear trigger register 0n (SIR0n)

SIR0n is a trigger register that is used to clear each error flag of channel n.

When each bit (FECT0n, PECT0n, OVCT0n) of this register is set to 1, the corresponding bit (FEF0n, PEF0n, OVF0n) of serial status register 0n is cleared to 0. Because SIR0n is a trigger register, it is cleared immediately when the corresponding bit of SSR0n is cleared.

SIR0n can be set by a 16-bit memory manipulation instruction.

The lower 8 bits of SIR0n can be set with an 8-bit memory manipulation instruction with SIR0nL.

Reset signal generation clears this register to 0000H.

Caution Be sure to clear bits 15 to 3 to "0".

Remarks 1. n: Channel number (n = 0 to 3)

2. When the SIR0n register is read, 0000H is always read.

(8) Serial channel enable status register 0 (SE0)

SE0 indicates whether data transmission/reception operation of each channel is enabled or stopped.

When 1 is written a bit of serial channel start register 0 (SS0), the corresponding bit of this register is set to 1.

When 1 is written a bit of serial channel stop register 0 (ST0), the corresponding bit is cleared to 0.

Channel n that is enabled to operate cannot rewrite by software the value of CKO0n of the serial output register 0 (SO0) to be described below, and a value reflected by a communication operation is output from the serial clock pin.

Channel n that stops operation can set the value of CKO0n of the SO0 register by software and output its value from the serial clock pin. In this way, any waveform, such as that of a start condition/stop condition, can be created by software.

SE0 can be read by a 16-bit memory manipulation instruction.

The lower 8 bits of SE0 can be set with an 1-bit or 8-bit memory manipulation instruction with SE0L.

Reset signal generation clears this register to 0000H.

Note Bits 6 and 5 (TSF0n, BFF0n) of the SSR0n register are cleared.

Remark n: Channel number (n = 0 to 3)

(9) Serial channel start register 0 (SS0)

SS0 is a trigger register that is used to enable starting communication/count by each channel.

When 1 is written a bit of this register (SS0n), the corresponding bit (SE0n) of serial channel enable status register 0 (SE0) is set to 1. Because SS0n is a trigger bit, it is cleared immediately when SE0n = 1.

SS0 can be set by a 16-bit memory manipulation instruction.

The lower 8 bits of SS0 can be set with an 1-bit or 8-bit memory manipulation instruction with SS0L.

Reset signal generation clears this register to 0000H.

Remarks 1. n: Channel number (n = 0 to 3)

2. When the SS0 register is read, 0000H is always read.

(10) Serial channel stop register 0 (ST0)

ST0 is a trigger register that is used to enable stopping communication/count by each channel.

When 1 is written a bit of this register (ST0n), the corresponding bit (SE0n) of serial channel enable status register 0 (SE0) is cleared to 0. Because ST0n is a trigger bit, it is cleared immediately when SE0n = 0.

ST0 can set written by a 16-bit memory manipulation instruction.

The lower 8 bits of ST0 can be set with an 1-bit or 8-bit memory manipulation instruction with ST0L.

Reset signal generation clears this register to 0000H.

Note Bits 6 and 5 (TSF0n, BFF0n) of the SSR0n register are cleared.

Caution Be sure to clear bits 15 to 4 to "0".

Remarks 1. n: Channel number (n = 0 to 3)

2. When the ST0 register is read, 0000H is always read.

(11) Serial output enable register 0 (SOE0)

SOE0 is a register that is used to enable or stop output of the serial communication operation of each channel. Channel n that enables serial output cannot rewrite by software the value of SO0n of the serial output register 0 (SO0) to be described below, and a value reflected by a communication operation is output from the serial data output pin.

For channel n, whose serial output is stopped, the SO0n value of the SO0 register can be set by software, and that value can be output from the serial data output pin. In this way, any waveform of the start condition and stop condition can be created by software.

SOE0 can be set by a 16-bit memory manipulation instruction.

The lower 8 bits of SOE0 can be set with an 1-bit or 8-bit memory manipulation instruction with SOE0L.

Reset signal generation clears this register to 0000H.

Remark n: Channel number (n = 0 to 2)

(12) Serial output register 0 (SO0)

SO0 is a buffer register for serial output of each channel.

The value of bit n of this register is output from the serial data output pin of channel n.

The value of bit (n + 8) of this register is output from the serial clock output pin of channel n.

SO0n of this register can be rewritten by software only when serial output is disabled (SOE0n = 0). When serial output is enabled (SOE0n = 1), rewriting by software is ignored, and the value of the register can be changed only by a serial communication operation.

CKO0n of this register can be rewritten by software only when the channel operation is stopped (SE0n = 0). While channel operation is enabled (SE0n = 1), rewriting by software is ignored, and the value of CKO0n can be changed only by a serial communication operation.

When using the P30/SO10/TxD1, P31/SI10/RxD1/SDA10/INTP1, P32/$\overline{\text{SCK10}}$/SCL10/INTP2, P70/KR0/SO01/INTP4, P72/KR2/$\overline{\text{SCK01}}$/INTP6, P73/KR3/SO00/TxD0, or P75/KR5/$\overline{\text{SCK00}}$ pin as a port function pin, set the corresponding CKO0n and SO0n bits to “1”.

SO0 can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0F0FH.

Caution Be sure to set bits 11 and 3 to “1”.
And be sure to clear bits 15 to 12 and 7 to 4 to “0”.

Remark n: Channel number (n = 0 to 2)

(13) Serial output level register 0 (SOL0)

SOL0 is a register that is used to set inversion of the data output level of each channel.

This register can be set only in the UART mode. Be sure to set 0000H in the CSI mode and simplifies I^2C mode.

Inverting channel n by using this register is reflected on pin output only when serial output is enabled (SOE0n = 1). When serial output is disabled (SOE0n = 0), the value of the SO0n bit is output as is.

Rewriting SOL0 is prohibited when the register is in operation (when SE0n = 1).

SOL0 can be set by a 16-bit memory manipulation instruction.

The lower 8 bits of SOL0 can be set with an 8-bit memory manipulation instruction with SOL0L.

Reset signal generation clears this register to 0000H.

Remark n: Channel number (n = 0, 2)

(14) Input switch control register (ISC)

ISC is used to realize a LIN-bus communication operation by UART0 in coordination with an external interrupt and the timer array unit TAUS.

When bit 0 is set to 1, the input signal of the serial data input (RxD0) pin is selected as an external interrupt (INTP0) that can be used to detect a wakeup signal.

When bit 1 is set to 1, the input signal of the serial data input (RxD0) pin is selected as a timer input, so that the pulse widths of a sync break field and a sync field can be measured by the timer.

ISC can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

1	Uses the input signal of the RxD0 pin as an external interrupt (to measure the pulse widths of the sync break field and sync field).

Caution Be sure to clear bits 7 to 3 to "0".

(15) Noise filter enable register 0 (NFEN0)

NFEN0 is used to set whether the noise filter can be used for the input signal from the serial data input pin to each channel.

Disable the noise filter of the pin used for CSI or simplified I^2C communication, by clearing the corresponding bit of this register to 0.

Enable the noise filter of the pin used for UART communication, by setting the corresponding bit of this register to 1.

When the noise filter is enabled, CPU/ peripheral hardware clock (f_{CLK}) is synchronized with 2-clock match detection.

NFEN0 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

(16) Port input mode registers 3, 7 (PIM3, PIM7)

These registers set the input buffer of ports 3 and 7 in 1-bit units.

PIM3 and PIM7 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears these registers to 00H.

(18) Port mode registers 3, 7 (PM3, PM7)

These registers set input/output of ports 3 and 7 in 1-bit units.

When using the P30/SO10/TxD1, P31/SI10/RxD1/SDA10/INTP1, P32/$\overline{\text{SCK10}}$/SCL10/INTP2, P70/KR0/SO01/INTP4, P72/KR2/$\overline{\text{SCK01}}$/INTP6, P73/KR3/SO00/TxD0, and P75/KR5/$\overline{\text{SCK00}}$ pins for serial data output or serial clock output, clear the PM30 to PM32, PM70, PM72, PM73, and PM75 bits to 0, and set the output latches of P30 to P32, P70, P72, P73, and P75 to 1.

When using the P31/SI10/RxD1/SDA10/INTP1, P32/$\overline{\text{SCK10}}$/SCL10/INTP2, P71/KR1/SI01/INTP5, P72/KR2/$\overline{\text{SCK01}}$/INTP6, P74/KR4/SI00/RxD0, and P75/KR5/$\overline{\text{SCK00}}$ pins for serial data input or serial clock input, set the PM31, PM32, PM71, PM72, PM74, and PM75 bits to 1. At this time, the output latches of P31, P32, P71, P72, P74, and P75 may be 0 or 1.

PM3 and PM7 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation sets these registers to FFH.

12.4 Operation stop mode

Each serial interface of serial array unit has the operation stop mode.

In this mode, serial communication cannot be executed, thus reducing the power consumption.

In addition, the P30/SO10/TxD1, P31/SI10/RxD1/SDA10/INTP1, P32/$\overline{\text{SCK10}}$/SCL10/INTP2, P70/KR0/SO01/INTP4, P71/KR1/SI01/INTP5, P72/KR2/$\overline{\text{SCK01}}$/INTP6, P73/KR3/SO00/TxD0, P74/KR4/SI00/RxD0, and P75/KR5/$\overline{\text{SCK00}}$ pins can be used as port function pins in this mode.

12.4.1 Stopping the operation by units

The stopping of the operation by units is set by using peripheral enable register 0 (PER0).

PER0 is used to enable or disable use of each peripheral hardware macro. Clock supply to a hardware macro that is not used is stopped in order to reduce the power consumption and noise.

To stop the operation of serial array unit, set bit 2 (SAU0EN) to 0.

Figure 12-21. Peripheral Enable Register 0 (PER0) Setting When Stopping the Operation by Units

(a) Peripheral enable register 0 (PER0)

0: Stops supply of input clock
1: Supplies input clock

Cautions 1. If SAU0EN = 0, writing to a control register of serial array unit is ignored, and, even if the register is read, only the default value is read (except for input switch control register (ISC), noise filter enable register (NFEN0), port input mode registers (PIM3, PIM7), port output mode registers (POM3, POM7), port mode registers (PM3, PM7), and port registers (P3, P7)).

2. Be sure to clear bits 6, 3, 1, and 0 to "0".

Remark ☐: Setting disabled (fixed by hardware)
×: Bits not used with serial array units (depending on the settings of other peripheral functions)
0/1: Set to 0 or 1 depending on the usage of the user

12.4.2 Stopping the operation by channels

The stopping of the operation by channels is set using each of the following registers.

Figure 12-22. Each Register Setting When Stopping the Operation by Channels (1/2)

(a) Serial Channel Enable Status Register 0 (SE0) … This register indicates whether data transmission/reception operation of each channel is enabled or stopped.

SE0

0: Operation stops

* The SE0 register is a read-only status register, whose operation is stopped by using the ST0 register.
With a channel whose operation is stopped, the value of CKO0n of the SO0 register can be set by software.

(b) Serial channel stop register 0 (ST0) … This register is a trigger register that is used to enable stopping communication/count by each channel.

1: Clears SE0n to 0 and stops the communication operation

* Because ST0n is a trigger bit, it is cleared immediately when SE0n = 0.

(c) Serial output enable register 0 (SOE0) … This register is a register that is used to enable or stop output of the serial communication operation of each channel.

SOE0

* When using pins corresponding to each channel as port function pins, set the corresponding CKO0n and SO0n bits to “1”.

Remark n: Channel number (n = 0 to 3)

□ : Setting disabled (fixed by hardware), 0/1: Set to 0 or 1 depending on the usage of the user

12.5 Operation of 3-Wire Serial I/O (CSI00, CSI01, CSI10) Communication

This is a clocked communication function that uses three lines: serial clock (SCK) and serial data (SI and SO) lines.

[Data transmission/reception]

- Data length of 7 or 8 bits
- Phase control of transmit/receive data
- MSB/LSB first selectable
- Level setting of transmit/receive data

[Clock control]

- Master/slave selection
- Phase control of I/O clock
- Setting of transfer period by prescaler and internal counter of each channel
- Maximum transfer rate

  During master communication: Max. $f_{CLK}/4$, during slave communication: Max. $f_{MCK}/6$ [Note]

[Interrupt function]

- Transfer end interrupt/buffer empty interrupt

[Error detection flag]

- Overrun error

Note Use the clocks within a range satisfying the $\overline{SCK}$ cycle time (t_{KCY}) characteristics (see **CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET)**).

The channels supporting 3-wire serial I/O (CSI00, CSI01, CSI10) are channels 0 to 2 of SAU.

Channel	Used as CSI	Used as UART	Used as Simplified I^2C
0	CSI00	UART0 (supporting LIN-bus)	–
1	CSI01		–
2	CSI10	UART1	IIC10
3	–		–

3-wire serial I/O (CSI00, CSI01, CIS10) performs the following six types of communication operations.

- Master transmission (See **12.5.1**.)
- Master reception (See **12.5.2**.)
- Master transmission/reception (See **12.5.3**.)
- Slave transmission (See **12.5.4**.)
- Slave reception (See **12.5.5**.)
- Slave transmission/reception (See **12.5.6**.)

12.5.1 Master transmission

Master transmission is that the 78K0R/Kx3-L outputs a transfer clock and transmits data to another device.

3-Wire Serial I/O	CSI00	CSI01	CSI10
Target channel	Channel 0 of SAU	Channel 1 of SAU	Channel 2 of SAU

	Transfer end interrupt (in single-transfer mode) or buffer empty interrupt (in continuous transfer mode) can be selected.		
Error detection flag	None		
Transfer data length	7 or 8 bits		
Transfer rate	Max. $f_{CLK}/4$ [MHz], Min. $f_{CLK}/(2 \times 2^{11} \times 128)$ [MHz] Note f_{CLK}: System clock frequency		
Data phase	Selectable by DAP0n bit • DAP0n = 0: Data output starts from the start of the operation of the serial clock. • DAP0n = 1: Data output starts half a clock before the start of the serial clock operation.		
Clock phase	Selectable by CKP0n bit • CKP0n = 0: Forward • CKP0n = 1: Reverse		
Data direction	MSB or LSB first		

Note Use this operation within a range that satisfies the conditions above and the AC characteristics in the electrical specifications (see **CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET)**).

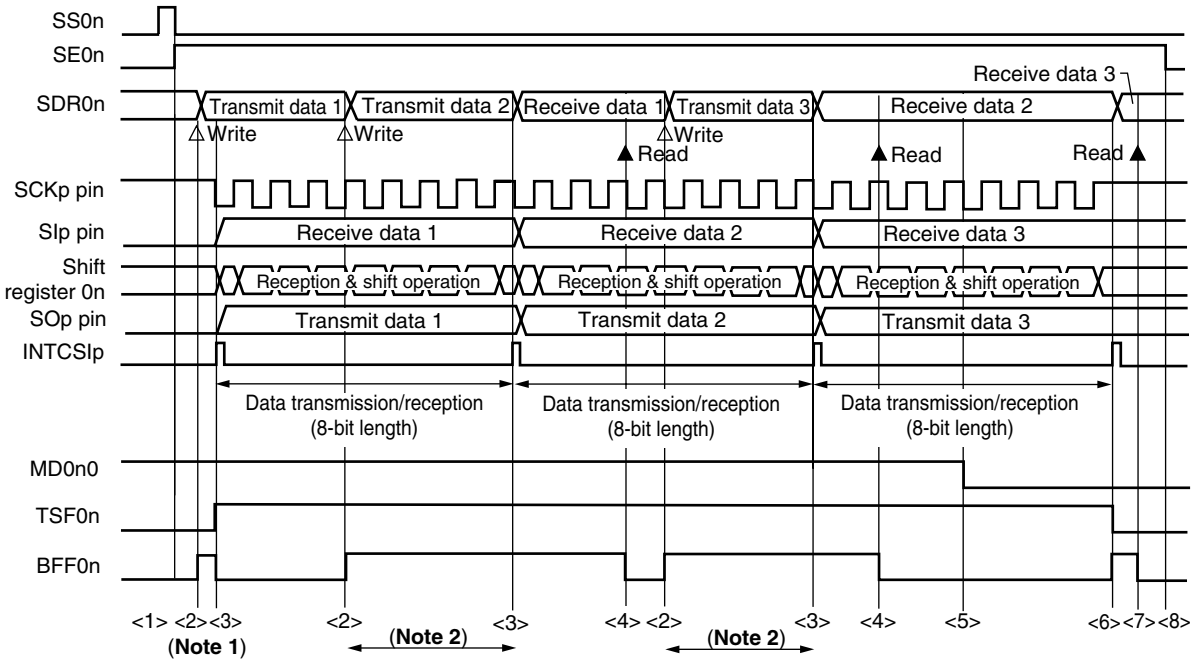
Figure 12-43. Timing Chart of Master Transmission/Reception (in Continuous Transmission/Reception Mode)



Notes 1. When transmit data is written to the SDR0n register while BFF0n = 1, the transmit data is overwritten.

2. The transmit data can be read by reading the SDR0n register during this period. At this time, the transfer operation is not affected.

Caution The MD0n0 bit can be rewritten even during operation.
However, rewrite it before transfer of the last bit is started, so that it has been rewritten before the transfer end interrupt of the last transmit data.

2. The transmit data can be read by reading the SDR0n register during this period. At this time, the transfer operation is not affected.

Caution The MD0n0 bit can be rewritten even during operation.
However, rewrite it before transfer of the last bit is started, so that it will be rewritten before the transfer end interrupt of the last transmit data.

12.5.7 Calculating transfer clock frequency

The transfer clock frequency for 3-wire serial I/O (CSI00, CSI01, CSI10) communication can be calculated by the following expressions.

(1) Master

(Transfer clock frequency) = {Operation clock (MCK) frequency of target channel} ÷ (SDR0n[15:9] + 1) ÷ 2 [Hz]

(2) Slave

(Transfer clock frequency) = {Frequency of serial clock (SCK) supplied by master}[Note] [Hz]

Note The permissible maximum frequency is the smaller of f_{CLK}/6 [MHz] and f_{MCK}/2 [MHz].

Remark The value of SDR0n[15:9] is the value of bits 15 to 9 of the SDR0n register (0000000B to 1111111B) and therefore is 0 to 127.

The operation clock (MCK) is determined by serial clock select register 0 (SPS0) and bit 15 (CKS0n) of serial mode register 0n (SMR0n).

Notes 1. When changing the clock selected for f_{CLK} (by changing the system clock control register (CKC) value), do so after having stopped (ST0 = 000FH) the operation of the serial array unit (SAU). When selecting INTTM02 for the operation clock, also stop the timer array unit TAUS (TT0 = 00FFH).

2. SAU can be operated at a fixed division ratio of the subsystem clock, regardless of the f_{CLK} frequency (main system clock, subsystem clock), by setting the TIS02 bit of the TIS0 register of TAUS to 1, selecting $f_{SUB}/4$ for the input clock, and selecting INTTM02 using the SPS0 register. When changing f_{CLK}, however, SAU and TAUS must be stopped as described in Note 1 above.

12.6 Operation of UART (UART0, UART1) Communication

This is a start-stop synchronization function using two lines: serial data transmission (TxD) and serial data reception (RxD) lines. It transmits or receives data in asynchronization with the party of communication (by using an internal baud rate). Full-duplex UART communication can be realized by using two channels, one dedicated to transmission (even channel) and the other to reception (odd channel).

[Data transmission/reception]

- Data length of 5, 7, or 8 bits
- Select the MSB/LSB first
- Level setting of transmit/receive data and select of reverse
- Parity bit appending and parity check functions
- Stop bit appending

[Interrupt function]

- Transfer end interrupt/buffer empty interrupt
- Error interrupt in case of framing error, parity error, or overrun error

[Error detection flag]

- Framing error, parity error, or overrun error

The LIN-bus is supported in UART0 (0, 1 channels of unit)

[LIN-bus functions]

- Wakeup signal detection
- Sync break field (SBF) detection
- Sync field measurement, baud rate calculation

} External interrupt (INTP0) or timer array unit TAUS is used.

UART0 uses channels 0 and 1 of SAU.
UART1 uses channels 2 and 3 of SAU.

Channel	Used as CSI	Used as UART	Used as Simplified I^2C
0	CSI00	UART0 (supporting LIN-bus)	–
1	CSI01		–
2	CSI10	UART1	IIC10
3	–		–

UART performs the following four types of communication operations.

- UART transmission (See **12.6.1**.)
- UART reception (See **12.6.2**.)
- LIN transmission (UART0 only) (See **12.6.3**.)
- LIN reception (UART0 only) (See **12.6.4**.)

12.6.1 UART transmission

UART transmission is an operation to transmit data from the 78K0R/Kx3-L to another device asynchronously (start-stop synchronization).

Of two channels used for UART, the even channel is used for UART transmission.

UART	UART0	UART1
Target channel	Channel 0 of SAU	Channel 2 of SAU

f_{CLK}: System clock frequency

LIN stands for Local Interconnect Network and is a low-speed (1 to 20 kbps) serial communication protocol designed to reduce the cost of an automobile network.

Communication of LIN is single-master communication and up to 15 slaves can be connected to one master.

The slaves are used to control switches, actuators, and sensors, which are connected to the master via LIN.

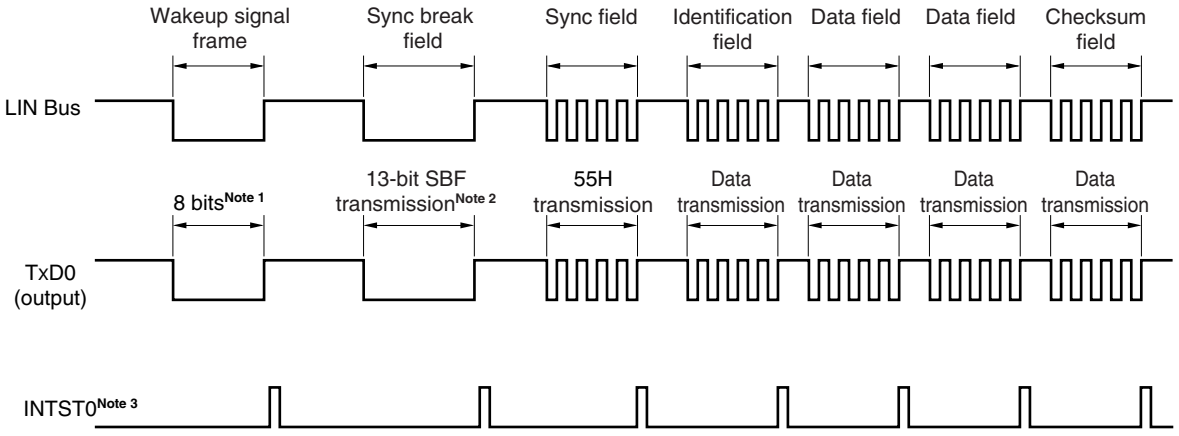
Usually, the master is connected to a network such as CAN (Controller Area Network).

A LIN bus is a single-wire bus to which nodes are connected via transceiver conforming to ISO9141.

According to the protocol of LIN, the master transmits a frame by attaching baud rate information to it. A slave receives this frame and corrects a baud rate error from the master. If the baud rate error of a slave is within ±15%, communication can be established.

Figure 12-81 outlines a transmission operation of LIN.

Figure 12-81. Transmission Operation of LIN



Notes 1. The baud rate is set so as to satisfy the standard of the wakeup signal and data of 00H is transmitted.

2. A sync break field is defined to have a width of 13 bits and output a low level. Where the baud rate for main transfer is N [bps], therefore, the baud rate of the sync break field is calculated as follows.

(Baud rate of sync break field) = 9/13 × N

By transmitting data of 00H at this baud rate, a sync break field is generated.

3. INTST0 is output upon completion of transmission. INTST0 is also output when SBF transmission is executed.

Remark The interval between fields is controlled by software.

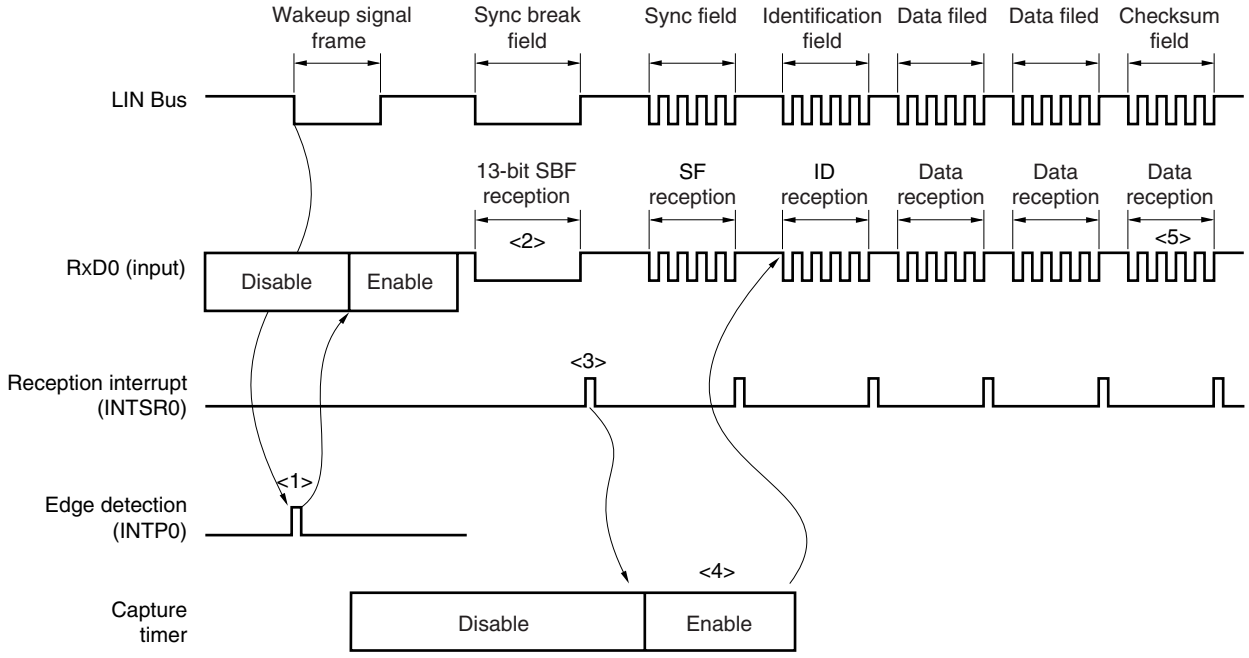
Remark f_{MCK}: Operation clock (MCK) frequency of target channel
f_{CLK}: System clock frequency

Figure 12-83 outlines a reception operation of LIN.

Figure 12-83. Reception Operation of LIN



Here is the flow of signal processing.

<1> The wakeup signal is detected by detecting an interrupt edge (INTP0) on a pin. When the wakeup signal is detected, enable reception of UART0 (RXE01 = 1) and wait for SBF reception.

<2> When the start bit of SBF is detected, reception is started and serial data is sequentially stored in the RXD0 register (= bits 7 to 0 of the serial data register 01 (SDR01)) at the set baud rate. When the stop bit is detected, the reception end interrupt request (INTSR0) is generated. When data of low levels of 11 bits or more is detected as SBF, it is judged that SBF reception has been correctly completed. If data of low levels of less than 11 bits is detected as SBF, it is judged that an SBF reception error has occurred, and the system returns to the SBF reception wait status.

<3> When SBF reception has been correctly completed, start channel 7 of the timer array unit TAUS and measure the bit interval (pulse width) of the sync field (see **6.7.5 Operation as input signal high-/low-level width measurement**).

<4> Calculate a baud rate error from the bit interval of sync field (SF). Stop UART0 once and adjust (re-set) the baud rate.

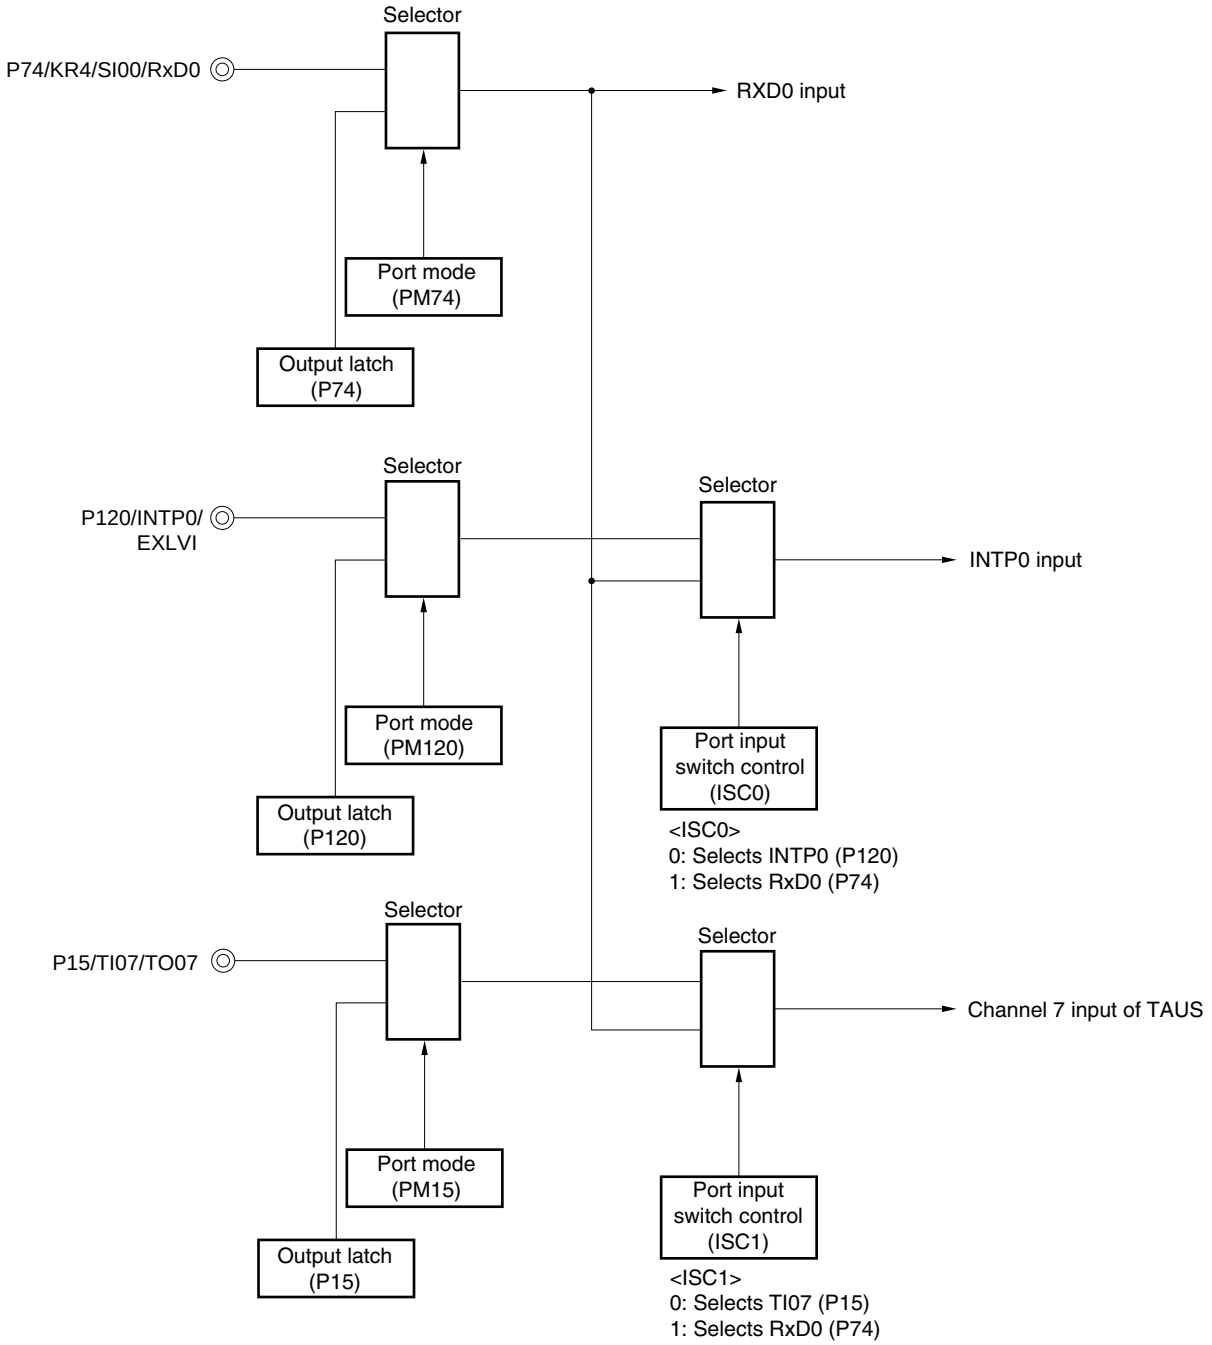
<5> The checksum field should be distinguished by software. In addition, processing to initialize UART0 after the checksum field is received and to wait for reception of SBF should also be performed by software.

Figure 12-84 shows the configuration of a port that manipulates reception of LIN.

The wakeup signal transmitted from the master of LIN is received by detecting an edge of an external interrupt (INTP0). The length of the sync field transmitted from the master can be measured by using the external event capture operation of the timer array unit TAUS to calculate a baud-rate error.

By controlling switch of port input (ISC0/ISC1), the input source of port input (RxD0) for reception can be input to the external interrupt pin (INTP0) and timer array unit TAUS.

Figure 12-84. Port Configuration for Manipulating Reception of LIN



Remark ISC0, ISC1: Bits 0 and 1 of the input switch control register (ISC) (See **Figure 12-16**.)

The peripheral functions used for the LIN communication operation are as follows.

<Peripheral functions used>

- External interrupt (INTP0); Wakeup signal detection
  Usage: To detect an edge of the wakeup signal and the start of communication
- Channel 7 of timer array unit TAUS; Baud rate error detection
  Usage: To detect the length of the sync field (SF) and divide it by the number of bits in order to detect an error (The interval of the edge input to RxD0 is measured in the capture mode.)
- Channels 0 and 1 (UART0) of serial array unit (SAU)

12.6.5 Calculating baud rate

(1) Baud rate calculation expression

The baud rate for UART (UART0, UART1) communication can be calculated by the following expressions.

(Baud rate) = {Operation clock (MCK) frequency of target channel} ÷ (SDR0n[15:9] + 1) ÷ 2 [bps]

Caution Setting SDR0n [15:9] = (0000000B, 0000001B) is prohibited.

Remarks 1. When UART is used, the value of SDR0n[15:9] is the value of bits 15 to 9 of the SDR0n register (0000010B to 1111111B) and therefore is 2 to 127.

2. n: Channel number (n = 0 to 3)

The operation clock (MCK) is determined by serial clock select register 0 (SPS0) and bit 15 (CKS0n) of serial mode register 0n (SMR0n).

Notes 1. When changing the clock selected for f_{CLK} (by changing the system clock control register (CKC) value), do so after having stopped (ST0 = 000FH) the operation of the serial array unit (SAU). When selecting INTTM02 for the operation clock, also stop the timer array unit TAUS (TT0 = 00FFH).

2. SAU can be operated at a fixed division ratio of the subsystem clock, regardless of the f_{CLK} frequency (main system clock, subsystem clock), by setting the TIS02 bit of the TIS0 register of TAUS to 1, selecting $f_{SUB}/4$ for the input clock, and selecting INTTM02 using the SPS0 register. When changing f_{CLK}, however, SAU and TAUS must be stopped as described in Note 1 above.

Remarks 1. X: Don't care

2. n: Channel number (n = 0 to 3)

(2) Baud rate error during transmission

The baud rate error of UART (UART0, UART1) communication during transmission can be calculated by the following expression. Make sure that the baud rate at the transmission side is within the permissible baud rate range at the reception side.

(Baud rate error) = (Calculated baud rate value) ÷ (Target baud rate) × 100 − 100 [%]

Here is an example of setting a UART baud rate at f_{CLK} = 20 MHz.

UART Baud Rate (Target Baud Rate)	f_{CLK} = 20 MHz			
	Operation Clock (MCK)	SDR0n[15:9]	Calculated Baud Rate	Error from Target Baud Rate
300 bps	$f_{CLK}/2^9$	64	300.48 bps	+0.16 %

312500 bps	f_{CLK}	31	312500 bps	±0.0 %

Remark n: Channel number (n = 0, 2)

(3) Permissible baud rate range for reception

The permissible baud rate range for reception during UART (UART0, UART1) communication can be calculated by the following expression. Make sure that the baud rate at the transmission side is within the permissible baud rate range at the reception side.

$$\text{(Maximum receivable baud rate)} = \frac{2 \times k \times Nfr}{2 \times k \times Nfr - k + 2} \times Brate$$

$$\text{(Minimum receivable baud rate)} = \frac{2 \times k \times (Nfr - 1)}{2 \times k \times Nfr - k - 2} \times Brate$$

Brate: Calculated baud rate value at the reception side (See **12.6.5 (1) Baud rate calculation expression**.)

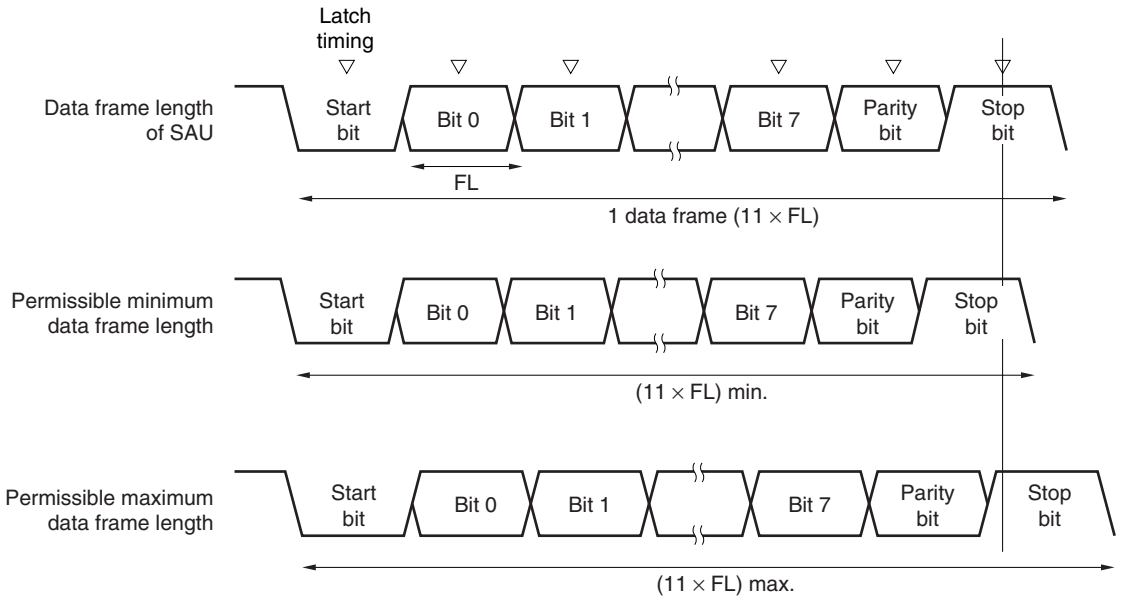
k: SDR0n[15:9] + 1

Nfr: 1 data frame length [bits]

= (Start bit) + (Data length) + (Parity bit) + (Stop bit)

Remark n: Channel number (n = 1, 3)

Figure 12-86. Permissible Baud Rate Range for Reception (1 Data Frame Length = 11 Bits)



As shown in Figure 12-86, the timing of latching receive data is determined by the division ratio set by bits 15 to 9 of the serial data register 0n (SDR0n) after the start bit is detected. If the last data (stop bit) is received before this latch timing, the data can be correctly received.

12.7 Operation of Simplified I²C (IIC10) Communication

This is a clocked communication function to communicate with two or more devices by using two lines: serial clock (SCL) and serial data (SDA). This communication function is designed to execute single communication with devices such as EEPROM, flash memory, and A/D converter, and therefore, can be used only by the master and does not have a wait detection function. Make sure by using software, as well as operating the control registers, that the AC specifications of the start and stop conditions are observed.

[Data transmission/reception]

- Master transmission, master reception (only master function with a single master)
- ACK output function[Note] and ACK detection function
- Data length of 8 bits
  (When an address is transmitted, the address is specified by the higher 7 bits, and the least significant bit is used for R/W control.)
- Manual generation of start condition and stop condition

[Interrupt function]

- Transfer end interrupt

[Error detection flag]

- Parity error (ACK error)

* [Functions not supported by simplified I²C]

- Slave transmission, slave reception
- Arbitration loss detection function
- Wait detection function

Note When receiving the last data, ACK will not be output if 0 is written to the SOE02 (SOE0 register) bit and serial communication data output is stopped. See the processing flow in **12.7.3 (2)** for details.

Remark To use an I²C bus of full function, see **CHAPTER 13 SERIAL INTERFACE IICA**.

The channel supporting simplified I²C (IIC10) is channel 2 of SAU.

Channel	Used as CSI	Used as UART	Used as Simplified I²C
0	CSI00	UART0 (supporting LIN-bus)	–
1	CSI01		–
2	CSI10	UART1	IIC10
3	–		–

Simplified I²C (IIC10) performs the following four types of communication operations.

- Address field transmission (See **12.7.1**.)
- Data transmission (See **12.7.2**.)
- Data reception (See **12.7.3**.)
- Stop condition generation (See **12.7.4**.)

12.7.1 Address field transmission

Address field transmission is a transmission operation that first executes in I^2C communication to identify the target for transfer (slave). After a start condition is generated, an address (7 bits) and a transfer direction (1 bit) are transmitted in one frame.

Transfer data length	8 bits (transmitted with specifying the higher 7 bits as address and the least significant bit as R/W control)
Transfer rate	Max. f_{CLK}/4 MHz f_{CLK}: System clock frequency However, the following condition must be satisfied in each mode of I^2C. • Max. 400 kHz (first mode) • Max. 100 kHz (standard mode)
Data level	Forward output (default: high level)
Parity bit	No parity bit
Stop bit	Appending 1 bit (for ACK reception timing)
Data direction	MSB first

12.7.5 Calculating transfer rate

The transfer rate for simplified I^2C (IIC10) communication can be calculated by the following expressions.

(Transfer rate) = {Operation clock (MCK) frequency of target channel} ÷ (SDR02[15:9] + 1) ÷ 2

Remark The value of SDR02[15:9] is the value of bits 15 to 9 of the SDR02 register (0000000B to 1111111B) and therefore is 0 to 127.

The operation clock (MCK) is determined by serial clock select register 0 (SPS0) and bit 15 (CKS02) of serial mode register 02 (SMR02).

Notes 1. When changing the clock selected for f_{CLK} (by changing the system clock control register (CKC) value), do so after having stopped (ST0 = 000FH) the operation of the serial array unit (SAU). When selecting INTTM02 for the operation clock, also stop the timer array unit TAUS (TT0 = 00FFH).

2. SAU can be operated at a fixed division ratio of the subsystem clock, regardless of the f_{CLK} frequency (main system clock, subsystem clock), by setting the TIS02 bit of the TIS0 register of TAUS to 1, selecting $f_{SUB}/4$ for the input clock, and selecting INTTM02 using the SPS0 register. When changing f_{CLK}, however, SAU and TAUS must be stopped as described in Note 1 above.

Remark X: Don't care

Here is an example of setting an IIC transfer rate where MCK = f_{CLK} = 20 MHz.

IIC Transfer Mode (Desired Transfer Rate)	f_{CLK} = 20 MHz			
	Operation Clock (MCK)	SDR02[15:9]	Calculated Transfer Rate	Error from Desired Transfer Rate
100 kHz	f_{CLK}	99	100 kHz	0.0%
400 kHz	f_{CLK}	24	400 kHz	0.0%

12.8 Processing Procedure in Case of Error

The processing procedure to be followed if an error of each type occurs is described in Figures 12-99 to 12-101.

Figure 12-99. Processing Procedure in Case of Parity Error or Overrun Error

Software Manipulation	Hardware Status	Remark
Reads SDR0n register. →	▶ BFF = 0, and channel n is enabled to receive data.	This is to prevent an overrun error if the next reception is completed during error processing.
Reads SSR0n register.		Error type is identified and the read value is used to clear error flag.
Writes SIR0n register. →	▶ Error flag is cleared.	Error can be cleared only during reading, by writing the value read from the SSR0n register to the SIR0n register without modification.

CHAPTER 13 SERIAL INTERFACE IICA

Remark 44-pin products of the 78K0R/KC3-L are not provided with serial interface IICA.

13.1 Functions of Serial Interface IICA

Serial interface IICA has the following three modes.

(1) Operation stop mode

This mode is used when serial transfers are not performed. It can therefore be used to reduce power consumption.

(2) I^2C bus mode (multimaster supported)

This mode is used for 8-bit data transfers with several devices via two lines: a serial clock (SCL0) line and a serial data bus (SDA0) line.

This mode complies with the I^2C bus format and the master device can generated “start condition”, “address”, “transfer direction specification”, “data”, and “stop condition” data to the slave device, via the serial data bus. The slave device automatically detects these received status and data by hardware. This function can simplify the part of application program that controls the I^2C bus.

Since the SCL0 and SDA0 pins are used for open drain outputs, IICA requires pull-up resistors for the serial clock line and the serial data bus line.

(3) Wakeup mode

The STOP mode can be released by generating an interrupt request signal (INTIICA) when an extension code from the master device or a local address has been received while in STOP mode. This can be set by using the WUP bit of IICA control register 1 (IICCTL1).

Figure 13-1 shows a block diagram of serial interface IICA.

Figure 13-1. Block Diagram of Serial Interface IICA

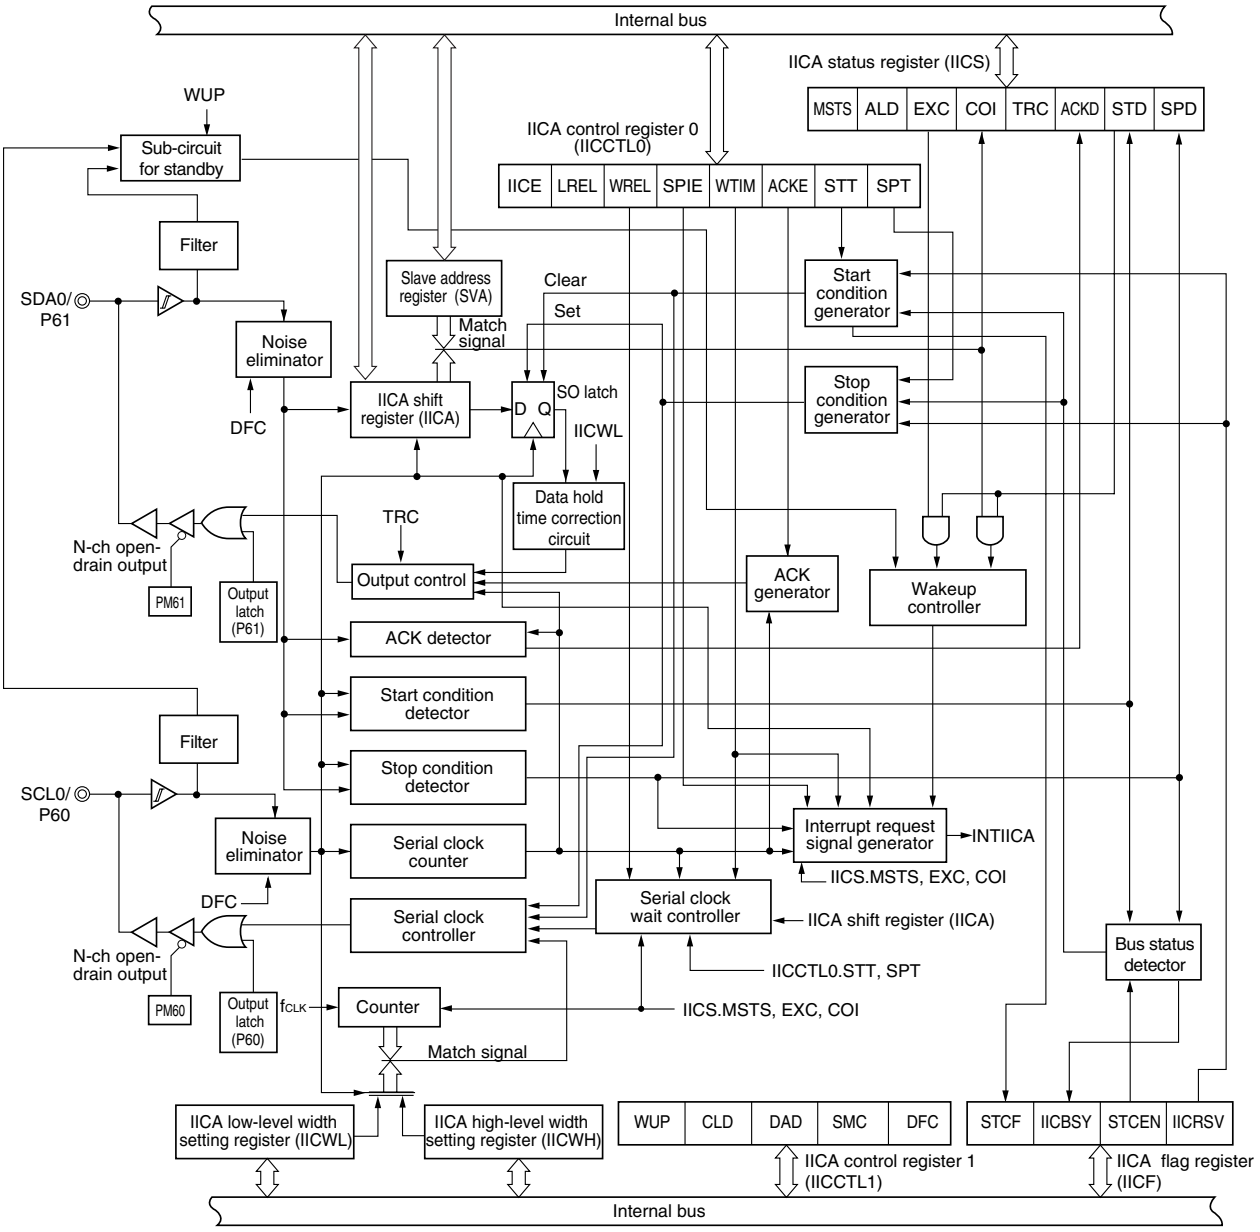

Figure 13-2 shows a serial bus configuration example.

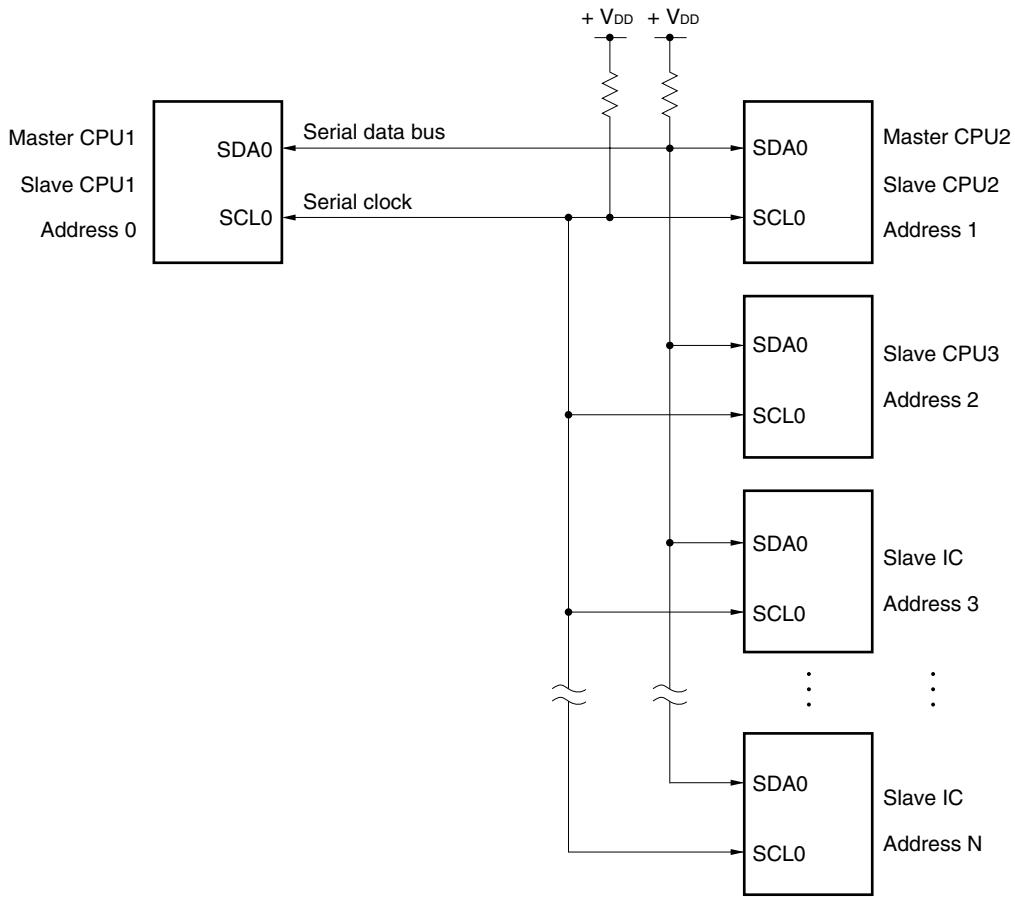
Figure 13-2. Serial Bus Configuration Example Using I^2C Bus



13.2 Configuration of Serial Interface IICA

Serial interface IICA includes the following hardware.

Table 13-1. Configuration of Serial Interface IICA

Item	Configuration
Registers	IICA shift register (IICA) Slave address register (SVA)
Control registers	Peripheral enable register 0 (PER0) IICA control register 0 (IICCTL0) IICA status register (IICS) IICA flag register (IICF) IICA control register 1 (IICCTL1) IICA low-level width setting register (IICWL) IICA high-level width setting register (IICWH) Port mode register 6 (PM6) Port register 6 (P6)

(1) IICA shift register (IICA)

IICA is used to convert 8-bit serial data to 8-bit parallel data and vice versa in synchronization with the serial clock. IICA can be used for both transmission and reception.

The actual transmit and receive operations can be controlled by writing and reading operations to IICA.

Cancel the wait state and start data transfer by writing data to IICA during the wait period.

IICA can be set by an 8-bit memory manipulation instruction.

Reset signal generation clears IICA to 00H.

Figure 13-3. Format of IICA Shift Register (IICA)

Address: FFF50H After reset: 00H R/W

Symbol	7	6	5	4	3	2	1	0
IICA								

Cautions 1. Do not write data to IICA during data transfer.

2. Write or read IICA only during the wait period. Accessing IICA in a communication state other than during the wait period is prohibited. When the device serves as the master, however, IICA can be written only once after the communication trigger bit (STT) is set to 1.

(2) Slave address register (SVA)

This register stores seven bits of local addresses {A6, A5, A4, A3, A2, A1, A0} when in slave mode.

SVA can be set by an 8-bit memory manipulation instruction.

However, rewriting to this register is prohibited while STD = 1 (while the start condition is detected).

Reset signal generation clears SVA to 00H.

Figure 13-4. Format of Slave Address Register (SVA)

Address: F0234H After reset: 00H R/W

Symbol	7	6	5	4	3	2	1	0
SVA	A6	A5	A4	A3	A2	A1	A0	0Note

Note Bit 0 is fixed to 0.

(3) SO latch

The SO latch is used to retain the SDA0 pin's output level.

(4) Wakeup controller

This circuit generates an interrupt request (INTIICA) when the address received by this register matches the address value set to the slave address register (SVA) or when an extension code is received.

(5) Serial clock counter

This counter counts the serial clocks that are output or input during transmit/receive operations and is used to verify that 8-bit data was transmitted or received.

(6) Interrupt request signal generator

This circuit controls the generation of interrupt request signals (INTIICA).

An I^2C interrupt request is generated by the following two triggers.

- Falling edge of eighth or ninth clock of the serial clock (set by WTIM bit)
- Interrupt request generated when a stop condition is detected (set by SPIE bit)

Remark WTIM bit: Bit 3 of IICA control register 0 (IICCTL0)
SPIE bit: Bit 4 of IICA control register 0 (IICCTL0)

(7) Serial clock controller

In master mode, this circuit generates the clock output via the SCL0 pin from a sampling clock.

(8) Serial clock wait controller

This circuit controls the wait timing.

(9) ACK generator, stop condition detector, start condition detector, and ACK detector

These circuits generate and detect each status.

(10) Data hold time correction circuit

This circuit generates the hold time for data corresponding to the falling edge of the serial clock.

(11) Start condition generator

This circuit generates a start condition when the STT bit is set to 1.

However, in the communication reservation disabled status (IICRSV bit = 1), when the bus is not released (IICBSY bit = 1), start condition requests are ignored and the STCF bit is set to 1.

(12) Stop condition generator

This circuit generates a stop condition when the SPT bit is set to 1.

(13) Bus status detector

This circuit detects whether or not the bus is released by detecting start conditions and stop conditions.

However, as the bus status cannot be detected immediately following operation, the initial status is set by the STCEN bit.

Remark STT bit: Bit 1 of IICA control register 0 (IICCTL0)
SPT bit: Bit 0 of IICA control register 0 (IICCTL0)
IICRSV bit: Bit 0 of IICA flag register (IICF)
IICBSY bit: Bit 6 of IICA flag register (IICF)
STCF bit: Bit 7 of IICA flag register (IICF)
STCEN bit: Bit 1 of IICA flag register (IICF)

13.3 Registers Controlling Serial Interface IICA

Serial interface IICA is controlled by the following eight registers.

- Peripheral enable register 0 (PER0)
- IICA control register 0 (IICCTL0)
- IICA flag register (IICF)
- IICA status register (IICS)
- IICA control register 1 (IICCTL1)
- IICA low-level width setting register (IICWL)
- IICA high-level width setting register (IICWH)
- Port mode register 6 (PM6)
- Port register 6 (P6)

(1) Peripheral enable register 0 (PER0)

PER0 is used to enable or disable use of each peripheral hardware macro. Clock supply to a hardware macro that is not used is stopped in order to reduce the power consumption and noise.

When serial interface IICA is used, be sure to set bit 4 (IICAEN) of this register to 1.

PER0 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Figure 13-5. Format of Peripheral Enable Register 0 (PER0)

Address: F00F0H After reset: 00H R/W

Symbol	<7>	6	<5>	<4>	3	<2>	1	0
PER0	RTCEN	0	ADCEN	IICAEN	0	SAU0EN	0	0

IICAEN	Control of serial interface IICA input clock supply
0	Stops supply of input clock. • SFR used by serial interface IICA cannot be written. • Serial interface IICA is in the reset status.
1	Supplies input clock. • SFR used by serial interface IICA can be read/written.

Cautions 1. When setting serial interface IICA, be sure to set IICAEN to 1 first. If IICAEN = 0, writing to a control register of serial interface IICA is ignored, and, even if the register is read, only the default value is read.

2. Be sure to clear bits 0, 1, 3, and 6 of the PER0 register to 0.

(2) IICA control register 0 (IICCTL0)

This register is used to enable/stop I^2C operations, set wait timing, and set other I^2C operations.

IICCTL0 can be set by a 1-bit or 8-bit memory manipulation instruction. However, set the SPIE, WTIM, and ACKE bits while IICE bit = 0 or during the wait period. These bits can be set at the same time when the IICE bit is set from “0” to “1”.

Reset signal generation clears this register to 00H.

0	Do not cancel wait
1	Cancel wait. This setting is automatically cleared after wait is canceled.
When WREL is set (wait canceled) during the wait period at the ninth clock pulse in the transmission status (TRC = 1), the SDA0 line goes into the high impedance state (TRC = 0).	
Condition for clearing (WREL = 0)	Condition for setting (WREL = 1)
• Automatically cleared after execution • Reset	• Set by instruction

Notes 1. The IICS register, the STCF and IICBSY bits of the IICF register, and the CLD and DAD bits of the IICCTL1 register are reset.

2. The signal of this bit is invalid while IICE0 is 0.

Caution The start condition is detected immediately after I^2C is enabled to operate (IICE = 1) while the SCL0 line is at high level and the SDA0 line is at low level. Immediately after enabling I^2C to operate (IICE = 1), set LREL (1) by using a 1-bit memory manipulation instruction.

WTIM[Note 1]	Control of wait and interrupt request generation
0	Interrupt request is generated at the eighth clock's falling edge. Master mode: After output of eight clocks, clock output is set to low level and wait is set. Slave mode: After input of eight clocks, the clock is set to low level and wait is set for master device.
1	Interrupt request is generated at the ninth clock's falling edge. Master mode: After output of nine clocks, clock output is set to low level and wait is set. Slave mode: After input of nine clocks, the clock is set to low level and wait is set for master device.

An interrupt is generated at the falling edge of the ninth clock during address transfer independently of the setting of this bit. The setting of this bit is valid when the address transfer is completed. When in master mode, a wait is inserted at the falling edge of the ninth clock during address transfers. For a slave device that has received a local address, a wait is inserted at the falling edge of the ninth clock after an acknowledge ($\overline{ACK}$) is issued. However, when the slave device has received an extension code, a wait is inserted at the falling edge of the eighth clock.

• Cleared by instruction • Reset	• Set by instruction

Notes 1. The signal of this bit is invalid while IICE0 is 0. Set this bit during that period.

2. The set value is invalid during address transfer and if the code is not an extension code. When the device serves as a slave and the addresses match, an acknowledgment is generated regardless of the set value.

Figure 13-6. Format of IICA Control Register 0 (IICCTL0) (3/4)

STT[Note]	Start condition trigger
0	Do not generate a start condition.
1	When bus is released (in STOP mode): Generate a start condition (for starting as master). When the SCL0 line is high level, the SDA0 line is changed from high level to low level and then the start condition is generated. Next, after the rated amount of time has elapsed, SCL0 is changed to low level (wait state). When a third party is communicating: • When communication reservation function is enabled (IICRSV = 0) Functions as the start condition reservation flag. When set to 1, automatically generates a start condition after the bus is released. • When communication reservation function is disabled (IICRSV = 1) STCF is set to 1 and information that is set (1) to STT is cleared. No start condition is generated. In the wait state (when master device): Generates a restart condition after releasing the wait.

Cautions concerning set timing

- For master reception: Cannot be set to 1 during transfer. Can be set to 1 only in the waiting period when ACKE has been cleared to 0 and slave has been notified of final reception.
- For master transmission: A start condition cannot be generated normally during the acknowledge period. Set to 1 during the wait period that follows output of the ninth clock.
- Cannot be set to 1 at the same time as SPT.
- Setting STT to 1 and then setting it again before it is cleared to 0 is prohibited.

Condition for clearing (STT = 0)	Condition for setting (STT = 1)
• Cleared by setting STT to 1 while communication reservation is prohibited. • Cleared by loss in arbitration • Cleared after start condition is generated by master device • Cleared by LREL = 1 (exit from communications) • When IICE = 0 (operation stop) • Reset	• Set by instruction

Note The signal of this bit is invalid while IICE0 is 0.

Remarks 1. Bit 1 (STT) becomes 0 when it is read after data setting.

2. IICRSV: Bit 0 of IIC flag register (IICF)
STCF: Bit 7 of IIC flag register (IICF)

SPT	Stop condition trigger
0	Stop condition is not generated.
1	Stop condition is generated (termination of master device's transfer). After the SDA0 line goes to low level, either set the SCL0 line to high level or wait until it goes to high level. Next, after the rated amount of time has elapsed, the SDA0 line changes from low level to high level and a stop condition is generated.

Cautions concerning set timing

- For master reception: Cannot be set to 1 during transfer.
  Can be set to 1 only in the waiting period when ACKE has been cleared to 0 and slave has been notified of final reception.
- For master transmission: A stop condition cannot be generated normally during the acknowledge period.
  Therefore, set it during the wait period that follows output of the ninth clock.
- Cannot be set to 1 at the same time as STT.
- SPT can be set to 1 only when in master mode[Note].
- When WTIM has been cleared to 0, if SPT is set to 1 during the wait period that follows output of eight clocks, note that a stop condition will be generated during the high-level period of the ninth clock. WTIM should be changed from 0 to 1 during the wait period following the output of eight clocks, and SPT should be set to 1 during the wait period that follows the output of the ninth clock.
- Setting SPT to 1 and then setting it again before it is cleared to 0 is prohibited.

Condition for clearing (SPT = 0)	Condition for setting (SPT = 1)
• Cleared by loss in arbitration • Automatically cleared after stop condition is detected • Cleared by LREL = 1 (exit from communications) • When IICE = 0 (operation stop) • Reset	• Set by instruction

Note Set SPT to 1 only in master mode. However, SPT must be set to 1 and a stop condition generated before the first stop condition is detected following the switch to the operation enabled status.

Caution When bit 3 (TRC) of the IICA status register (IICS) is set to 1, WREL is set to 1 during the ninth clock and wait is canceled, after which TRC is cleared and the SDA0 line is set to high impedance.

Remark Bit 0 (SPT) becomes 0 when it is read after data setting.

(3) IICA status register (IICS)

This register indicates the status of I^2C.

IICS is read by a 1-bit or 8-bit memory manipulation instruction only when STT = 1 and during the wait period.

Reset signal generation clears this register to 00H.

Caution Reading the IICA status register (IICS) while WUP of IICA control register 1 (IICCTL1) is set to 1 is prohibited. When WUP is changed from 0 to 1, regardless of the INTIICA interrupt request, the change in status is not reflected until the next start condition or stop condition is detected. To use the wakeup mode, therefore, enable (SPIE = 1) the interrupt generated by detecting a stop condition and read the IICS register after the interrupt has been detected.

(4) IICA flag register (IICF)

This register sets the operation mode of I^2C and indicates the status of the I^2C bus.

IICF can be set by a 1-bit or 8-bit memory manipulation instruction. However, the STCF and IICBSY bits are read-only.

The IICRSV bit can be used to enable/disable the communication reservation function.

STCEN can be used to set the initial value of the IICBSY bit.

IICRSV and STCEN can be written only when the operation of I^2C is disabled (bit 7 (IICE) of IICA control register 0 (IICCTL0) = 0). When operation is enabled, the IICF register can be read.

Reset signal generation clears this register to 00H.

Note Bits 6 and 7 are read-only.

Cautions 1. Write to STCEN only when the operation is stopped (IICE = 0).

2. As the bus release status (IICBSY = 0) is recognized regardless of the actual bus status when STCEN = 1, when generating the first start condition (STT = 1), it is necessary to verify that no third party communications are in progress in order to prevent such communications from being destroyed.

3. Write to IICRSV only when the operation is stopped (IICE = 0).

IICCTL1 can be set by a 1-bit or 8-bit memory manipulation instruction. However, the CLD and DAD bits are read-only.

Set IICCTL1, except the WUP bit, while bit 7 (IICE) of IICA control register 0 (IICCTL0) is 0.

Reset signal generation clears this register to 00H.

Clear (0) WUP after the address has matched or an extension code has been received. The subsequent communication can be entered by clearing (0) WUP. (The wait must be released and transmit data must be written after WUP has been cleared (0).)

The interrupt timing when the address has matched or when an extension code has been received, while WUP = 1, is identical to the interrupt timing when WUP = 0. (A delay of the difference of sampling by the clock will occur.) Furthermore, when WUP = 1, a stop condition interrupt is not generated even if the SPIE bit is set to 1. When WUP = 0 is set by a source other than an interrupt from serial interface IICA, operation as the master device cannot be performed until the subsequent start condition or stop condition is detected. Do not output a start condition by setting (1) the STT bit, without waiting for the detection of the subsequent start condition or stop condition.

(6) IICA low-level width setting register (IICWL)

This register is used to set the low-level width of the SCL0 pin signal that is output by serial interface IICA being in master mode.

IICWL can be set by an 8-bit memory manipulation instruction.

Set IICWL when bit 7 (IICE) of IICA control register 0 (IICCTL0) is 0.

13.4 I²C Bus Mode Functions

13.4.1 Pin configuration

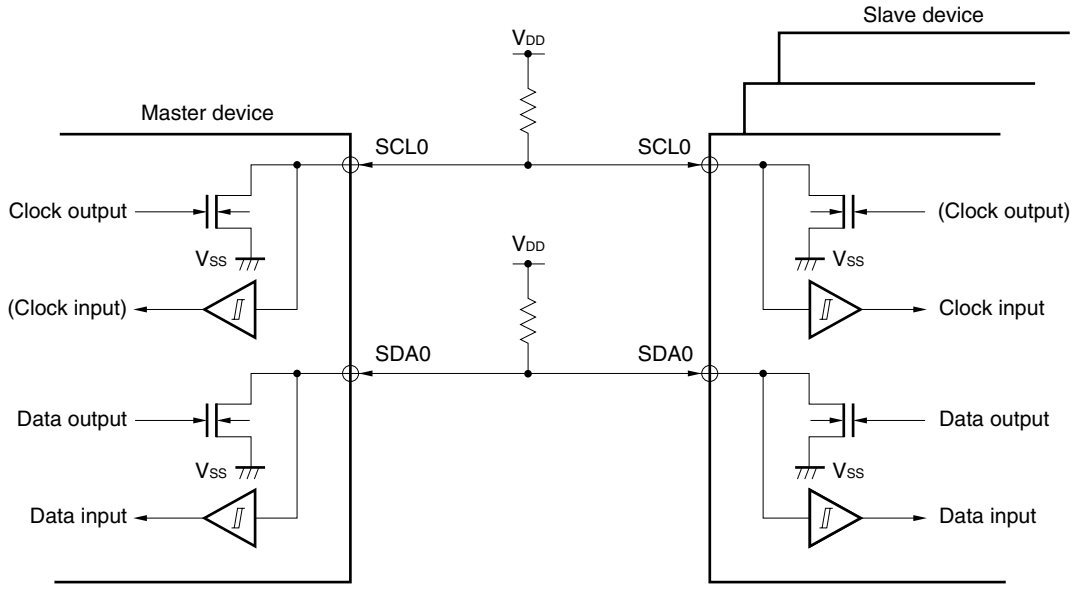
The serial clock pin (SCL0) and serial data bus pin (SDA0) are configured as follows.

(1) SCL0..... This pin is used for serial clock input and output.
This pin is an N-ch open-drain output for both master and slave devices. Input is Schmitt input.

(2) SDA0 ..... This pin is used for serial data input and output.
This pin is an N-ch open-drain output for both master and slave devices. Input is Schmitt input.

Since outputs from the serial clock line and the serial data bus line are N-ch open-drain outputs, an external pull-up resistor is required.

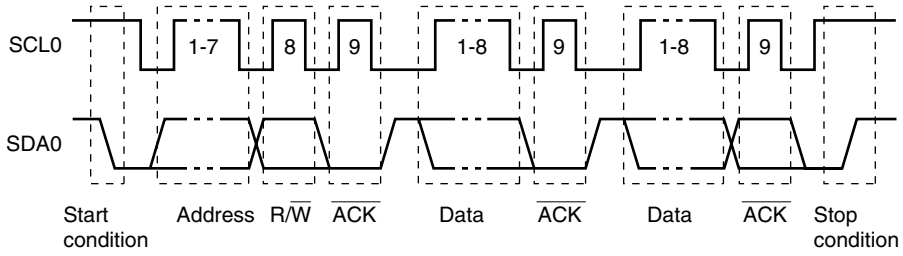
Figure 13-13. Pin Configuration Diagram



13.5 I²C Bus Definitions and Control Methods

The following section describes the I²C bus's serial data communication format and the signals used by the I²C bus. Figure 13-14 shows the transfer timing for the "start condition", "address", "data", and "stop condition" output via the I²C bus's serial data bus.

Figure 13-14. I²C Bus Serial Data Transfer Timing



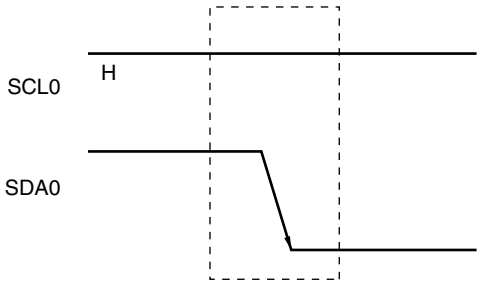
The master device generates the start condition, slave address, and stop condition.
The acknowledge ($\overline{ACK}$) can be generated by either the master or slave device (normally, it is output by the device that receives 8-bit data).

The serial clock (SCL0) is continuously output by the master device. However, in the slave device, the SCL0's low level period can be extended and a wait can be inserted.

13.5.1 Start conditions

A start condition is met when the SCL0 pin is at high level and the SDA0 pin changes from high level to low level. The start conditions for the SCL0 pin and SDA0 pin are signals that the master device generates to the slave device when starting a serial transfer. When the device is used as a slave, start conditions can be detected.

Figure 13-15. Start Conditions



A start condition is output when bit 1 (STT) of IICA control register 0 (IICCTL0) is set (1) after a stop condition has been detected (SPD: Bit 0 of the IICA status register (IICS) = 1). When a start condition is detected, bit 1 (STD) of IICS is set (1).

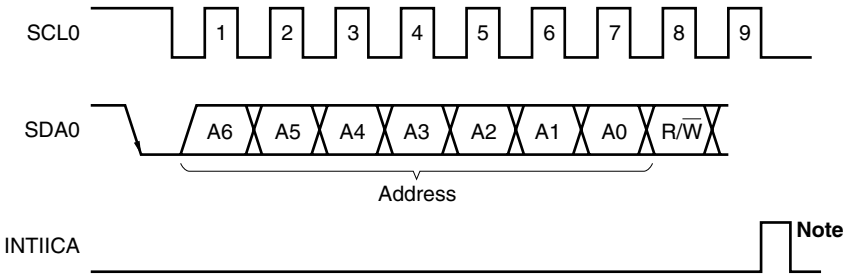
13.5.2 Addresses

The address is defined by the 7 bits of data that follow the start condition.

An address is a 7-bit data segment that is output in order to select one of the slave devices that are connected to the master device via the bus lines. Therefore, each slave device connected via the bus lines must have a unique address.

The slave devices include hardware that detects the start condition and checks whether or not the 7-bit address data matches the data values stored in the slave address register (SVA). If the address data matches the SVA values, the slave device is selected and communicates with the master device until the master device generates a start condition or stop condition.

Figure 13-16. Address



Note INTIICA is not issued if data other than a local address or extension code is received during slave device operation.

Addresses are output when a total of 8 bits consisting of the slave address and the transfer direction described in **13.5.3 Transfer direction specification** are written to the IICA shift register (IICA). The received addresses are written to IICA.

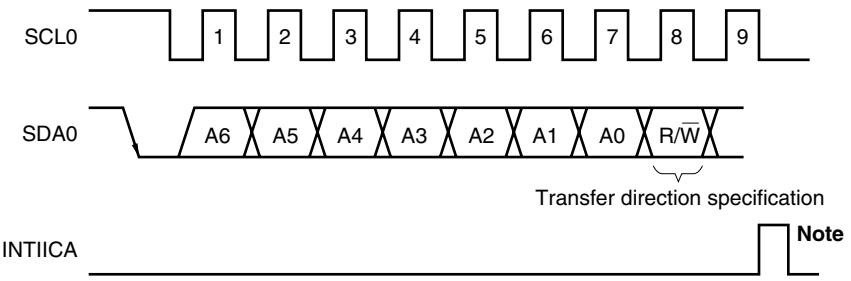
The slave address is assigned to the higher 7 bits of IICA.

13.5.3 Transfer direction specification

In addition to the 7-bit address data, the master device sends 1 bit that specifies the transfer direction.

When this transfer direction specification bit has a value of “0”, it indicates that the master device is transmitting data to a slave device. When the transfer direction specification bit has a value of “1”, it indicates that the master device is receiving data from a slave device.

Figure 13-17. Transfer Direction Specification



Note INTIICA is not issued if data other than a local address or extension code is received during slave device operation.

13.5.4 Acknowledge ($\overline{ACK}$)

$\overline{ACK}$ is used to check the status of serial data at the transmission and reception sides.

The reception side returns $\overline{ACK}$ each time it has received 8-bit data.

The transmission side usually receives $\overline{ACK}$ after transmitting 8-bit data. When $\overline{ACK}$ is returned from the reception side, it is assumed that reception has been correctly performed and processing is continued. Whether $\overline{ACK}$ has been detected can be checked by using bit 2 (ACKD) of the IICA status register (IICS).

When the master receives the last data item, it does not return $\overline{ACK}$ and instead generates a stop condition. If a slave does not return $\overline{ACK}$ after receiving data, the master outputs a stop condition or restart condition and stops transmission. If $\overline{ACK}$ is not returned, the possible causes are as follows.

<1> Reception was not performed normally.
<2> The final data item was received.
<3> The reception side specified by the address does not exist.

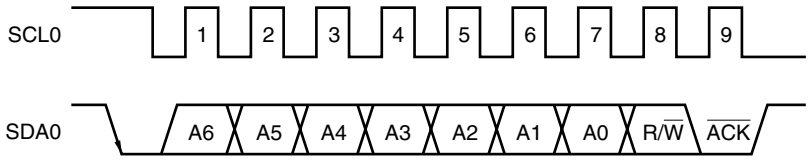
To generate $\overline{ACK}$, the reception side makes the SDA0 line low at the ninth clock (indicating normal reception).

Automatic generation of $\overline{ACK}$ is enabled by setting bit 2 (ACKE) of IICA control register 0 (IICCTL0) to 1. Bit 3 (TRC) of the IICS register is set by the data of the eighth bit that follows 7-bit address information. Usually, set ACKE to 1 for reception (TRC = 0).

If a slave can receive no more data during reception (TRC = 0) or does not require the next data item, then the slave must inform the master, by clearing ACKE to 0, that it will not receive any more data.

When the master does not require the next data item during reception (TRC = 0), it must clear ACKE to 0 so that $\overline{ACK}$ is not generated. In this way, the master informs a slave at the transmission side that it does not require any more data (transmission will be stopped).

Figure 13-18. $\overline{ACK}$



When the local address is received, $\overline{ACK}$ is automatically generated, regardless of the value of ACKE. When an address other than that of the local address is received, $\overline{ACK}$ is not generated (NACK).

When an extension code is received, $\overline{ACK}$ is generated if ACKE is set to 1 in advance.

How $\overline{ACK}$ is generated when data is received differs as follows depending on the setting of the wait timing.

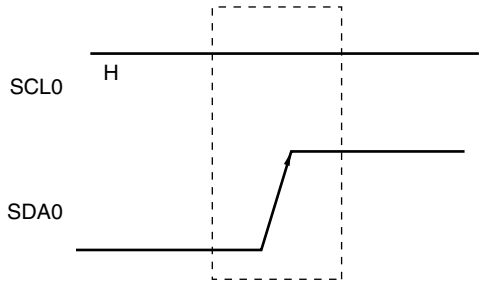
- When 8-clock wait state is selected (bit 3 (WTIM) of IICCTL0 register = 0):
  By setting ACKE to 1 before releasing the wait state, $\overline{ACK}$ is generated at the falling edge of the eighth clock of the SCL0 pin.
- When 9-clock wait state is selected (bit 3 (WTIM) of IICCTL0 register = 1):
  $\overline{ACK}$ is generated by setting ACKE to 1 in advance.

13.5.5 Stop condition

When the SCL0 pin is at high level, changing the SDA0 pin from low level to high level generates a stop condition.

A stop condition is a signal that the master device generates to the slave device when serial transfer has been completed. When the device is used as a slave, stop conditions can be detected.

Figure 13-19. Stop Condition



A stop condition is generated when bit 0 (SPT) of IICA control register 0 (IICCTL0) is set to 1. When the stop condition is detected, bit 0 (SPD) of the IICA status register (IICS) is set to 1 and INTIICA is generated when bit 4 (SPIE) of IICCTL0 is set to 1.

13.5.6 Wait

The wait is used to notify the communication partner that a device (master or slave) is preparing to transmit or receive data (i.e., is in a wait state).

Setting the SCL0 pin to low level notifies the communication partner of the wait state. When wait state has been canceled for both the master and slave devices, the next data transfer can begin.

(1) When master device has a nine-clock wait and slave device has an eight-clock wait (master transmits, slave receives, and ACKE = 1)

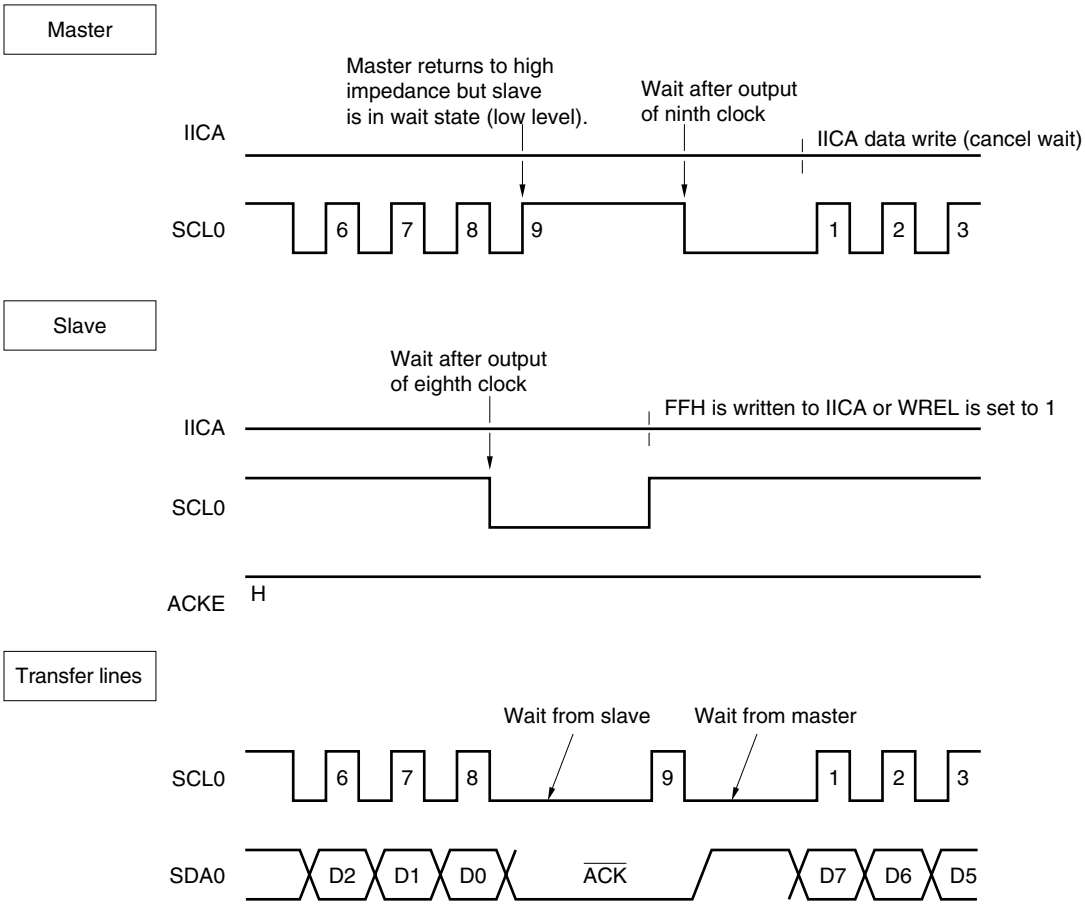

Figure 13-20. Wait (2/2)

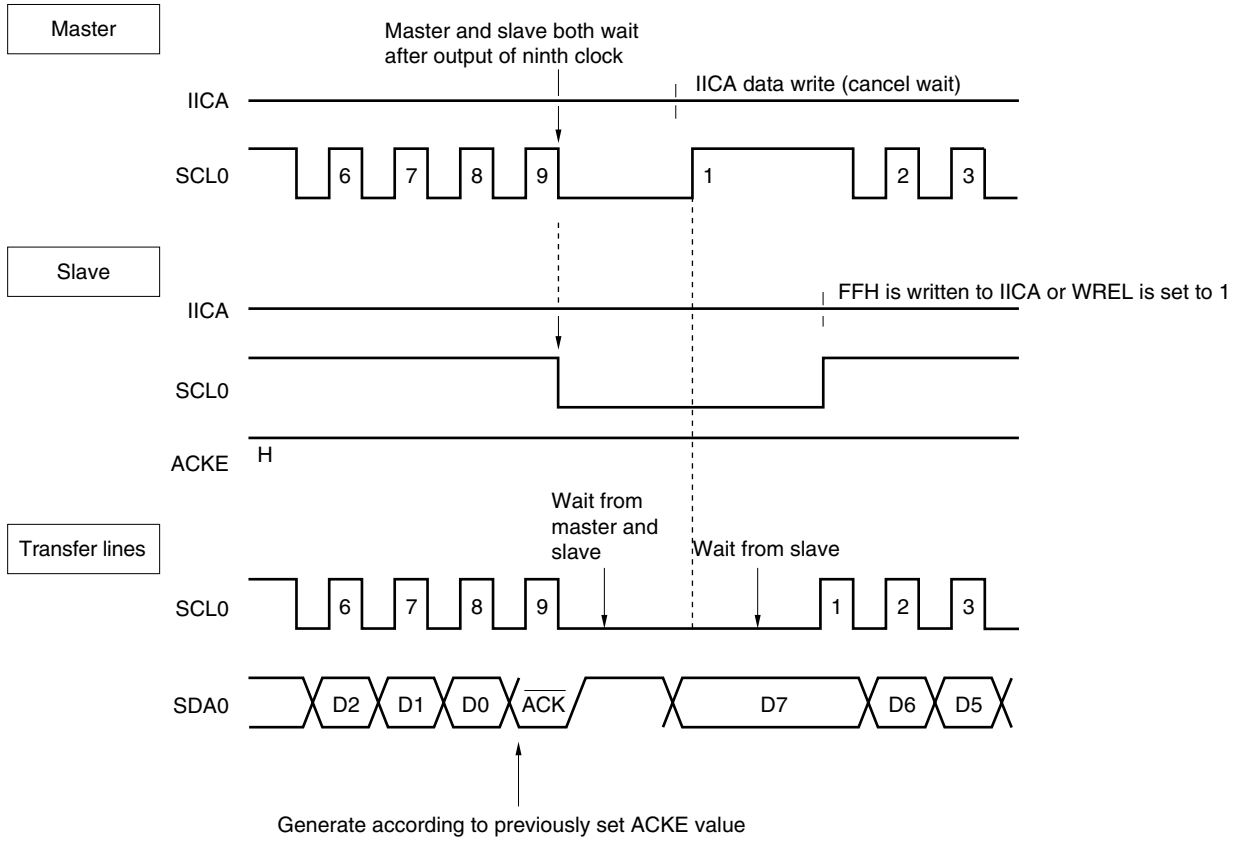
(2) When master and slave devices both have a nine-clock wait (master transmits, slave receives, and ACKE = 1)



Remark ACKE: Bit 2 of IICA control register 0 (IICCTL0)
WREL: Bit 5 of IICA control register 0 (IICCTL0)

A wait may be automatically generated depending on the setting of bit 3 (WTIM) of IICA control register 0 (IICCTL0).

Normally, the receiving side cancels the wait state when bit 5 (WREL) of IICCTL0 is set to 1 or when FFH is written to the IICA shift register (IICA), and the transmitting side cancels the wait state when data is written to IICA.

The master device can also cancel the wait state via either of the following methods.

- By setting bit 1 (STT) of IICCTL0 to 1
- By setting bit 0 (SPT) of IICCTL0 to 1

13.5.7 Canceling wait

The I^2C usually cancels a wait state by the following processing.

- Writing data to IICA shift register (IICA)
- Setting bit 5 (WREL) of IICA control register 0 (IICCTL0) (canceling wait)
- Setting bit 1 (STT) of IICCTL0 register (generating start condition)[Note]
- Setting bit 0 (SPT) of IICCTL0 register (generating stop condition)[Note]

Note Master only

When the above wait canceling processing is executed, the I^2C cancels the wait state and communication is resumed.

To cancel a wait state and transmit data (including addresses), write the data to IICA.

To receive data after canceling a wait state, or to complete data transmission, set bit 5 (WREL) of IICA control register 0 (IICCTL0) to 1.

To generate a restart condition after canceling a wait state, set bit 1 (STT) of IICCTL0 to 1.

To generate a stop condition after canceling a wait state, set bit 0 (SPT) of IICCTL0 to 1.

Execute the canceling processing only once for one wait state.

If, for example, data is written to IICA after canceling a wait state by setting WREL to 1, an incorrect value may be output to SDA0 because the timing for changing the SDA0 line conflicts with the timing for writing IICA.

In addition to the above, communication is stopped if IICE is cleared to 0 when communication has been aborted, so that the wait state can be canceled.

If the I^2C bus has deadlocked due to noise, processing is saved from communication by setting bit 6 (LREL) of IICCTL0, so that the wait state can be canceled.

Caution If a processing to cancel a wait state is executed when WUP = 1, the wait state will not be canceled.

13.5.8 Interrupt request (INTIICA) generation timing and wait control

The setting of bit 3 (WTIM) of IICA control register 0 (IICCTL0) determines the timing by which INTIICA is generated and the corresponding wait control, as shown in Table 13-2.

Table 13-2. INTIICA Generation Timing and Wait Control

WTIM	During Slave Device Operation			During Master Device Operation		
	Address	Data Reception	Data Transmission	Address	Data Reception	Data Transmission
0	9 Notes 1, 2	8 Note 2	8 Note 2	9	8	8
1	9 Notes 1, 2	9 Note 2	9 Note 2	9	9	9

Notes 1. The slave device's INTIICA signal and wait period occurs at the falling edge of the ninth clock only when there is a match with the address set to the slave address register (SVA).
At this point, $\overline{ACK}$ is generated regardless of the value set to IICCTL0's bit 2 (ACKE). For a slave device that has received an extension code, INTIICA occurs at the falling edge of the eighth clock.
However, if the address does not match after restart, INTIICA is generated at the falling edge of the 9th clock, but wait does not occur.

2. If the received address does not match the contents of the slave address register (SVA) and extension code is not received, neither INTIICA nor a wait occurs.

Remark The numbers in the table indicate the number of the serial clock's clock signals. Interrupt requests and wait control are both synchronized with the falling edge of these clock signals.

(1) During address transmission/reception

- Slave device operation: Interrupt and wait timing are determined depending on the conditions described in Notes 1 and 2 above, regardless of the WTIM bit.
- Master device operation: Interrupt and wait timing occur at the falling edge of the ninth clock regardless of the WTIM bit.

(2) During data reception

- Master/slave device operation: Interrupt and wait timing are determined according to the WTIM bit.

(3) During data transmission

- Master/slave device operation: Interrupt and wait timing are determined according to the WTIM bit.

(4) Wait cancellation method

The four wait cancellation methods are as follows.

- Writing data to IICA shift register (IICA)
- Setting bit 5 (WREL) of IICA control register 0 (IICCTL0) (canceling wait)
- Setting bit 1 (STT) of IICCTL0 register (generating start condition)Note
- Setting bit 0 (SPT) of IICCTL0 register (generating stop condition)Note

Note Master only.

When an 8-clock wait has been selected (WTIM = 0), the presence/absence of $\overline{ACK}$ generation must be determined prior to wait cancellation.

(5) Stop condition detection

INTIICA is generated when a stop condition is detected (only when SPIE = 1).

13.5.9 Address match detection method

In I^2C bus mode, the master device can select a particular slave device by transmitting the corresponding slave address.

Address match can be detected automatically by hardware. An interrupt request (INTIICA) occurs when a local address has been set to the slave address register (SVA) and when the address set to SVA matches the slave address sent by the master device, or when an extension code has been received.

13.5.10 Error detection

In I^2C bus mode, the status of the serial data bus (SDA0) during data transmission is captured by the IICA shift register (IICA) of the transmitting device, so the IICA data prior to transmission can be compared with the transmitted IICA data to enable detection of transmission errors. A transmission error is judged as having occurred when the compared data values do not match.

13.5.11 Extension code

(1) When the higher 4 bits of the receive address are either “0000” or “1111”, the extension code reception flag (EXC) is set to 1 for extension code reception and an interrupt request (INTIICA) is issued at the falling edge of the eighth clock. The local address stored in the slave address register (SVA) is not affected.

(2) If “11110××0” is set to SVA by a 10-bit address transfer and “11110××0” is transferred from the master device, the results are as follows. Note that INTIICA occurs at the falling edge of the eighth clock.

- Higher four bits of data match: EXC = 1
- Seven bits of data match: COI = 1

Remark EXC: Bit 5 of IICA status register (IICS)
COI: Bit 4 of IICA status register (IICS)

(3) Since the processing after the interrupt request occurs differs according to the data that follows the extension code, such processing is performed by software.
If the extension code is received while a slave device is operating, then the slave device is participating in communication even if its address does not match.
For example, after the extension code is received, if you do not wish to operate the target device as a slave device, set bit 6 (LREL) of the IICA control register 0 (IICCTL0) to 1 to set the standby mode for the next communication operation.

Table 13-3. Bit Definitions of Major Extension Codes

Slave Address	R/W Bit	Description
0 0 0 0 0 0 0	0	General call address
1 1 1 1 0 x x	0	10-bit slave address specification (during address authentication)
1 1 1 1 0 x x	1	10-bit slave address specification (after address match, when read command is issued)

Remark See the I^2C bus specifications issued by NXP Semiconductors for details of extension codes other than those described above.

13.5.12 Arbitration

When several master devices simultaneously generate a start condition (when STT is set to 1 before STD is set to 1), communication among the master devices is performed as the number of clocks are adjusted until the data differs. This kind of operation is called arbitration.

When one of the master devices loses in arbitration, an arbitration loss flag (ALD) in the IICA status register (IICS) is set (1) via the timing by which the arbitration loss occurred, and the SCL0 and SDA0 lines are both set to high impedance, which releases the bus.

The arbitration loss is detected based on the timing of the next interrupt request (the eighth or ninth clock, when a stop condition is detected, etc.) and the ALD = 1 setting that has been made by software.

For details of interrupt request timing, see **13.5.8 Interrupt request (INTIICA) generation timing and wait control**.

Remark STD: Bit 1 of IICA status register (IICS)
STT: Bit 1 of IICA control register 0 (IICCTL0)

Notes 1. When WTIM (bit 3 of IICA control register 0 (IICCTL0)) = 1, an interrupt request occurs at the falling edge of the ninth clock. When WTIM = 0 and the extension code's slave address is received, an interrupt request occurs at the falling edge of the eighth clock.

2. When there is a chance that arbitration will occur, set SPIE = 1 for master device operation.

Remark SPIE: Bit 4 of IICA control register 0 (IICCTL0)

13.5.13 Wakeup function

The I^2C bus slave function is a function that generates an interrupt request signal (INTIICA) when a local address and extension code have been received.

This function makes processing more efficient by preventing unnecessary INTIICA signal from occurring when addresses do not match.

When a start condition is detected, wakeup standby mode is set. This wakeup standby mode is in effect while addresses are transmitted due to the possibility that an arbitration loss may change the master device (which has generated a start condition) to a slave device.

However, when a stop condition is detected, bit 4 (SPIE) of IICA control register 0 (IICCTL0) is set regardless of the wakeup function, and this determines whether interrupt requests are enabled or disabled.

To use the wakeup function in the STOP mode, set WUP to 1. Addresses can be received regardless of the operation clock. An interrupt request signal (INTIICA) is also generated when a local address and extension code have been received. Operation returns to normal operation by using an instruction to clear (0) the WUP bit after this interrupt has been generated.

The flows of when setting the WUP bit and clearing (0) the WUP bit upon an address match are shown below.

Figure 13-22. Flow When Setting WUP = 1

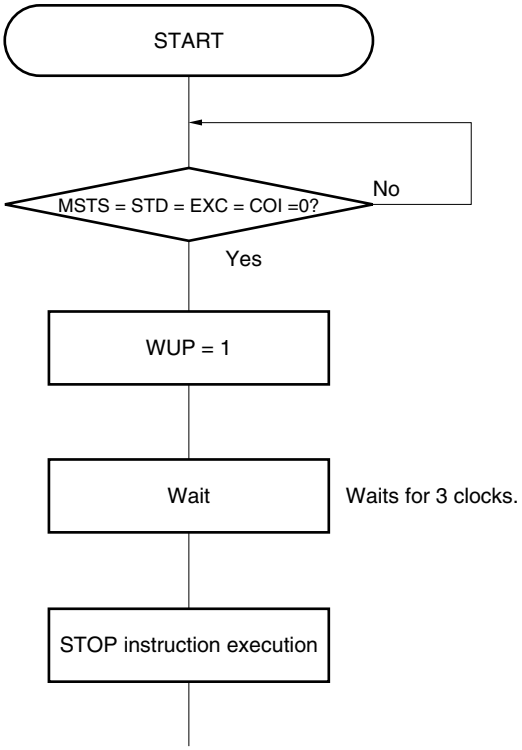

Figure 13-23. Flow When Setting WUP = 0 upon Address Match (Including Extension Code Reception)

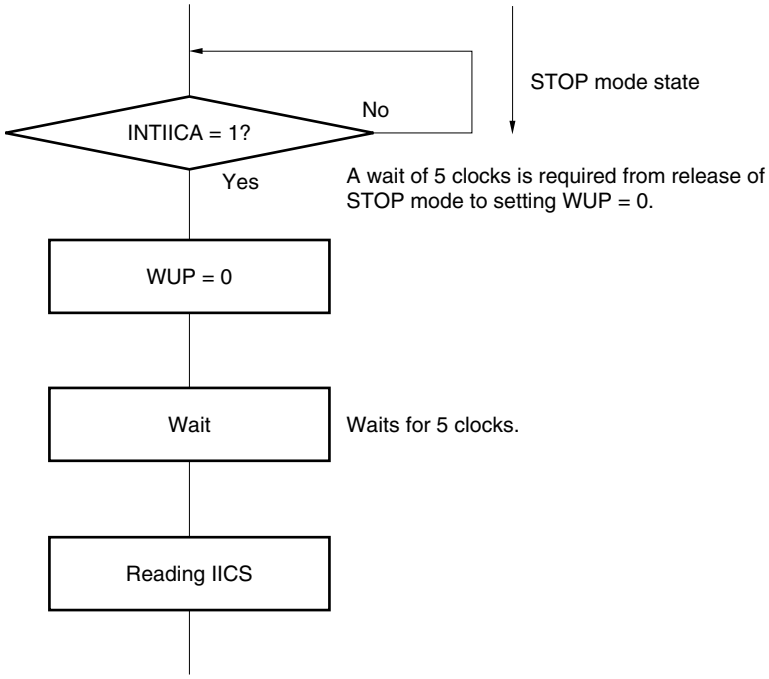

Executes processing corresponding to the operation to be executed after checking the operation state of serial interface IICA.

Use the following flows to perform the processing to release the STOP mode other than by an interrupt request (INTIICA) generated from serial interface IICA.

- Master device operation: Flow shown in Figure 13-24
- Slave device operation: Flow shown in Figure 13-23 or Figure 13-25

When operating the 78K0R/Kx3-L as a slave device, basically, use the flow shown in Figure 13-23. In this flow, however, extra time to keep communication waiting is required, because setting WUP to 0 takes processing time. To shorten the time for which communication is kept waiting, use the flow shown in Figure 13-25 to operate the 78K0R/Kx3-L.

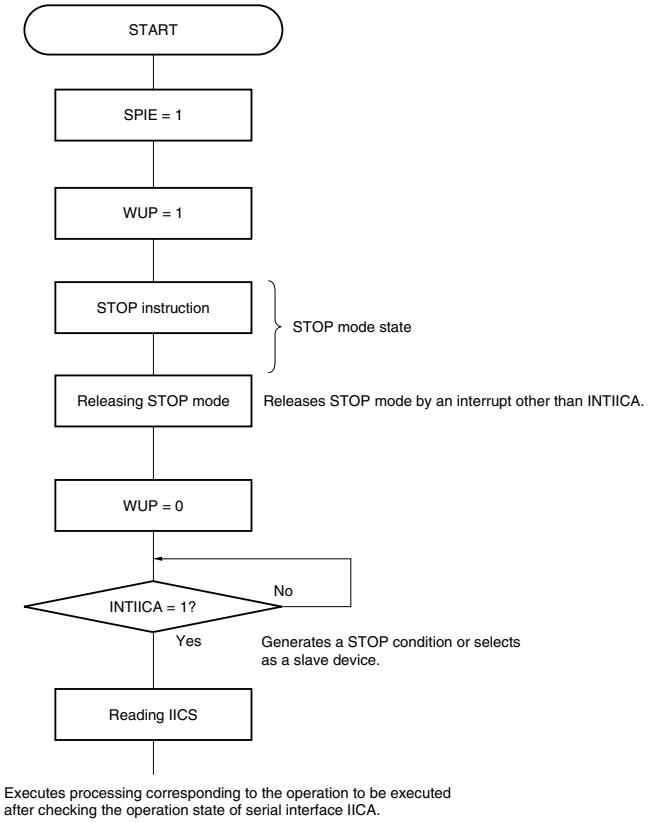

Figure 13-25. When Operating as Slave Device after Releasing STOP Mode other than by INTIICA (When Not Required to Operate as Master Device)

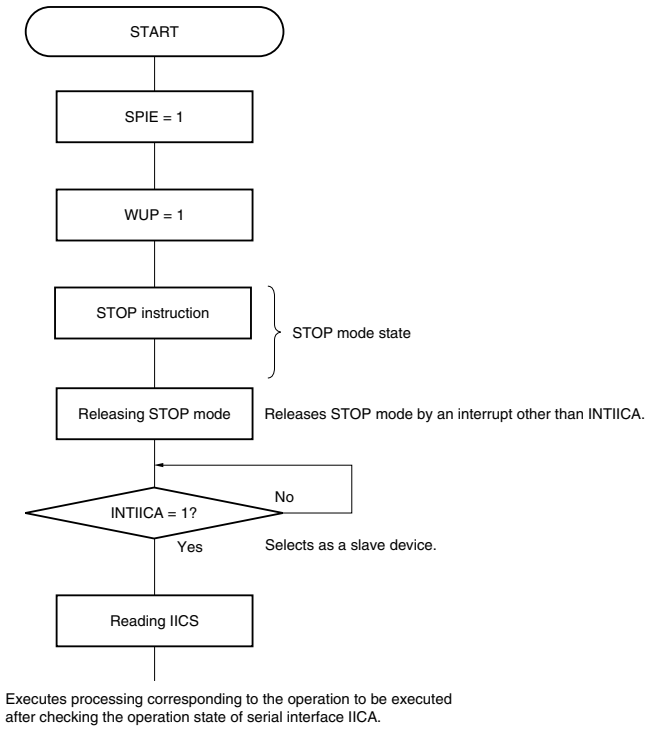


13.5.14 Communication reservation

(1) When communication reservation function is enabled (bit 0 (IICRSV) of IICA flag register (IICF) = 0)

To start master device communications when not currently using a bus, a communication reservation can be made to enable transmission of a start condition when the bus is released. There are two modes under which the bus is not used.

- When arbitration results in neither master nor slave operation
- When an extension code is received and slave operation is disabled ($\overline{ACK}$ is not returned and the bus was released by setting bit 6 (LREL) of IICA control register 0 (IICCTL0) to 1 and saving communication).

If bit 1 (STT) of IICCTL0 is set to 1 while the bus is not used (after a stop condition is detected), a start condition is automatically generated and wait state is set.

If an address is written to the IICA shift register (IICA) after bit 4 (SPIE) of IICCTL0 was set to 1, and it was detected by generation of an interrupt request signal (INTIICA) that the bus was released (detection of the stop condition), then the device automatically starts communication as the master. Data written to IICA before the stop condition is detected is invalid.

When STT has been set to 1, the operation mode (as start condition or as communication reservation) is determined according to the bus status.

- If the bus has been released.....a start condition is generated
- If the bus has not been released (standby mode) .....communication reservation

Check whether the communication reservation operates or not by using MSTS (bit 7 of the IICA status register (IICS)) after STT is set to 1 and the wait time elapses.

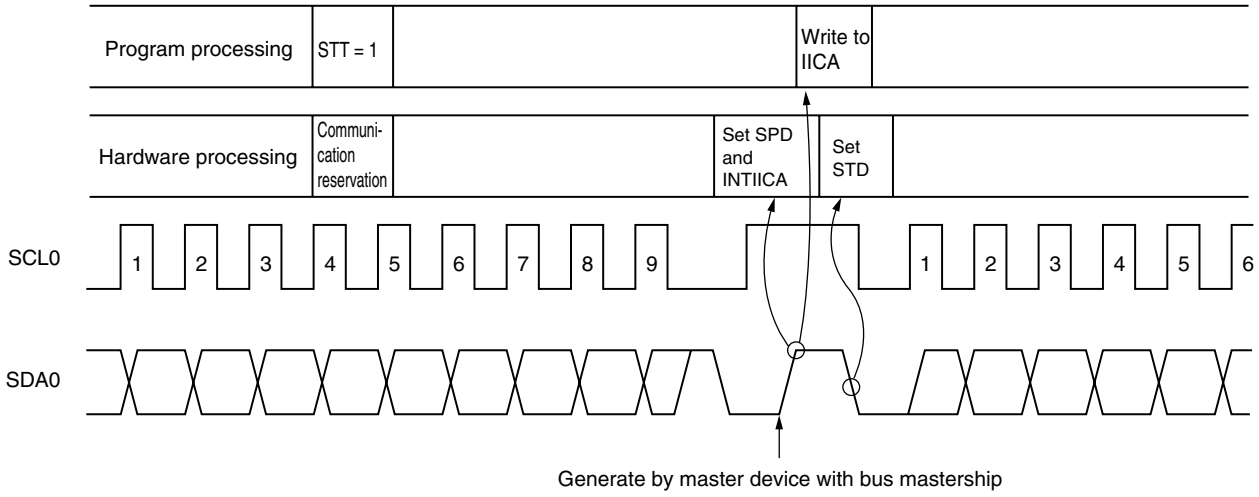
Use software to secure the wait time calculated by the following expression.

Wait time from setting STT = 1 to checking the MSTS flag: (IICWL setting value + IICWH setting value + 4 (clocks)) × f_{CLK} + t_F × 2

Remark IICWL: IICA low-level width setting register
IICWH: IICA high-level width setting register
t_F: SDA0 and SCL0 signal falling times (see **CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET)**)
f_{CLK}: CPU/peripheral hardware clock frequency

Figure 13-26 shows the communication reservation timing.

Figure 13-26. Communication Reservation Timing



Remark IICA: IICA shift register
STT: Bit 1 of IICA control register 0 (IICCTL0)
STD: Bit 1 of IICA status register (IICS)
SPD: Bit 0 of IICA status register (IICS)

Communication reservations are accepted via the timing shown in Figure 13-27. After bit 1 (STD) of the IICA status register (IICS) is set to 1, a communication reservation can be made by setting bit 1 (STT) of IICA control register 0 (IICCTL0) to 1 before a stop condition is detected.

Figure 13-27. Timing for Accepting Communication Reservations

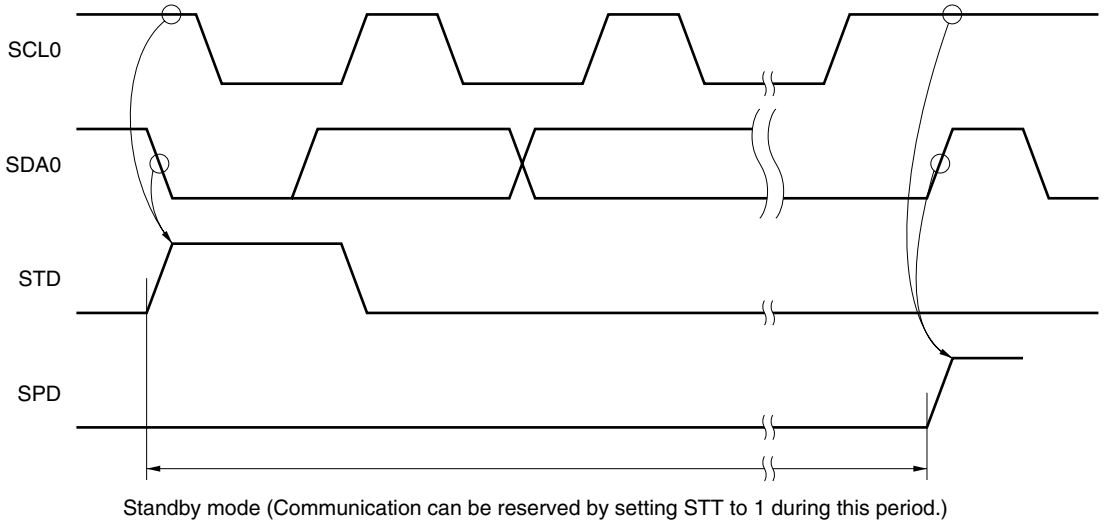


Figure 13-28 shows the communication reservation protocol.

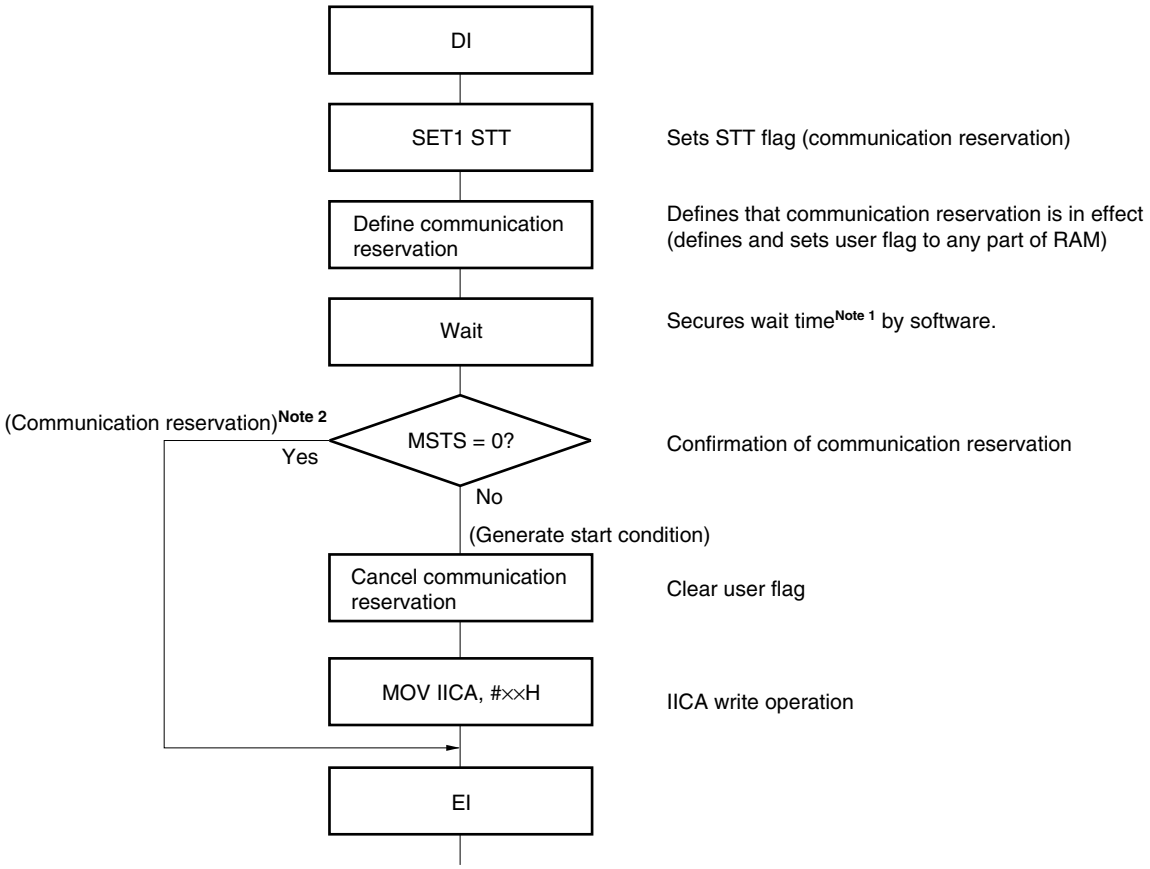
Figure 13-28. Communication Reservation Protocol



Notes 1. The wait time is calculated as follows.
(IICWL setting value + IICWH setting value + 4 (clocks)) × f_{CLK} + t_F × 2

2. The communication reservation operation executes a write to the IICA shift register (IICA) when a stop condition interrupt request occurs.

Remark STT: Bit 1 of IICA control register 0 (IICCTL0)
MSTS: Bit 7 of IICA status register (IICS)
IICA: IICA shift register
IICWL: IICA low-level width setting register
IICWH: IICA high-level width setting register
t_F: SDA0 and SCL0 signal falling times (see **CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET)**)
f_{CLK}: CPU/peripheral hardware clock frequency

(2) When communication reservation function is disabled (bit 0 (IICRSV) of IICA flag register (IICF) = 1)

When bit 1 (STT) of IICA control register 0 (IICCTL0) is set to 1 when the bus is not used in a communication during bus communication, this request is rejected and a start condition is not generated. The following two statuses are included in the status where bus is not used.

- When arbitration results in neither master nor slave operation
- When an extension code is received and slave operation is disabled ($\overline{\text{ACK}}$ is not returned and the bus was released by setting bit 6 (LREL) of IICCTL0 to 1 and saving communication)

To confirm whether the start condition was generated or request was rejected, check STCF (bit 7 of IICF). It takes up to 5 clocks until STCF is set to 1 after setting STT = 1. Therefore, secure the time by software.

13.5.15 Cautions

(1) When STCEN (bit 1 of IICA flag register (IICF)) = 0

Immediately after I^2C operation is enabled (IICE = 1), the bus communication status (IICBSY (bit 6 of IICF) = 1) is recognized regardless of the actual bus status. When changing from a mode in which no stop condition has been detected to a master device communication mode, first generate a stop condition to release the bus, then perform master device communication.

When using multiple masters, it is not possible to perform master device communication when the bus has not been released (when a stop condition has not been detected).

Use the following sequence for generating a stop condition.

<1> Set IICA control register 1 (IICCTL1).
<2> Set bit 7 (IICE) of IICA control register 0 (IICCTL0) to 1.
<3> Set bit 0 (SPT) of IICCTL0 to 1.

(2) When STCEN = 1

Immediately after I^2C operation is enabled (IICE = 1), the bus released status (IICBSY = 0) is recognized regardless of the actual bus status. To generate the first start condition (STT (bit 1 of IICA control register 0 (IICCTL0)) = 1), it is necessary to confirm that the bus has been released, so as to not disturb other communications.

(3) If other I^2C communications are already in progress

If I^2C operation is enabled and the device participates in communication already in progress when the SDA0 pin is low and the SCL0 pin is high, the macro of I^2C recognizes that the SDA0 pin has gone low (detects a start condition). If the value on the bus at this time can be recognized as an extension code, $\overline{ACK}$ is returned, but this interferes with other I^2C communications. To avoid this, start I^2C in the following sequence.

<1> Clear bit 4 (SPIE) of IICCTL0 to 0 to disable generation of an interrupt request signal (INTIICA) when the stop condition is detected.
<2> Set bit 7 (IICE) of IICCTL0 to 1 to enable the operation of I^2C.
<3> Wait for detection of the start condition.
<4> Set bit 6 (LREL) of IICCTL0 to 1 before $\overline{ACK}$ is returned (4 to 80 clocks after setting IICE to 1), to forcibly disable detection.

(4) Setting STT and SPT (bits 1 and 0 of IICCTL0) again after they are set and before they are cleared to 0 is prohibited.

(5) When transmission is reserved, set SPIE (bit 4 of IICTL0) to 1 so that an interrupt request is generated when the stop condition is detected. Transfer is started when communication data is written to IICA after the interrupt request is generated. Unless the interrupt is generated when the stop condition is detected, the device stops in the wait state because the interrupt request is not generated when communication is started. However, it is not necessary to set SPIE to 1 when MSTS (bit 7 of IICS) is detected by software.

13.5.16 Communication operations

The following shows three operation procedures with the flowchart.

(1) Master operation in single master system

The flowchart when using the 78K0R/Kx3-L as the master in a single master system is shown below.

This flowchart is broadly divided into the initial settings and communication processing. Execute the initial settings at startup. If communication with the slave is required, prepare the communication and then execute communication processing.

(2) Master operation in multimaster system

In the I^2C bus multimaster system, whether the bus is released or used cannot be judged by the I^2C bus specifications when the bus takes part in a communication. Here, when data and clock are at a high level for a certain period (1 frame), the 78K0R/Kx3-L takes part in a communication with bus released state.

This flowchart is broadly divided into the initial settings, communication waiting, and communication processing. The processing when the 78K0R/Kx3-L looses in arbitration and is specified as the slave is omitted here, and only the processing as the master is shown. Execute the initial settings at startup to take part in a communication. Then, wait for the communication request as the master or wait for the specification as the slave. The actual communication is performed in the communication processing, and it supports the transmission/reception with the slave and the arbitration with other masters.

(3) Slave operation

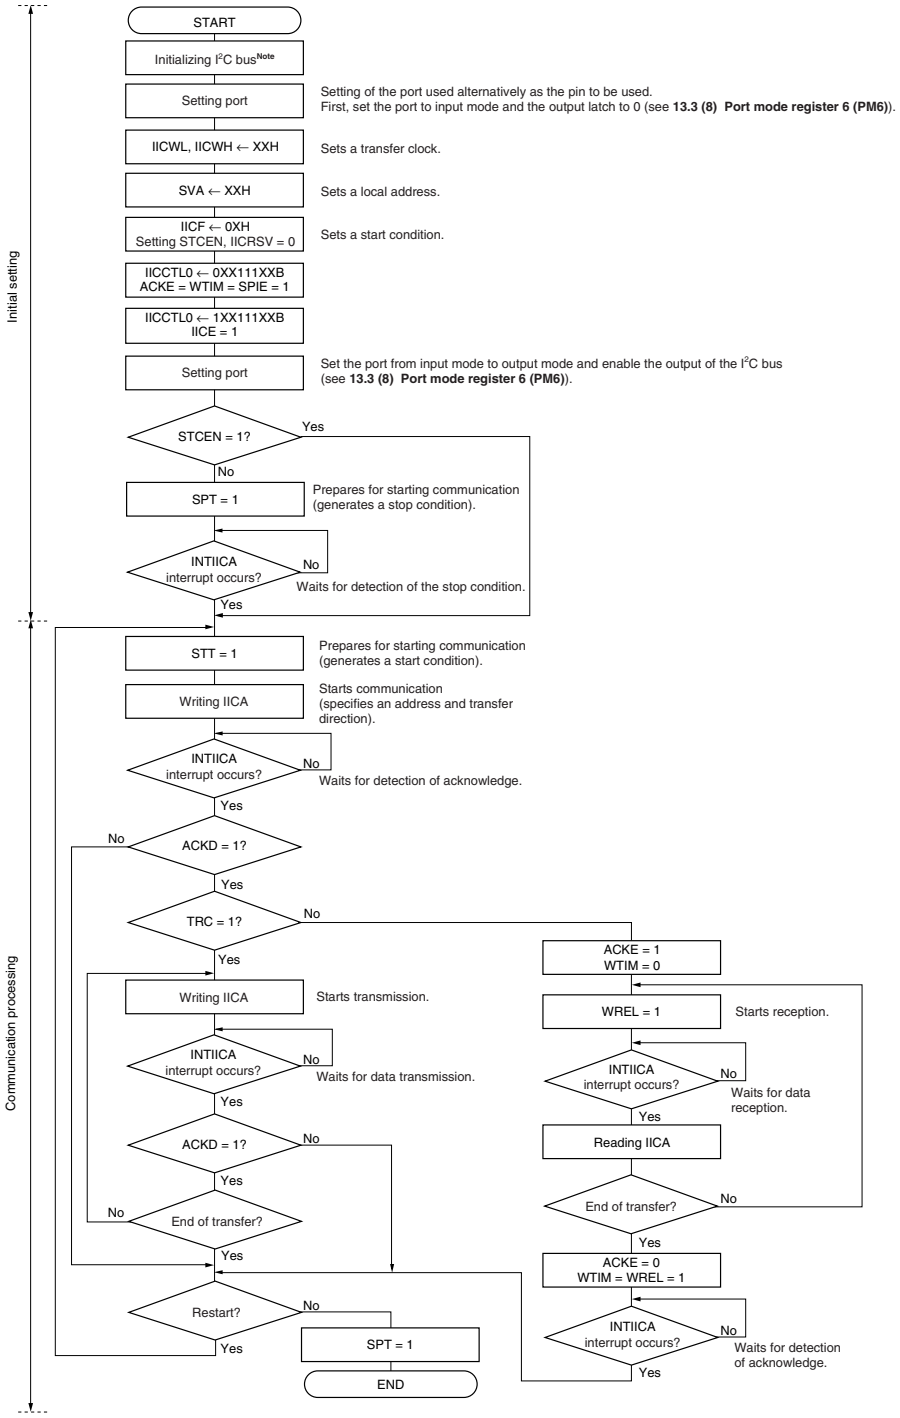
An example of when the 78K0R/Kx3-L is used as the I^2C bus slave is shown below.

When used as the slave, operation is started by an interrupt. Execute the initial settings at startup, then wait for the INTIICA interrupt occurrence (communication waiting). When an INTIICA interrupt occurs, the communication status is judged and its result is passed as a flag over to the main processing.

By checking the flags, necessary communication processing is performed.

(1) Master operation in single-master system

Figure 13-29. Master Operation in Single-Master System

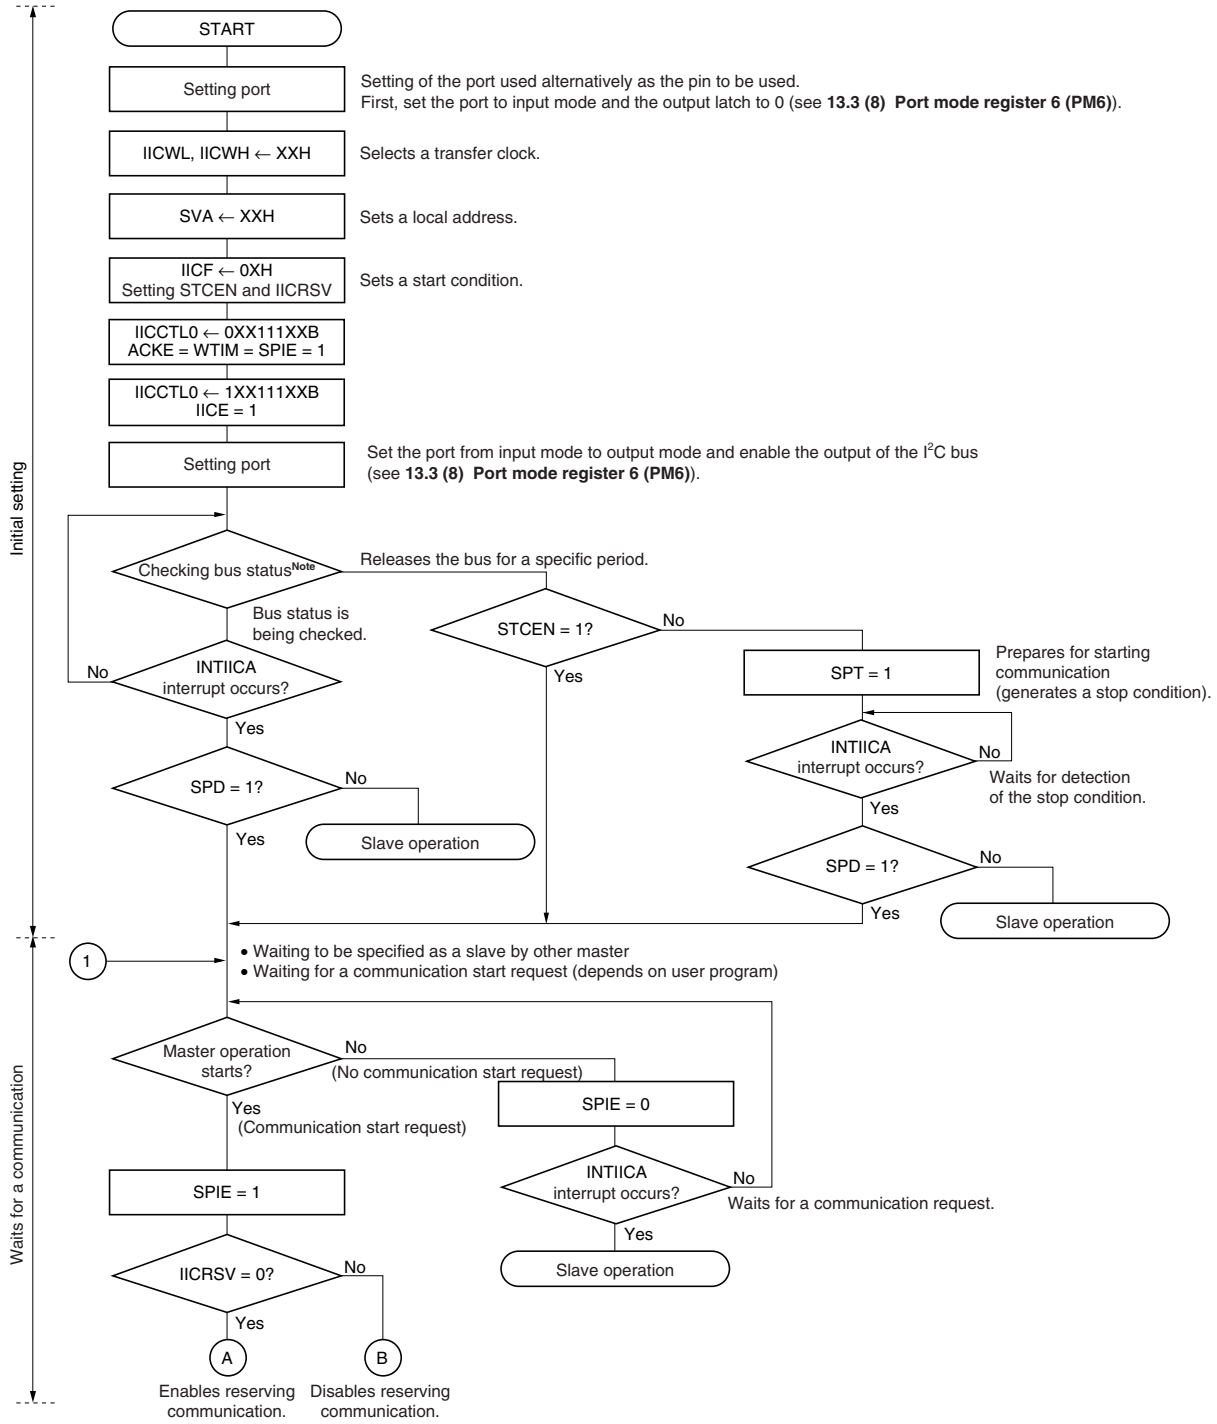


Note Release (SCL0 and SDA0 pins = high level) the I²C bus in conformance with the specifications of the product that is communicating. If EEPROM is outputting a low level to the SDA0 pin, for example, set the SCL0 pin in the output port mode, and output a clock pulse from the output port until the SDA0 pin is constantly at high level.

Remark Conform to the specifications of the product that is communicating, with respect to the transmission and reception formats.

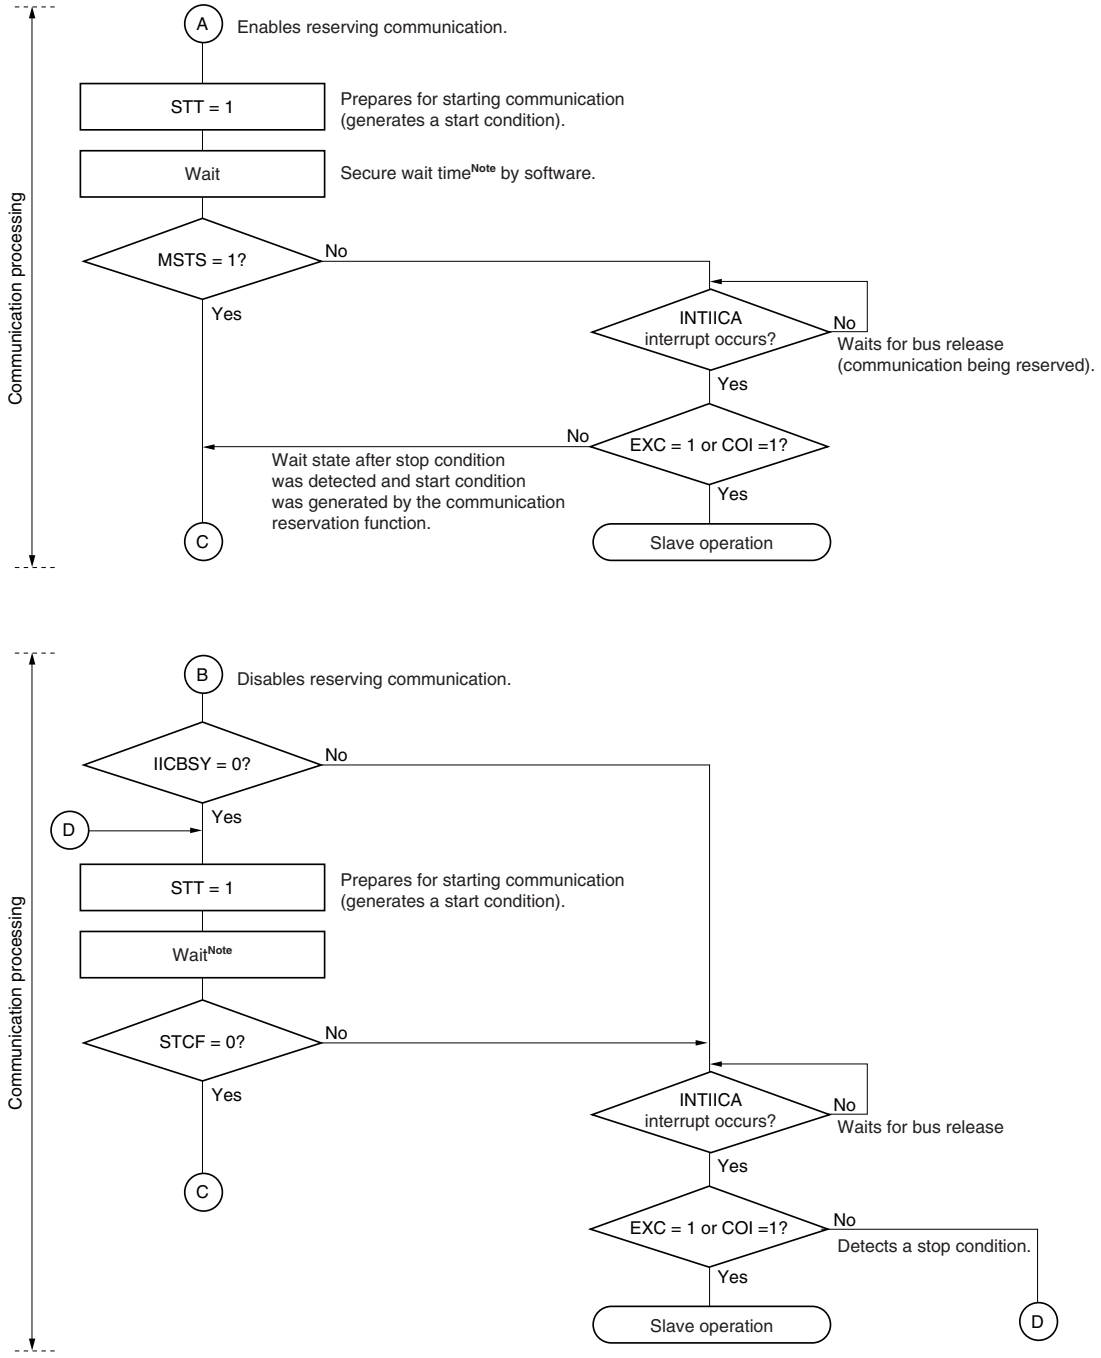
(2) Master operation in multi-master system

Figure 13-30. Master Operation in Multi-Master System (1/3)



Note Confirm that the bus is released (CLD bit = 1, DAD bit = 1) for a specific period (for example, for a period of one frame). If the SDA0 pin is constantly at low level, decide whether to release the I^2C bus (SCL0 and SDA0 pins = high level) in conformance with the specifications of the product that is communicating.

Figure 13-30. Master Operation in Multi-Master System (2/3)



Note The wait time is calculated as follows.

(IICWL setting value + IICWH setting value + 4 (clocks)) × f_{CLK} + t_F × 2

Remark IICWL: IICA low-level width setting register

IICWH: IICA high-level width setting register

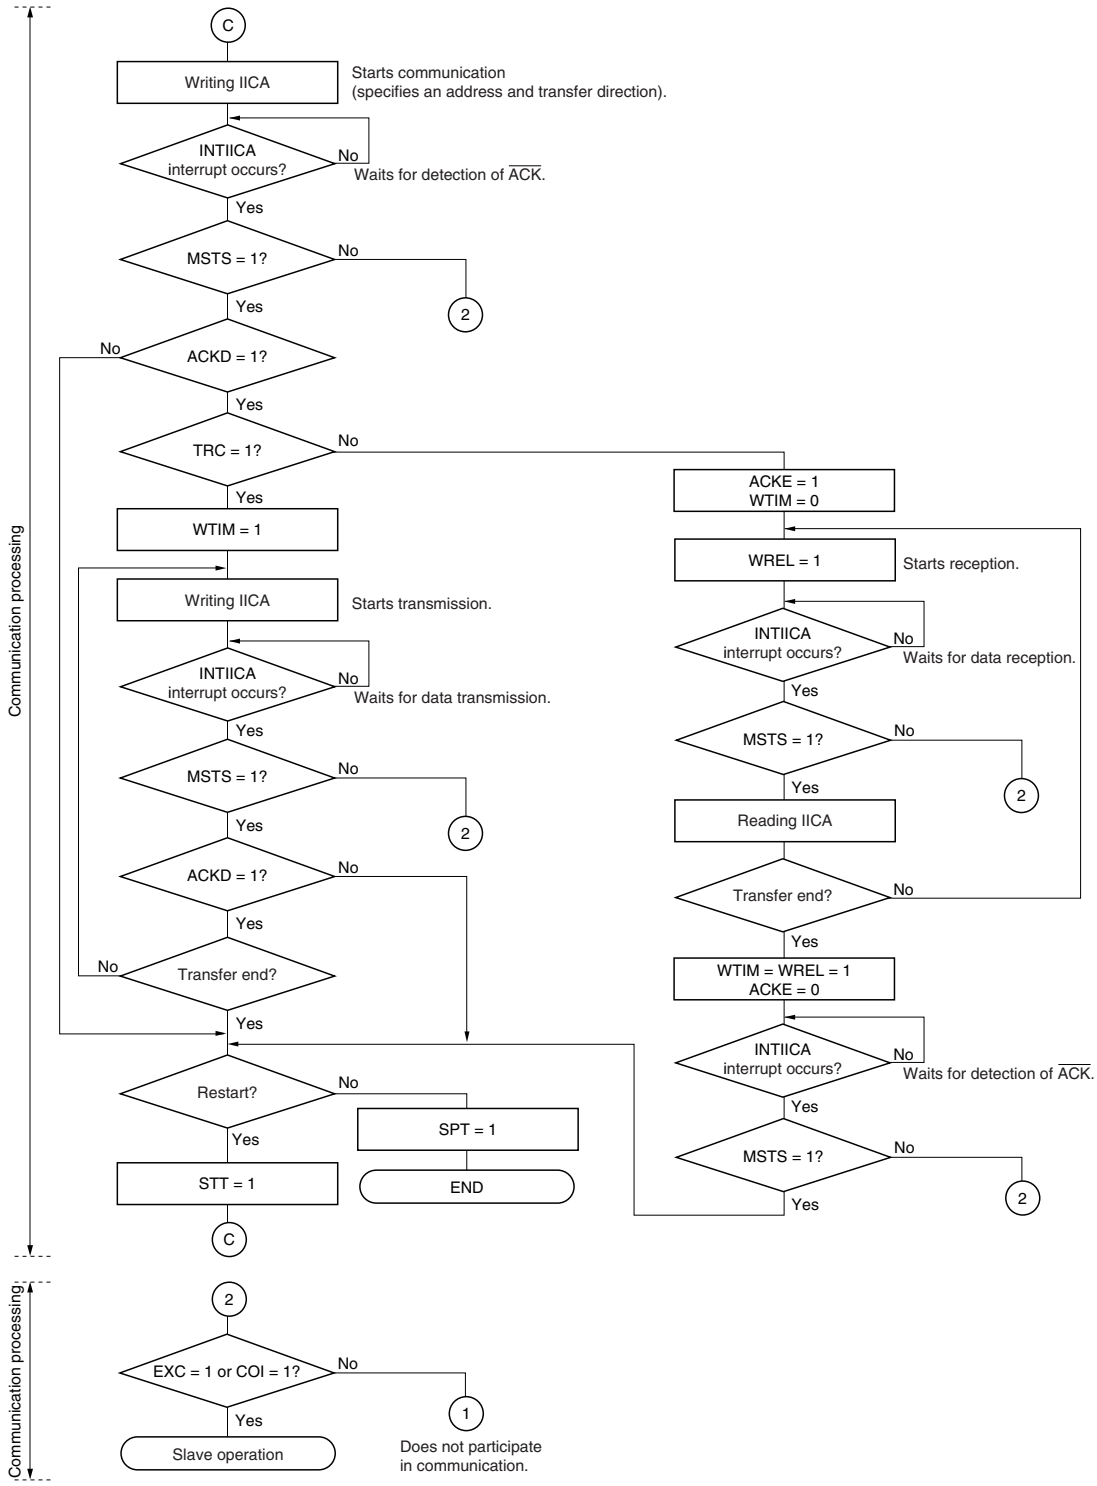
f_{CLK}: CPU/peripheral hardware clock frequency

Figure 13-30. Master Operation in Multi-Master System (3/3)



Remarks 1. Conform to the specifications of the product that is communicating, with respect to the transmission and reception formats.

2. To use the device as a master in a multi-master system, read the MSTS bit each time interrupt INTIICA has occurred to check the arbitration result.

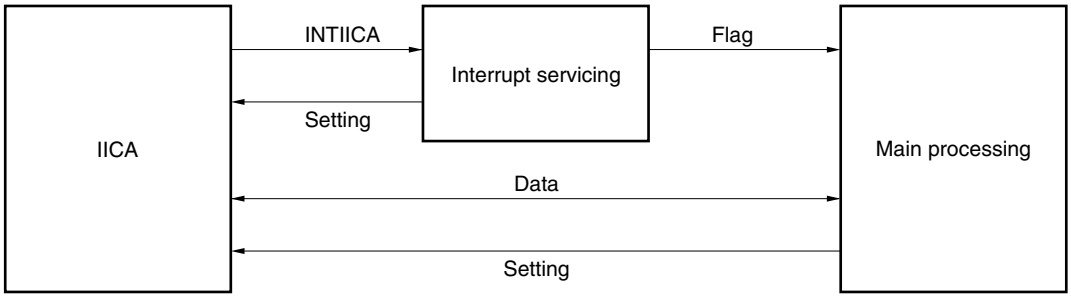
3. To use the device as a slave in a multi-master system, check the status by using the IICS and IICF registers each time interrupt INTIICA has occurred, and determine the processing to be performed next.

(3) Slave operation

The processing procedure of the slave operation is as follows.

Basically, the slave operation is event-driven. Therefore, processing by the INTIICA interrupt (processing that must substantially change the operation status such as detection of a stop condition during communication) is necessary.

In the following explanation, it is assumed that the extension code is not supported for data communication. It is also assumed that the INTIICA interrupt servicing only performs status transition processing, and that actual data communication is performed by the main processing.



Therefore, data communication processing is performed by preparing the following three flags and passing them to the main processing instead of INTIICA.

<1> Communication mode flag

This flag indicates the following two communication statuses.

- Clear mode: Status in which data communication is not performed
- Communication mode: Status in which data communication is performed (from valid address detection to stop condition detection, no detection of $\overline{\text{ACK}}$ from master, address mismatch)

<2> Ready flag

This flag indicates that data communication is enabled. Its function is the same as the INTIICA interrupt for ordinary data communication. This flag is set by interrupt servicing and cleared by the main processing. Clear this flag by interrupt servicing when communication is started. However, the ready flag is not set by interrupt servicing when the first data is transmitted. Therefore, the first data is transmitted without the flag being cleared (an address match is interpreted as a request for the next data).

<3> Communication direction flag

This flag indicates the direction of communication. Its value is the same as TRC.

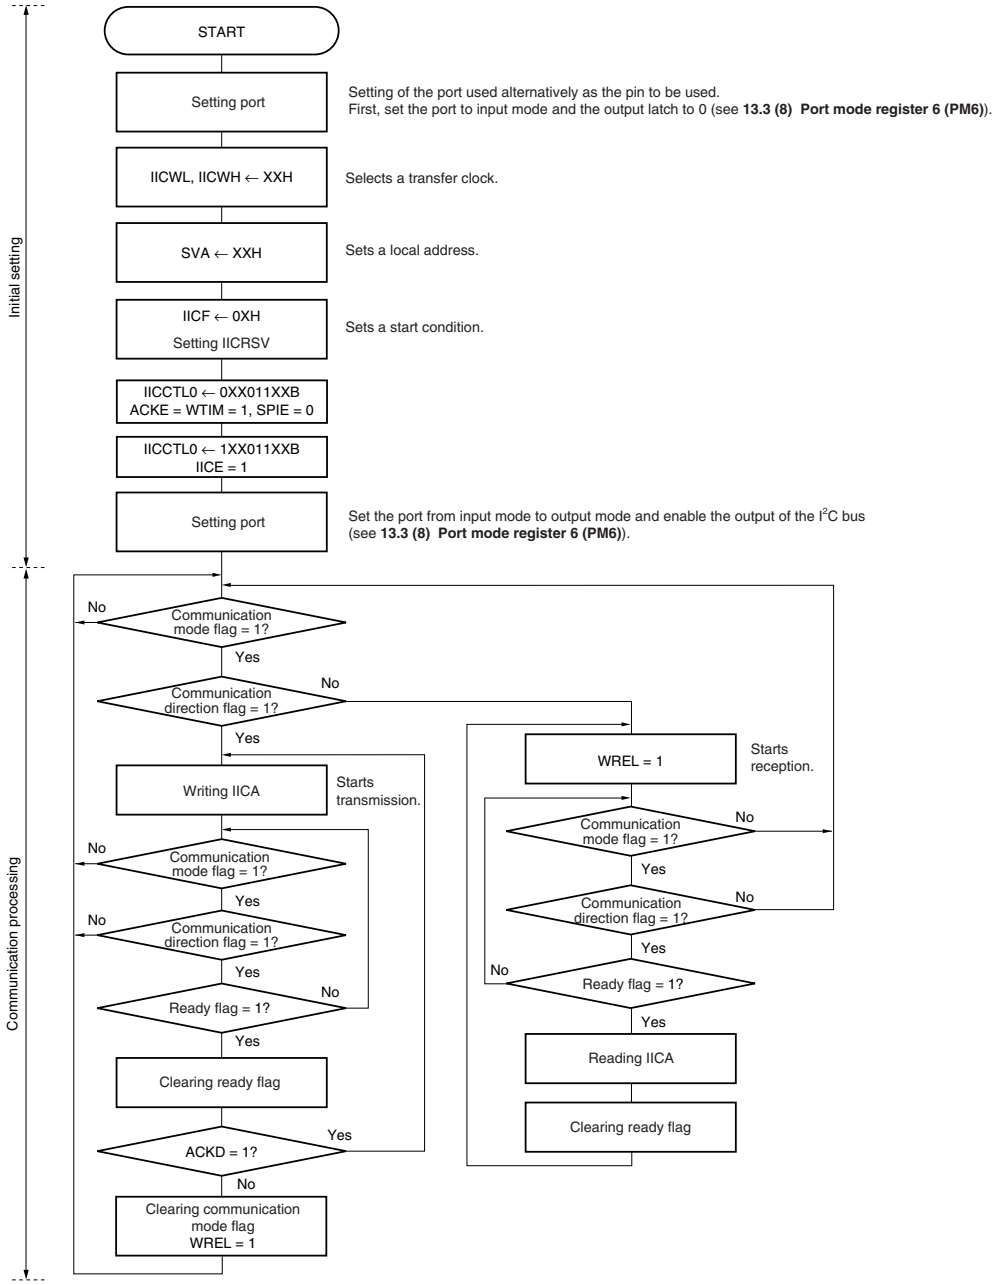
The main processing of the slave operation is explained next.

Start serial interface IICA and wait until communication is enabled. When communication is enabled, execute communication by using the communication mode flag and ready flag (processing of the stop condition and start condition is performed by an interrupt. Here, check the status by using the flags).

The transmission operation is repeated until the master no longer returns $\overline{ACK}$. If $\overline{ACK}$ is not returned from the master, communication is completed.

For reception, the necessary amount of data is received. When communication is completed, $\overline{ACK}$ is not returned as the next data. After that, the master generates a stop condition or restart condition. Exit from the communication status occurs in this way.

Figure 13-31. Slave Operation Flowchart (1)



Remark Conform to the specifications of the product that is in communication, regarding the transmission and reception formats.

An example of the processing procedure of the slave with the INTIICA interrupt is explained below (processing is performed assuming that no extension code is used). The INTIICA interrupt checks the status, and the following operations are performed.

<1> Communication is stopped if the stop condition is issued.

<2> If the start condition is issued, the address is checked and communication is completed if the address does not match. If the address matches, the communication mode is set, wait is cancelled, and processing returns from the interrupt (the ready flag is cleared).

<3> For data transmit/receive, only the ready flag is set. Processing returns from the interrupt with the I^2C bus remaining in the wait state.

Remark <1> to <3> above correspond to <1> to <3> in Figure 13-32 Slave Operation Flowchart (2).

13.6 Timing Charts

When using the I^2C bus mode, the master device outputs an address via the serial bus to select one of several slave devices as its communication partner.

After outputting the slave address, the master device transmits the TRC bit (bit 3 of the IICA status register (IICS)), which specifies the data transfer direction, and then starts serial communication with the slave device.

Figures 13-33 and 13-34 show timing charts of the data communication.

The IICA shift register (IICA)'s shift operation is synchronized with the falling edge of the serial clock (SCL0). The transmit data is transferred to the SO latch and is output (MSB first) via the SDA0 pin.

Data input via the SDA0 pin is captured into IICA at the rising edge of SCL0.

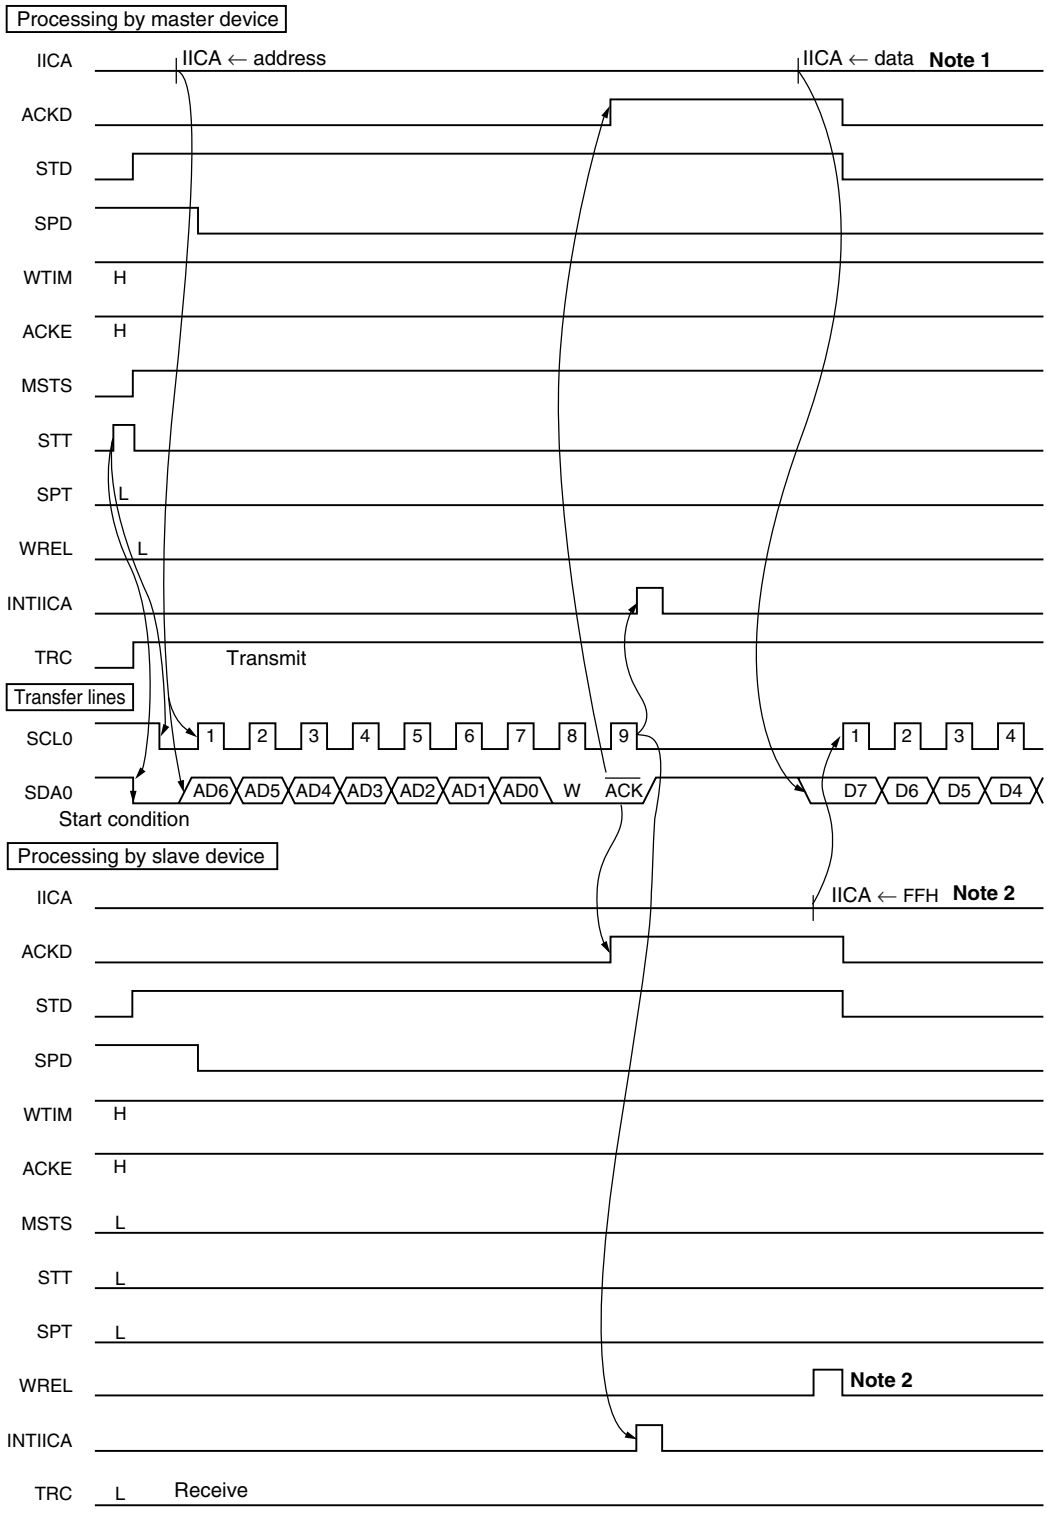
(1) Start condition ~ address



Notes 1. Write data to IICA, not setting WREL, in order to cancel a wait state during master transmission.

2. To cancel slave wait, write “FFH” to IICA or set WREL.

3. If a wait state during slave transmission is canceled by setting WREL, TRC will be cleared.

CHAPTER 14 MULTIPLIER/DIVIDER

14.1 Functions of Multiplier/Divider

The multiplier/divider has the following functions.

- 16 bits × 16 bits = 32 bits (multiplication)
- 32 bits ÷ 32 bits = 32 bits, 32-bit remainder (division)

14.2 Configuration of Multiplier/Divider

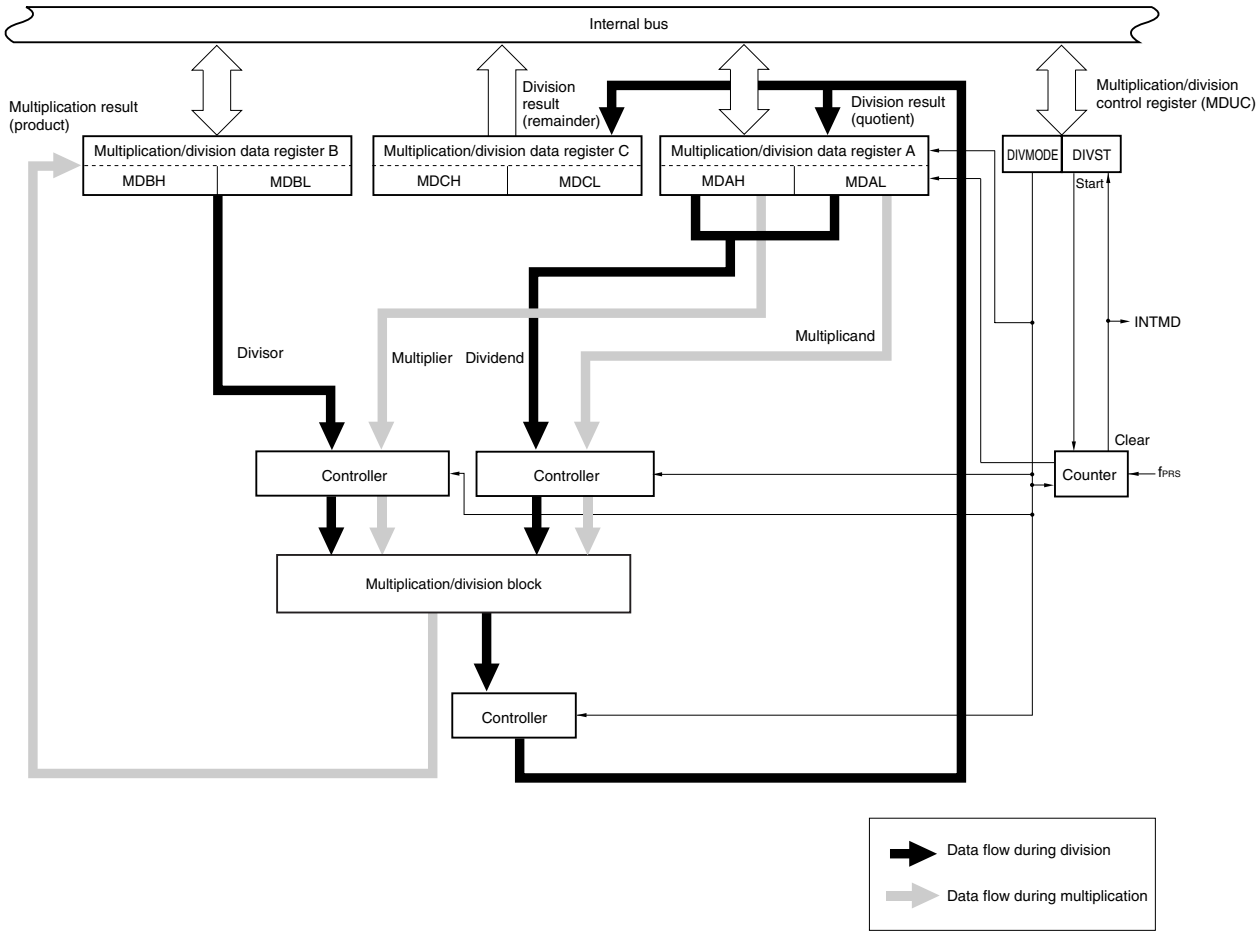
The multiplier/divider consists of the following hardware.

Table 14-1. Configuration of Multiplier/Divider

Item	Configuration
Registers	Multiplication/division data register A (L) (MDAL) Multiplication/division data register A (H) (MDAH) Multiplication/division data register B (L) (MDBL) Multiplication/division data register B (H) (MDBH) Multiplication/division data register C (L) (MDCL) Multiplication/division data register C (H) (MDCH)
Control register	Multiplication/division control register (MDUC)

Figure 14-1 shows a block diagram of the multiplier/divider.

Figure 14-1. Block Diagram of Multiplier/Divider



(1) Multiplication/division data register A (MDAH, MDAL)

The MDAH and MDAL registers set the values that are used for a multiplication or division operation and store the operation result. They set the multiplier and multiplicand data in the multiplication mode, and set the dividend data in the division mode. Furthermore, the operation result (quotient) is stored in the MDAH and MDAL registers in the division mode.

MDAH and MDAL can be set by a 16-bit manipulation instruction.

Reset signal generation clears these registers to 0000H.

Figure 14-2. Format of Multiplication/Division Data Register A (MDAH, MDAL)

Cautions 1. Do not rewrite the MDAH and MDAL values during division operation processing (while the multiplication/division control register (MDUC) is 81H). The operation will be executed in this case, but the operation result will be an undefined value.

2. The MDAH and MDAL values read during division operation processing (while MDUC is 81H) will not be guaranteed.

The following table shows the functions of MDAH and MDAL during operation execution.

Table 14-2. Functions of MDAH and MDAL During Operation Execution

DIVMODE	Operation Mode	Setting	Operation Result
0	Multiplication mode	MDAH: Multiplier MDAL: Multiplicand	–

Remark DIVMODE: Bit 7 of the multiplication/division control register (MDUC)

(2) Multiplication/division data register B (MDBL, MDBH)

The MDBH and MDBL registers set the values that are used for multiplication or division operation and store the operation result. They store the operation result (product) in the multiplication mode and set the divisor data in the division mode.

MDBH and MDBL can be set by a 16-bit manipulation instruction.

Reset signal generation clears these registers to 0000H.

Cautions 1. Do not rewrite the MDBH and MDBL values during division operation processing (while the multiplication/division control register (MDUC) is 81H). The operation result will be an undefined value.

2. Do not set MDBH and MDBL to 0000H in the division mode. If they are set, the operation result will be an undefined value.

The following table shows the functions of MDBH and MDBL during operation execution.

Table 14-3. Functions of MDBH and MDBL During Operation Execution

Remark DIVMODE: Bit 7 of the multiplication/division control register (MDUC)

(3) Multiplication/division data register C (MDCL, MDCH)

The MDCH and MDCL registers store remainder value of the operation result in the division mode. They are not used in the multiplication mode.

MDCH and MDCL can be read by a 16-bit manipulation instruction.

Reset signal generation clears these registers to 0000H.

0	Multiplication mode	–	–
1	Division mode	–	MDCH: Remainder (higher 16 bits) MDCL: Remainder (lower 16 bits)

Remark DIVMODE: Bit 7 of the multiplication/division control register (MDUC)

The register configuration differs between when multiplication is executed and when division is executed, as follows.

- Register configuration during multiplication

<Multiplier A> <Multiplier B> <Product>

MDAL (bits 15 to 0) × MDAH (bits 15 to 0) = [MDBH (bits 15 to 0), MDBL (bits 15 to 0)]

- Register configuration during division

<Dividend> <Divisor>

[MDAH (bits 15 to 0), MDAL (bits 15 to 0)] ÷ [MDBH (bits 15 to 0), MDBL (bits 15 to 0)] =

<Quotient> <Remainder>

[MDAH (bits 15 to 0), MDAL (bits 15 to 0)] ··· [MDCH (bits 15 to 0), MDCL (bits 15 to 0)]

14.3 Register Controlling Multiplier/Divider

The multiplier/divider is controlled by using the multiplication/division control register (MDUC).

(1) Multiplication/division control register (MDUC)

MDUC is an 8-bit register that controls the operation of the multiplier/divider.

MDUC can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Figure 14-5. Format of Multiplication/Division Control Register (MDUC)

Address: F00E8H After reset: 00H R/W

Symbol	<7>	6	5	4	3	2	1	<0>
MDUC	DIVMODE	0	0	0	0	0	0	DIVST

DIVMODE	Operation mode (multiplication/division) selection
0	Multiplication mode
1	Division mode

DIVST[Note]	Division operation start/stop
0	Division operation processing complete
1	Starts division operation/division operation processing in progress

Note DIVST can only be set (1) in the division mode. In the division mode, division operation is started by setting (1) DIVST. DIVST is automatically cleared (0) when the operation ends. In the multiplication mode, operation is automatically started by setting the multiplier and multiplicand to MDAH and MDAL, respectively.

Cautions 1. Do not rewrite DIVMODE during operation processing (while DIVST is 1). If it is rewritten, the operation result will be an undefined value.

2. DIVST cannot be cleared (0) by using software during division operation processing (while DIVST is 1).

14.4 Operations of Multiplier/Divider

14.4.1 Multiplication operation

- Initial setting
  - <1> Set bit 7 (DIVMODE) of the multiplication/division control register (MDUC) to 0.
  - <2> Set the multiplicand to the multiplication/division data register A (L) (MDAL).
  - <3> Set the multiplier to the multiplication/division data register A (H) (MDAH).
    (There is no preference in the order of executing steps <2> and <3>. Multiplication operation is automatically started when the multiplier and multiplicand are set to MDAH and MDAL, respectively.)
- During operation processing
  - <4> Wait for at least one clock. The operation will end when one clock has been issued.
- Operation end
  - <5> Read the product (lower 16 bits) from the multiplication/division data register B (L) (MDBL).
  - <6> Read the product (higher 16 bits) from the multiplication/division data register B (H) (MDBH).
    (There is no preference in the order of executing steps <5> and <6>.)
- Next operation

CHAPTER 15 DMA CONTROLLER

The 78K0R/Kx3-L has an internal DMA (Direct Memory Access) controller.

Data can be automatically transferred between the peripheral hardware supporting DMA, SFRs, and internal RAM without via CPU.

As a result, the normal internal operation of the CPU and data transfer can be executed in parallel with transfer between the SFR and internal RAM, and therefore, a large capacity of data can be processed. In addition, real-time control using communication, timer, and A/D can also be realized.

15.1 Functions of DMA Controller

- ○ Number of DMA channels: 2
- ○ Transfer unit: 8 or 16 bits
- ○ Maximum transfer unit: 1024 times
- ○ Transfer type: 2-cycle transfer (One transfer is processed in 2 clocks and the CPU stops during that processing.)
- ○ Transfer mode: Single-transfer mode
- ○ Transfer request: Selectable from the following peripheral hardware interrupts
  - A/D converter
  - Serial interface (CSI00, CSI01, CSI10, UART0, UART1, or IIC10)
  - Timer (channel 0, 1, 4, or 5)
- ○ Transfer target: Between SFR and internal RAM

Here are examples of functions using DMA.

- Successive transfer of serial interface
- Batch transfer of analog data
- Capturing A/D conversion result at fixed interval
- Capturing port value at fixed interval

15.2 Configuration of DMA Controller

The DMA controller includes the following hardware.

Table 15-1. Configuration of DMA Controller

Item	Configuration
Address registers	• DMA SFR address registers 0, 1 (DSA0, DSA1) • DMA RAM address registers 0, 1 (DRA0, DRA1)
Count register	• DMA byte count registers 0, 1 (DBC0, DBC1)
Control registers	• DMA mode control registers 0, 1 (DMC0, DMC1) • DMA operation control register 0, 1 (DRC0, DRC1)

(1) DMA SFR address register n (DSAn)

This is an 8-bit register that is used to set an SFR address that is the transfer source or destination of DMA channel n.

Set the lower 8 bits of the SFR addresses FFF00H to FFFFFH.

This register is not automatically incremented but fixed to a specific value.

In the 16-bit transfer mode, the least significant bit is ignored and is treated as an even address.

DSAn can be read or written in 8-bit units. However, it cannot be written during DMA transfer.

Reset signal generation clears this register to 00H.

Remark n: DMA channel number (n = 0, 1)

(2) DMA RAM address register n (DRAn)

This is a 16-bit register that is used to set a RAM address that is the transfer source or destination of DMA channel n.

Addresses of the internal RAM area other than the general-purpose registers (FF900H to FFEDFH in the case of the μPD78F1001, 78F1004, and 78F1007) can be set to this register.

Set the lower 16 bits of the RAM address.

This register is automatically incremented when DMA transfer has been started. It is incremented by +1 in the 8-bit transfer mode and by +2 in the 16-bit transfer mode. DMA transfer is started from the address set to this DRAn register. When the data of the last address has been transferred, DRAn stops with the value of the last address +1 in the 8-bit transfer mode, and the last address +2 in the 16-bit transfer mode.

In the 16-bit transfer mode, the least significant bit is ignored and is treated as an even address.

DRAn can be read or written in 8-bit or 16-bit units. However, it cannot be written during DMA transfer.

Reset signal generation clears this register to 0000H.

(n = 0, 1)

Remark n: DMA channel number (n = 0, 1)

(3) DMA byte count register n (DBCn)

This is a 10-bit register that is used to set the number of times DMA channel n executes transfer. Be sure to set the number of times of transfer to this DBCn register before executing DMA transfer (up to 1024 times).

Each time DMA transfer has been executed, this register is automatically decremented. By reading this DBCn register during DMA transfer, the remaining number of times of transfer can be learned.

DBCn can be read or written in 8-bit or 16-bit units. However, it cannot be written during DMA transfer.

Reset signal generation clears this register to 0000H.

3FEH	1022	Waiting for remaining 1022 times of DMA transfer
3FFH	1023	Waiting for remaining 1023 times of DMA transfer

Cautions 1. Be sure to clear bits 15 to 10 to "0".

2. If the general-purpose register is specified or the internal RAM space is exceeded as a result of continuous transfer, the general-purpose register or SFR space are written or read, resulting in loss of data in these spaces. Be sure to set the number of times of transfer that is within the internal RAM space.

Remark n: DMA channel number (n = 0, 1)

15.3 Registers Controlling DMA Controller

DMA controller is controlled by the following registers.

- DMA mode control register n (DMCn)
- DMA operation control register n (DRCn)

Remark n: DMA channel number (n = 0, 1)

(1) DMA mode control register n (DMCn)

DMCn is a register that is used to set a transfer mode of DMA channel n. It is used to select a transfer direction, data size, setting of pending, and start source. Bit 7 (STGn) is a software trigger that starts DMA.
Rewriting bits 6, 5, and 3 to 0 of DMCn is prohibited during operation (when DSTn = 1).
DMCn can be set by a 1-bit or 8-bit memory manipulation instruction.
Reset signal generation clears this register to 00H.

STGn[Note]	DMA transfer start software trigger
0	No trigger operation
1	DMA transfer is started when DMA operation is enabled (DENn = 1).
DMA transfer is started by writing 1 to STGn when DMA operation is enabled (DENn = 1). When this bit is read, 0 is always read.	

DRSn	Selection of DMA transfer direction
0	SFR to internal RAM
1	Internal RAM to SFR

DSn	Specification of transfer data size for DMA transfer
0	8 bits
1	16 bits

DWAITn	Pending of DMA transfer
0	Executes DMA transfer upon DMA start request (not held pending).
1	Holds DMA start request pending if any.
DMA transfer that has been held pending can be started by clearing the value of DWAITn to 0. It takes 2 clocks to actually hold DMA transfer pending when the value of DWAITn is set to 1.	

Note The software trigger (STGn) can be used regardless of the IFCn0 to IFCn3 values.

Other than above				Setting prohibited	

Note The software trigger (STGn) can be used regardless of the IFCn0 to IFCn3 values.

Remark n: DMA channel number (n = 0, 1)

(2) DMA operation control register n (DRCn)

DRCn is a register that is used to enable or disable transfer of DMA channel n.

Rewriting bit 7 (DENn) of this register is prohibited during operation (when DSTn = 1).

DRCn can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Symbol	<7>	6	5	4	3	2	1	<0>
DRCn	DENn	0	0	0	0	0	0	DSTn

DENn	DMA operation enable flag
0	Disables operation of DMA channel n (stops operating cock of DMA).
1	Enables operation of DMA channel n.
DMAC waits for a DMA trigger when DSTn = 1 after DMA operation is enabled (DENn = 1).	

DSTn	DMA transfer mode flag
0	DMA transfer of DMA channel n is completed.
1	DMA transfer of DMA channel n is not completed (still under execution).
DMAC waits for a DMA trigger when DSTn = 1 after DMA operation is enabled (DENn = 1). When a software trigger (STGn) or the start source trigger set by IFCn3 to IFCn0 is input, DMA transfer is started. When DMA transfer is completed after that, this bit is automatically cleared to 0. Write 0 to this bit to forcibly terminate DMA transfer under execution.	

Cautions 1. The DSTn flag is automatically cleared to 0 when a DMA transfer is completed. Writing the DENn flag is enabled only when DSTn = 0. When a DMA transfer is terminated without waiting for generation of the interrupt (INTDMAn) of DMAn, therefore, set DSTn to 0 and then DENn to 0 (for details, refer to 15.5.5 Forced termination by software).

2. When the FSEL bit of the OSMC register has been set to 1, do not enable (DENn = 1) DMA operation for at least three clocks after the setting.

Remark n: DMA channel number (n = 0, 1)

15.4 Operation of DMA Controller

15.4.1 Operation procedure

<1> The DMA controller is enabled to operate when DENn = 1. Before writing the other registers, be sure to set DENn to 1. Use 80H to write with an 8-bit manipulation instruction.

<2> Set an SFR address, a RAM address, the number of times of transfer, and a transfer mode of DMA transfer to the DSAn, DRAn, CBCn, and DMCn registers.

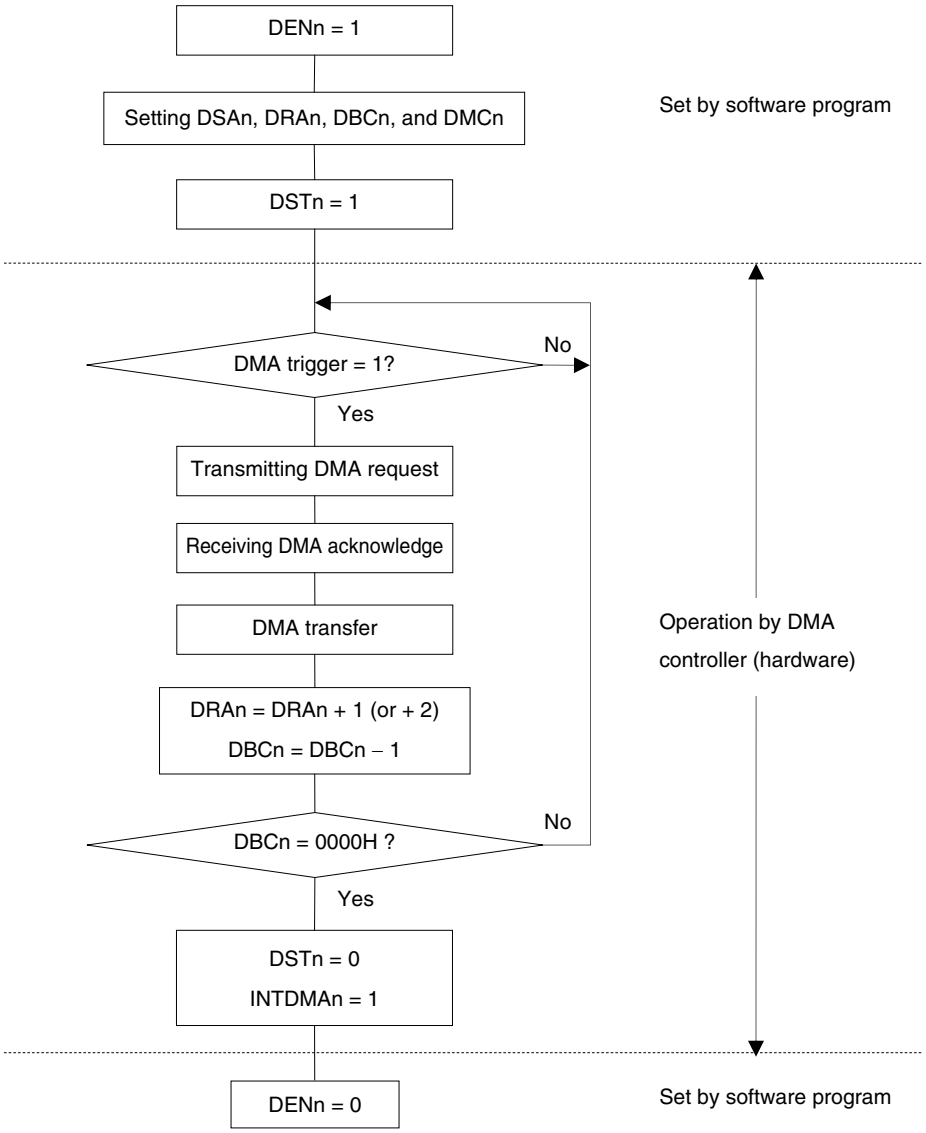
<3> The DMA controller waits for a DMA trigger when DSTn = 1. Use 81H to write with an 8-bit manipulation instruction.

<4> When a software trigger (STGn) or a start source trigger specified by IFCn3 to IFCn0 is input, a DMA transfer is started.

<5> Transfer is completed when the number of times of transfer set by the DBCn register reaches 0, and transfer is automatically terminated by occurrence of an interrupt (INTDMAn).

<6> Stop the operation of the DMA controller by clearing DENn to 0 when the DMA controller is not used.

Figure 15-6. Operation Procedure



Remark n: DMA channel number (n = 0, 1)

15.4.2 Transfer mode

The following four modes can be selected for DMA transfer by using bits 6 and 5 (DRSn and DSn) of the DMCn register.

DRSn	DSn	DMA Transfer Mode
0	0	Transfer from SFR of 1-byte data (fixed address) to RAM (address is incremented by +1)
0	1	Transfer from SFR of 2-byte data (fixed address) to RAM (address is incremented by +2)
1	0	Transfer from RAM of 1-byte data (address is incremented by +1) to SFR (fixed address)
1	1	Transfer from RAM of 2-byte data (address is incremented by +2) to SFR (fixed address)

By using these transfer modes, up to 1024 bytes of data can be consecutively transferred by using the serial interface, data resulting from A/D conversion can be consecutively transferred, and port data can be scanned at fixed time intervals by using a timer.

15.4.3 Termination of DMA transfer

When DBCn = 00H and DMA transfer is completed, the DSTn bit is automatically cleared to 0. An interrupt request (INTDMAn) is generated and transfer is terminated.

When the DSTn bit is cleared to 0 to forcibly terminate DMA transfer, the DBCn and DRAn registers hold the value when transfer is terminated.

The interrupt request (INTDMAn) is not generated if transfer is forcibly terminated.

Remark n: DMA channel number (n = 0, 1)

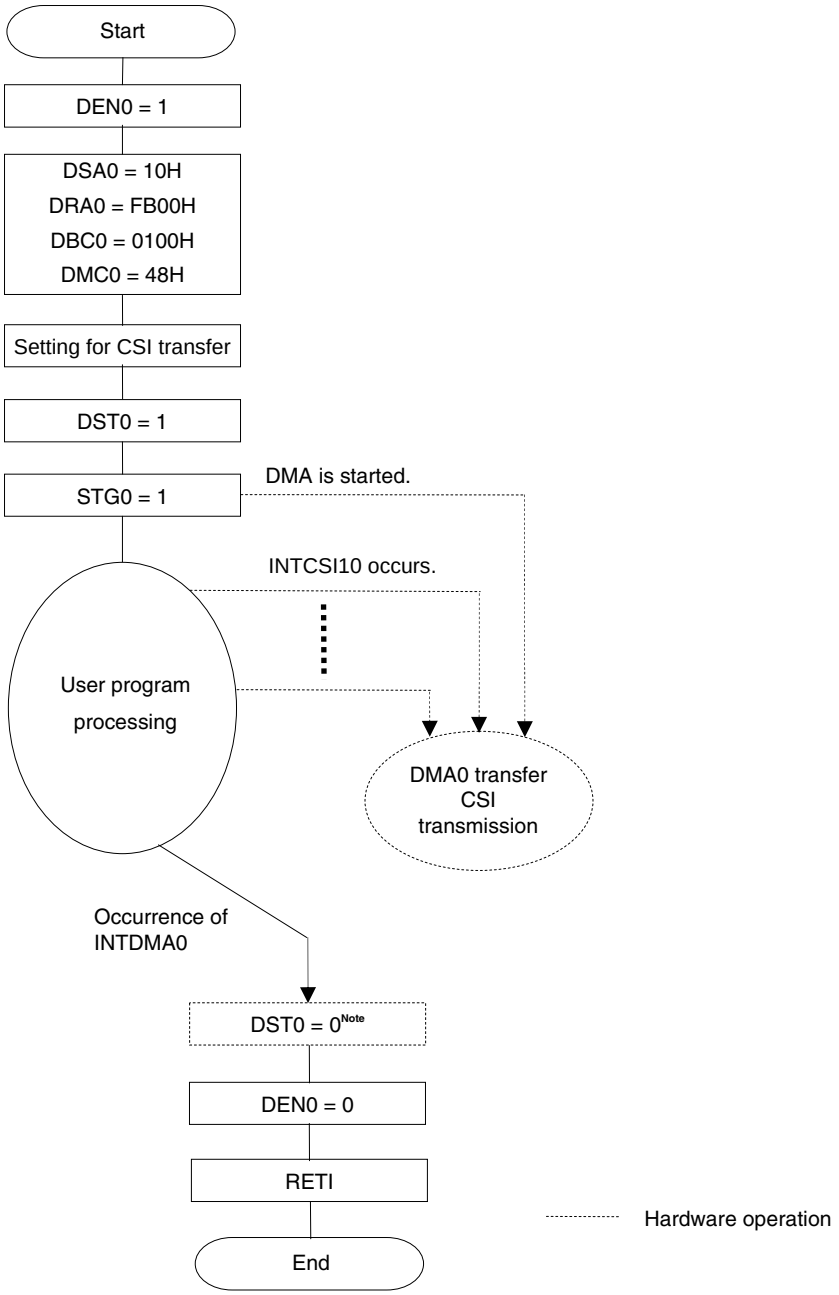
15.5 Example of Setting of DMA Controller

15.5.1 CSI consecutive transmission

A flowchart showing an example of setting for CSI consecutive transmission is shown below.

- Consecutive transmission of CSI10
- DMA channel 0 is used for DMA transfer.
- DMA start source: INTCSI10 (software trigger (STG0) only for the first start source)
- Interrupt of CSI10 is specified by IFC03 to IFC00 (bits 3 to 0 of the DMC0 register) = 1000B.
- Transfers FFB00H to FFBFFH (256 bytes) of RAM to FFF10H of the transmit buffer (SIO10) of CSI.

Figure 15-7. Example of Setting for CSI Consecutive Transmission



Note The DST0 flag is automatically cleared to 0 when a DMA transfer is completed.
Writing the DEN0 flag is enabled only when DST0 = 0. To terminate a DMA transfer without waiting for occurrence of the interrupt of DMA0 (INTDMA0), set DST0 to 0 and then DEN0 to 0 (for details, refer to **15.5.5 Forced termination by software**).

The fist trigger for consecutive transmission is not started by the interrupt of CSI. Start it by a software trigger.

CSI transmission of the second time and onward is automatically executed.

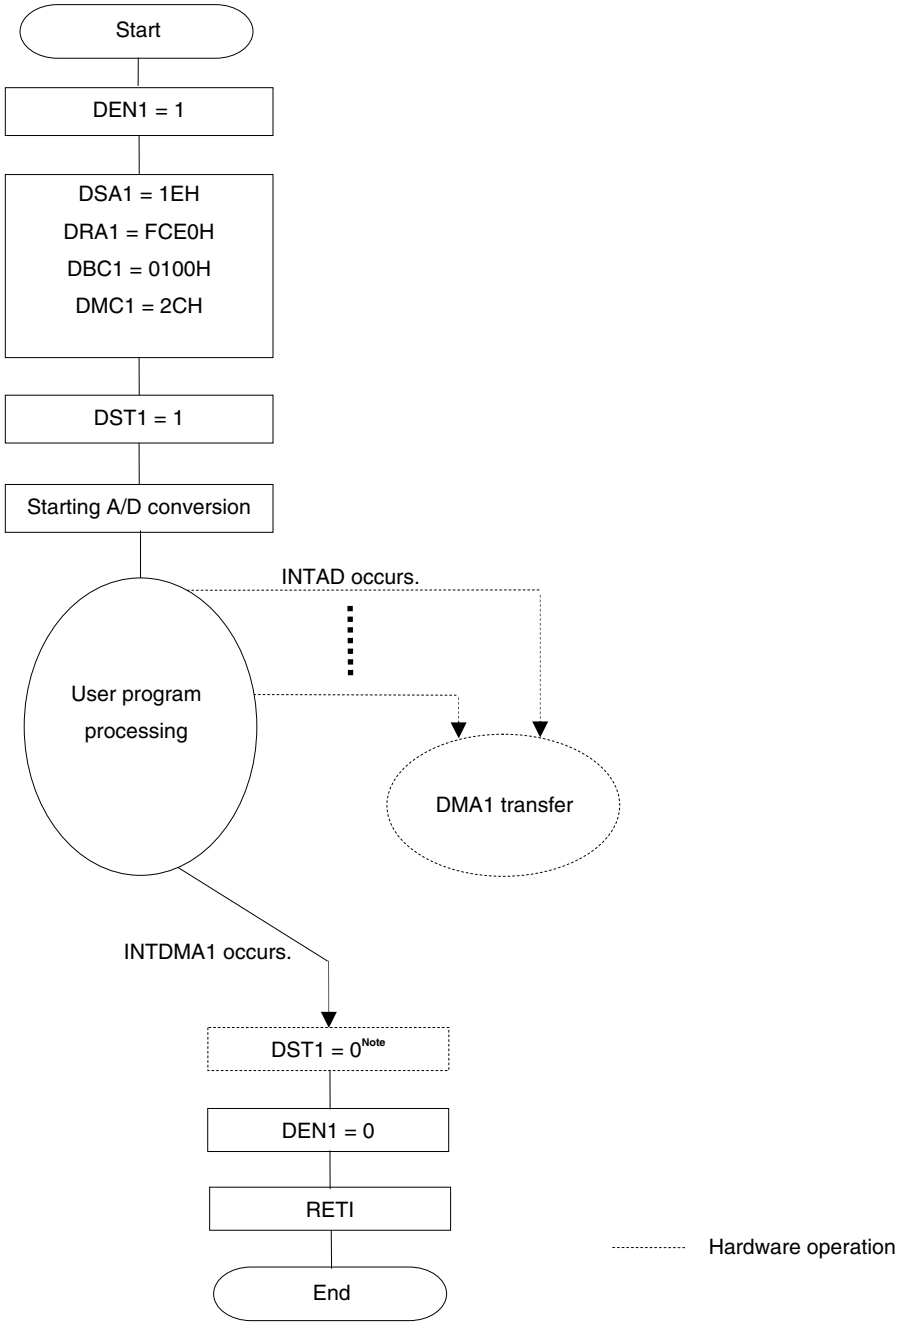
The DMA interrupt (INTDMA0) is generated as soon as the last data has been written to the transmit buffer. At this point, the last data of CSI is being transmitted. To start DMA transfer again, therefore, wait until transfer of CSI is completed.

15.5.2 Consecutive capturing of A/D conversion results

A flowchart of an example of setting for consecutively capturing A/D conversion results is shown below.

- Consecutive capturing of A/D conversion results.
- DMA channel 1 is used for DMA transfer.
- DMA start source: INTAD
- Interrupt of A/D is specified by IFC13 to IFC10 (bits 3 to 0 of the DMC1 register) = 1100B.
- Transfers FFF1EH and FFF1FH (2 bytes) of the 10-bit A/D conversion result register to 512 bytes of FFCE0H to FFEDFH of RAM.

Figure 15-8. Example of Setting of Consecutively Capturing A/D Conversion Results



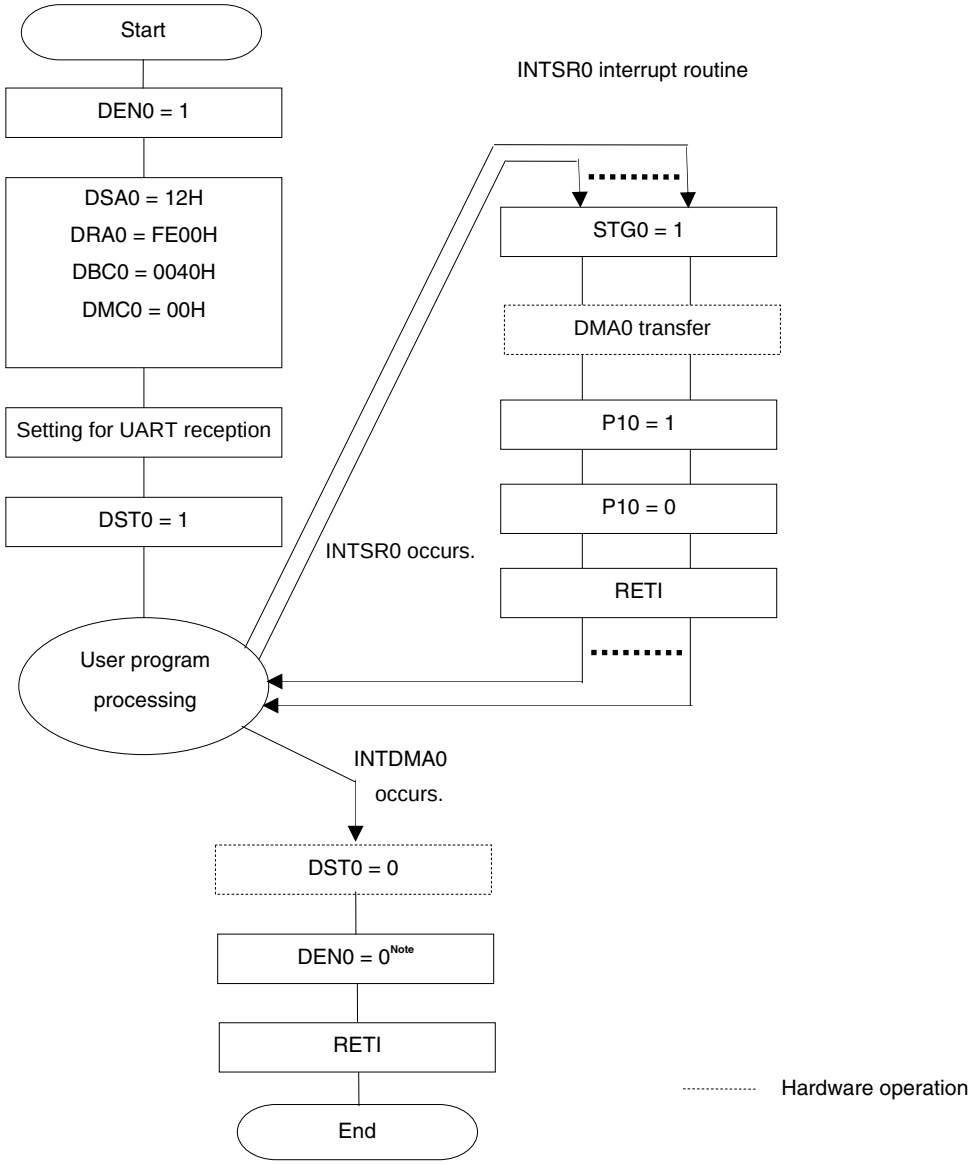
Note The DST1 flag is automatically cleared to 0 when a DMA transfer is completed.
Writing the DEN1 flag is enabled only when DST1 = 0. To terminate a DMA transfer without waiting for occurrence of the interrupt of DMA1 (INTDMA1), set DST1 to 0 and then DEN1 to 0 (for details, refer to **15.5.5 Forced termination by software**).

15.5.3 UART consecutive reception + ACK transmission

A flowchart illustrating an example of setting for UART consecutive reception + ACK transmission is shown below.

- Consecutively receives data from UART0 and outputs ACK to P10 on completion of reception.
- DMA channel 0 is used for DMA transfer.
- DMA start source: Software trigger (DMA transfer on occurrence of an interrupt is disabled.)
- Transfers FFF12H of UART receive data register 0 (RXD0) to 64 bytes of FFE00H to FFE3FH of RAM.

Figure 15-9. Example of Setting for UART Consecutive Reception + ACK Transmission



Note The DST0 flag is automatically cleared to 0 when a DMA transfer is completed.
Writing the DEN0 flag is enabled only when DST0 = 0. To terminate a DMA transfer without waiting for occurrence of the interrupt of DMA0 (INTDMA0), set DST0 to 0 and then DEN0 to 0 (for details, refer to **15.5.5 Forced termination by software**).

Remark This is an example where a software trigger is used as a DMA start source.
If ACK is not transmitted and if only data is consecutively received from UART, the UART reception end interrupt (INTSR0) can be used to start DMA for data reception.

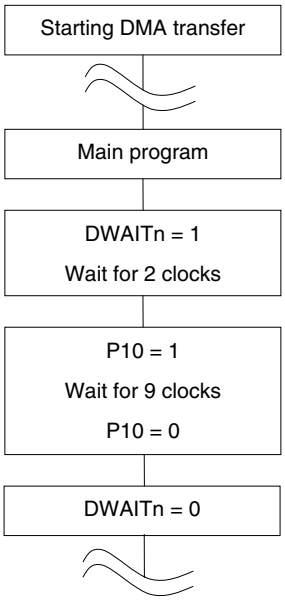
15.5.4 Holding DMA transfer pending by DWAITn

When DMA transfer is started, transfer is performed while an instruction is executed. At this time, the operation of the CPU is stopped and delayed for the duration of 2 clocks. If this poses a problem to the operation of the set system, a DMA transfer can be held pending by setting DWAITn to 1.

To output a pulse with a width of 10 clocks of the operating frequency from the P10 pin, for example, the clock width increases to 12 if a DMA transfer is started midway. In this case, the DMA transfer can be held pending by setting DWAITn to 1.

After setting DWAITn to 1, it takes two clocks until a DMA transfer is held pending.

Figure 15-10. Example of Setting for Holding DMA Transfer Pending by DWAITn



Remarks 1. n: DMA channel number (n = 0, 1)

2. 1 clock: $1/f_{CLK}$ (f_{CLK}: CPU clock)

15.5.5 Forced termination by software

After DSTn is set to 0 by software, it takes up to 2 clocks until a DMA transfer is actually stopped and DSTn is set to 0. To forcibly terminate a DMA transfer by software without waiting for occurrence of the interrupt (INTDMAn) of DMAn, therefore, perform either of the following processes.

- Set DSTn to 0 (use DRCn = 80H to write with an 8-bit manipulation instruction) by software, confirm by polling that DSTn has actually been cleared to 0, and then set DENn to 0 (use DRCn = 00H to write with an 8-bit manipulation instruction).

- Set DSTn to 0 (use DRCn = 80H to write with an 8-bit manipulation instruction) by software and then set DENn to 0 (use DRCn = 00H to write with an 8-bit manipulation instruction) two or more clocks after.

15.6 Cautions on Using DMA Controller

(1) Priority of DMA

During DMA transfer, a request from the other DMA channel is held pending even if generated. The pending DMA transfer is started after the ongoing DMA transfer is completed. When the requests from either of the DMA channels are successively generated in a short period [Note], they are successively transferred, and on completion of that, the requests from the other DMA channel are executed. In this case, one or tow instructions are executed between the first DMA transfer and next DMA transfer.

If two DMA requests are generated at the same time, however, DMA channel 0 takes priority over DMA channel 1.

If a DMA request and an interrupt request are generated at the same time, the DMA transfer takes precedence, and then interrupt servicing is executed.

Note The short period refers to a period of eight or fewer CPU clocks. The relationship between the lengths of clock period and DMA operations is as follows.

1 clock period:	Setting disabled DMA request cannot be accepted.
2 to 4 clock period:	DMA transfer of the channel where requests are successively generated is executed.
5 to 8 clock period:	Whether DMA transfer of the channel where requests are successively generated is executed or DMA requests from the other channel are executed depends on the number of times CPU instructions are executed.

(2) DMA response time

The response time of DMA transfer is as follows.

Table 15-2. Response Time of DMA Transfer

	Minimum Time	Maximum Time
Response time	4 clocks	10 clocks

Remark 1 clock: $1/f_{CLK}$ (f_{CLK}: CPU clock)

In the following cases, however, DMA transfer may be delayed further. The number of clocks by which DMA transfer is delayed differs depending on the condition.

- Instruction execution by RAM
- Execution of DMA pending instruction

(3) Operation in standby mode

The DMA controller operates as follows in the standby mode.

Table 15-3. DMA Operation in Standby Mode

Status	DMA Operation
HALT mode	Normal operation
STOP mode	Stops operation. If DMA transfer and STOP instruction execution contend, DMA transfer may be damaged. Therefore, stop DMA before executing the STOP instruction.

(4) DMA pending instruction

Even if a DMA request is generated, DMA transfer is held pending immediately after the following instructions.

- CALL !addr16
- CALL &!addr16
- CALL !!addr20
- CALL rp
- CALLT [addr5]
- BRK
- Bit manipulation instructions for registers IF0L, IF0H, IF1L, IF1H, IF2L, IF2H, MK0L, MK0H, MK1L, MK1H, MK2L, MK2H, PR00L, PR00H, PR01L, PR01H, PR02L, PR02H, PR10L, PR10H, PR11L, PR11H, PR12L, PR12H and PSW each, and 8-bit manipulation instructions with operands including ES registers

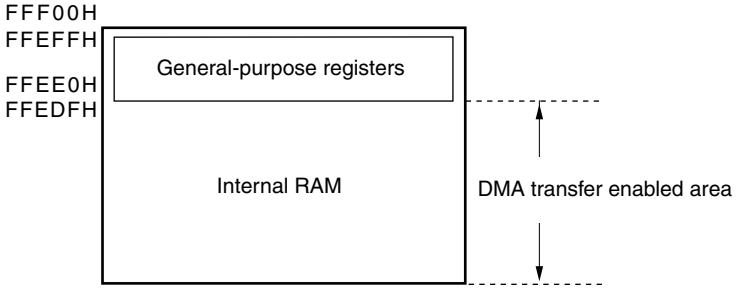
(5) Operation if address in general-purpose register area or other than those of internal RAM area is specified

The address indicated by DRA0n is incremented during DMA transfer. If the address is incremented to an address in the general-purpose register area or exceeds the area of the internal RAM, the following operation is performed.

- In mode of transfer from SFR to RAM
  The data of that address is lost.

- In mode of transfer from RAM to SFR
  Undefined data is transferred to SFR.

In either case, malfunctioning may occur or damage may be done to the system. Therefore, make sure that the address is within the internal RAM area other than the general-purpose register area.



CHAPTER 16 INTERRUPT FUNCTIONS

The number of interrupt sources differs, depending on the product.

		78K0R/KC3-L (44-pin)	78K0R/KC3-L (48-pin)	78K0R/KD3-L	78K0R/KE3-L
Maskable interrupts	Internal	9	9	9	9
	External	24	25	25	25

16.1 Interrupt Function Types

The following two types of interrupt functions are used.

(1) Maskable interrupts

These interrupts undergo mask control. Maskable interrupts can be divided into four priority groups by setting the priority specification flag registers (PR00L, PR00H, PR01L, PR01H, PR02L, PR10L, PR10H, PR11L, PR11H, PR12L).

Multiple interrupt servicing can be applied to low-priority interrupts when high-priority interrupts are generated. If two or more interrupt requests, each having the same priority, are simultaneously generated, then they are processed according to the priority of vectored interrupt servicing. For the priority order, see **Table 16-1**.

A standby release signal is generated and STOP and HALT modes are released.

External interrupt requests and internal interrupt requests are provided as maskable interrupts.

(2) Software interrupt

This is a vectored interrupt generated by executing the BRK instruction. It is acknowledged even when interrupts are disabled. The software interrupt does not undergo interrupt priority control.

16.2 Interrupt Sources and Configuration

Interrupt sources include maskable interrupts and software interrupts. In addition, they also have up to five reset sources (see **Table 16-1**).

Table 16-1. Interrupt Source List (1/2)

16.3 Registers Controlling Interrupt Functions

The following 6 types of registers are used to control the interrupt functions.

- Interrupt request flag registers (IF0L, IF0H, IF1L, IF1H, IF2L)
- Interrupt mask flag registers (MK0L, MK0H, MK1L, MK1H, MK2L)
- Priority specification flag registers (PR00L, PR00H, PR01L, PR01H, PR02L, PR10L, PR10H, PR11L, PR11H, PR12L)
- External interrupt rising edge enable register (EGP0)
- External interrupt falling edge enable register (EGN0)
- Program status word (PSW)

Table 16-2 shows a list of interrupt request flags, interrupt mask flags, and priority specification flags corresponding to interrupt request sources.

Notes 1. Do not use UART0 and CSI00 at the same time because they share flags for the interrupt request sources. If one of the interrupt sources INST0 and INTCSI00 is generated, bit 5 of IF0H is set to 1. Bit 5 of MK0H, PR00H, and PR10H supports these two interrupt sources.

2. Do not use UART0 and CSI01 at the same time because they share flags for the interrupt request sources. If one of the interrupt sources INSR0 and INTCSI01 is generated, bit 6 of IF0H is set to 1. Bit 6 of MK0H, PR00H, and PR10H supports these two interrupt sources.

Notes 1. Do not use UART1, CSI10, and IIC10 at the same time because they share flags for the interrupt request sources. If one of the interrupt sources INTST1, INTCSI10, and INTIIC10 is generated, bit 0 of IF1L is set to 1. Bit 0 of MK1L, PR01L, and PR11L supports these three interrupt sources.

2. 44-pin products of 78K0R/KC3-L is not provided.

(1) Interrupt request flag registers (IF0L, IF0H, IF1L, IF1H, IF2L)

The interrupt request flags are set to 1 when the corresponding interrupt request is generated or an instruction is executed. They are cleared to 0 when an instruction is executed upon acknowledgment of an interrupt request or upon reset signal generation.

When an interrupt is acknowledged, the interrupt request flag is automatically cleared and then the interrupt routine is entered.

IF0L, IF0H, IF1L, IF1H, and IF2L can be set by a 1-bit or 8-bit memory manipulation instruction. When IF0L and IF0H, and IF1L and IF1H are combined to form 16-bit registers IF0 and IF1, they can be set by a 16-bit memory manipulation instruction. Using IF2L as IF2 can be set also by using a 16-bit memory manipulation instruction.

Reset signal generation clears these registers to 00H.

Remark If an instruction that writes data to this register is executed, the number of instruction execution clocks increases by 2 clocks.

Figure 16-2. Format of Interrupt Request Flag Registers (IF0L, IF0H, IF1L, IF1H, IF2L) (2/2)

XXIFX	Interrupt request flag
0	No interrupt request signal is generated
1	Interrupt request is generated, interrupt request status

Cautions 1. Be sure to clear bit 0 of IF0H, bits 4 and 5 of IF1H, and bits 5 to 7 of IF2L to 0.

2. When operating a timer, serial interface, or A/D converter after standby release, operate it once after clearing the interrupt request flag. An interrupt request flag may be set by noise.

3. When manipulating a flag of the interrupt request flag register, use a 1-bit memory manipulation instruction (CLR1). When describing in C language, use a bit manipulation instruction such as "IF0L.0 = 0;" or "_asm("clr1 IF0L, 0");" because the compiled assembler must be a 1-bit memory manipulation instruction (CLR1).

If a program is described in C language using an 8-bit memory manipulation instruction such as "IF0L &= 0xfe;" and compiled, it becomes the assembler of three instructions.

```
mov a, IF0L
and a, #0FEH
mov IF0L, a
```

In this case, even if the request flag of another bit of the same interrupt request flag register (IF0L) is set to 1 at the timing between "mov a, IF0L" and "mov IF0L, a", the flag is cleared to 0 at "mov IF0L, a". Therefore, care must be exercised when using an 8-bit memory manipulation instruction in C language.

(2) Interrupt mask flag registers (MK0L, MK0H, MK1L, MK1H, MK2L)

The interrupt mask flags are used to enable/disable the corresponding maskable interrupt servicing.

MK0L, MK0H, MK1L, MK1H, and MK2L can be set by a 1-bit or 8-bit memory manipulation instruction. When MK0L and MK0H, and MK1L and MK1H are combined to form 16-bit registers MK0 and MK1, they can be set by a 16-bit memory manipulation instruction. Using MK2L as MK2 can be set also by using a 16-bit memory manipulation instruction.

Reset signal generation sets these registers to FFH.

Remark If an instruction that writes data to this register is executed, the number of instruction execution clocks increases by 2 clocks.

(3) Priority specification flag registers (PR00L, PR00H, PR01L, PR01H, PR02L, PR10L, PR10H, PR11L, PR11H, PR12L)

The priority specification flag registers are used to set the corresponding maskable interrupt priority level.

A priority level is set by using the PR0xy and PR1xy registers in combination (xy = 0L, 0H, 1L, 1H, or 2L).

PR00L, PR00H, PR01L, PR01H, PR02L, PR10L, PR10H, PR11L, PR11H, and PR12L can be set by a 1-bit or 8-bit memory manipulation instruction. If PR00L and PR00H, PR01L and PR01H, PR10L and PR10H, and PR11L and PR11H are combined to form 16-bit registers PR00, PR01, PR10, and PR11, they can be set by a 16-bit memory manipulation instruction. Using PR02L as PR02 and PR12L as PR12 can be set also by using a 16-bit memory manipulation instruction.

Reset signal generation sets these registers to FFH.

Remark If an instruction that writes data to this register is executed, the number of instruction execution clocks increases by 2 clocks.

(4) External interrupt rising edge enable register (EGP0), external interrupt falling edge enable register (EGN0)

These registers specify the valid edge for INTP0 to INTP7.

EGP0 and EGN0 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears these registers to 00H.

Remark n = 0 to 7

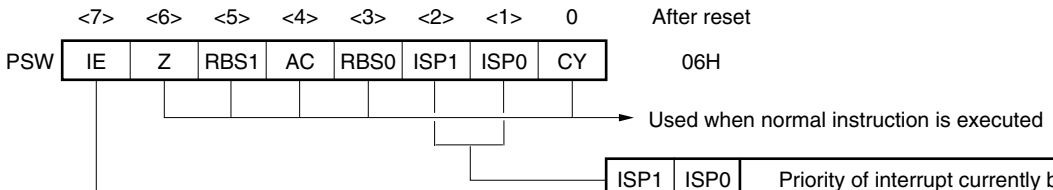
(5) Program status word (PSW)

The program status word is a register used to hold the instruction execution result and the current status for an interrupt request. The IE flag that sets maskable interrupt enable/disable and the ISP0 and ISP1 flags that controls multiple interrupt servicing are mapped to the PSW.

Besides 8-bit read/write, this register can carry out operations using bit manipulation instructions and dedicated instructions (EI and DI). When a vectored interrupt request is acknowledged, if the BRK instruction is executed, the contents of the PSW are automatically saved into a stack and the IE flag is reset to 0. If a maskable interrupt request is acknowledged, the contents of the priority specification flag of the acknowledged interrupt are transferred to the ISP0 and ISP1 flags. The PSW contents are also saved into the stack with the PUSH PSW instruction. They are restored from the stack with the RETI, RETB, and POP PSW instructions.

Reset signal generation sets PSW to 06H.

Figure 16-6. Configuration of Program Status Word



ISP1	ISP0	Priority of interrupt currently being serviced
0	0	Enables interrupt of level 0 (while interrupt of level 1 or 0 is being serviced).
0	1	Enables interrupt of level 0 and 1 (while interrupt of level 2 is being serviced).
1	0	Enables interrupt of level 0 to 2 (while interrupt of level 3 is being serviced).
1	1	Enables all interrupts (waits for acknowledgment of an interrupt).

16.4 Interrupt Servicing Operations

16.4.1 Maskable interrupt request acknowledgment

A maskable interrupt request becomes acknowledgeable when the interrupt request flag is set to 1 and the mask (MK) flag corresponding to that interrupt request is cleared to 0. A vectored interrupt request is acknowledged if interrupts are in the interrupt enabled state (when the IE flag is set to 1). However, a low-priority interrupt request is not acknowledged during servicing of a higher priority interrupt request.

The times from generation of a maskable interrupt request until vectored interrupt servicing is performed are listed in Table 16-4 below.

For the interrupt request acknowledgment timing, see **Figures 16-8** and **16-9**.

Table 16-4. Time from Generation of Maskable Interrupt Until Servicing

	Minimum Time	Maximum Time[Note]
Servicing time	9 clocks	14 clocks

Note If an interrupt request is generated just before the RET instruction, the wait time becomes longer.

Remark 1 clock: $1/f_{CLK}$ (f_{CLK}: CPU clock)

If two or more maskable interrupt requests are generated simultaneously, the request with a higher priority level specified in the priority specification flag is acknowledged first. If two or more interrupts requests have the same priority level, the request with the highest default priority is acknowledged first.

An interrupt request that is held pending is acknowledged when it becomes acknowledgeable.

Figure 16-7 shows the interrupt request acknowledgment algorithm.

If a maskable interrupt request is acknowledged, the contents are saved into the stacks in the order of PSW, then PC, the IE flag is reset (0), and the contents of the priority specification flag corresponding to the acknowledged interrupt are transferred to the ISP1 and ISP0 flags. The vector table data determined for each interrupt request is the loaded into the PC and branched.

Restoring from an interrupt is possible by using the RETI instruction.

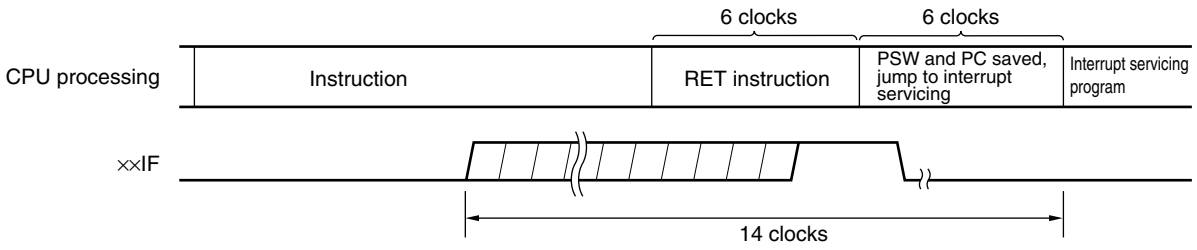
Remark 1 clock: 1/f_{CLK} (f_{CLK}: CPU clock)

Figure 16-9. Interrupt Request Acknowledgment Timing (Maximum Time)



Remark 1 clock: 1/f_{CLK} (f_{CLK}: CPU clock)

16.4.2 Software interrupt request acknowledgment

A software interrupt request is acknowledged by BRK instruction execution. Software interrupts cannot be disabled.

If a software interrupt request is acknowledged, the contents are saved into the stacks in the order of the program status word (PSW), then program counter (PC), the IE flag is reset (0), and the contents of the vector table (0007EH, 0007FH) are loaded into the PC and branched.

Restoring from a software interrupt is possible by using the RETB instruction.

Caution Do not use the RETI instruction for restoring from the software interrupt.

16.4.3 Multiple interrupt servicing

Multiple interrupt servicing occurs when another interrupt request is acknowledged during execution of an interrupt.

Multiple interrupt servicing does not occur unless the interrupt request acknowledgment enabled state is selected (IE = 1). When an interrupt request is acknowledged, interrupt request acknowledgment becomes disabled (IE = 0). Therefore, to enable multiple interrupt servicing, it is necessary to set (1) the IE flag with the EI instruction during interrupt servicing to enable interrupt acknowledgment.

Moreover, even if interrupts are enabled, multiple interrupt servicing may not be enabled, this being subject to interrupt priority control. Two types of priority control are available: default priority control and programmable priority control. Programmable priority control is used for multiple interrupt servicing.

In the interrupt enabled state, if an interrupt request with a priority equal to or higher than that of the interrupt currently being serviced is generated, it is acknowledged for multiple interrupt servicing. If an interrupt with a priority lower than that of the interrupt currently being serviced is generated during interrupt servicing, it is not acknowledged for multiple interrupt servicing. Interrupt requests that are not enabled because interrupts are in the interrupt disabled state or because they have a lower priority are held pending. When servicing of the current interrupt ends, the pending interrupt request is acknowledged following execution of at least one main processing instruction execution.

Table 16-5 shows relationship between interrupt requests enabled for multiple interrupt servicing and Figure 16-10 shows multiple interrupt servicing examples.

Table 16-5. Relationship Between Interrupt Requests Enabled for Multiple Interrupt Servicing During Interrupt Servicing

Software interrupt		○	×	○	×	○	×	○	×	○

Remarks 1. ○: Multiple interrupt servicing enabled

2. ×: Multiple interrupt servicing disabled

3. ISP0, ISP1, and IE are flags contained in the PSW.

ISP1 = 0, ISP0 = 0: An interrupt of level 1 or level 0 is being serviced.

ISP1 = 0, ISP0 = 1: An interrupt of level 2 is being serviced.

ISP1 = 1, ISP0 = 0: An interrupt of level 3 is being serviced.

ISP1 = 1, ISP0 = 1: Wait for An interrupt acknowledgment.

IE = 0: Interrupt request acknowledgment is disabled.

IE = 1: Interrupt request acknowledgment is enabled.

4. PR is a flag contained in PR00L, PR00H, PR01L, PR01H, PR02L, PR10L, PR10H, PR11L, PR11H, and PR12L.

PR = 00: Specify level 0 with ××PR1× = 0, ××PR0× = 0 (higher priority level)

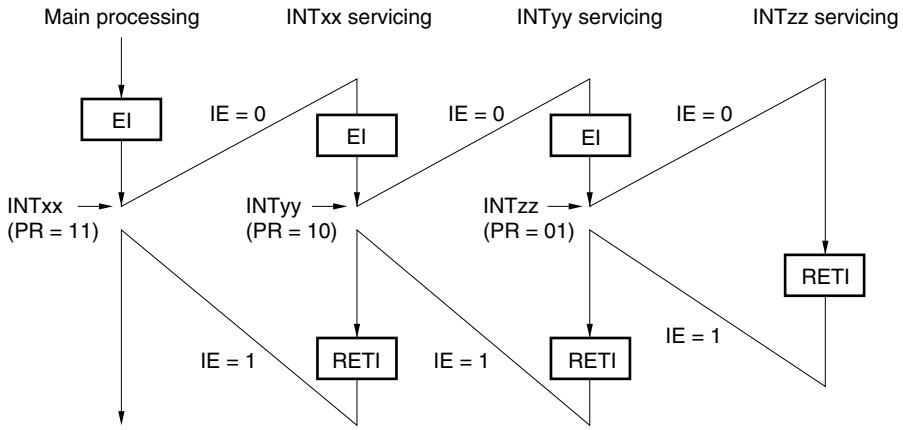
PR = 01: Specify level 1 with ××PR1× = 0, ××PR0× = 1

PR = 10: Specify level 2 with ××PR1× = 1, ××PR0× = 0

PR = 11: Specify level 3 with ××PR1× = 1, ××PR0× = 1 (lower priority level)

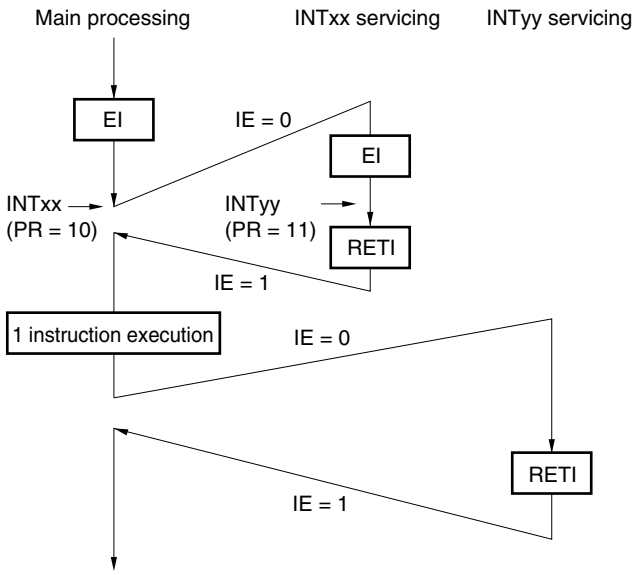
Figure 16-10. Examples of Multiple Interrupt Servicing (1/2)

Example 1. Multiple interrupt servicing occurs twice



During servicing of interrupt INTxx, two interrupt requests, INTyy and INTzz, are acknowledged, and multiple interrupt servicing takes place. Before each interrupt request is acknowledged, the EI instruction must always be issued to enable interrupt request acknowledgment.

Example 2. Multiple interrupt servicing does not occur due to priority control

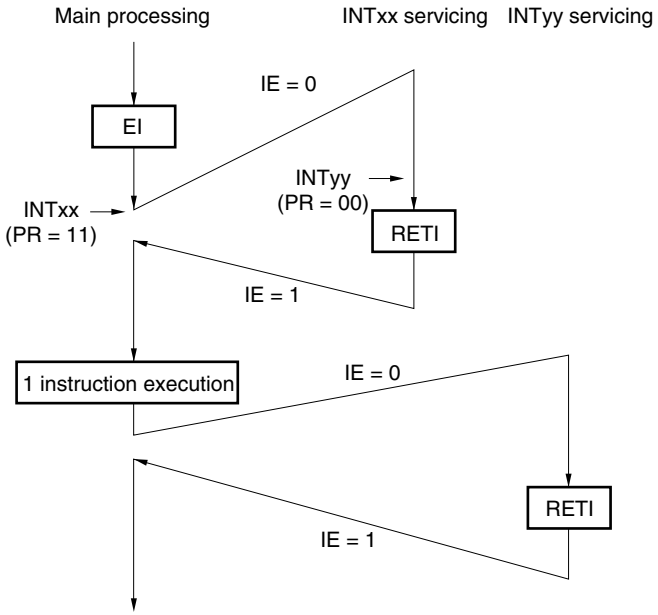


Interrupt request INTyy issued during servicing of interrupt INTxx is not acknowledged because its priority is lower than that of INTxx, and multiple interrupt servicing does not take place. The INTyy interrupt request is held pending, and is acknowledged following execution of one main processing instruction.

PR = 00: Specify level 0 with ××PR1× = 0, ××PR0× = 0 (higher priority level)
PR = 01: Specify level 1 with ××PR1× = 0, ××PR0× = 1
PR = 10: Specify level 2 with ××PR1× = 1, ××PR0× = 0
PR = 11: Specify level 3 with ××PR1× = 1, ××PR0× = 1 (lower priority level)
IE = 0: Interrupt request acknowledgment is disabled
IE = 1: Interrupt request acknowledgment is enabled.

Figure 16-10. Examples of Multiple Interrupt Servicing (2/2)

Example 3. Multiple interrupt servicing does not occur because interrupts are not enabled



Interrupts are not enabled during servicing of interrupt INTxx (EI instruction is not issued), therefore, interrupt request INTyy is not acknowledged and multiple interrupt servicing does not take place. The INTyy interrupt request is held pending, and is acknowledged following execution of one main processing instruction.

PR = 00: Specify level 0 with ××PR1× = 0, ××PR0× = 0 (higher priority level)
PR = 01: Specify level 1 with ××PR1× = 0, ××PR0× = 1
PR = 10: Specify level 2 with ××PR1× = 1, ××PR0× = 0
PR = 11: Specify level 3 with ××PR1× = 1, ××PR0× = 1 (lower priority level)
IE = 0: Interrupt request acknowledgment is disabled
IE = 1: Interrupt request acknowledgment is enabled.

16.4.4 Interrupt request hold

There are instructions where, even if an interrupt request is issued for them while another instruction is being executed, request acknowledgment is held pending until the end of execution of the next instruction. These instructions (interrupt request hold instructions) are listed below.

- MOV PSW, #byte
- MOV PSW, A
- MOV1 PSW. bit, CY
- SET1 PSW. bit
- CLR1 PSW. bit
- RETB
- RETI
- POP PSW
- BTCLR PSW. bit, $addr8
- EI
- DI
- SKC
- SKNC
- SKZ
- SKNZ
- Manipulation instructions for the IF0L, IF0H, IF1L, IF1H, IF2L, MK0L, MK0H, MK1L, MK1H, MK2L, PR00L, PR00H, PR01L, PR01H, PR02L, PR10L, PR10H, PR11L, PR11H, and PR12L registers

Caution The BRK instruction is not one of the above-listed interrupt request hold instructions. However, the software interrupt activated by executing the BRK instruction causes the IE flag to be cleared. Therefore, even if a maskable interrupt request is generated during execution of the BRK instruction, the interrupt request is not acknowledged.

Figure 16-11 shows the timing at which interrupt requests are held pending.

17.1 Functions of Key Interrupt

A key interrupt (INTKR) can be generated by setting the key return mode register (KRM) and inputting a falling edge to the key interrupt input pins (KR0 to KR7).

Table 17-1. Assignment of Key Interrupt Detection Pins

Flag	Description
KRM0	Controls KR0 signal in 1-bit units.
KRM1	Controls KR1 signal in 1-bit units.
KRM2	Controls KR2 signal in 1-bit units.
KRM3	Controls KR3 signal in 1-bit units.
KRM4	Controls KR4 signal in 1-bit units.
KRM5	Controls KR5 signal in 1-bit units.
KRM6	Controls KR6 signal in 1-bit units.
KRM7	Controls KR7 signal in 1-bit units.

17.2 Configuration of Key Interrupt

The key interrupt includes the following hardware.

17.3 Register Controlling Key Interrupt

(1) Key return mode register (KRM)

This register controls the KRM0 to KRM7 bits using the KR0 to KR7 signals, respectively.

KRM can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

KRMn	Key interrupt mode control
0	Does not detect key interrupt signal
1	Detects key interrupt signal

Cautions 1. If any of the KRM0 to KRM7 bits used is set to 1, set bits 0 to 7 (PU70 to PU77) of the corresponding pull-up resistor register 7 (PU7) to 1.

2. If KRM is changed, the interrupt request flag may be set. Therefore, disable interrupts and then change the KRM register. Clear the interrupt request flag and enable interrupts.

3. The bits not used in the key interrupt mode can be used as normal ports.

Remarks 1. n = 0 to 7

CHAPTER 18 STANDBY FUNCTION

18.1 Standby Function and Configuration

18.1.1 Standby function

The standby function reduces the operating current of the system, and the following two modes are available.

(1) HALT mode

HALT instruction execution sets the HALT mode. In the HALT mode, the CPU operation clock is stopped. If the high-speed system clock oscillator, internal high-speed oscillator, 20 MHz internal high-speed oscillator, or subsystem clock oscillator is operating before the HALT mode is set, oscillation of each clock continues. In this mode, the operating current is not decreased as much as in the STOP mode, but the HALT mode is effective for restarting operation immediately upon interrupt request generation and carrying out intermittent operations frequently.

(2) STOP mode

STOP instruction execution sets the STOP mode. In the STOP mode, the high-speed system clock oscillator and internal high-speed oscillator stop, stopping the whole system, thereby considerably reducing the CPU operating current.

Because this mode can be cleared by an interrupt request, it enables intermittent operations to be carried out. However, because a wait time is required to secure the oscillation stabilization time after the STOP mode is released when the X1 clock is selected, select the HALT mode if it is necessary to start processing immediately upon interrupt request generation.

In either of these two modes, all the contents of registers, flags and data memory just before the standby mode is set are held. The I/O port output latches and output buffer statuses are also held.

Cautions 1. The STOP mode can be used only when the CPU is operating on the main system clock. The STOP mode cannot be set while the CPU operates with the subsystem clock. The HALT mode can be used when the CPU is operating on either the main system clock or the subsystem clock.

2. When shifting to the STOP mode, be sure to stop the peripheral hardware operation operating with main system clock before executing STOP instruction.

3. The following sequence is recommended for operating current reduction of the A/D converter when the standby function is used: First clear bit 7 (ADCS) and bit 0 (ADCE) of the A/D converter mode register (ADM) to 0 to stop the A/D conversion operation, and then execute the STOP instruction.

4. The following sequence is recommended for operating current reduction of the comparator when the standby function is used: First clear bit 7 (CnEN) of the comparator n control register (CnCTL) and bit 7 (CnVRE) of the comparator n internal reference voltage selection register to 0 to stop the comparator operation, and then execute the STOP instruction.

5. The following sequence is recommended for operating current reduction of the programmable gain amplifier when the standby function is used: First clear bit 7 (OAEN) of the programmable gain amplifier control register (OAM) to 0 to stop the programmable gain amplifier operation, and then execute the STOP instruction.

Remark n = 0, 1

Cautions 6. It can be selected by the option byte whether the internal low-speed oscillator continues oscillating or stops in the HALT or STOP mode. For details, see CHAPTER 23 OPTION BYTE.

7. The STOP instruction cannot be executed when the CPU operates on the 20 MHz internal high-speed oscillation clock. Be sure to execute the STOP instruction after shifting to internal high-speed oscillation clock operation.

18.1.2 Registers controlling standby function

The standby function is controlled by the following two registers.

- Oscillation stabilization time counter status register (OSTC)
- Oscillation stabilization time select register (OSTS)

Remark For the registers that start, stop, or select the clock, see **CHAPTER 5 CLOCK GENERATOR**.

(1) Oscillation stabilization time counter status register (OSTC)

This is the register that indicates the count status of the X1 clock oscillation stabilization time counter.

The X1 clock oscillation stabilization time can be checked in the following case.

- If the X1 clock starts oscillation while the internal high-speed oscillation clock or subsystem clock is being used as the CPU clock.
- If the STOP mode is entered and then released while the internal high-speed oscillation clock is being used as the CPU clock with the X1 clock oscillating.

OSTC can be read by a 1-bit or 8-bit memory manipulation instruction.

When reset is released (reset by $\overline{\text{RESET}}$ input, POC, LVI, WDT, and executing an illegal instruction), the STOP instruction and MSTOP (bit 7 of CSC register) = 1 clear this register to 00H.

1	1	1	1	1	1	1	1	2^{18}/fx min.	26.21 ms min.	13.11 ms min.

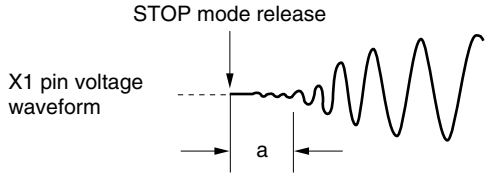
Cautions 1. After the above time has elapsed, the bits are set to 1 in order from MOST8 and remain 1.

2. The oscillation stabilization time counter counts up to the oscillation stabilization time set by OSTS. If the STOP mode is entered and then released while the internal high-speed oscillation clock is being used as the CPU clock, set the oscillation stabilization time as follows.

- **Desired OSTC oscillation stabilization time ≤ Oscillation stabilization time set by OSTS**

Note, therefore, that only the status up to the oscillation stabilization time set by OSTS is set to OSTC after STOP mode is released.

3. The X1 clock oscillation stabilization wait time does not include the time until clock oscillation starts ("a" below).



Remark fx: X1 clock oscillation frequency

(2) Oscillation stabilization time select register (OSTS)

This register is used to select the X1 clock oscillation stabilization wait time when the STOP mode is released.

When the X1 clock is selected as the CPU clock, the operation waits for the time set using OSTS after the STOP mode is released.

When the internal high-speed oscillation clock is selected as the CPU clock, confirm with OSTC that the desired oscillation stabilization time has elapsed after the STOP mode is released. The oscillation stabilization time can be checked up to the time set using OSTC.

OSTS can be set by an 8-bit memory manipulation instruction.

Reset signal generation sets this register to 07H.

1	1	0	$2^{17}/f_X$	13.11 ms	6.55 ms
1	1	1	$2^{18}/f_X$	26.21 ms	13.11 ms

Cautions 1. To set the STOP mode when the X1 clock is used as the CPU clock, set OSTS before executing the STOP instruction.

2. Setting the oscillation stabilization time to 20 μs or less is prohibited.

3. Before changing the setting of the OSTS register, confirm that the count operation of the OSTC register is completed.

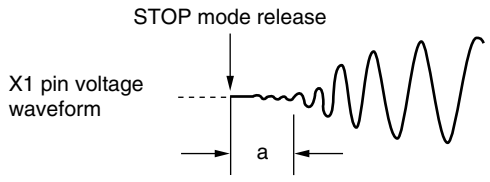
4. Do not change the value of the OSTS register during the X1 clock oscillation stabilization time.

5. The oscillation stabilization time counter counts up to the oscillation stabilization time set by OSTS. If the STOP mode is entered and then released while the internal high-speed oscillation clock is being used as the CPU clock, set the oscillation stabilization time as follows.

- **Desired OSTC oscillation stabilization time ≤ Oscillation stabilization time set by OSTS**

Note, therefore, that only the status up to the oscillation stabilization time set by OSTS is set to OSTC after STOP mode is released.

6. The X1 clock oscillation stabilization wait time does not include the time until clock oscillation starts ("a" below).



Remark f_X: X1 clock oscillation frequency

18.2 Standby Function Operation

18.2.1 HALT mode

(1) HALT mode

The HALT mode is set by executing the HALT instruction. HALT mode can be set regardless of whether the CPU clock before the setting was the high-speed system clock, internal high-speed oscillation clock, 20 MHz internal high-speed oscillation clock, or subsystem clock.

The operating statuses in the HALT mode are shown below.

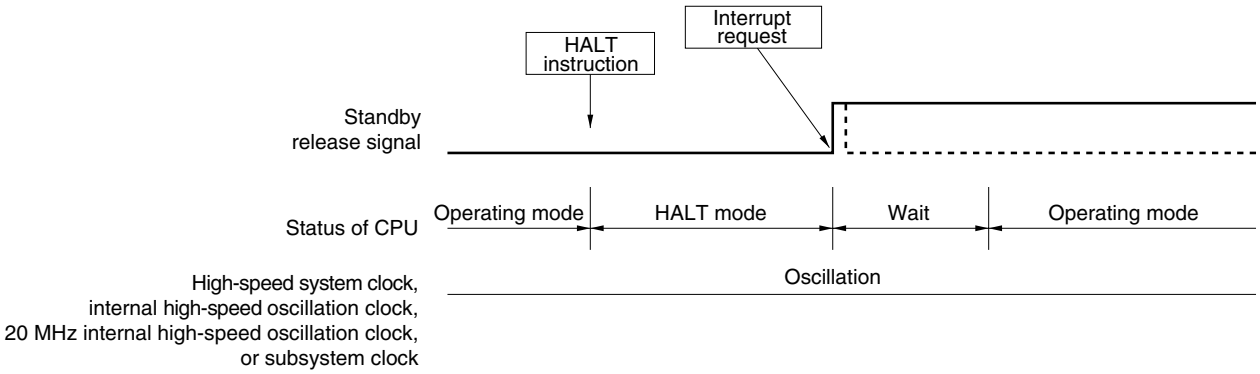
(2) HALT mode release

The HALT mode can be released by the following two sources.

(a) Release by unmasked interrupt request

When an unmasked interrupt request is generated, the HALT mode is released. If interrupt acknowledgment is enabled, vectored interrupt servicing is carried out. If interrupt acknowledgment is disabled, the next address instruction is executed.

Figure 18-3. HALT Mode Release by Interrupt Request Generation



Remark The broken lines indicate the case when the interrupt request which has released the standby mode is acknowledged.

(b) Release by reset signal generation

When the reset signal is generated, HALT mode is released, and then, as in the case with a normal reset operation, the program is executed after branching to the reset vector address.

18.2.2 STOP mode

(1) STOP mode setting and operating statuses

The STOP mode is set by executing the STOP instruction, and it can be set only when the CPU clock before the setting was the internal high-speed oscillation clock, X1 clock, or external main system clock.

Cautions 1. Because the interrupt request signal is used to clear the standby mode, if there is an interrupt source with the interrupt request flag set and the interrupt mask flag reset, the standby mode is immediately cleared if set. Thus, the STOP mode is reset to the HALT mode immediately after execution of the STOP instruction and the system returns to the operating mode as soon as the wait time set using the oscillation stabilization time select register (OSTS) has elapsed.

2. The STOP instruction cannot be executed when the CPU operates on the 20 MHz internal high-speed oscillation clock. Be sure to execute the STOP instruction after shifting to internal high-speed oscillation clock operation.

The operating statuses in the STOP mode are shown below.

Table 18-2. Operating Statuses in STOP Mode

Remark f_{IH}: Internal high-speed oscillation clock
f_X: X1 clock
f_{EX}: External main system clock
f_{XT}: XT1 clock
f_{IL}: Internal low-speed oscillation clock

Cautions 1. To use the peripheral hardware that stops operation in the STOP mode, and the peripheral hardware for which the clock that stops oscillating in the STOP mode after the STOP mode is released, restart the peripheral hardware.

2. To stop the internal low-speed oscillation clock in the STOP mode, use an option byte to stop the watchdog timer operation in the HALT/STOP mode (bit 0 (WDSTBYON) of 000C0H = 0), and then execute the STOP instruction.

3. To shorten oscillation stabilization time after the STOP mode is released when the CPU operates with the high-speed system clock (X1 oscillation), temporarily switch the CPU clock to the internal high-speed oscillation clock before the next execution of the STOP instruction. Before changing the CPU clock from the internal high-speed oscillation clock to the high-speed system clock (X1 oscillation) after the STOP mode is released, check the oscillation stabilization time with the oscillation stabilization time counter status register (OSTC).

4. The STOP instruction cannot be executed when the CPU operates on the 20 MHz internal high-speed oscillation clock. Be sure to execute the STOP instruction after shifting to internal high-speed oscillation clock operation.

(2) STOP mode release

The STOP mode can be released by the following two sources.

(a) Release by unmasked interrupt request

When an unmasked interrupt request is generated, the STOP mode is released. After the oscillation stabilization time has elapsed, if interrupt acknowledgment is enabled, vectored interrupt servicing is carried out. If interrupt acknowledgment is disabled, the next address instruction is executed.

(b) Release by reset signal generation

When the reset signal is generated, STOP mode is released, and then, as in the case with a normal reset operation, the program is executed after branching to the reset vector address.

CHAPTER 19 RESET FUNCTION

The following five operations are available to generate a reset signal.

(1) External reset input via $\overline{\text{RESET}}$ pin
(2) Internal reset by watchdog timer program loop detection
(3) Internal reset by comparison of supply voltage and detection voltage of power-on-clear (POC) circuit
(4) Internal reset by comparison of supply voltage of the low-voltage detector (LVI) or input voltage (EXLVI) from external input pin, and detection voltage
(5) Internal reset by execution of illegal instruction[Note]

External and internal resets start program execution from the address at 0000H and 0001H when the reset signal is generated.

A reset is effected when a low level is input to the $\overline{\text{RESET}}$ pin, the watchdog timer overflows, or by POC and LVI circuit voltage detection or execution of illegal instruction[Note], and each item of hardware is set to the status shown in Tables 19-1 and 19-2. Each pin is high impedance during reset signal generation or during the oscillation stabilization time just after a reset release, except for P140, which is low-level output.

When a low level is input to the $\overline{\text{RESET}}$ pin, the device is reset. It is released from the reset status when a high level is input to the $\overline{\text{RESET}}$ pin and program execution is started with the internal high-speed oscillation clock after reset processing. A reset by the watchdog timer is automatically released, and program execution starts using the internal high-speed oscillation clock (see **Figures 19-2** to **19-4**) after reset processing. Reset by POC and LVI circuit power supply detection is automatically released when $V_{DD} \geq V_{POR}$ or $V_{DD} \geq V_{LVI}$ after the reset, and program execution starts using the internal high-speed oscillation clock (see **CHAPTER 20 POWER-ON-CLEAR CIRCUIT** and **CHAPTER 21 LOW-VOLTAGE DETECTOR**) after reset processing.

Note The illegal instruction is generated when instruction code FFH is executed.
Reset by the illegal instruction execution not issued by emulation with the in-circuit emulator or on-chip debug emulator.

Cautions 1. For an external reset, input a low level for 10 μs or more to the $\overline{\text{RESET}}$ pin.
(To perform an external reset upon power application, a low level of at least 10 μs must be continued during the period in which the supply voltage is within the operating range ($V_{DD} \geq$ 1.8 V).)
2. During reset input, the X1 clock, XT1 clock, internal high-speed oscillation clock, and internal low-speed oscillation clock stop oscillating. External main system clock input becomes invalid.
3. When the STOP mode is released by a reset, the RAM contents in the STOP mode are held during reset input.
4. When reset is effected, port pin P140 is set to low-level output and other port pins become high-impedance, because each SFR and 2nd SFR are initialized.

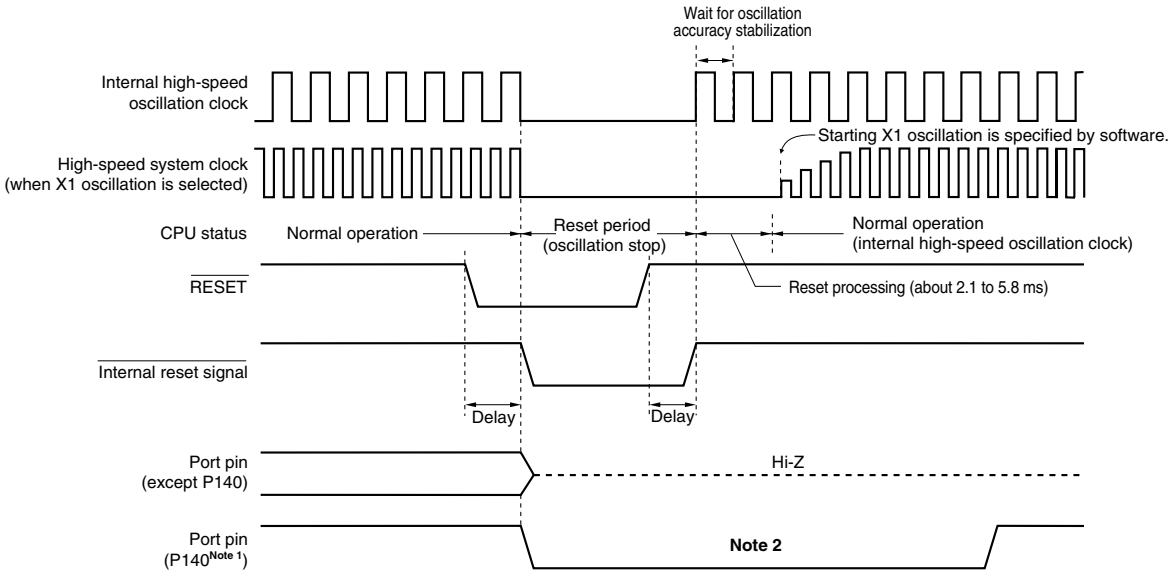

Figure 19-3. Timing of Reset Due to Watchdog Timer Overflow

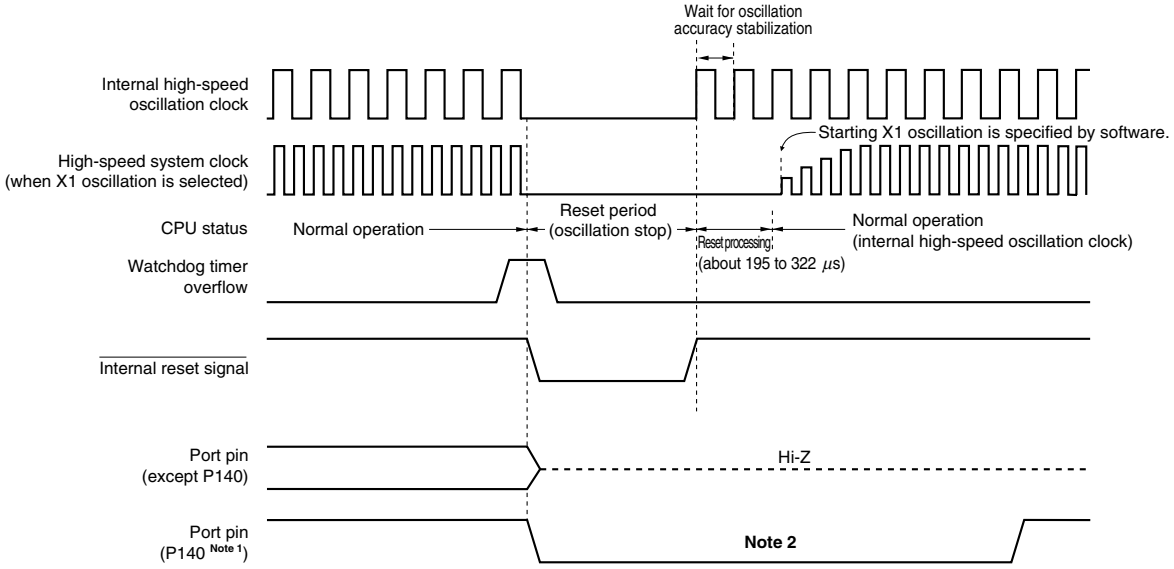
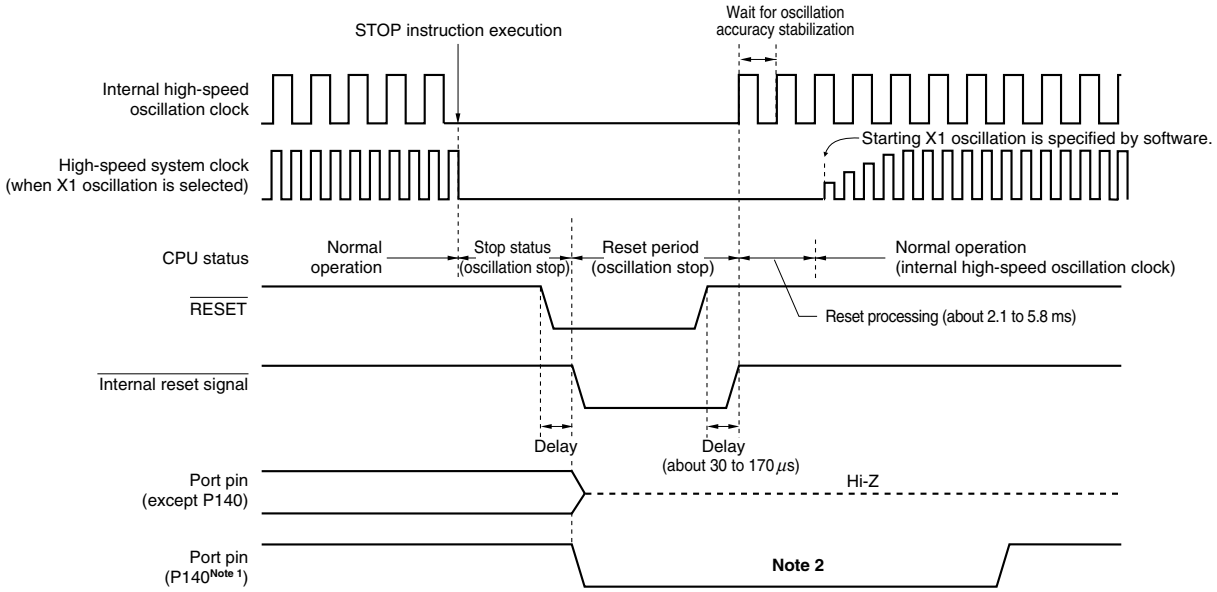


Notes 1. P140 pin is not mounted onto 44-pin products of the 78K0R/KC3-L.

2. When P140 is set to high-level output before reset is effected, the output signal of P140 can be dummy-output as a reset signal to an external device, because P140 outputs a low level when reset is effected. To release a reset signal to an external device, set P140 to high-level output by software.

Caution A watchdog timer internal reset resets the watchdog timer.

Figure 19-4. Timing of Reset in STOP Mode by $\overline{\text{RESET}}$ Input



Notes 1. P140 pin is not mounted onto 44-pin products of the 78K0R/KC3-L.

2. Set P140 to high-level output by software. When P140 is set to high-level output before reset is effected, the output signal of P140 can be dummy-output as a reset signal to an external device, because P140 outputs a low level when reset is effected. To release a reset signal to an external device, set P140 to high-level output by software.

19.1 Register for Confirming Reset Source

Many internal reset generation sources exist in the 78K0R/Kx3-L. The reset control flag register (RESF) is used to store which source has generated the reset request.

RESF can be read by an 8-bit memory manipulation instruction.

$\overline{\text{RESET}}$ input, reset by power-on-clear (POC) circuit, and reading RESF clear TRAP, WDRF, and LVIRF.

Notes 1. The value after reset varies depending on the reset source.

2. The illegal instruction is generated when instruction code FFH is executed.
Reset by the illegal instruction execution not issued by emulation with the in-circuit emulator or on-chip debug emulator.

Cautions 1. Do not read data by a 1-bit memory manipulation instruction.

2. Do not make a judgment based on only the read value of the RESF register 8-bit data, because bits other than TRAP, WDRF, and LVIRF become undefined.

3. When the LVI default start function (bit 0 (LVIOFF) of 000C1H = 0) is used, LVIRF flag may become 1 from the beginning depending on the power-on waveform.

The status of RESF when a reset request is generated is shown in Table 19-3.

CHAPTER 20 POWER-ON-CLEAR CIRCUIT

20.1 Functions of Power-on-Clear Circuit

The power-on-clear circuit (POC) has the following functions.

- Generates internal reset signal at power on.
  The reset signal is released when the supply voltage (V_{DD}) exceeds 1.61 V ±0.09 V[Note].

  Caution If the low-voltage detector (LVI) is set to ON by an option byte by default, the reset signal is not released until the supply voltage (V_{DD}) exceeds 2.07 V ±0.2 V[Note].

- Compares supply voltage (V_{DD}) and detection voltage (V_{PDR} = 1.59 V ±0.09 V[Note]), generates internal reset signal when $V_{DD} < V_{PDR}$.

  Note These are preliminary values and subject to change.

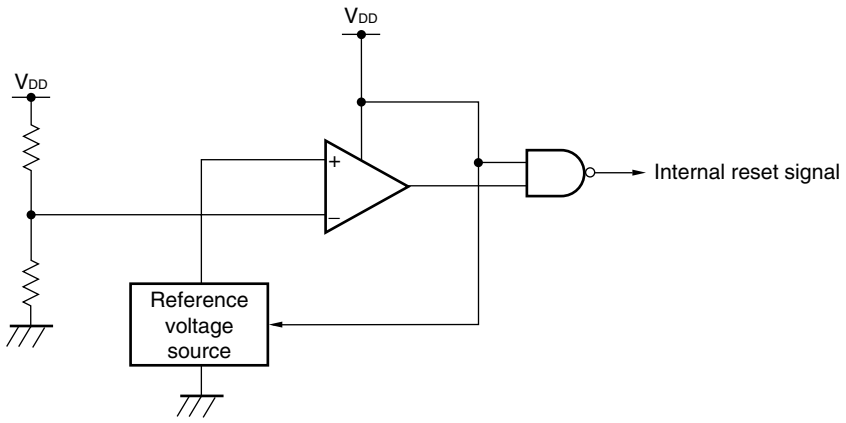
  Caution If an internal reset signal is generated in the POC circuit, TRAP, WDRF, and LVIRF of the reset control flag register (RESF) is cleared.

  Remark This product incorporates multiple hardware functions that generate an internal reset signal. A flag that indicates the reset source is located in the reset control flag register (RESF) for when an internal reset signal is generated by the watchdog timer (WDT), low-voltage-detector (LVI), or illegal instruction execution. RESF is not cleared to 00H and the flag is set to 1 when an internal reset signal is generated by WDT or LVI.
  For details of RESF, see **CHAPTER 19 RESET FUNCTION**.

20.2 Configuration of Power-on-Clear Circuit

The block diagram of the power-on-clear circuit is shown in Figure 20-1.

Figure 20-1. Block Diagram of Power-on-Clear Circuit



20.3 Operation of Power-on-Clear Circuit

- An internal reset signal is generated on power application. When the supply voltage (V_{DD}) exceeds the detection voltage (V_{PDR} = 1.61 V ±0.09 V[Note]), the reset status is released.

  Caution If the low-voltage detector (LVI) is set to ON by an option byte by default, the reset signal is not released until the supply voltage (V_{DD}) exceeds 2.07 V ±0.2 V[Note].

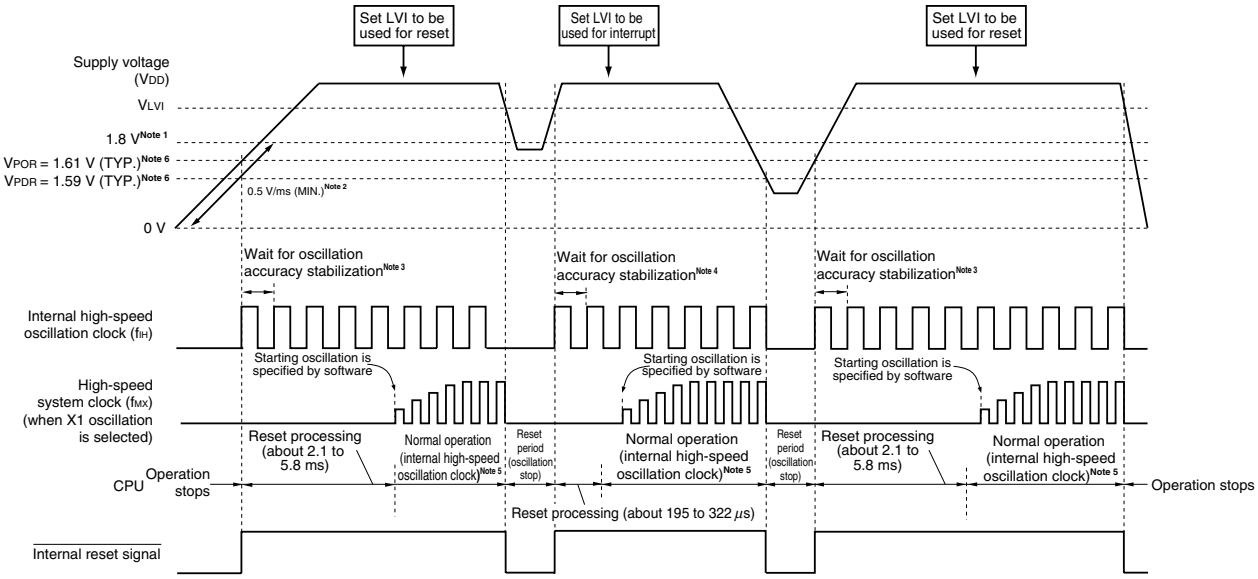
- The supply voltage (V_{DD}) and detection voltage (V_{PDR} = 1.59 V ±0.09 V[Note]) are compared. When $V_{DD} < V_{PDR}$, the internal reset signal is generated.

  Note These are preliminary values and subject to change.

The timing of generation of the internal reset signal by the power-on-clear circuit and low-voltage detector is shown below.

Figure 20-2. Timing of Generation of Internal Reset Signal by Power-on-Clear Circuit and Low-Voltage Detector (1/2)

(1) When LVI is OFF upon power application (option byte: LVIOFF = 1)



Notes 1. The operation guaranteed range is 1.8 V ≤ V_{DD} ≤ 5.5 V. To make the state at lower than 1.8 V reset state when the supply voltage falls, use the reset function of the low-voltage detector, or input the low level to the $\overline{\text{RESET}}$ pin.

2. If the rate at which the voltage rises to 1.8 V after power application is slower than 0.5 V/ms (MIN.), input a low level to the $\overline{\text{RESET}}$ pin before the voltage reaches to 1.8 V, or set LVI to ON by default by using an option byte (option byte: LVIOFF = 0).

3. The reset processing time, such as when waiting for internal voltage stabilization, includes the oscillation accuracy stabilization time of the internal high-speed oscillation clock.

4. The internal reset processing time includes the oscillation accuracy stabilization time of the internal high-speed oscillation clock.

5. The internal high-speed oscillation clock and a high-speed system clock or subsystem clock can be selected as the CPU clock. To use the X1 clock, use the OSTC register to confirm the lapse of the oscillation stabilization time. To use the XT1 clock, use the timer function for confirmation of the lapse of the stabilization time.

6. This is a preliminary value and subject to change.

Caution Set the low-voltage detector by software after the reset status is released (see CHAPTER 21 LOW-VOLTAGE DETECTOR).

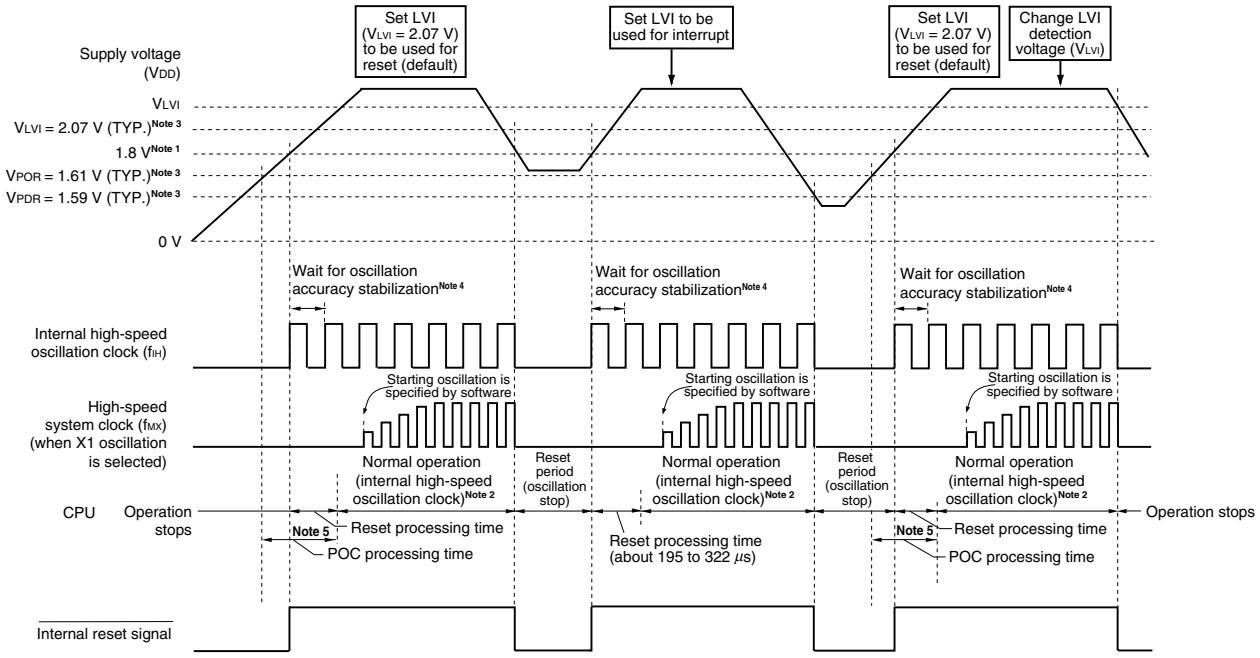
(2) When LVI is ON upon power application (option byte: LVIOFF = 0)



Notes 1. The operation guaranteed range is 1.8 V ≤ V_{DD} ≤ 5.5 V. To make the state at lower than 1.8 V reset state when the supply voltage falls, use the reset function of the low-voltage detector, or input the low level to the $\overline{\text{RESET}}$ pin.

2. The internal high-speed oscillation clock and a high-speed system clock or subsystem clock can be selected as the CPU clock. To use the X1 clock, use the OSTC register to confirm the lapse of the oscillation stabilization time. To use the XT1 clock, use the timer function for confirmation of the lapse of the stabilization time.

3. These are preliminary values and subject to change.

4. The internal reset processing time includes the oscillation accuracy stabilization time of the internal high-speed oscillation clock.

5. The following times are required between reaching the POC detection voltage (1.61 V (TYP.)) and starting normal operation.

- When the time to reach 2.07 V (TYP.) from 1.61 V (TYP.) is less than 5.8 ms:
  A POC processing time of about 2.1 to 6.2 ms is required between reaching 1.61 V (TYP.) and starting normal operation.
- When the time to reach 2.07 V (TYP.) from 1.61 V (TYP.) is greater than 5.8 ms:
  A reset processing time of about 195 to 322 μs is required between reaching 2.07 V (TYP.) and starting normal operation.

Caution Set the low-voltage detector by software after the reset status is released (see CHAPTER 21 LOW-VOLTAGE DETECTOR).

Remark V_{LVI}: LVI detection voltage
V_{POR}: POC power supply rise detection voltage
V_{PDR}: POC power supply fall detection voltage

20.4 Cautions for Power-on-Clear Circuit

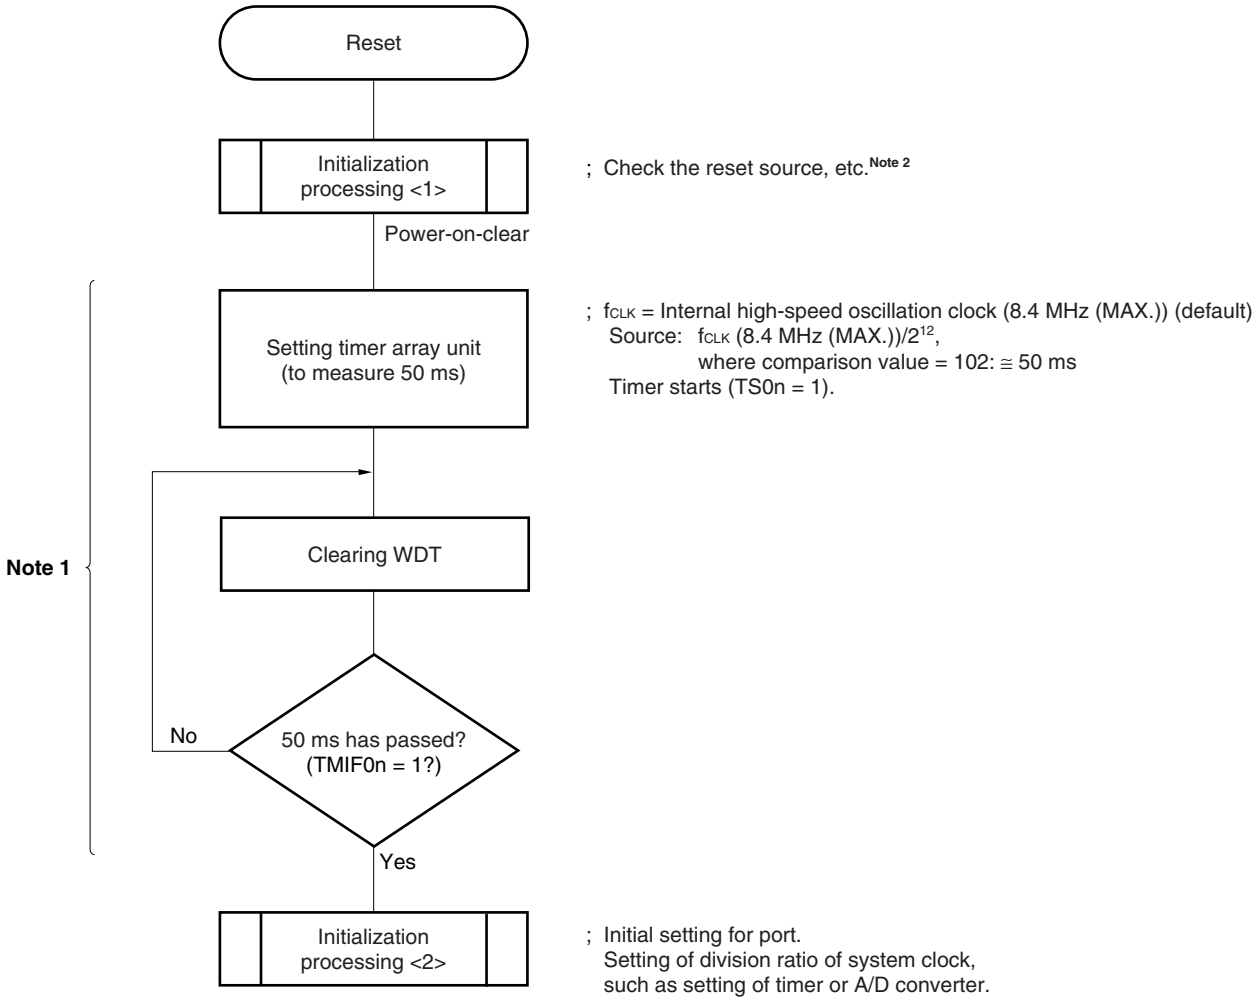
In a system where the supply voltage (V_{DD}) fluctuates for a certain period in the vicinity of the POC detection voltage (V_{POR}, V_{PDR}), the system may be repeatedly reset and released from the reset status. In this case, the time from release of reset to the start of the operation of the microcontroller can be arbitrarily set by taking the following action.

<Action>

After releasing the reset signal, wait for the supply voltage fluctuation period of each system by means of a software counter that uses a timer, and then initialize the ports.

Figure 20-3. Example of Software Processing After Reset Release (1/2)

• If supply voltage fluctuation is 50 ms or less in vicinity of POC detection voltage



Notes 1. If reset is generated again during this period, initialization processing <2> is not started.

2. A flowchart is shown on the next page.

Remark n = 0 to 7

Note The illegal instruction is generated when instruction code FFH is executed.
Reset by the illegal instruction execution not issued by emulation with the in-circuit emulator or on-chip debug emulator.

CHAPTER 21 LOW-VOLTAGE DETECTOR

21.1 Functions of Low-Voltage Detector

The low-voltage detector (LVI) has the following functions.

- The LVI circuit compares the supply voltage (V_{DD}) with the detection voltage (V_{LVI}) or the input voltage from an external input pin (EXLVI) with the detection voltage (V_{EXLVI} = 1.21 V ±0.1 V[Note]), and generates an internal reset or internal interrupt signal.
- The low-voltage detector (LVI) can be set to ON by an option byte by default. If it is set to ON to raise the power supply from the POC detection voltage (V_{POR} = 1.61 V (TYP.)) or lower, the internal reset signal is generated when the supply voltage (V_{DD}) < detection voltage (V_{LVI} = 2.07 V ±0.2 V[Note]). After that, the internal reset signal is generated when the supply voltage (V_{DD}) < detection voltage (V_{LVI} = 2.07 V ±0.1 V[Note]).
- The supply voltage (V_{DD}) or the input voltage from the external input pin (EXLVI) can be selected to be detected by software.
- A reset or an interrupt can be selected to be generated after detection by software.
- Detection levels (V_{LVI},16 levels) of supply voltage can be changed by software.
- Operable in STOP mode.

Note This is a preliminary value and subject to change.

The reset and interrupt signals are generated as follows depending on selection by software.

Selection of Level Detection of Supply Voltage (V_{DD}) (LVISEL = 0)		Selection Level Detection of Input Voltage from External Input Pin (EXLVI) (LVISEL = 1)	
Selects reset (LVIMD = 1).	Selects interrupt (LVIMD = 0).	Selects reset (LVIMD = 1).	Selects interrupt (LVIMD = 0).
Generates an internal reset signal when $V_{DD} < V_{LVI}$ and releases the reset signal when $V_{DD} \geq V_{LVI}$.	Generates an internal interrupt signal when V_{DD} drops lower than V_{LVI} ($V_{DD} < V_{LVI}$) or when V_{DD} becomes V_{LVI} or higher ($V_{DD} \geq V_{LVI}$).	Generates an internal reset signal when EXLVI < V_{EXLVI} and releases the reset signal when EXLVI ≥ V_{EXLVI}.	Generates an internal interrupt signal when EXLVI drops lower than V_{EXLVI} (EXLVI < V_{EXLVI}) or when EXLVI becomes V_{EXLVI} or higher (EXLVI ≥ V_{EXLVI}).

Remark LVISEL: Bit 2 of low-voltage detection register (LVIM)
LVIMD: Bit 1 of LVIM

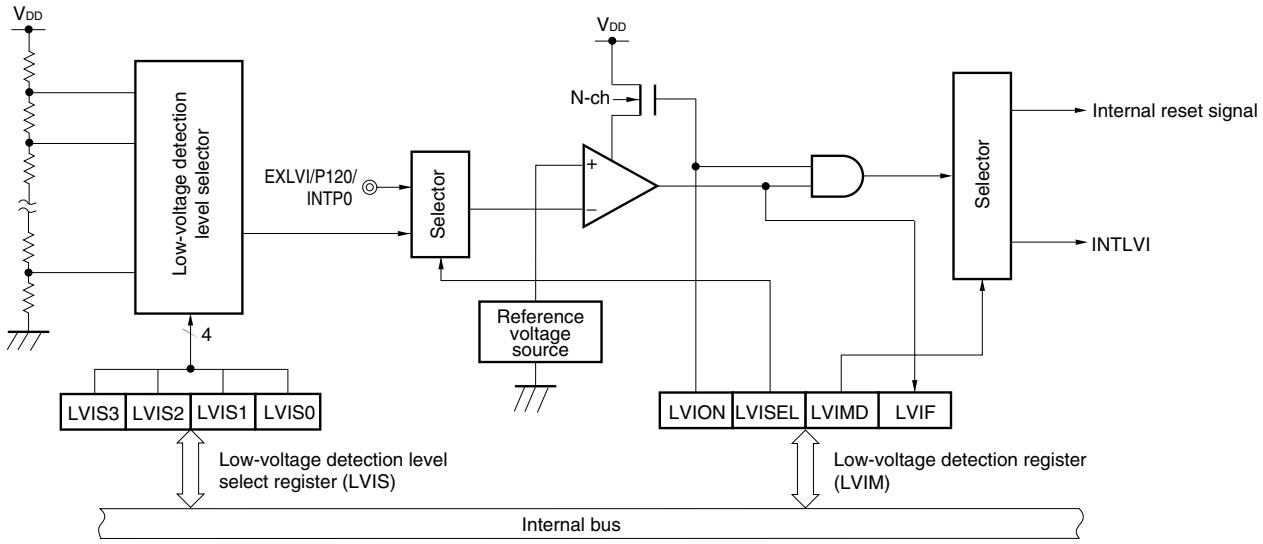
While the low-voltage detector is operating, whether the supply voltage or the input voltage from an external input pin is more than or less than the detection level can be checked by reading the low-voltage detection flag (LVIF: bit 0 of LVIM).

When the low-voltage detector is used to reset, bit 0 (LVIRF) of the reset control flag register (RESF) is set to 1 if reset occurs. For details of RESF, see **CHAPTER 19 RESET FUNCTION**.

21.2 Configuration of Low-Voltage Detector

The block diagram of the low-voltage detector is shown in Figure 21-1.

Figure 21-1. Block Diagram of Low-Voltage Detector



21.3 Registers Controlling Low-Voltage Detector

The low-voltage detector is controlled by the following registers.

- Low-voltage detection register (LVIM)
- Low-voltage detection level select register (LVIS)
- Port mode register 12 (PM12)

(1) Low-voltage detection register (LVIM)

This register sets low-voltage detection and the operation mode.

This register can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation clears this register to 00H.

Figure 21-2. Format of Low-Voltage Detection Register (LVIM)

Address: FFFA9H After reset: 00H[Note 1] R/W[Note 2]

Symbol	<7>	6	5	4	3	<2>	<1>	<0>
LVIM	LVION	0	0	0	0	LVISEL	LVIMD	LVIF

LVION[Notes 3, 4]	Enables low-voltage detection operation
0	Disables operation
1	Enables operation

LVISEL[Note 3]	Voltage detection selection
0	Detects level of supply voltage (V_{DD})
1	Detects level of input voltage from external input pin (EXLVI)

LVIMD	Low-voltage detection operation mode (interrupt/reset) selection
0	• LVISEL = 0: Generates an internal interrupt signal when the supply voltage (V_{DD}) drops lower than the detection voltage (V_{LVI}) ($V_{DD} < V_{LVI}$) or when V_{DD} becomes V_{LVI} or higher ($V_{DD} \geq V_{LVI}$). • LVISEL = 1: Generates an interrupt signal when the input voltage from an external input pin (EXLVI) drops lower than the detection voltage (V_{EXLVI}) (EXLVI < V_{EXLVI}) or when EXLVI becomes V_{EXLVI} or higher (EXLVI ≥ V_{EXLVI}).
1	• LVISEL = 0: Generates an internal reset signal when the supply voltage (V_{DD}) < detection voltage (V_{LVI}) and releases the reset signal when $V_{DD} \geq V_{LVI}$. • LVISEL = 1: Generates an internal reset signal when the input voltage from an external input pin (EXLVI) < detection voltage (V_{EXLVI}) and releases the reset signal when EXLVI ≥ V_{EXLVI}.

LVIF	Low-voltage detection flag
0	• LVISEL = 0: Supply voltage (V_{DD}) ≥ detection voltage (V_{LVI}), or when LVI operation is disabled • LVISEL = 1: Input voltage from external input pin (EXLVI) ≥ detection voltage (V_{EXLVI}), or when LVI operation is disabled
1	• LVISEL = 0: Supply voltage (V_{DD}) < detection voltage (V_{LVI}) • LVISEL = 1: Input voltage from external input pin (EXLVI) < detection voltage (V_{EXLVI})

Notes 1. The reset value changes depending on the reset source and the setting of the option byte.
This register is not cleared (00H) by LVI reset.
It is set to “82H” when a reset signal other than LVI is applied if option byte LVIOFF = 0, and to “00H” if option byte LVIOFF = 1.

2. Bit 0 is read-only.

3. LVION, LVIMD, and LVISEL are cleared to 0 in the case of a reset other than an LVI reset. These are not cleared to 0 in the case of an LVI reset.

Note 4. When LVION is set to 1, operation of the comparator in the LVI circuit is started. Use software to wait for the following periods of time, between when LVION is set to 1 and when the voltage is confirmed with LVIF.

- Operation stabilization time (10 μs (MAX.))
- Minimum pulse width (200 μs (MIN.))
- Detection delay time (200 μs (MAX.))

The LVIF value for these periods may be set/cleared regardless of the voltage level, and can therefore not be used. Also, the LVIIF interrupt request flag may be set to 1 in these periods.

Cautions 1. To stop LVI, follow either of the procedures below.

- **When using 8-bit memory manipulation instruction: Write 00H to LVIM.**
- **When using 1-bit memory manipulation instruction: Clear LVION to 0.**

2. Input voltage from external input pin (EXLVI) must be EXLVI < V_{DD}.

3. When LVI is used in interrupt mode (LVIMD = 0) and LVISEL is set to 0, an interrupt request signal (INTLVI) that disables LVI operation (clears LVION) when the supply voltage (V_{DD}) is less than or equal to the detection voltage (V_{LVI}) (if LVISEL = 1, input voltage of external input pin (EXLVI) is less than or equal to the detection voltage (V_{EXLVI})) is generated and LVIIF may be set to 1.

(2) Low-voltage detection level select register (LVIS)

This register selects the low-voltage detection level.

This register can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation input sets this register to 0EH.

Figure 21-3. Format of Low-Voltage Detection Level Select Register (LVIS)

1	0	0	0	V_{LVI8} (2.99 ±0.1 V)[Note 2]
1	0	0	1	V_{LVI9} (2.84 ±0.1 V)[Note 2]
1	0	1	0	V_{LVI10} (2.68 ±0.1 V)[Note 2]
1	0	1	1	V_{LVI11} (2.53 ±0.1 V)[Note 2]
1	1	0	0	V_{LVI12} (2.38 ±0.1 V)[Note 2]
1	1	0	1	V_{LVI13} (2.22 ±0.1 V)[Note 2]
1	1	1	0	V_{LVI14} (2.07 ±0.1 V)[Note 2]
1	1	1	1	V_{LVI15} (1.91 ±0.1 V)[Note 2]

Notes 1. The reset value changes depending on the reset source.
If the LVIS register is reset by LVI, it is not reset but holds the current value. The value of this register is reset to “0EH” if a reset other than by LVI is effected.

2. These are preliminary values and subject to change.

Caution 1. Be sure to clear bits 4 to 7 to “0”.

Cautions 2. Change the LVIS value with either of the following methods.

- **When changing the value after stopping LVI**
  - **<1> Stop LVI (LVION = 0).**
  - **<2> Change the LVIS register.**
  - **<3> Set to the mode used as an interrupt (LVIMD = 0).**
  - **<4> Mask LVI interrupts (LVIMK = 1).**
  - **<5> Enable LVI operation (LVION = 1).**
  - **<6> Before cancelling the LVI interrupt mask (LVIMK = 0), clear it with software because an LVIIF flag may be set when LVI operation is enabled.**
- **When changing the value after setting to the mode used as an interrupt (LVIMD = 0)**
  - **<1> Mask LVI interrupts (LVIMK = 1).**
  - **<2> Set to the mode used as an interrupt (LVIMD = 0).**
  - **<3> Change the LVIS register.**
  - **<4> Before cancelling the LVI interrupt mask (LVIMK = 0), clear it with software because an LVIIF flag may be set when the LVIS register is changed.**

3. When an input voltage from the external input pin (EXLVI) is detected, the detection voltage (V_{EXLVI}) is fixed. Therefore, setting of LVIS is not necessary.

(3) Port mode register 12 (PM12)

When using the P120/EXLVI/INTP0 pin for external low-voltage detection potential input, set PM120 to 1. At this time, the output latch of P120 may be 0 or 1.

PM12 can be set by a 1-bit or 8-bit memory manipulation instruction.

Reset signal generation sets this register to FFH.

21.4 Operation of Low-Voltage Detector

The low-voltage detector can be used in the following two modes.

(1) Used as reset (LVIMD = 1)

- If LVISEL = 0, compares the supply voltage (V_{DD}) and detection voltage (V_{LVI}), generates an internal reset signal when $V_{DD} < V_{LVI}$, and releases internal reset when $V_{DD} \geq V_{LVI}$.
- If LVISEL = 1, compares the input voltage from external input pin (EXLVI) and detection voltage (V_{EXLVI}), generates an internal reset signal when EXLVI < V_{EXLVI}, and releases internal reset when EXLVI ≥ V_{EXLVI}.

Remark The low-voltage detector (LVI) can be set to ON by an option byte by default. If it is set to ON to raise the power supply from the POC detection voltage (V_{POR} = 1.61 V (TYP.)) or lower, the internal reset signal is generated when the supply voltage (V_{DD}) < detection voltage (V_{LVI} = 2.07 V ±0.2 V[Note]). After that, the internal reset signal is generated when the supply voltage (V_{DD}) < detection voltage (V_{LVI} = 2.07 V ±0.1 V[Note]).

(2) Used as interrupt (LVIMD = 0)

- If LVISEL = 0, compares the supply voltage (V_{DD}) and detection voltage (V_{LVI}). When V_{DD} drops lower than V_{LVI} ($V_{DD} < V_{LVI}$) or when V_{DD} becomes V_{LVI} or higher ($V_{DD} \geq V_{LVI}$), generates an interrupt signal (INTLVI).
- If LVISEL = 1, compares the input voltage from external input pin (EXLVI) and detection voltage (V_{EXLVI} = 1.21 V ±0.1 V[Note]). When EXLVI drops lower than V_{EXLVI} (EXLVI < V_{EXLVI}) or when EXLVI becomes V_{EXLVI} or higher (EXLVI ≥ V_{EXLVI}), generates an interrupt signal (INTLVI).

Note This is a preliminary value and subject to change.

While the low-voltage detector is operating, whether the supply voltage or the input voltage from an external input pin is more than or less than the detection level can be checked by reading the low-voltage detection flag (LVIF: bit 0 of LVIM).

Remark LVIMD: Bit 1 of low-voltage detection register (LVIM)
LVISEL: Bit 2 of LVIM

21.4.1 When used as reset

(1) When detecting level of supply voltage (V_{DD})

(a) When LVI default start function stopped is set (LVIOFF = 1)

- When starting operation

<1> Mask the LVI interrupt (LVIMK = 1).

<2> Clear bit 2 (LVISEL) of the low-voltage detection register (LVIM) to 0 (detects level of supply voltage (V_{DD})) (default value).

<3> Set the detection voltage using bits 3 to 0 (LVIS3 to LVIS0) of the low-voltage detection level selection register (LVIS).

<4> Set bit 7 (LVION) of LVIM to 1 (enables LVI operation).

<5> Use software to wait for the following periods of time (Total 410 μs).

- Operation stabilization time (10 μs (MAX.))
- Minimum pulse width (200 μs (MIN.))
- Detection delay time (200 μs (MAX.))

<6> Wait until it is checked that (supply voltage (V_{DD}) $\geq$ detection voltage (V_{LVI})) by bit 0 (LVIF) of LVIM.

<7> Set bit 1 (LVIMD) of LVIM to 1 (generates reset when the level is detected).

Figure 21-5 shows the timing of the internal reset signal generated by the low-voltage detector. The numbers in this timing chart correspond to <1> to <7> above.

Cautions 1. Be sure to execute <1>. When LVIMK = 0, an interrupt may occur immediately after the processing in <4>.

2. If supply voltage (V_{DD}) $\geq$ detection voltage (V_{LVI}) when LVIMD is set to 1, an internal reset signal is not generated.

- When stopping operation

Either of the following procedures must be executed.

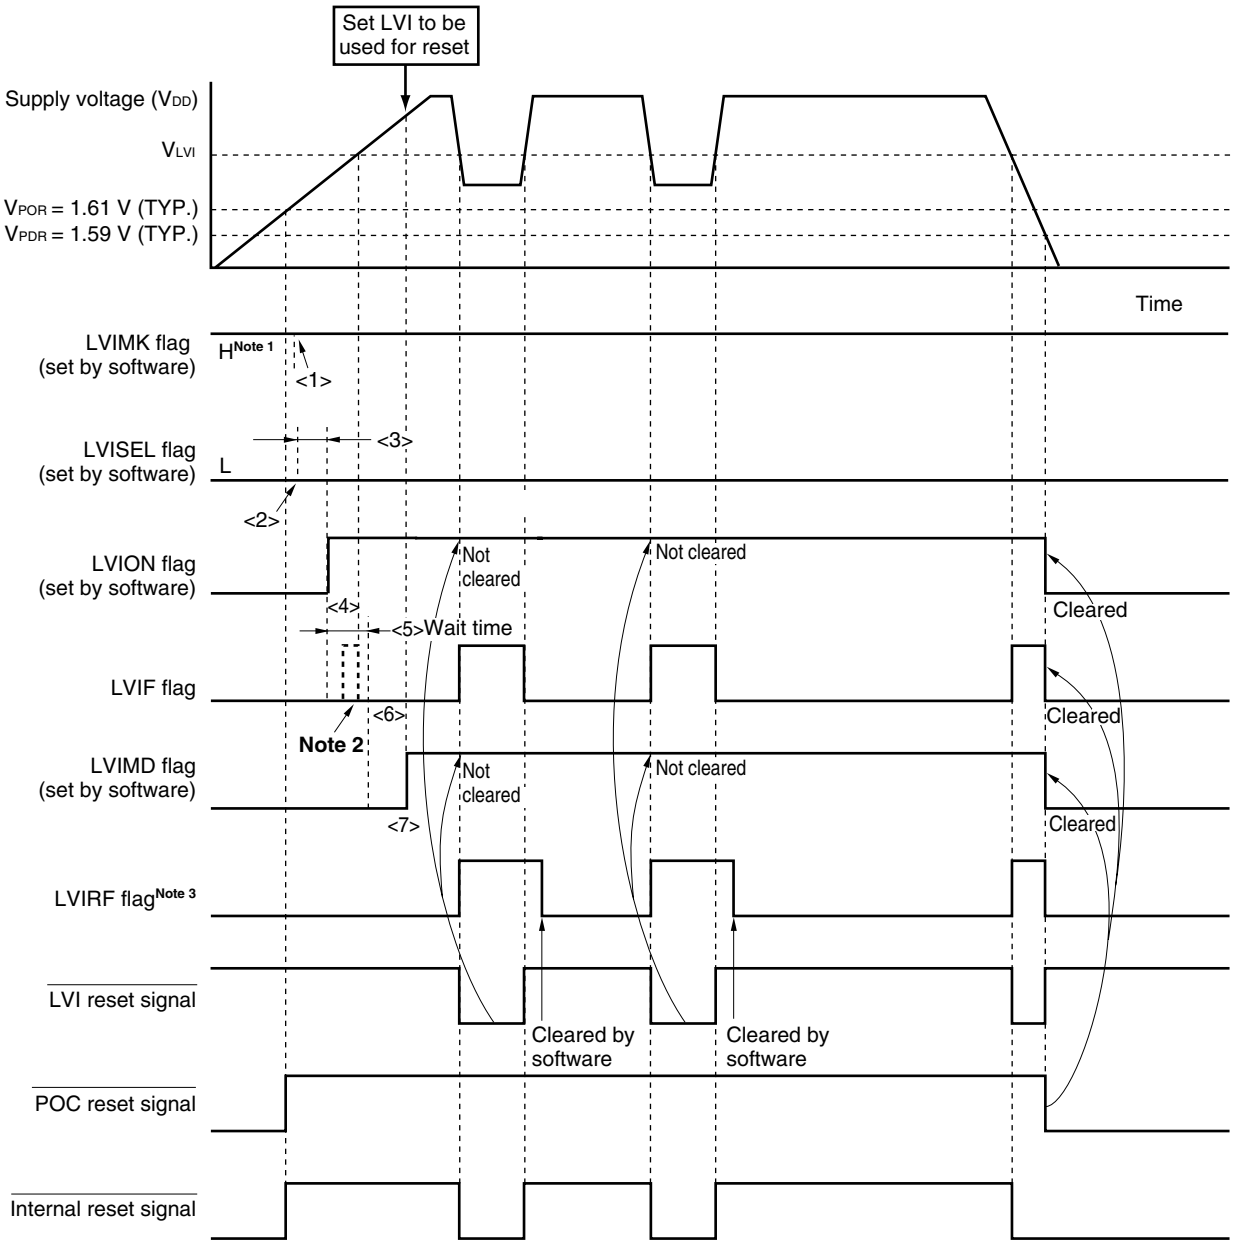
- When using 8-bit memory manipulation instruction:

Write 00H to LVIM.

- When using 1-bit memory manipulation instruction:

Clear LVIMD to 0 and then LVION to 0.

Figure 21-5. Timing of Low-Voltage Detector Internal Reset Signal Generation (Bit: LVISEL = 0, Option Byte: LVIOFF = 1)



Notes 1. The LVIMK flag is set to “1” by reset signal generation.

2. The LVIIF flag of the interrupt request flag registers and the LVIF flag may be set (1).

3. LVIRF is bit 0 of the reset control flag register (RESF). For details of RESF, see **CHAPTER 19 RESET FUNCTION**.

Remarks 1. <1> to <7> in Figure 21-5 above correspond to <1> to <7> in the description of “When starting operation” in **21.4.1 (1) (a) When LVI default start function stopped is set (LVIOFF = 1).**

2. VPOR: POC power supply rise detection voltage
VPDR: POC power supply fall detection voltage

(b) When LVI default start function enabled is set (LVIOFF = 0)

- When starting operation

  Start in the following initial setting state.

  - Set bit 7 (LVION) of LVIM to 1 (enables LVI operation)
  - Clear bit 2 (LVISEL) of the low-voltage detection register (LVIM) to 0 (detects level of supply voltage (V_{DD}))
  - Set the low-voltage detection level selection register (LVIS) to 0EH (default value: V_{LVI} = 2.07 V ±0.1 V).
  - Set bit 1 (LVIMD) of LVIM to 1 (generates reset when the level is detected)
  - Set bit 0 (LVIF) of LVIM to 0 (“Supply voltage (V_{DD}) ≥ detection voltage (V_{LVI})”)

  Figure 21-6 shows the timing of the internal reset signal generated by the low-voltage detector.

- When stopping operation

  Either of the following procedures must be executed.

  - When using 8-bit memory manipulation instruction:

    Write 00H to LVIM.

  - When using 1-bit memory manipulation instruction:

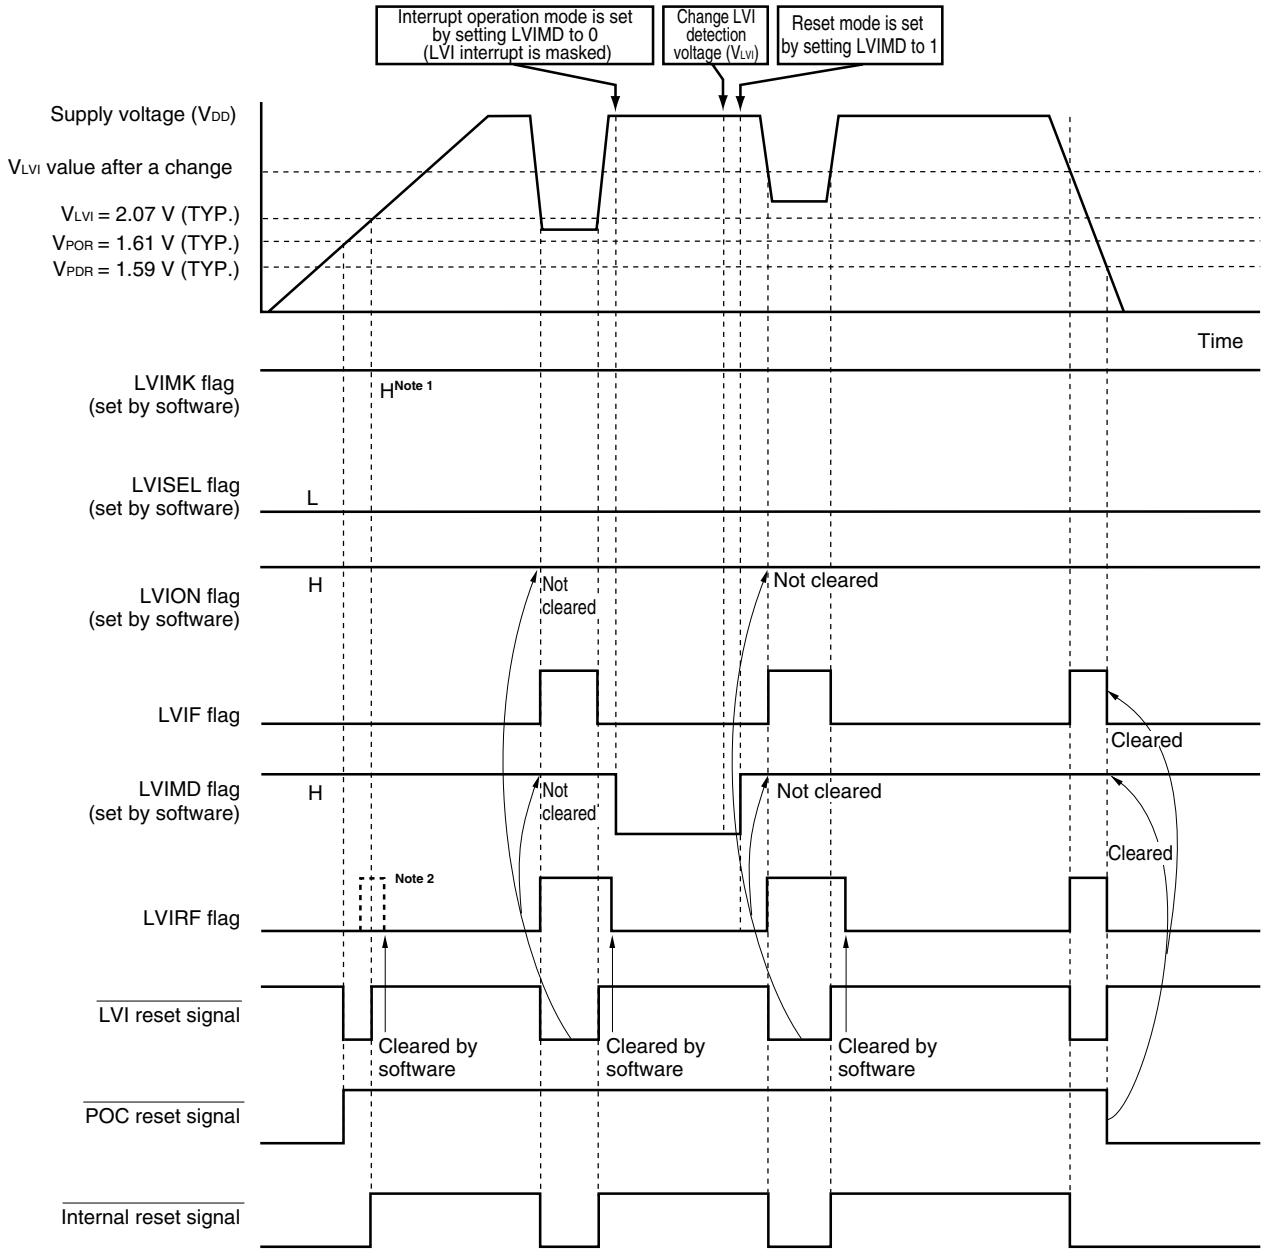
    Clear LVIMD to 0 and then LVION to 0.

Caution Even when the LVI default start function is used, if it is set to LVI operation prohibition by the software, it operates as follows:

- **Does not perform low-voltage detection during LVION = 0.**
- **If a reset is generated while LVION = 0, LVION will be re-set to 1 when the CPU starts after reset release. There is a period when low-voltage detection cannot be performed normally, however, when a reset occurs due to WDT and illegal instruction execution.**

  This is due to the fact that while the pulse width detected by LVI must be 200 μs max., LVION = 1 is set upon reset occurrence, and the CPU starts operating without waiting for the LVI stabilization time.

Figure 21-6. Timing of Low-Voltage Detector Internal Reset Signal Generation (Bit: LVISEL = 0, Option Byte: LVIOFF = 0)



Notes 1. The LVIMK flag is set to “1” by reset signal generation.

2. LVIRF is bit 0 of the reset control flag register (RESF).
When the LVI default start function (bit 0 (LVIOFF) of 000C1H = 0) is used, the LVIRF flag may become 1 from the beginning due to the power-on waveform.
For details of RESF, see **CHAPTER 19 RESET FUNCTION**.

V_{PDR}: POC power supply fall detection voltage

(2) When detecting level of input voltage from external input pin (EXLVI)

- When starting operation
  - <1> Mask the LVI interrupt (LVIMK = 1).
  - <2> Set bit 2 (LVISEL) of the low-voltage detection register (LVIM) to 1 (detects level of input voltage from external input pin (EXLVI)).
  - <3> Set bit 7 (LVION) of LVIM to 1 (enables LVI operation).
  - <4> Use software to wait for the following periods of time (Total 410 μs).
    - Operation stabilization time (10 μs (MAX.))
    - Minimum pulse width (200 μs (MIN.))
    - Detection delay time (200 μs (MAX.))
  - <5> Wait until it is checked that (input voltage from external input pin (EXLVI) $\geq$ detection voltage (V_{EXLVI} = 1.21 V (TYP.))) by bit 0 (LVIF) of LVIM.
  - <6> Set bit 1 (LVIMD) of LVIM to 1 (generates reset signal when the level is detected).

  Figure 21-7 shows the timing of the internal reset signal generated by the low-voltage detector. The numbers in this timing chart correspond to <1> to <6> above.

  Cautions 1. Be sure to execute <1>. When LVIMK = 0, an interrupt may occur immediately after the processing in <3>.
  2. If input voltage from external input pin (EXLVI) $\geq$ detection voltage (V_{EXLVI} = 1.21 V (TYP.)) when LVIMD is set to 1, an internal reset signal is not generated.
  3. Input voltage from external input pin (EXLVI) must be EXLVI < V_{DD}.

- When stopping operation
  Either of the following procedures must be executed.

  - When using 8-bit memory manipulation instruction:
    Write 00H to LVIM.

  - When using 1-bit memory manipulation instruction:
    Clear LVIMD to 0 and then LVION to 0.

Notes 1. The LVIMK flag is set to "1" by reset signal generation.

2. The LVIIF flag of the interrupt request flag registers and the LVIF flag may be set (1).

3. LVIRF is bit 0 of the reset control flag register (RESF). For details of RESF, see **CHAPTER 19 RESET FUNCTION**.

21.4.2 When used as interrupt

(1) When detecting level of supply voltage (V_{DD})

(a) When LVI default start function stopped is set (LVIOFF = 1)

- When starting operation

<1> Mask the LVI interrupt (LVIMK = 1).

<2> Clear bit 2 (LVISEL) of the low-voltage detection register (LVIM) to 0 (detects level of supply voltage (V_{DD})) (default value).
Clear bit 1 (LVIMD) of LVIM to 0 (generates interrupt signal when the level is detected) (default value).

<3> Set the detection voltage using bits 3 to 0 (LVIS3 to LVIS0) of the low-voltage detection level selection register (LVIS).

<4> Set bit 7 (LVION) of LVIM to 1 (enables LVI operation).

<5> Use software to wait for the following periods of time (Total 410 μs).
- Operation stabilization time (10 μs (MAX.))
- Minimum pulse width (200 μs (MIN.))
- Detection delay time (200 μs (MAX.))

<6> Confirm that "supply voltage (V_{DD}) $\geq$ detection voltage (V_{LVI})" when detecting the falling edge of V_{DD}, or "supply voltage (V_{DD}) < detection voltage (V_{LVI})" when detecting the rising edge of V_{DD}, at bit 0 (LVIF) of LVIM.

<7> Clear the interrupt request flag of LVI (LVIIF) to 0.

<8> Release the interrupt mask flag of LVI (LVIMK).

<9> Execute the EI instruction (when vector interrupts are used).

Figure 21-8 shows the timing of the interrupt signal generated by the low-voltage detector. The numbers in this timing chart correspond to <1> to <8> above.

- When stopping operation

Either of the following procedures must be executed.

- When using 8-bit memory manipulation instruction:
  Write 00H to LVIM.

- When using 1-bit memory manipulation instruction:
  Clear LVION to 0.

- Clear bit 2 (LVISEL) of the low-voltage detection register (LVIM) to 0 (detects level of supply voltage (V_{DD}))
- Set the low-voltage detection level selection register (LVIS) to 0EH (default value: V_{LVI} = 2.07 V ±0.1 V).
- Set bit 1 (LVIMD) of LVIM to 1 (generates reset when the level is detected)
- Set bit 0 (LVIF) of LVIM to 0 (Detects falling edge "Supply voltage (V_{DD}) ≥ detection voltage (V_{LVI})")

<2> Clear bit 1 (LVIMD) of LVIM to 0 (generates interrupt signal when the level is detected) (default value).

<3> Release the interrupt mask flag of LVI (LVIMK).

<4> Execute the EI instruction (when vector interrupts are used).

Figure 21-9 shows the timing of the interrupt signal generated by the low-voltage detector. The numbers in this timing chart correspond to <1> to <3> above.

- When stopping operation

Either of the following procedures must be executed.

- When using 8-bit memory manipulation instruction:

Write 00H to LVIM.

- When using 1-bit memory manipulation instruction:

21.5 Cautions for Low-Voltage Detector

(1) Measures method when supply voltage (V_{DD}) frequently fluctuates in the vicinity of the LVI detection voltage (V_{LVI})

In a system where the supply voltage (V_{DD}) fluctuates for a certain period in the vicinity of the LVI detection voltage (V_{LVI}), the operation is as follows depending on how the low-voltage detector is used.

Operation example 1: When used as reset

The system may be repeatedly reset and released from the reset status.

The time from reset release through microcontroller operation start can be set arbitrarily by the following action.

<Action>

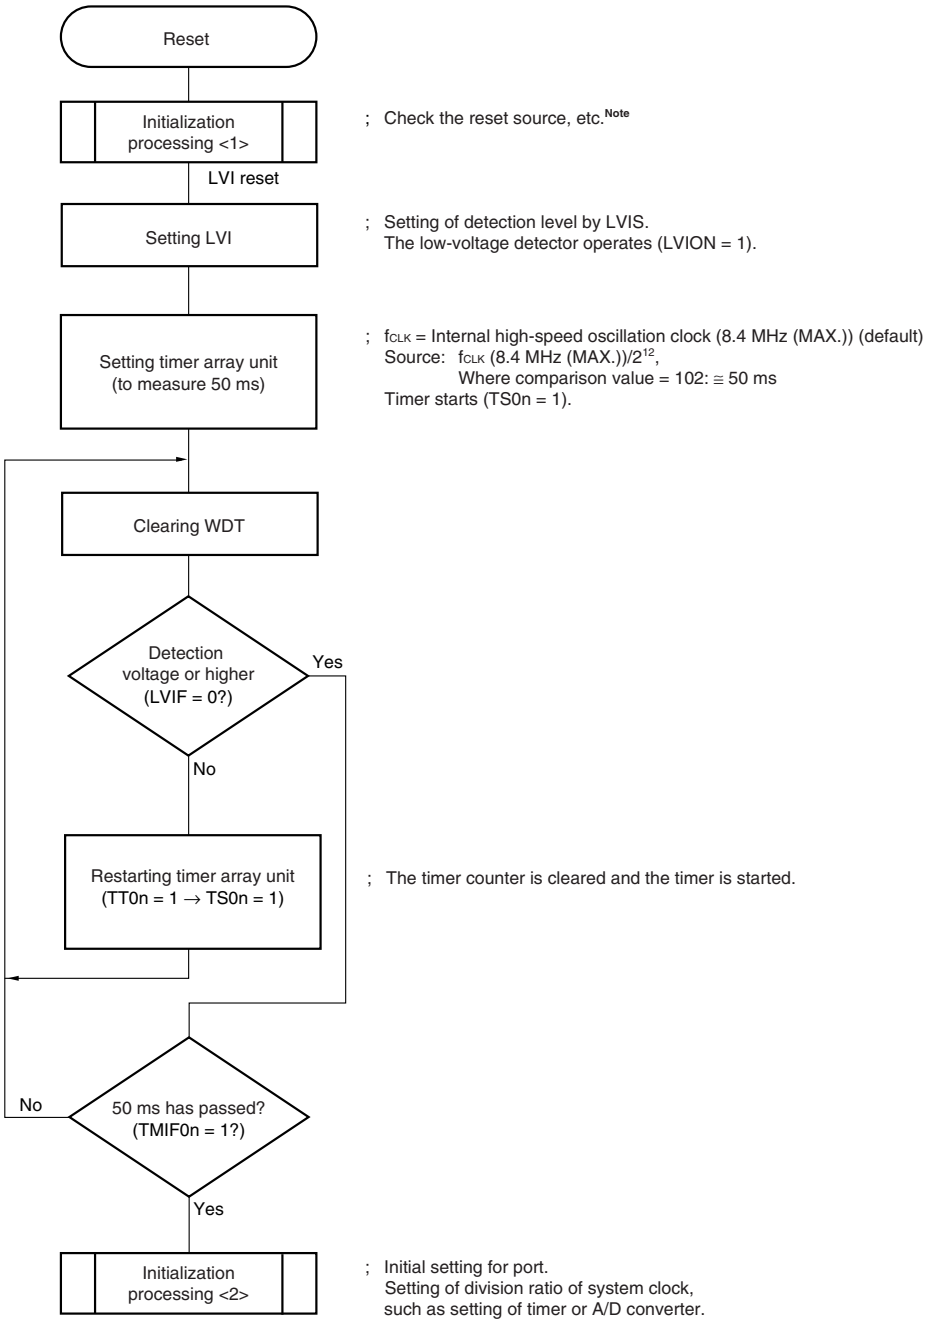
After releasing the reset signal, wait for the supply voltage fluctuation period of each system by means of a software counter that uses a timer, and then initialize the ports (see **Figure 21-11**).

Remark If bit 2 (LVISEL) of the low voltage detection register (LVIM) is set to “1”, the meanings of the above words change as follows.

- Supply voltage (V_{DD}) → Input voltage from external input pin (EXLVI)
- Detection voltage (V_{LVI}) → Detection voltage (V_{EXLVI} = 1.21 V)

Figure 21-11. Example of Software Processing After Reset Release (1/2)

• If supply voltage fluctuation is 50 ms or less in vicinity of LVI detection voltage



Note A flowchart is shown on the next page.

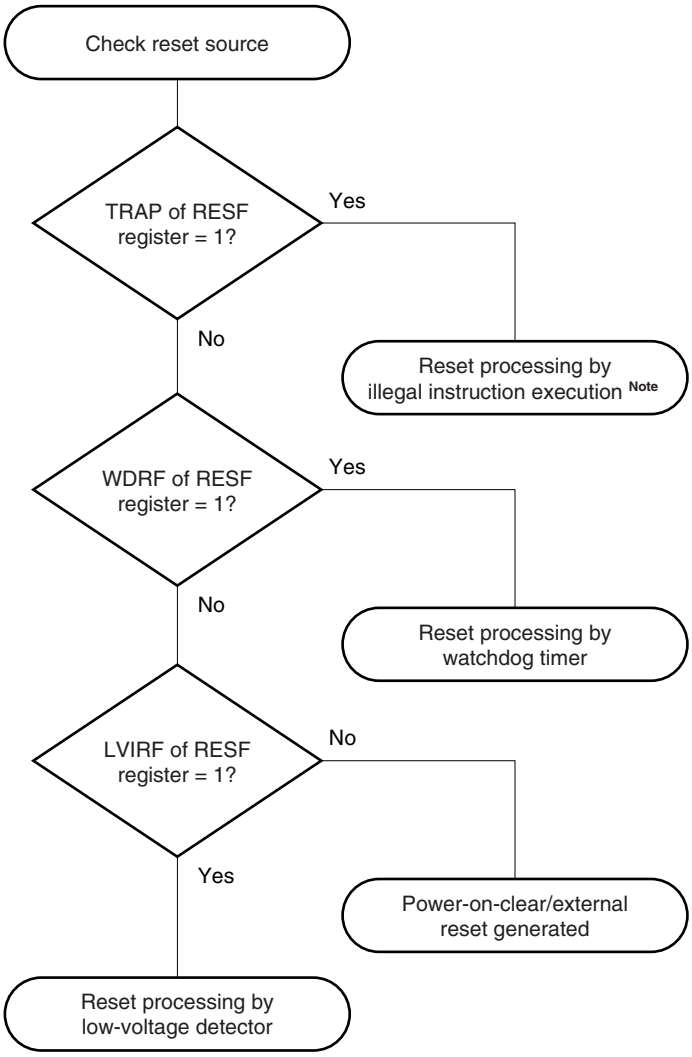
Remarks 1. If bit 2 (LVISEL) of the low voltage detection register (LVIM) is set to "1", the meanings of the above words change as follows.

- Supply voltage (V_{DD}) → Input voltage from external input pin (EXLVI)
- Detection voltage (V_{LVI}) → Detection voltage (V_{EXLVI} = 1.21 V)

2. n = 0 to 7

Figure 21-11. Example of Software Processing After Reset Release (2/2)

• Checking reset source



Note When instruction code FFH is executed.
Reset by the illegal instruction execution not issued by emulation with the in-circuit emulator or on-chip debug emulator.

Remark If bit 2 (LVISEL) of the low voltage detection register (LVIM) is set to “1”, the meanings of the above words change as follows.

- Supply voltage (V_{DD}) → Input voltage from external input pin (EXLVI)
- Detection voltage (V_{LVI}) → Detection voltage (V_{EXLVI} = 1.21 V)

Operation example 2: When used as interrupt

Interrupt requests may be generated frequently.

Take the following action.

<Action>

Confirm that "supply voltage (V_{DD}) ≥ detection voltage (V_{LVI})" when detecting the falling edge of V_{DD}, or "supply voltage (V_{DD}) < detection voltage (V_{LVI})" when detecting the rising edge of V_{DD}, in the servicing routine of the LVI interrupt by using bit 0 (LVIF) of the low-voltage detection register (LVIM). Clear bit 1 (LVIIF) of interrupt request flag register 0L (IF0L) to 0.

For a system with a long supply voltage fluctuation period near the LVI detection voltage, take the above action after waiting for the supply voltage fluctuation time.

Remark If bit 2 (LVISEL) of the low voltage detection register (LVIM) is set to "1", the meanings of the above words change as follows.

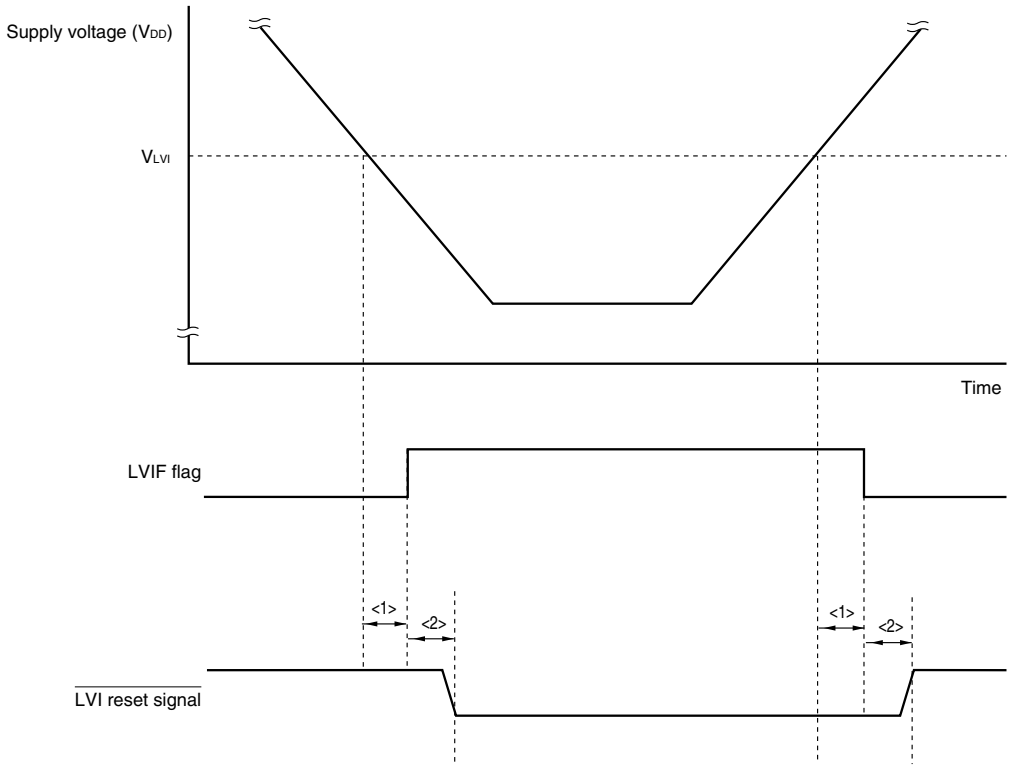
- Supply voltage (V_{DD}) → Input voltage from external input pin (EXLVI)
- Detection voltage (V_{LVI}) → Detection voltage (V_{EXLVI} = 1.21 V)

(2) Delay from the time LVI reset source is generated until the time LVI reset has been generated or released

There is some delay from the time supply voltage (V_{DD}) < LVI detection voltage (V_{LVI}) until the time LVI reset has been generated.

In the same way, there is also some delay from the time LVI detection voltage (V_{LVI}) ≤ supply voltage (V_{DD}) until the time LVI reset has been released (see **Figure 21-12**).

Figure 21-12. Delay from the time LVI reset source is generated until the time LVI reset has been generated or released



<1>: Minimum pulse width (200 μs (MIN.))

<2>: Detection delay time (200 μs (MAX.))

CHAPTER 22 REGULATOR

22.1 Regulator Overview

The 78K0R/Kx3-L contains a circuit for operating the device with a constant voltage. At this time, in order to stabilize the regulator output voltage, connect the REGC pin to V_{SS} via a capacitor (0.47 to 1 μF: target). However, when using the STOP mode that has been entered since operation of the internal high-speed oscillation clock and external main system clock, 0.47 μF is recommended. Also, use a capacitor with good characteristics, since it is used to stabilize internal voltage.

The regulator output voltage is normally 2.4 V (typ.), and in the low consumption current mode, 1.8 V (typ.).

22.2 Registers Controlling Regulator

(1) Regulator mode control register (RMC)

This register sets the output voltage of the regulator.

RMC is set with an 8-bit memory manipulation instruction.

Reset input sets this register to 00H.

Figure 22-1. Format of Regulator Mode Control Register (RMC)

Address: F00F4H After reset: 00H R/W

Symbol	7	6	5	4	3	2	1	0
RMC								

RMC[7:0]	Control of output voltage of regulator
5AH	Fixed to low consumption current mode (1.8 V)
00H	Switches normal current mode (2.4 V) and low consumption current mode (1.8 V) according to the condition (refer to **Table 22-1**)
Other than above	Setting prohibited

Cautions 1. The RMC register can be rewritten only in the low consumption current mode (refer to Table 22-1). In other words, rewrite this register during CPU operation with the subsystem clock (f_{XT}) while the high-speed system clock (f_{MX}), the high-speed internal oscillation clock (f_{IH}), and the 20 MHz internal high-speed oscillation clock (f_{IH20}) are both stopped.

2. When using the setting fixed to the low consumption current mode, the RMC register can be used in the following cases.

<When X1 clock is selected as the CPU clock> $f_X \leq 5$ MHz and $f_{CLK} \leq 1$ MHz

<When the high-speed internal oscillation clock, external input clock, or subsystem clock are selected for the CPU clock> $f_{CLK} \leq 1$ MHz

3. The self-programming function is disabled in the low consumption current mode.

(Caution is given on the next page.)

Caution 4. A wait is required to change the operation speed mode control register (OSMC) after changing the RMC register. Wait for 2 ms by software when setting to low consumption current mode and 10 μs when setting to normal current mode, as described in the procedure shown below.

• When setting to low consumption current mode

<1> Select a frequency of 1 MHz for f_{CLK}.

<2> Set RMC to 5AH (set the regulator to low consumption current mode).

<3> Wait for 2 ms.

<4> Set FLPC and FSEL of OSMC to 1 and 0, respectively.

• When setting to normal current mode

<1> Set RMC to 00H (set the regulator to normal current mode).

<2> Wait for 10 μs.

<3> Change FLPC and FSEL of OSMC.

<4> Change the f_{CLK} frequency.

Table 22-1. Regulator Output Voltage Conditions

Mode	Output Voltage	Condition
Low consumption current mode	1.8 V	During $\overline{\text{RESET}}$ pin reset
		In STOP mode (except during OCD mode)
		When both the high-speed system clock (f_{MX}), the high-speed internal oscillation clock (f_{IH}), and the 20 MHz internal high-speed oscillation clock (f_{IH20}) are stopped during CPU operation with the subsystem clock (f_{XT})
		When both the high-speed system clock (f_{MX}), the high-speed internal oscillation clock (f_{IH}), and the 20 MHz internal high-speed oscillation clock (f_{IH20}) are stopped during the HALT mode when the CPU operation with the subsystem clock (f_{XT}) has been set
Normal current mode	2.4 V	Other than above

CHAPTER 23 OPTION BYTE

23.1 Functions of Option Bytes

Addresses 000C0H to 000C3H of the flash memory of the 78K0R/Kx3-L form an option byte area.

Option bytes consist of user option byte (000C0H to 000C2H) and on-chip debug option byte (000C3H).

Upon power application or resetting and starting, an option byte is automatically referenced and a specified function is set. When using the product, be sure to set the following functions by using the option bytes.

To use the boot swap operation during self programming, 000C0H to 000C3H are replaced by 010C0H to 010C3H. Therefore, set the same values as 000C0H to 000C3H to 010C0H to 010C3H.

Caution Be sure to set FFH to 000C2H (000C2H/010C2H when the boot swap operation is used).

23.1.1 User option byte (000C0H to 000C2H/010C0H to 010C2H)

(1) 000C0H/010C0H

- ○ Operation of watchdog timer
  - • Operation is stopped or enabled in the HALT or STOP mode.
- ○ Setting of interval time of watchdog timer
- ○ Operation of watchdog timer
  - • Operation is stopped or enabled.
- ○ Setting of window open period of watchdog timer
- ○ Setting of interval interrupt of watchdog timer
  - • Used or not used

Caution Set the same value as 000C0H to 010C0H when the boot swap operation is used because 000C0H is replaced by 010C0H.

(2) 000C1H/010C1H

- ○ Setting of LVI upon reset release (upon power application)
  - • LVI is ON or OFF by default upon reset release (reset by $\overline{\text{RESET}}$ pin excluding LVI, POC, WDT, or illegal instructions).
- ○ Setting of internal high-speed oscillator frequency
  - • Select from 1 MHz, 8 MHz, or 20 MHz.

Caution Set the same value as 000C1H to 010C1H when the boot swap operation is used because 000C1H is replaced by 010C1H.

(3) 000C2H/010C2H

- ○ Be sure to set FFH, as these addresses are reserved areas.

Caution Set FFH to 010C2H when the boot swap operation is used because 000C2H is replaced by 010C2H.

23.1.2 On-chip debug option byte (000C3H/ 010C3H)

- Control of on-chip debug operation
  - On-chip debug operation is disabled or enabled.
- Handling of data of flash memory in case of failure in on-chip debug security ID authentication
  - Data of flash memory is erased or not erased in case of failure in on-chip debug security ID authentication.

Caution Set the same value as 000C3H to 010C3H when the boot swap operation is used because 000C3H is replaced by 010C3H.

23.2 Format of User Option Byte

The format of user option byte is shown below.

Notes 1. Set the same value as 000C0H to 010C0H when the boot swap operation is used because 000C0H is replaced by 010C0H.

2. The window open period is 100% when WDSTBYON = 0, regardless the value of WINDOW1 and WINDOW0.

Caution The watchdog timer continues its operation during self-programming of the flash memory and EEPROM emulation. During processing, the interrupt acknowledge time is delayed. Set the overflow time and window size taking this delay into consideration.

0	LVI is ON by default (LVI default start function enabled) upon reset release (upon power application)
1	LVI is OFF by default (LVI default start function stopped) upon reset release (upon power application)

Notes 1. Set the same value as 000C1H to 010C1H when the boot swap operation is used because 000C1H is replaced by 010C1H.

2. When 8 MHz or 20 MHz has been selected, the 8 MHz internal high-speed oscillator automatically starts oscillating after reset release. To use the 20 MHz internal high-speed oscillator to operate the microcontroller, oscillation is started by setting bit 0 (DSCON) of the 20 MHz internal high-speed oscillation control register (DSCCTL) to 1 with $V_{DD} \geq 2.7$ V. The circuit cannot be changed to a 1 MHz internal high-speed oscillator while the microcontroller operates.

3. When 1 MHz has been selected, the microcontroller operates on the 1 MHz internal high-speed oscillator after reset release. The circuit cannot be changed to an 8 MHz or 20 MHz internal high-speed oscillator while the microcontroller operates.

(**Cautions** are listed on the next page.)

Cautions 1. Be sure to set bits 7 to 3 to "1".

2. Even when the LVI default start function is used, if it is set to LVI operation prohibition by the software, it operates as follows:

- **Does not perform low-voltage detection during LVION = 0.**
- **If a reset is generated while LVION = 0, LVION will be re-set to 1 when the CPU starts after reset release. There is a period when low-voltage detection cannot be performed normally, however, when a reset occurs due to WDT and illegal instruction execution.**
  This is due to the fact that while the pulse width detected by LVI must be 200 μs max., LVION = 1 is set upon reset occurrence, and the CPU starts operating without waiting for the LVI stabilization time.

Note Be sure to set FFH to 000C2H, as these addresses are reserved areas. Also set FFH to 010C2H when the boot swap operation is used because 000C2H is replaced by 010C2H.

23.3 Format of On-chip Debug Option Byte

The format of on-chip debug option byte is shown below.

0	0	Disables on-chip debug operation.
0	1	Setting prohibited
1	0	Erases data of flash memory in case of failures in enabling on-chip debugging and authenticating on-chip debug security ID.
1	1	Does not erases data of flash memory in case of failures in enabling on-chip debugging and authenticating on-chip debug security ID.

Note Set the same value as 000C3H to 010C3H when the boot swap operation is used because 000C3H is replaced by 010C3H.

Caution Bits 7 and 0 (OCDENSET and OCDERSD) can only be specified a value.
Be sure to set 000010B to bits 6 to 1.

Remark The value on bits 3 to 1 will be written over when the on-chip debug function is in use and thus it will become unstable after the setting.
However, be sure to set the default values (0, 1, and 0) to bits 3 to 1 at setting.

23.4 Setting of Option Byte

The user option byte and on-chip debug option byte can be set using the RA78K0R or PM+ linker option, in addition to describing to the source. When doing so, the contents set by using the linker option take precedence, even if descriptions exist in the source, as mentioned below.

See the RA78K0R Assembler Package User's Manual for how to set the linker option.

A software description example of the option byte setting is shown below.

```
OPT   CSEG        OPT_BYTE
      DB          10H     ; Does not use interval interrupt of watchdog timer,
                          ; Enables watchdog timer operation,
                          ; Window open period of watchdog timer is 25%,
                          ; Overflow time of watchdog timer is 2^10/fIL,
                          ; Stops watchdog timer operation during HALT/STOP mode
      DB          0FBH    ; Select 8 MHz or 20 MHz for internal high-speed oscillator

                          ; data when security ID authorization fails
```

When the boot swap function is used during self programming, 000C0H to 000C3H is switched to 010C0H to 010C3H. Describe to 010C0H to 010C3H, therefore, the same values as 000C0H to 000C3H as follows.

```
OPT2  CSEG   AT   010C0H
      DB          10H     ; Does not use interval interrupt of watchdog timer,
                          ; Enables watchdog timer operation,
                          ; Window open period of watchdog timer is 25%,
                          ; Overflow time of watchdog timer is 2^10/fIL,
                          ; Stops watchdog timer operation during HALT/STOP mode
      DB          0FBH    ; Select 8 MHz or 20 MHz for internal high-speed oscillator
                          ; Stops LVI default start function
      DB          0FFH    ; Reserved area
      DB          85H     ; Enables on-chip debug operation, does not erase flash memory
                          ; data when security ID authorization fails
```

Caution To specify the option byte by using assembly language, use OPT_BYTE as the relocation attribute name of the CSEG pseudo instruction. To specify the option byte to 010C0H to 010C3H in order to use the boot swap function, use the relocation attribute AT to specify an absolute address.

CHAPTER 24 FLASH MEMORY

The 78K0R/Kx3-L incorporates the flash memory to which a program can be written, erased, and overwritten while mounted on the board.

24.1 Writing with Flash Memory Programmer

Data can be written to the flash memory on-board or off-board, by using a dedicated flash memory programmer.

(1) On-board programming

The contents of the flash memory can be rewritten after the 78K0R/Kx3-L has been mounted on the target system. The connectors that connect the dedicated flash memory programmer must be mounted on the target system.

(2) Off-board programming

Data can be written to the flash memory with a dedicated program adapter (FA series) before the 78K0R/Kx3-L is mounted on the target system.

Remark The FA series is a product of Naito Densei Machida Mfg. Co., Ltd.

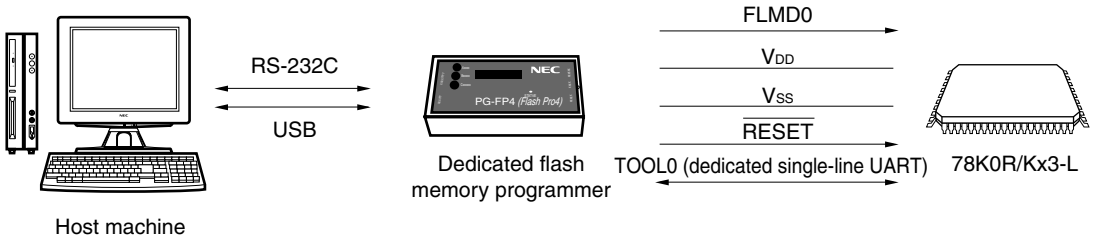
24.2 Programming Environment

The environment required for writing a program to the flash memory of the 78K0R/Kx3-L is illustrated below.

Figure 24-5. Environment for Writing Program to Flash Memory



A host machine that controls the dedicated flash memory programmer is necessary.

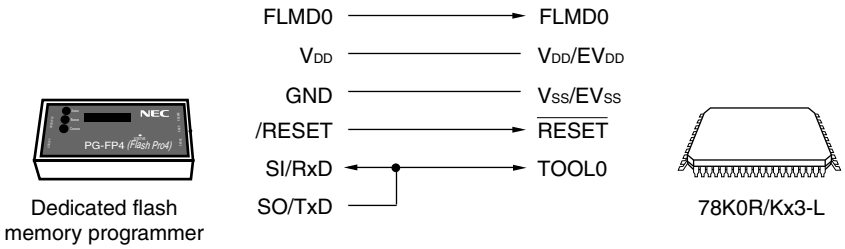
To interface between the dedicated flash memory programmer and the 78K0R/Kx3-L, the TOOL0 pin is used for manipulation such as writing and erasing via a dedicated single-line UART. To write the flash memory off-board, a dedicated program adapter (FA series) is necessary.

24.3 Communication Mode

Communication between the dedicated flash memory programmer and the 78K0R/Kx3-L is established by serial communication using the TOOL0 pin via a dedicated single-line UART of the 78K0R/Kx3-L.

Transfer rate: 115,200 bps to 1,000,000 bps

Figure 24-6. Communication with Dedicated Flash Memory Programmer



When using the FlashPro4 as the dedicated flash memory programmer, the FlashPro4, FlashPro5 generates the following signals for the 78K0R/Kx3-L. For details, refer to the user's manual for the FlashPro4, FlashPro5.

Table 24-2. Pin Connection

FlashPro4, FlashPro5			78K0R/Kx3-L	Connection

SO/TxD	Output	Transmit signal		
SCK	Output	Transfer clock	–	×

Remark ◎: Be sure to connect the pin.
×: The pin does not have to be connected.

24.4 Connection of Pins on Board

To write the flash memory on-board, connectors that connect the dedicated flash memory programmer must be provided on the target system. First provide a function that selects the normal operation mode or flash memory programming mode on the board.

When the flash memory programming mode is set, all the pins not used for programming the flash memory are in the same status as immediately after reset. Therefore, if the external device does not recognize the state immediately after reset, the pins must be handled as described below.

24.4.1 FLMD0 pin

(1) In flash memory programming mode

Directly connect this pin to a flash memory programmer when data is written by the flash memory programmer. This supplies a writing voltage of the V_{DD} level to the FLMD0 pin.

The FLMD0 pin does not have to be pulled down externally because it is internally pulled down by reset. To pull it down externally, use a resistor of 1 kΩ to 200 kΩ.

(2) In normal operation mode

It is recommended to leave this pin open during normal operation.

The FLMD0 pin must always be kept at the V_{SS} level before reset release but does not have to be pulled down externally because it is internally pulled down by reset. However, pulling it down must be kept selected (i.e., FLMDPUP = "0", default value) by using bit 7 (FLMDPUP) of the background event control register (BECTL) (see **24.5 (1) Back ground event control register**). To pull it down externally, use a resistor of 200 kΩ or smaller.

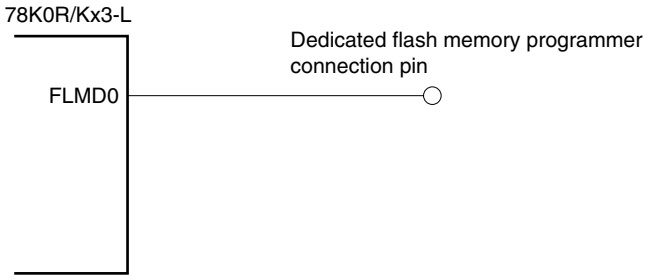
Self programming and the rewriting of flash memory with the programmer can be prohibited using hardware, by directly connecting this pin to the V_{SS} pin.

(3) In self programming mode

It is recommended to leave this pin open when using the self programming function. To pull it down externally, use a resistor of 100 kΩ to 200 kΩ.

In the self programming mode, the setting is switched to pull up in the self programming library.

Figure 24-7. FLMD0 Pin Connection Example



24.4.2 TOOL0 pin

In the flash memory programming mode, connect this pin directly to the dedicated flash memory programmer or pull it up by connecting it to EV_{DD} via an external resistor.

When on-chip debugging is enabled in the normal operation mode, pull this pin up by connecting it to EV_{DD} via an external resistor, and be sure to keep inputting the V_{DD} level to the TOOL0 pin before reset is released (pulling down this pin is prohibited).

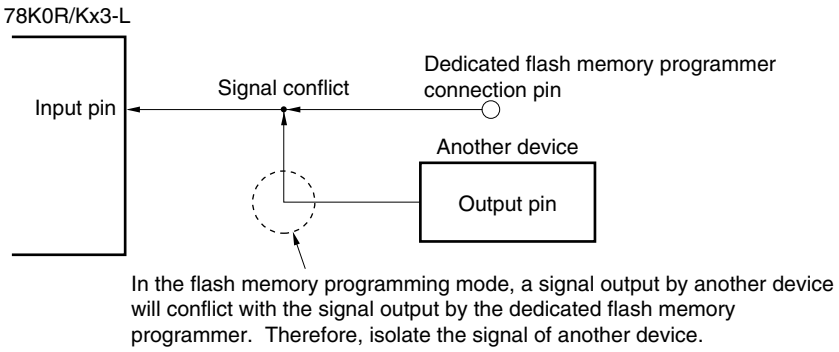
Remark The SAU and IICA pins are not used for communication between the 78K0R/Kx3-L and dedicated flash memory programmer, because single-line UART is used.

24.4.3 $\overline{\text{RESET}}$ pin

Signal conflict will occur if the reset signal of the dedicated flash memory programmer is connected to the $\overline{\text{RESET}}$ pin that is connected to the reset signal generator on the board. To prevent this conflict, isolate the connection with the reset signal generator.

The flash memory will not be correctly programmed if the reset signal is input from the user system while the flash memory programming mode is set . Do not input any signal other than the reset signal of the dedicated flash memory programmer.

Figure 24-8. Signal Conflict ($\overline{\text{RESET}}$ Pin)



24.4.4 Port pins

When the flash memory programming mode is set, all the pins not used for flash memory programming enter the same status as that immediately after reset. If external devices connected to the ports do not recognize the port status immediately after reset, the port pin must be connected to EV_{DD} Note or EV_{SS} Note via a resistor.

Note With products without an EV_{SS} pin, connect them to V_{SS}. With products without an EV_{DD} pin, connect them to V_{DD}.

24.4.5 REGC pin

Connect the REGC pin to GND via a capacitor (0.47 to 1 μF: target) in the same manner as during normal operation. However, when using the STOP mode that has been entered since operation of the internal high-speed oscillation clock and external main system clock, 0.47 μF is recommended. Also, use a capacitor with good characteristics, since it is used to stabilize internal voltage.

24.4.6 X1 and X2 pins

Connect X1 and X2 in the same status as in the normal operation mode.

Remark In the flash memory programming mode, the internal high-speed oscillation clock (f_{IH}) is used.

24.4.7 Power supply

To use the supply voltage output of the flash memory programmer, connect the V_{DD} pin to V_{DD} of the flash memory programmer, and the V_{SS} pin to GND of the flash memory programmer.

To use the on-board supply voltage, connect in compliance with the normal operation mode.

However, when using the on-board supply voltage, be sure to connect the V_{DD} and V_{SS} pins to V_{DD} and GND of the flash memory programmer to use the power monitor function with the flash memory programmer.

Supply the same other power supplies (EV_{DD}, EV_{SS}, AV_{REF}, and AV_{SS}) as those in the normal operation mode.

24.5 Registers Controlling Flash Memory

(1) Background event control register (BECTL)

Even if the FLMD0 pin is not controlled externally, it can be controlled by software with the BECTL register to set the self-programming mode.

However, depending on the processing of the FLMD0 pin, it may not be possible to set the self-programming mode by software. When using BECTL, leaving the FLMD0 pin open is recommended. When pulling it down externally, use a resistor with a resistance of 100 kΩ or more. In addition, in the normal operation mode, use BECTL with the pull down selection. In the self-programming mode, the setting is switched to pull up in the self-programming library.

The BECTL register is set by a 1-bit or 8-bit memory manipulation instruction.

Reset input sets this register to 00H.

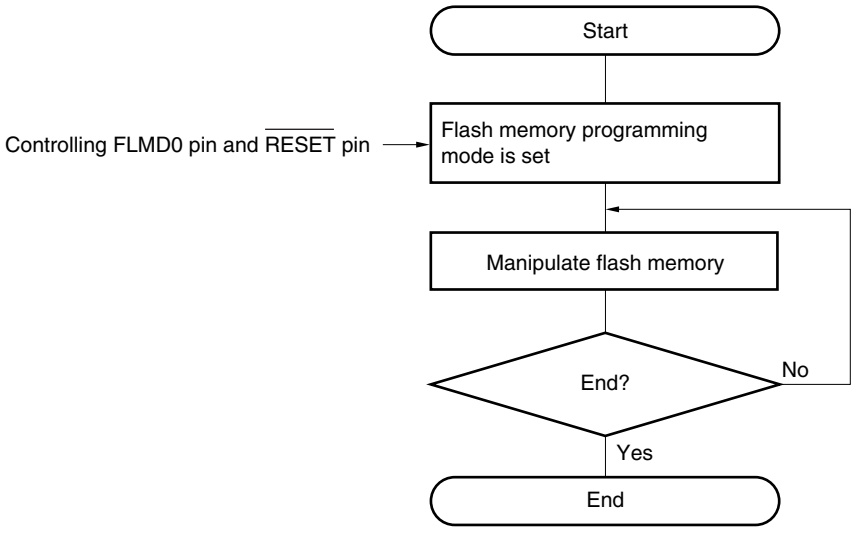
24.6 Programming Method

24.6.1 Controlling flash memory

The following figure illustrates the procedure to manipulate the flash memory.

Figure 24-10. Flash Memory Manipulation Procedure



26.6.2 Flash memory programming mode

To rewrite the contents of the flash memory by using the dedicated flash memory programmer, set the 78K0R/Kx3-L in the flash memory programming mode. To set the mode, set the FLMD0 pin and TOOL0 pin to V_{DD} and clear the reset signal.

Change the mode by using a jumper when writing the flash memory on-board.

24.6.3 Selecting communication mode

Communication mode of the 78K0R/Kx3-L as follows.

Table 24-4. Communication Modes

Communication Mode	Standard Setting[Note 1]				Pins Used
	Port	Speed	Frequency	Multiply Rate	
1-line mode (dedicated single-line UART)	UART-ch0	1 Mbps[Note 2]	–	–	TOOL0

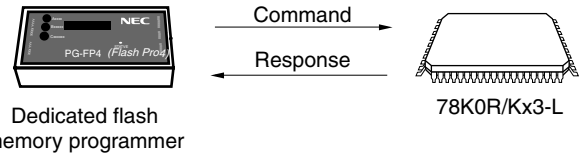
Notes 1. Selection items for Standard settings on GUI of the flash memory programmer.

2. Because factors other than the baud rate error, such as the signal waveform slew, also affect UART communication, thoroughly evaluate the slew as well as the baud rate error.

24.6.4 Communication commands

The 78K0R/Kx3-L communicates with the dedicated flash memory programmer by using commands. The signals sent from the flash memory programmer to the 78K0R/Kx3-L are called commands, and the signals sent from the 78K0R/Kx3-L to the dedicated flash memory programmer are called response.

Figure 24-12. Communication Commands



The flash memory control commands of the 78K0R/Kx3-L are listed in the table below. All these commands are issued from the programmer and the 78K0R/Kx3-L perform processing corresponding to the respective commands.

Table 24-5. Flash Memory Control Commands

Classification	Command Name	Function
Verify	Verify	Compares the contents of a specified area of the flash memory with data transmitted from the programmer.
Erase	Chip Erase	Erases the entire flash memory.
	Block Erase	Erases a specified area in the flash memory.
Blank check	Block Blank Check	Checks if a specified block in the flash memory has been correctly erased.
Write	Programming	Writes data to a specified area in the flash memory.
Getting information	Silicon Signature	Gets 78K0R/Kx3-L information (such as the part number and flash memory configuration).
	Version Get	Gets the 78K0R/Kx3-L firmware version.
	Checksum	Gets the checksum data for a specified area.
Security	Security Set	Sets security information.
Others	Reset	Used to detect synchronization status of communication.
	Baud Rate Set	Sets baud rate when UART communication mode is selected.

The 78K0R/Kx3-L returns a response for the command issued by the dedicated flash memory programmer. The response names sent from the 78K0R/Kx3-L are listed below.

Table 24-6. Response Names

Response Name	Function
ACK	Acknowledges command/data.
NAK	Acknowledges illegal command/data.

24.7 Security Settings

The 78K0R/Kx3-L supports a security function that prohibits rewriting the user program written to the internal flash memory, so that the program cannot be changed by an unauthorized person.

The operations shown below can be performed using the Security Set command. The security setting is valid when the programming mode is set next.

- Disabling batch erase (chip erase)
  Execution of the block erase and batch erase (chip erase) commands for entire blocks in the flash memory is prohibited by this setting during on-board/off-board programming. Once execution of the batch erase (chip erase) command is prohibited, all of the prohibition settings (including prohibition of batch erase (chip erase)) can no longer be cancelled.

  Caution After the security setting for the batch erase is set, erasure cannot be performed for the device. In addition, even if a write command is executed, data different from that which has already been written to the flash memory cannot be written, because the erase command is disabled.

- Disabling block erase
  Execution of the block erase command for a specific block in the flash memory is prohibited during on-board/off-board programming. However, blocks can be erased by means of self programming.

- Disabling write
  Execution of the write and block erase commands for entire blocks in the flash memory is prohibited during on-board/off-board programming. However, blocks can be written by means of self programming.

- Disabling rewriting boot cluster 0
  Execution of the batch erase (chip erase) command, block erase command, and write command on boot cluster 0 (00000H to 00FFFH) in the flash memory is prohibited by this setting.

The batch erase (chip erase), block erase, write commands, and rewriting boot cluster 0 are enabled by the default setting when the flash memory is shipped. Security can be set by on-board/off-board programming and self programming. Each security setting can be used in combination.

All the security settings are cleared by executing the batch erase (chip erase) command.

Table 24-7 shows the relationship between the erase and write commands when the 78K0R/Kx3-L security function is enabled.

Remark To prohibit writing and erasing during self-programming, use the flash sealed window function (see **24.8.2** for detail).

Table 24-7. Relationship Between Enabling Security Function and Command

(1) During on-board/off-board programming

Valid Security	Executed Command		
	Batch Erase (Chip Erase)	Block Erase	Write
Prohibition of batch erase (chip erase)	Cannot be erased in batch	Blocks cannot be erased.	Can be performed[Note].
Prohibition of block erase	Can be erased in batch.		Can be performed.
Prohibition of writing			Cannot be performed.
Prohibition of rewriting boot cluster 0	Cannot be erased in batch	Boot cluster 0 cannot be erased.	Boot cluster 0 cannot be written.

Note Confirm that no data has been written to the write area. Because data cannot be erased after batch erase (chip erase) is prohibited, do not write data if the data has not been erased.

(2) During self programming

Valid Security	Executed Command	
	Block Erase	Write
Prohibition of batch erase (chip erase)	Blocks can be erased.	Can be performed.
Prohibition of block erase		
Prohibition of writing		
Prohibition of rewriting boot cluster 0	Boot cluster 0 cannot be erased.	Boot cluster 0 cannot be written.

Remark To prohibit writing and erasing during self-programming, use the flash sealed window function (see **24.8.2** for detail).

Table 24-8. Setting Security in Each Programming Mode

(1) On-board/off-board programming

Security	Security Setting	How to Disable Security Setting
Prohibition of batch erase (chip erase)	Set via GUI of dedicated flash memory programmer, etc.	Cannot be disabled after set.
Prohibition of block erase		Execute batch erase (chip erase) command
Prohibition of writing		
Prohibition of rewriting boot cluster 0		Cannot be disabled after set.

(2) Self programming

Security	Security Setting	How to Disable Security Setting
Prohibition of batch erase (chip erase)	Set by using information library.	Cannot be disabled after set.
Prohibition of block erase		Execute batch erase (chip erase) command during on-board/off-board programming (cannot be disabled during self programming)
Prohibition of writing		
Prohibition of rewriting boot cluster 0		

24.8 Flash Memory Programming by Self-Programming

The 78K0R/Kx3-L supports a self-programming function that can be used to rewrite the flash memory via a user program. Because this function allows a user application to rewrite the flash memory by using the 78K0R/Kx3-L self-programming library, it can be used to upgrade the program in the field.

If an interrupt occurs during self-programming, self-programming can be temporarily stopped and interrupt servicing can be executed. If an unmasked interrupt request is generated in the EI state, the request branches directly from the self-programming library to the interrupt routine. After the self-programming mode is later restored, self-programming can be resumed. However, the interrupt response time is different from that of the normal operation mode.

Cautions 1. The self-programming function cannot be used when the CPU operates with the subsystem clock.

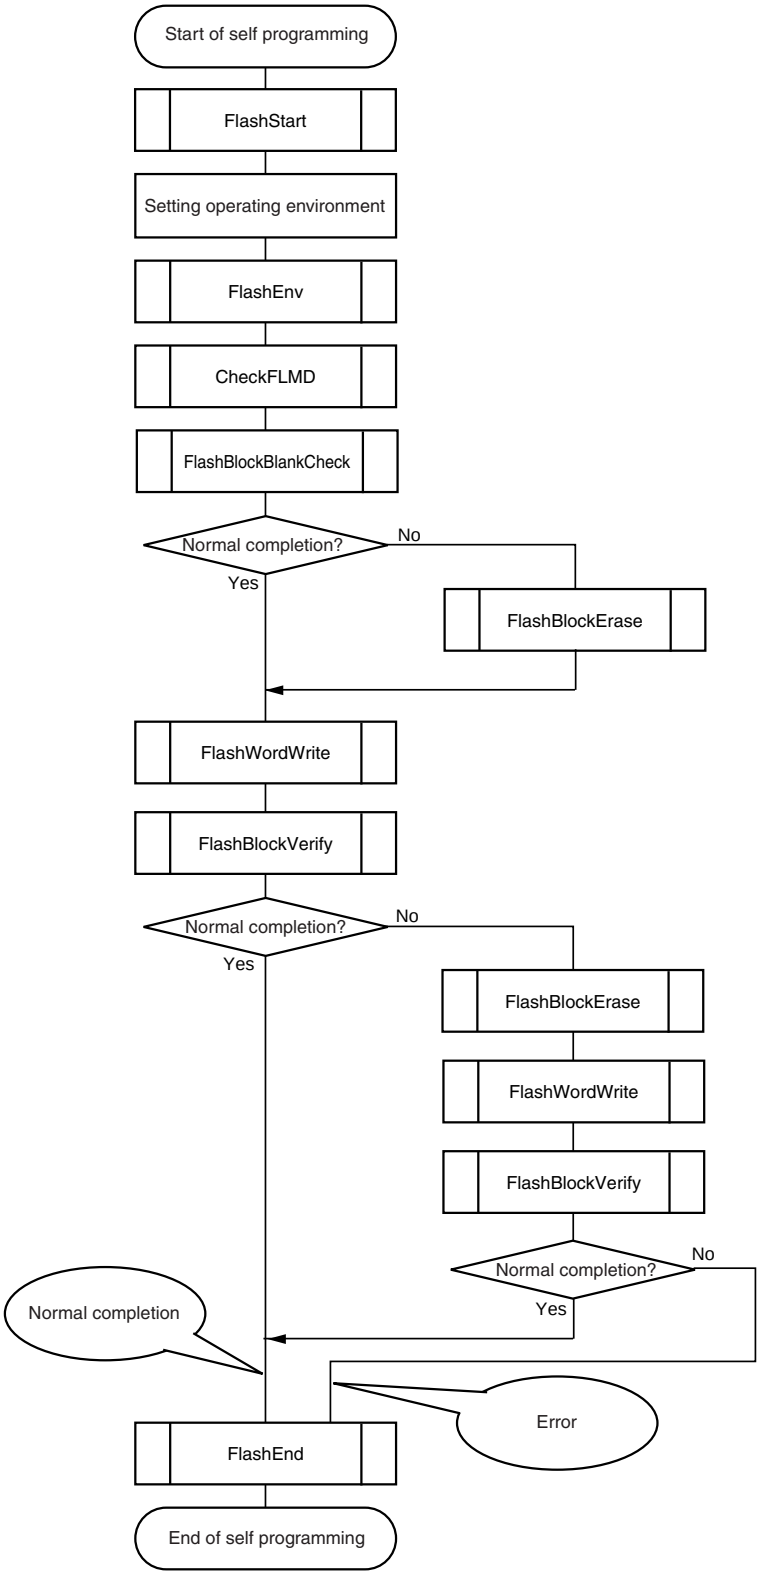
2. In the self-programming mode, call the self-programming start library (FlashStart).

3. To prohibit an interrupt during self-programming, in the same way as in the normal operation mode, execute the self-programming library in the state where the IE flag is cleared (0) by the DI instruction. To enable an interrupt, clear (0) the interrupt mask flag to accept in the state where the IE flag is set (1) by the EI instruction, and then execute the self-programming library.

4. The self-programming function is disabled in the low consumption current mode. For details of the low consumption current mode, see CHAPTER 22 REGULATOR.

The following figure illustrates a flow of rewriting the flash memory by using a self programming library.

Figure 24-13. Flow of Self Programming (Rewriting Flash Memory)



24.8.1 Boot swap function

If rewriting the boot area failed by temporary power failure or other reasons, restarting a program by resetting or overwriting is disabled due to data destruction in the boot area.

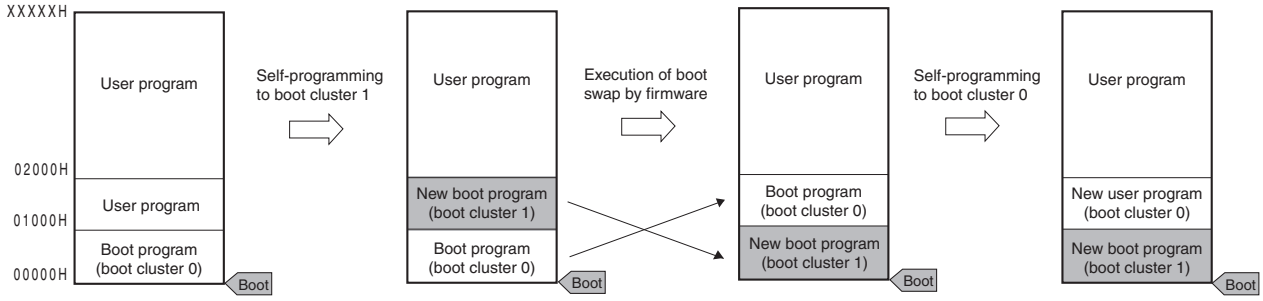
The boot swap function is used to avoid this problem.

Before erasing boot cluster 0[Note], which is a boot program area, by self-programming, write a new boot program to boot cluster 1 in advance. When the program has been correctly written to boot cluster 1, swap this boot cluster 1 and boot cluster 0 by using the set information function of the firmware of the 78K0R/Kx3-L, so that boot cluster 1 is used as a boot area. After that, erase or write the original boot program area, boot cluster 0.

As a result, even if a power failure occurs while the boot programming area is being rewritten, the program is executed correctly because it is booted from boot cluster 1 to be swapped when the program is reset and started next.

Note A boot cluster is a 4 KB area and boot clusters 0 and 1 are swapped by the boot swap function.

Figure 24-14. Boot Swap Function

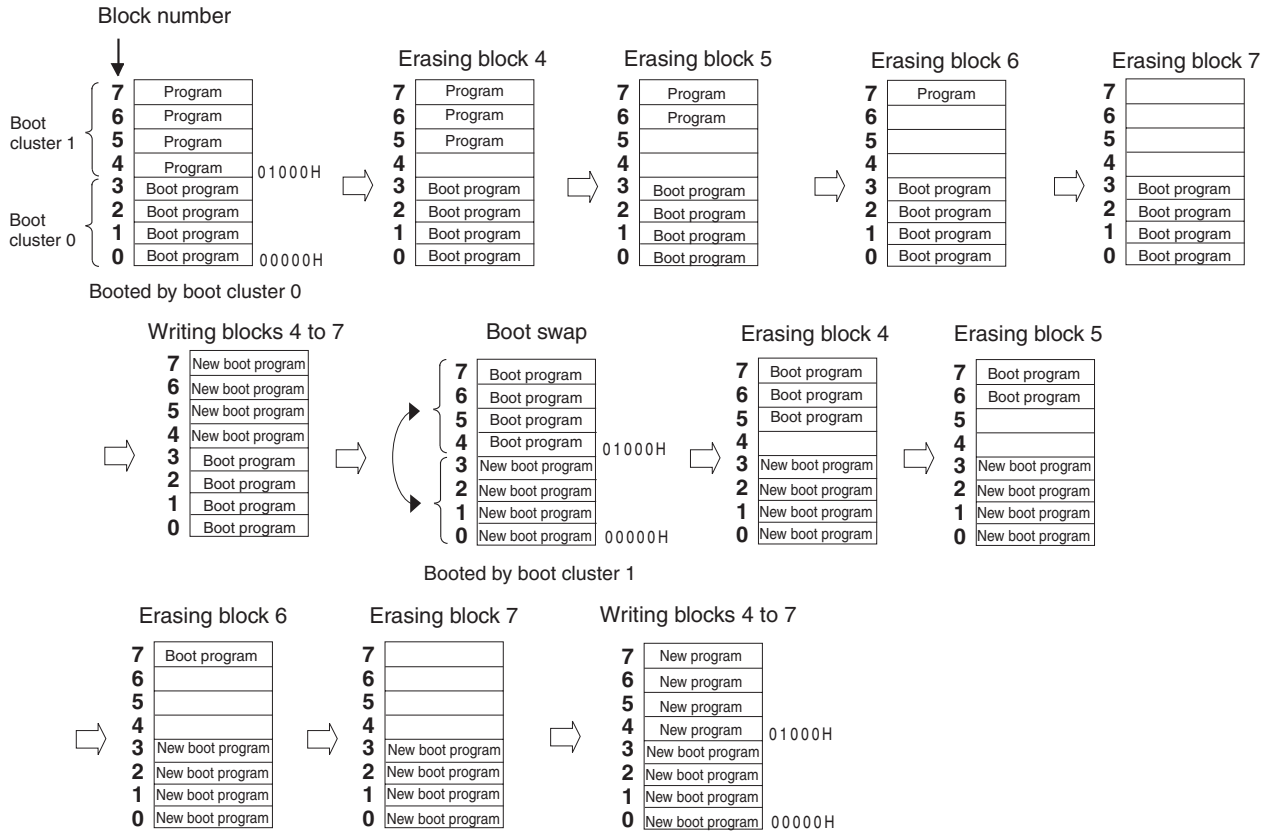


In an example of above figure, it is as follows.

Boot cluster 0: Boot program area before boot swap

Boot cluster 1: Boot program area after boot swap

Figure 24-15. Example of Executing Boot Swapping



24.8.2 Flash shield window function

The flash shield window function is provided as one of the security functions for self-programming.

Writing and erasing to the flash memory within the range specified as a window are enabled during self-programming, and writing and erasing to the flash memory outside the specified range are prohibited.

The window range can be expanded or reduced by setting and change during on-board/off-board programming and self-programming. However, the shield function becomes effective only during self-programming. In on-board/off-board programming, writing and erasing to the flash memory outside the window range are enabled.

Caution If the rewrite-prohibited area of the boot cluster 0 overlaps with the flash shield window range, prohibition to rewrite the boot cluster 0 takes priority.

Table 24-9. Relationship between Flash Shield Window Function Setting/Change Methods and Commands

Programming conditions	Window Range Setting/Change Methods	Execution Commands	
		Block erase	Write
Self-programming	Specify the starting and ending blocks by the set information library.	Block erasing is enabled only within the window range.	Writing is enabled only within the range of window range.
On-board/Off-board programming	Specify the starting and ending blocks on GUI of dedicated flash memory programmer, etc.	Block erasing is enabled also outside the window range.	Writing is enabled also outside the window range.

Remark See **24.7 Security Settings** to prohibit writing/erasing during on-board/off-board programming.

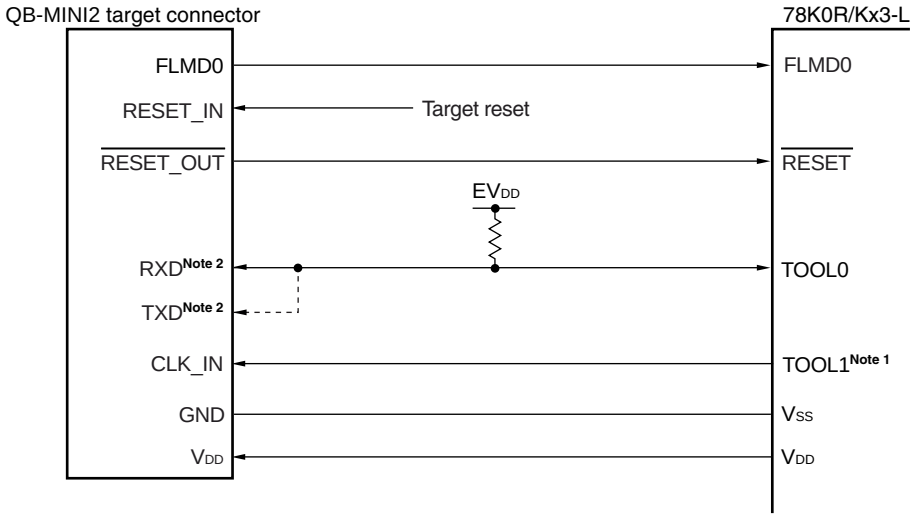
CHAPTER 25 ON-CHIP DEBUG FUNCTION

25.1 Connecting QB-MINI2 to 78K0R/Kx3-L

The 78K0R/Kx3-L uses the V_{DD}, FLMD0, $\overline{RESET}$, TOOL0, TOOL1[Note 1], and V_{SS} pins to communicate with the host machine via an on-chip debug emulator (QB-MINI2).

Caution The 78K0R/Kx3-L has an on-chip debug function, which is provided for development and evaluation. Do not use the on-chip debug function in products designated for mass production, because the guaranteed number of rewritable times of the flash memory may be exceeded when this function is used, and product reliability therefore cannot be guaranteed. NEC Electronics is not liable for problems occurring when the on-chip debug function is used.

Figure 25-1. Connection Example of QB-MINI2 and 78K0R/Kx3-L



Notes 1. Connection is not required for communication in 1-line mode but required for communication in 2-line mode. At this time, perform necessary connections according to Table 2-2 Connection of Unused Pins since TOOL1 is an unused pin when QB-MINI2 is unconnected.

2. Connecting the dotted line is not necessary since RXD and TXD are shorted within QB-MIN2. When using the other flash memory programmer, RXD and TXD may not be shorted within the programmer. In this case, they must be shorted on the target system.

Remark The FLMD0 pin is recommended to be open for self-programming in on-chip debugging. To pull down externally, use a resistor of 100 kΩ or more.

1-line mode (single line UART) using the TOOL0 pin or 2-line mode using the TOOL0 and TOOL1 pins is used for serial communication For flash memory programming, 1-line mode is used. 1-line mode or 2-line mode is used for on-chip debugging. Table 25-1 lists the differences between 1-line mode and 2-line mode.

Table 25-1. Lists the Differences Between 1-line Mode and 2-line Mode.

Communication mode	Flash memory programming function	Debugging function
1-line mode	Available	• Pseudo real-time RAM monitor (RRM) function not supported. • DMM function (rewriting memory in RUN) not supported. • The debugger speed is two to four times slower than 2-line mode.
2-line mode	None	• Pseudo real-time RAM monitor (RRM) function supported • DMM function (rewriting memory in RUN) supported

Remark 2-line mode is not used for flash programming, however, even if TOOL1 pin is connected with CLK_IN of QB-MINI2, writing is performed normally with no problem.

25.2 On-Chip Debug Security ID

The 78K0R/Kx3-L has an on-chip debug operation control bit in the flash memory at 000C3H (see **CHAPTER 23 OPTION BYTE**) and an on-chip debug security ID setting area at 000C4H to 000CDH, to prevent third parties from reading memory content.

When the boot swap function is used, also set a value that is the same as that of 010C3H and 010C4H to 010CDH in advance, because 000C3H, 000C4H to 000CDH and 010C3H, and 010C4H to 010CDH are switched.

For details on the on-chip debug security ID, refer to the **QB-MINI2 On-Chip Debug Emulator with Programming Function User's Manual (U18371E)**.

Table 25-2. On-Chip Debug Security ID

Address	On-Chip Debug Security ID
000C4H to 000CDH	Any ID code of 10 bytes
010C4H to 010CDH	

25.3 Securing of User Resources

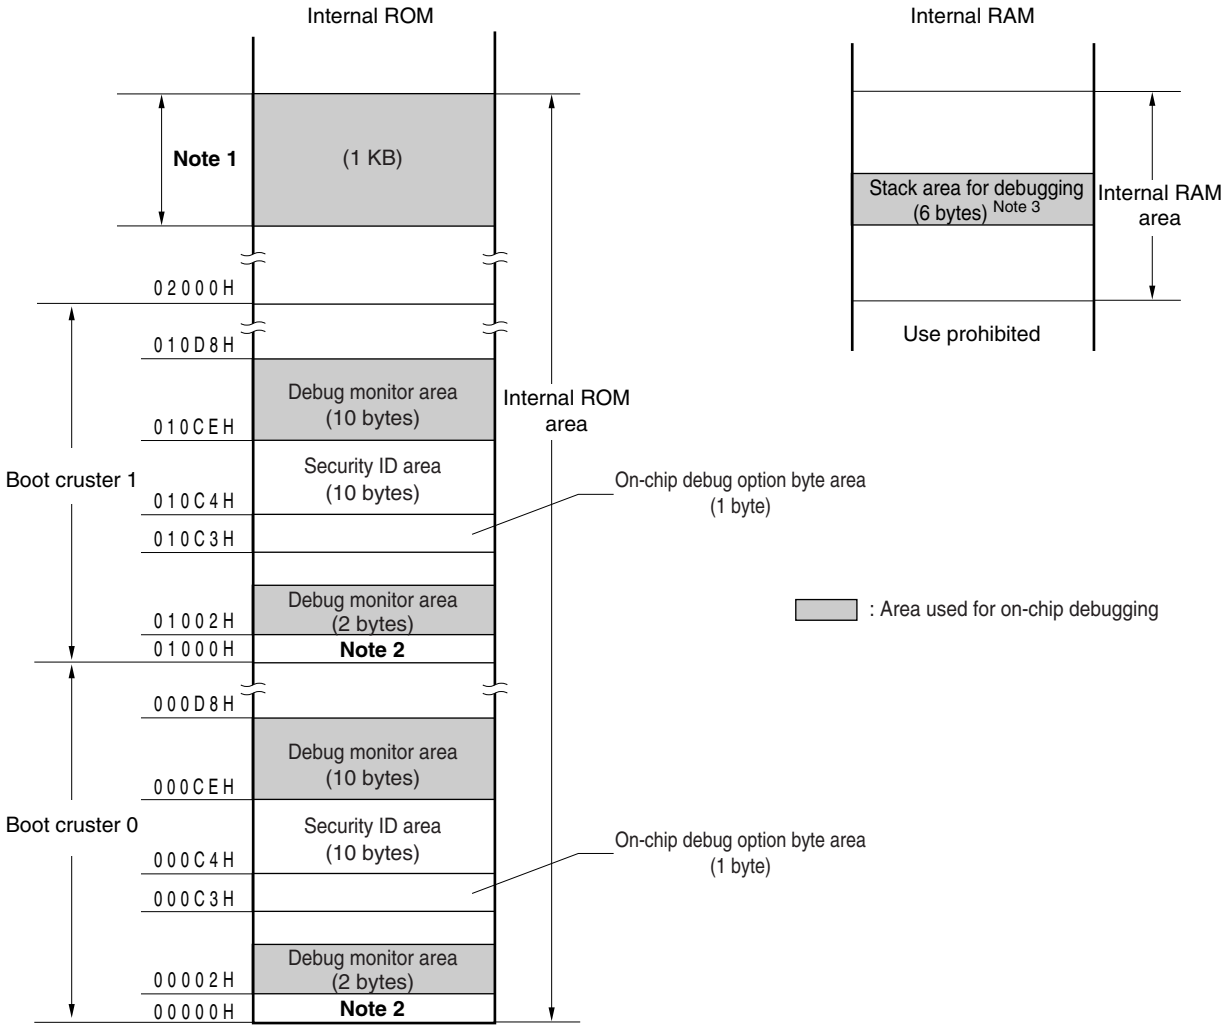
To perform communication between the 78K0R/Kx3-L and QB-MINI2, as well as each debug function, the securing of memory space must be done beforehand.

If NEC Electronics assembler RA78K0R or compiler CC78K0R is used, the items can be set by using linker options.

(1) Securement of memory space

The shaded portions in Figure 25-2 are the areas reserved for placing the debug monitor program, so user programs or data cannot be allocated in these spaces. When using the on-chip debug function, these spaces must be secured so as not to be used by the user program. Moreover, this area must not be rewritten by the user program.

Figure 25-2. Memory Spaces Where Debug Monitor Programs Are Allocated



Notes 1. Address differs depending on products as follows.

Products ( ): Internal ROM	Address of **Note 1**
μPD78F1000 (16 KB)	03C00H to 03FFFH
μPD78F1001, 78F1004, 78F1007 (32 KB)	07C00H to 07FFFH
μPD78F1002, 78F1005, 78F1008 (48 KB)	0BC00H to 0BFFFH
μPD78F1003, 78F1006, 78F1009 (64 KB)	0FC00H to 0FFFFH

2. In debugging, reset vector is rewritten to address allocated to a monitor program.

3. Since this area is allocated immediately before the stack area, the address of this area varies depending on the stack increase and decrease. That is, 6 extra bytes are consumed for the stack area used.

For details of the way to secure of the memory space, refer to the **QB-MINI2 On-Chip Debug Emulator with Programming Function User's Manual (U18371E)**.

CHAPTER 26 BCD CORRECTION CIRCUIT

26.1 BCD Correction Circuit Function

The result of addition/subtraction of the BCD (binary-coded decimal) code and BCD code can be obtained as BCD code with this circuit.

The decimal correction operation result is obtained by performing addition/subtraction having the A register as the operand and then adding/ subtracting the BCDADJ register.

26.2 Registers Used by BCD Correction Circuit

The BCD correction circuit uses the following registers.

- BCD correction result register (BCDADJ)

(1) BCD correction result register (BCDADJ)

The BCDADJ register stores correction values for obtaining the add/subtract result as BCD code through add/subtract instructions using the A register as the operand.

The value read from the BCDADJ register varies depending on the value of the A register when it is read and those of the CY and AC flags.

BCDADJ is read by an 8-bit memory manipulation instruction.

Reset input sets this register to undefined.

Figure 26-1. Format of BCD Correction Result Register (BCDADJ)

Address: F00FEH After reset: undefined R

Symbol	7	6	5	4	3	2	1	0
BCDADJ								

26.3 BCD Correction Circuit Operation

The basic operation of the BCD correction circuit is as follows.

(1) Addition: Calculating the result of adding a BCD code value and another BCD code value by using a BCD code value

<1> The BCD code value to which addition is performed is stored in the A register.

<2> By adding the value of the A register and the second operand (value of one more BCD code to be added) as are in binary, the binary operation result is stored in the A register and the correction value is stored in the BCDADJ register.

<3> Decimal correction is performed by adding in binary the value of the A register (addition result in binary) and the BCDADJ register (correction value), and the correction result is stored in the A register and CY register.

Caution The value read from the BCDADJ register varies depending on the value of the A register when it is read and those of the CY and AC flags. Therefore, execute the instruction <3> after the instruction <2> instead of executing any other instructions. To perform BCD correction in the interrupt enabled state, saving and restoring the A register is required within the interrupt function. PSW (CY flag and AC flag) is restored by the RETI instruction.

An example is shown below.

Examples 1: 99 + 89 = 188

Instruction	A Register	CY Register	AC Flag	BCDADJ Register
`MOV A, #99H ; <1>`	99H	–	–	–
`ADD A, #89H ; <2>`	22H	1	1	66H
`ADD A, !BCDADJ ; <3>`	88H	1	0	–

Examples 2: 85 + 15 = 100

Instruction	A Register	CY Register	AC Flag	BCDADJ Register
`MOV A, #85H ; <1>`	85H	–	–	–
`ADD A, #15H ; <2>`	9AH	0	0	06H
`ADD A, !BCDADJ ; <3>`	00H	1	1	–

Examples 3: 80 + 80 = 160

Instruction	A Register	CY Register	AC Flag	BCDADJ Register
`MOV A, #80H ; <1>`	80H	–	–	–
`ADD A, #80H ; <2>`	00H	1	0	60H
`ADD A, !BCDADJ ; <3>`	60H	1	0	–

(2) Subtraction: Calculating the result of subtracting a BCD code value from another BCD code value by using a BCD code value

<1> The BCD code value from which subtraction is performed is stored in the A register.

<2> By subtracting the value of the second operand (value of BCD code to be subtracted) from the A register as is in binary, the calculation result in binary is stored in the A register, and the correction value is stored in the BCDADJ register.

<3> Decimal correction is performed by subtracting the value of the BCDADJ register (correction value) from the A register (subtraction result in binary) in binary, and the correction result is stored in the A register and CY register.

Caution The value read from the BCDADJ register varies depending on the value of the A register when it is read and those of the CY and AC flags. Therefore, execute the instruction <3> after the instruction <2> instead of executing any other instructions. To perform BCD correction in the interrupt enabled state, saving and restoring the A register is required within the interrupt function. PSW (CY flag and AC flag) is restored by the RETI instruction.

An example is shown below.

Example: 91 − 52 = 39

Instruction	A Register	CY Register	AC Flag	BCDADJ Register
`MOV A, #91H ; <1>`	91H	−	−	−
`SUB A, #52H ; <2>`	3FH	0	1	06H
`SUB A, !BCDADJ ; <3>`	39H	0	0	−

CHAPTER 27 INSTRUCTION SET

This chapter lists the instructions in the 78K0R microcontroller instruction set. For details of each operation and operation code, refer to the separate document **78K0R Microcontrollers Instructions User's Manual (U17792E)**.

Remark The shaded parts of the tables in **Table 27-5 Operation List** indicate the operation or instruction format that is newly added for the 78K0R microcontrollers.

27.1 Conventions Used in Operation List

27.1.1 Operand identifiers and specification methods

Operands are described in the "Operand" column of each instruction in accordance with the description method of the instruction operand identifier (refer to the assembler specifications for details). When there are two or more description methods, select one of them. Alphabetic letters in capitals and the symbols, #, !, !!, $, $!, [ ], and ES: are keywords and are described as they are. Each symbol has the following meaning.

- #: Immediate data specification
- !: 16-bit absolute address specification
- !!: 20-bit absolute address specification
- $: 8-bit relative address specification
- $!: 16-bit relative address specification
- [ ]: Indirect address specification
- ES:: Extension address specification

In the case of immediate data, describe an appropriate numeric value or a label. When using a label, be sure to describe the #, !, !!, $, $!, [ ], and ES: symbols.

For operand register identifiers, r and rp, either function names (X, A, C, etc.) or absolute names (names in parentheses in the table below, R0, R1, R2, etc.) can be used for description.

Table 27-1. Operand Identifiers and Specification Methods

Identifier	Description Method
r	X (R0), A (R1), C (R2), B (R3), E (R4), D (R5), L (R6), H (R7)
rp	AX (RP0), BC (RP1), DE (RP2), HL (RP3)
sfr	Special-function register symbol (SFR symbol)
sfrp	Special-function register symbols (16-bit manipulatable SFR symbol. Even addresses only[Note])
saddr	FFE20H to FFF1FH Immediate data or labels
saddrp	FFE20H to FF1FH Immediate data or labels (even addresses only[Note])
addr20	00000H to FFFFFH Immediate data or labels
addr16	0000H to FFFFH Immediate data or labels (only even addresses for 16-bit data transfer instructions[Note])
addr5	0080H to 00BFH Immediate data or labels (even addresses only)
word	16-bit immediate data or label
byte	8-bit immediate data or label
bit	3-bit immediate data or label
RBn	RB0 to RB3

Note Bit 0 = 0 when an odd address is specified.

Remark For special-function register symbol, see **Table 3-5 SFR List** and **Table 3-6 Extended SFR (2nd SFR) List**.

27.1.2 Description of operation column

The operation when the instruction is executed is shown in the “Operation” column using the following symbols.

Table 27-2. Symbols in “Operation” Column

Symbol	Function
A	A register; 8-bit accumulator
X	X register
B	B register
C	C register
D	D register
E	E register
H	H register
L	L register
ES	ES register
CS	CS register
AX	AX register pair; 16-bit accumulator
BC	BC register pair
DE	DE register pair
HL	HL register pair
PC	Program counter
SP	Stack pointer
PSW	Program status word
CY	Carry flag
AC	Auxiliary carry flag
Z	Zero flag
RBS	Register bank select flag
IE	Interrupt request enable flag
()	Memory contents indicated by address or register contents in parentheses
X_H, X_L X_S, X_H, X_L	16-bit registers: X_H = higher 8 bits, X_L = lower 8 bits 20-bit registers: X_S = (bits 19 to 16), X_H = (bits 15 to 8), X_L = (bits 7 to 0)
∧	Logical product (AND)
∨	Logical sum (OR)
∨̲	Exclusive logical sum (exclusive OR)
¯	Inverted data
addr5	16-bit immediate data (even addresses only in 0080H to 00BFH)
addr16	16-bit immediate data
addr20	20-bit immediate data
jdisp8	Signed 8-bit data (displacement value)
jdisp16	Signed 16-bit data (displacement value)

27.1.3 Description of flag operation column

The change of the flag value when the instruction is executed is shown in the “Flag” column using the following symbols.

Table 27-3. Symbols in “Flag” Column

Symbol	Change of Flag Value
(Blank)	Unchanged
0	Cleared to 0
1	Set to 1
×	Set/cleared according to the result
R	Previously saved value is restored

27.1.4 PREFIX instruction

Instructions with “ES:” have a PREFIX operation code as a prefix to extend the accessible data area to the 1 MB space (00000H to FFFFFH), by adding the ES register value to the 64 KB space from F0000H to FFFFFH. When a PREFIX operation code is attached as a prefix to the target instruction, only one instruction immediately after the PREFIX operation code is executed as the addresses with the ES register value added.

Table 27-4. Use Example of PREFIX Operation Code

Instruction	Opcode				
	1	2	3	4	5
MOV !addr16, #byte	CFH	!addr16		#byte	–
MOV ES:!addr16, #byte	11H	CFH	!addr16		#byte
MOV A, [HL]	8BH	–	–	–	–
MOV A, ES:[HL]	11H	8BH	–	–	–

Caution Set the ES register value with MOV ES, A, etc., before executing the PREFIX instruction.

Notes 1. When the internal RAM area or SFR area is accessed, or for an instruction with no data access.

2. When the program memory area is accessed.

3. This indicates the number of clocks “when condition is not met/when condition is met”.

Remarks 1. One instruction clock cycle is one cycle of the CPU clock (f_{CPU}) selected by the system clock control register (CKC).

2. This number of clocks is for when the program is in the internal ROM (flash memory) area.

3. n indicates the number of register banks (n = 0 to 3)

CHAPTER 28 ELECTRICAL SPECIFICATIONS (TARGET)

Cautions 1. These specifications of the 78K0R/Kx3-L are target values, which may change after device evaluation.

2. The 78K0R/Kx3-L has an on-chip debug function, which is provided for development and evaluation. Do not use the on-chip debug function in products designated for mass production, because the guaranteed number of rewritable times of the flash memory may be exceeded when this function is used, and product reliability therefore cannot be guaranteed. NEC Electronics is not liable for problems occurring when the on-chip debug function is used.

3. The pins mounted are as follows according to product.

(1) Port functions

Port	78K0R/KC3-L		78K0R/KD3-L	78K0R/KE3-L

Notes 1. Must be 6.5 V or lower.

2. Connect the REGC pin to Vss via a capacitor (0.47 to 1 μF: target). This value regulates the absolute maximum rating of the REGC pin. Do not use this pin with voltage applied to it.

Caution Product quality may suffer if the absolute maximum rating is exceeded even momentarily for any parameter. That is, the absolute maximum ratings are rated values at which the product is on the verge of suffering physical damage, and therefore the product must be used under conditions that ensure that the absolute maximum ratings are not exceeded.

Remark Unless specified otherwise, the characteristics of alternate-function pins are the same as those of port pins.

Caution The pins mounted depend on the product. Refer to Caution 3 at the beginning of this chapter.

X1 Oscillator Characteristics

(T_A = −40 to +85°C, 1.8 V ≤ V_{DD} = EV_{DD} ≤ 5.5 V, V_{SS} = EV_{SS} = AV_{SS} = 0 V)

Resonator	Recommended Circuit	Parameter	Conditions	MIN.	TYP.	MAX.	Unit
Ceramic resonator		X1 clock oscillation frequency (f_X)[Note]	2.7 V ≤ V_{DD} ≤ 5.5 V	2.0		20.0	MHz
			1.8 V ≤ V_{DD} < 2.7 V	2.0		5.0	
Crystal resonator		X1 clock oscillation frequency (f_X)[Note]	2.7 V ≤ V_{DD} ≤ 5.5 V	2.0		20.0	MHz
			1.8 V ≤ V_{DD} < 2.7 V	2.0		5.0	

Note Indicates only oscillator characteristics. Refer to AC Characteristics for instruction execution time.

Cautions 1. When using the X1 oscillator, wire as follows in the area enclosed by the broken lines in the above figures to avoid an adverse effect from wiring capacitance.

- **Keep the wiring length as short as possible.**
- **Do not cross the wiring with the other signal lines.**
- **Do not route the wiring near a signal line through which a high fluctuating current flows.**
- **Always make the ground point of the oscillator capacitor the same potential as V_{SS}.**
- **Do not ground the capacitor to a ground pattern through which a high current flows.**
- **Do not fetch signals from the oscillator.**

2. Since the CPU is started by the internal high-speed oscillation clock after a reset release, check the X1 clock oscillation stabilization time using the oscillation stabilization time counter status register (OSTC) by the user. Determine the oscillation stabilization time of the OSTC register and oscillation stabilization time select register (OSTS) after sufficiently evaluating the oscillation stabilization time with the resonator to be used.

Remark For the resonator selection and oscillator constant, customers are requested to either evaluate the oscillation themselves or apply to the resonator manufacturer for evaluation.

Caution The pins mounted depend on the product. Refer to Caution 3 at the beginning of this chapter.

Internal Oscillator Characteristics

(T_A = –40 to +85°C, 1.8 V ≤ V_{DD} = EV_{DD} ≤ 5.5 V, V_{SS} = EV_{SS} = AV_{SS} = 0 V)

Oscillators	Parameters	Conditions	MIN.	TYP.	MAX.	Unit
Internal high-speed oscillation clock frequency Note	f_{IH1M}			1		MHz
	f_{IH8M}	2.7 V ≤ V_{DD} ≤ 5.5 V		8		MHz
		1.8 V ≤ V_{DD} < 2.7 V		8		MHz
	f_{IH20M}	2.7 V ≤ V_{DD} ≤ 5.5 V		20		MHz
Internal low-speed oscillation clock frequency	f_{IL}			30		kHz

Note This only indicates the oscillator characteristics. Refer to AC Characteristics for instruction execution time.

XT1 Oscillator Characteristics

(T_A = –40 to +85°C, 1.8 V ≤ V_{DD} = EV_{DD} ≤ 5.5 V, V_{SS} = EV_{SS} = AV_{SS} = 0 V)

Resonator	Recommended Circuit	Items	Conditions	MIN.	TYP.	MAX.	Unit
Crystal resonator		XT1 clock oscillation frequency (f_{XT}) Note		32	32.768	35	kHz

Note Indicates only oscillator characteristics. Refer to AC Characteristics for instruction execution time.

Cautions 1. When using the XT1 oscillator, wire as follows in the area enclosed by the broken lines in the above figures to avoid an adverse effect from wiring capacitance.

- **Keep the wiring length as short as possible.**
- **Do not cross the wiring with the other signal lines.**
- **Do not route the wiring near a signal line through which a high fluctuating current flows.**
- **Always make the ground point of the oscillator capacitor the same potential as V_{SS}.**
- **Do not ground the capacitor to a ground pattern through which a high current flows.**
- **Do not fetch signals from the oscillator.**

2. The XT1 oscillator is designed as a low-amplitude circuit for reducing power consumption, and is more prone to malfunction due to noise than the X1 oscillator. Particular care is therefore required with the wiring method when the XT1 clock is used.

Remark For the resonator selection and oscillator constant, customers are requested to either evaluate the oscillation themselves or apply to the resonator manufacturer for evaluation.

Caution The pins mounted depend on the product. Refer to Caution 3 at the beginning of this chapter.

Recommended Oscillator Circuit Constants

XT1 oscillation: Crystal resonator (T_A = –40 to +85°C)

Manufacturer	Part Number	SMD/ Lead	Frequency (MHz)	Load Capacitance CL (pF)	XT1 oscllator oscillation mode [Note]	Recommended Circuit Constants		Oscillation Voltage Range	
						C1 (pF)	C2 (pF)	MIN. (V)	MAX. (V)
Seiko Instruments Inc.	SP-T2A	SMD	32.768	4.4	Low power consumption oscillation	7	7	1.8	5.5
					Ultra-low power consumption oscillation	7	7		
	VT-200	Lead		6.0	Low power consumption oscillation	5	5		
					Ultra-low power consumption oscillation	5	5		
	SSP-T7	Small SMD		3.7	Low power consumption oscillation	4	3		
					Ultra-low power consumption oscillation	4	3		

Note Set the XT1 oscillation mode by using bits AMPHS1 and AMPHS0 of clock operation mode control register (CMC).

Caution The oscillator constants shown above are reference values based on evaluation in a specific environment by the resonator manufacturer. If it is necessary to optimize the oscillator characteristics in the actual application, apply to the resonator manufacturer for evaluation on the implementation circuit. The oscillation voltage and oscillation frequency only indicate the oscillator characteristic. Use the 78K0R/Kx3-L so that the internal operation conditions are within the specifications of the DC and AC characteristics.

Caution The pins mounted depend on the product. Refer to Caution 3 at the beginning of this chapter.

DC Characteristics (1/11)

(T_A = −40 to +85°C, 1.8 V ≤ V_{DD} = EV_{DD} ≤ 5.5 V, 1.8 V ≤ AV_{REF} ≤ V_{DD}, V_{SS} = EV_{SS} = AV_{SS} = 0 V)

	I_{OH2}	Per pin for P20 to P27, P80 to P83, P150 to P153	AV_{REF} ≤ V_{DD}			−0.1	mA

Notes 1. Value of current at which the device operation is guaranteed even if the current flows from the EV_{DD} pin to an output pin.

2. Specification under conditions where the duty factor is 60% or 70%.
The output current value that has changed the duty ratio can be calculated with the following expression (when changing the duty factor from 70% to n%).
• Total output current of pins = (I_{OH} × 0.7)/(n × 0.01)
<Example> Where n = 50% and I_{OH} = 20.0 mA
Total output current of pins = (−20.0 × 0.7)/(50 × 0.01) = −28.0 mA
However, the current that is allowed to flow into one pin does not vary depending on the duty factor. A current higher than the absolute maximum rating must not flow into one pin.

Caution P30 to P32, P70, P72, P73, and P75 do not output high level in N-ch open-drain mode.

Remark Unless specified otherwise, the characteristics of alternate-function pins are the same as those of port pins.

Caution The pins mounted depend on the product. Refer to Caution 3 at the beginning of this chapter.

Notes 1. Value of current at which the device operation is guaranteed even if the current flows from an output pin to the EV_{SS}, V_{SS}, and AV_{SS} pins.

2. Specification under conditions where the duty factor is 60% or 70%.
The output current value that has changed the duty ratio can be calculated with the following expression (when changing the duty factor from 70% to n%).
• Total output current of pins = (I_{OL} × 0.7)/(n × 0.01)
<Example> Where n = 50% and I_{OL} = 20.0 mA
Total output current of pins = (20.0 × 0.7)/(50 × 0.01) = 28.0 mA
However, the current that is allowed to flow into one pin does not vary depending on the duty factor. A current higher than the absolute maximum rating must not flow into one pin.

Remark Unless specified otherwise, the characteristics of alternate-function pins are the same as those of port pins.

Caution The pins mounted depend on the product. Refer to Caution 3 at the beginning of this chapter.

DC Characteristics (3/11)

Note Must be 0.9V_{DD} or higher when used in the flash memory programming mode.

Caution The maximum value of V_{IH} of pins P30 to P32, P70, P72, P73, and P75 is V_{DD}, even in the N-ch open-drain mode.

Remark Unless specified otherwise, the characteristics of alternate-function pins are the same as those of port pins.

Caution The pins mounted depend on the product. Refer to Caution 3 at the beginning of this chapter.

Notes 1. Current flowing only to the real-time counter (excluding the operating current of the XT1 oscillator). The TYP. value of the current value of the 78K0R/Kx3-L is the sum of the TYP. values of either I_{DD1} or I_{DD2}, and I_{RTC}, when the real-time counter operates in operation mode or HALT mode. The I_{DD1} and I_{DD2} MAX. values also include the real-time counter operating current. When the real-time counter operates during f_{CLK} = f_{SUB}/2, the TYP. value of I_{DD2} includes the real-time counter operating current.

2. When internal high-speed oscillation, 20 MHz internal high-speed oscillation, and high-speed system clock are stopped.

3. Current flowing only to the watchdog timer (including the operating current of the 30 kHz internal oscillator). The current value of the 78K0R/Kx3-L is the sum of I_{DD1}, I_{DD2} or I_{DD3} and I_{WDT} when f_{CLK} = f_{SUB}/2 when the watchdog timer operates in STOP mode.

4. Current flowing only to the A/D converter (AV_{REF} pin). The current value of the 78K0R/Kx3-L is the sum of I_{DD1} or I_{DD2} and I_{ADC} when the A/D converter operates in an operation mode or the HALT mode.

5. Current flowing only to the programmable gain amplifier (AV_{REF} pin). The current value of the 78K0R/Kx3-L is the sum of I_{DD1} or I_{DD2} and I_{AMP} when the programmable gain amplifier operates in an operation mode or the HALT mode.

6. Current flowing only to the comparator (AV_{REF} pin). The current value of the 78K0R/Kx3-L is the sum of I_{DD1} or I_{DD2} and I_{CMP} when the comparator operates in an operation mode or the HALT mode.

7. Current flowing only to the LVI circuit. The current value of the 78K0R/Kx3-L is the sum of I_{DD1}, I_{DD2} or I_{DD3} and I_{LVI} when the LVI circuit operates in the Operating, HALT or STOP mode.

Remarks 1. f_{IL}: Internal low-speed oscillation clock frequency

2. f_{SUB}: Subsystem clock frequency (XT1 clock oscillation frequency)

3. f_{CLK}: CPU/peripheral hardware clock frequency

Notes 1. The smaller maximum transfer rate derived by using f_{MCK}/6 or the following expression is the valid maximum transfer rate.

Expression for calculating the transfer rate when 4.0 V ≤ V_{DD} = EV_{DD} ≤ 5.5 V and 2.7 V ≤ V_b ≤ 4.0 V

$$\text{Maximum transfer rate} = \frac{1}{\{-C_b \times R_b \times \ln(1-\frac{2.2}{V_b})\} \times 3} \text{ [bps]}$$

$$\text{Baud rate error (theoretical value)} = \frac{\frac{1}{\text{Transfer rate} \times 2} - \{-C_b \times R_b \times \ln(1-\frac{2.2}{V_b})\}}{(\frac{1}{\text{Transfer rate}}) \times \text{Number of transferred bits}} \times 100 \text{ [\%]}$$

* This value is the theoretical value of the relative difference between the transmission and reception sides.

2. This value as an example is calculated when the conditions described in the “Conditions” column are met. Refer to **Note 1** above to calculate the maximum transfer rate under conditions of the customer.

3. The smaller maximum transfer rate derived by using f_{MCK}/6 or the following expression is the valid maximum transfer rate.

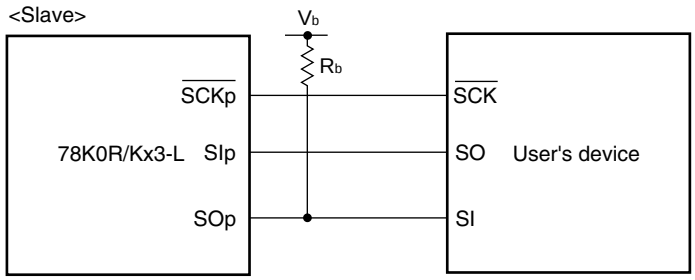
Notes 1. When DAP0n = 0 and CKP0n = 0, or DAP0n = 1 and CKP0n = 1. The SIp setup time becomes "to $\overline{SCKp}\downarrow$" when DAP0n = 0 and CKP0n = 1, or DAP0n = 1 and CKP0n = 0.

2. When DAP0n = 0 and CKP0n = 0, or DAP0n = 1 and CKP0n = 1. The SIp hold time becomes "from $\overline{SCKp}\downarrow$" when DAP0n = 0 and CKP0n = 1, or DAP0n = 1 and CKP0n = 0.

3. When DAP0n = 0 and CKP0n = 0, or DAP0n = 1 and CKP0n = 1. The delay time to SOp output becomes "from $\overline{SCKp}\uparrow$" when DAP0n = 0 and CKP0n = 1, or DAP0n = 1 and CKP0n = 0.

CSI mode connection diagram (communication at different potential)



Caution Select the TTL input buffer for SIp and $\overline{SCKp}$ and the N-ch open drain output (V_{DD} tolerance) mode for SOp by using the PIMg and POMg registers.

Remarks 1. $R_b[\Omega]$:Communication line (SOp) pull-up resistance,
$C_b[F]$: Communication line (SOp, $\overline{SCKp}$) load capacitance, $V_b[V]$: Communication line voltage

2. p: CSI number (p = 00, 01, 10), g: PIM and POM number (g = 3, 7)

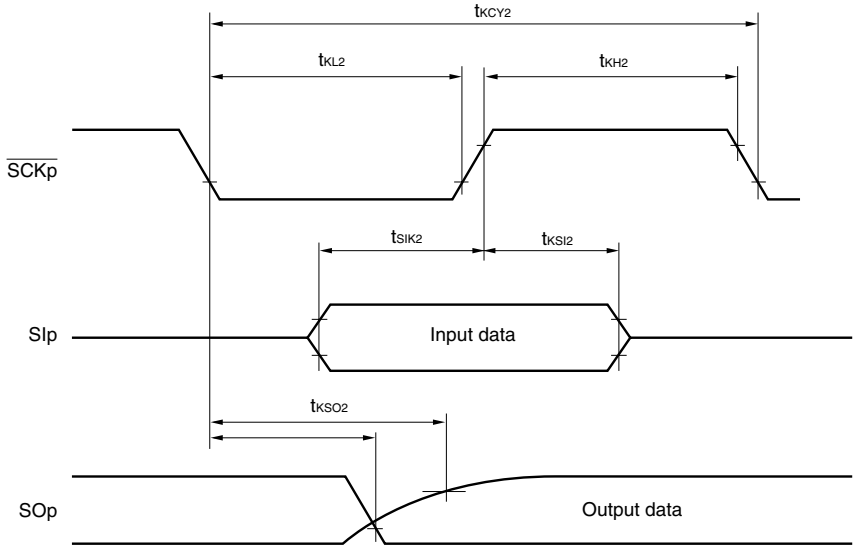
3. f_{MCK}: Serial array unit operation clock frequency
(Operation clock to be set by the CKS0n bit of the SMR0n register. n: Channel number (n = 0 to 2))

4. V_{IH} and V_{IL} below are observation points for the AC characteristics of the serial array unit when communicating at different potentials in CSI mode.
$4.0\ V \le V_{DD} \le 5.5\ V$, $2.7\ V \le V_b \le 4.0\ V$: $V_{IH} = 2.2\ V$, $V_{IL} = 0.8\ V$
$2.7\ V \le V_{DD} \le 4.0\ V$, $2.3\ V \le V_b \le 2.7\ V$: $V_{IH} = 2.0\ V$, $V_{IL} = 0.5\ V$

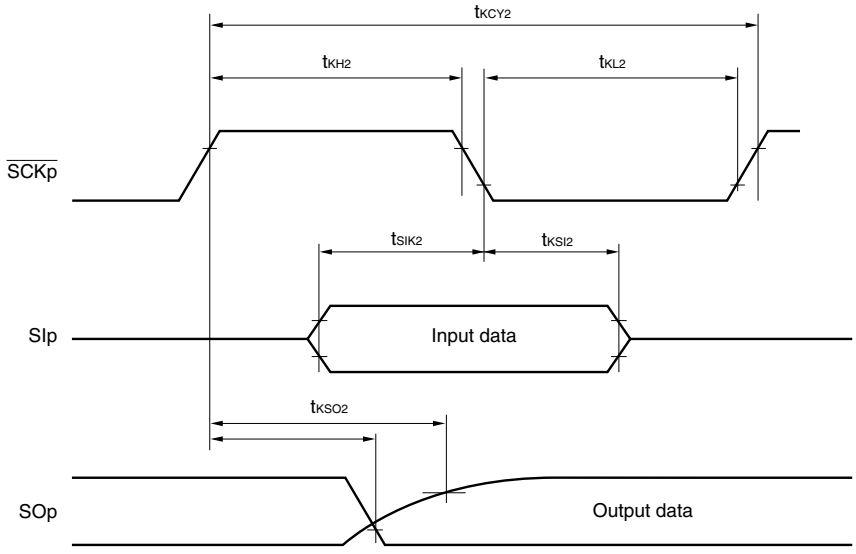
Caution The pins mounted depend on the product. Refer to Caution 3 at the beginning of this chapter.

(2) Serial interface: Serial array unit (15/17)

CSI mode serial transfer timing: slave mode (communication at different potential)
(When DAP0n = 0 and CKP0n = 0, or DAP0n = 1 and CKP0n = 1)



CSI mode serial transfer timing: slave mode (communication at different potential)
(When DAP0n = 0 and CKP0n = 1, or DAP0n = 1 and CKP0n = 0)



Caution Select the TTL input buffer for SIp and $\overline{\text{SCKp}}$ and the N-ch open drain output (V_{DD} tolerance) mode for SOp by using the PIMg and POMg registers.

Remark p: CSI number (p = 00, 01, 10), n: Channel number (n = 0 to 2), g: PIM and POM number (g = 3, 7)

Caution The pins mounted depend on the product. Refer to Caution 3 at the beginning of this chapter.

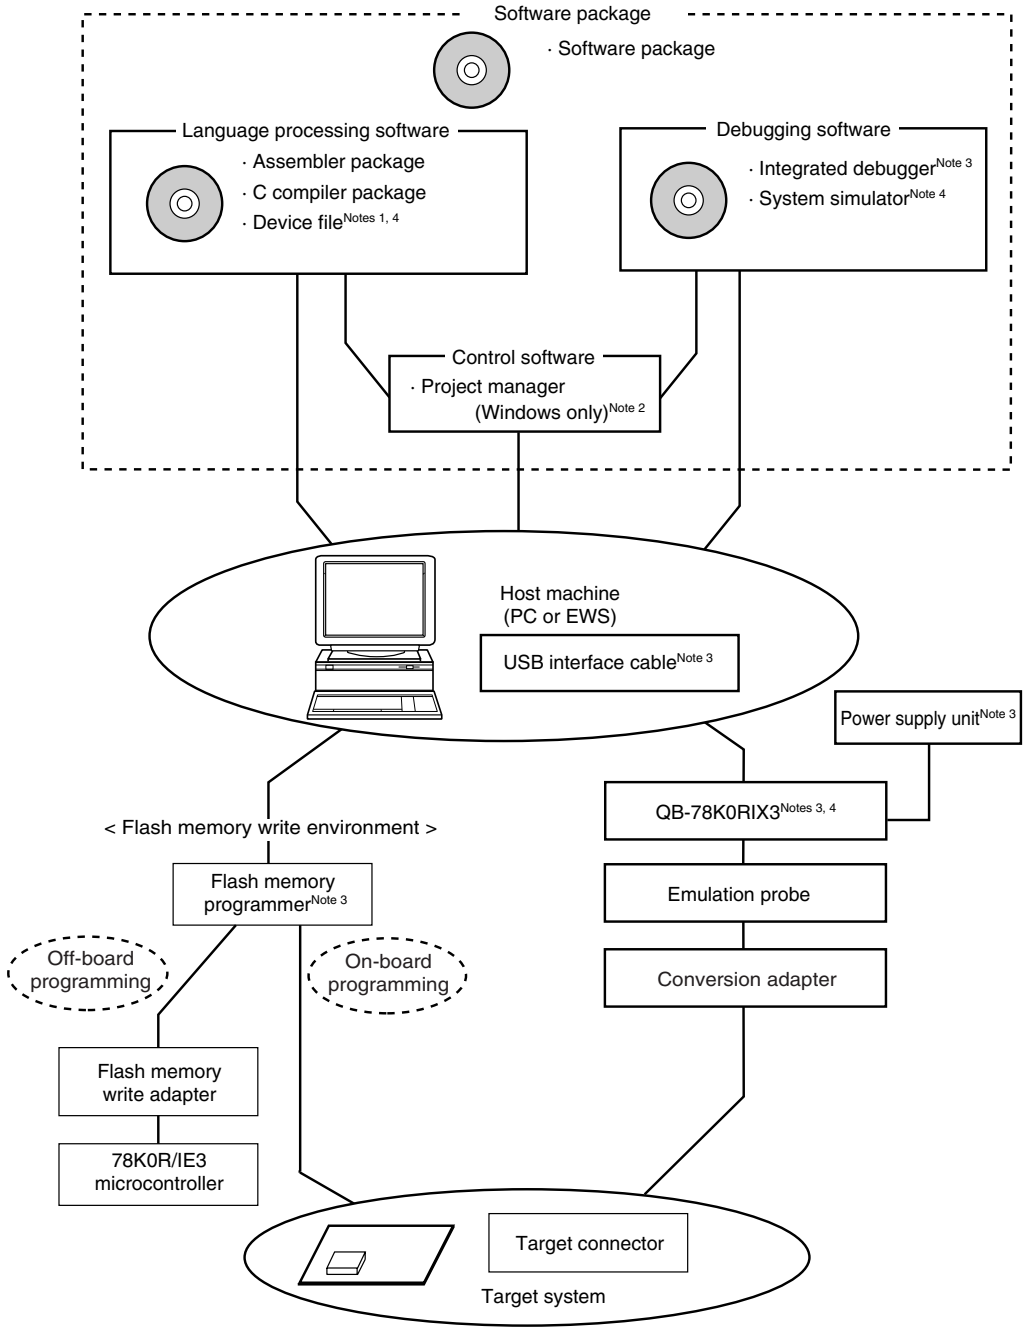
APPENDIX A DEVELOPMENT TOOLS

The following development tools are available for the development of systems that employ the 78K0R/Kx3-L. Figure A-1 shows the development tool configuration.

Figure A-1. Development Tool Configuration (1/2)

(1) When using the in-circuit emulator QB-78K0RIX3 Note 4



Notes 1. Download the device file for 78K0R/Kx3-L (DF781009) from the download site for development tools (http://www.necel.com/micro/ods/eng/index.html).

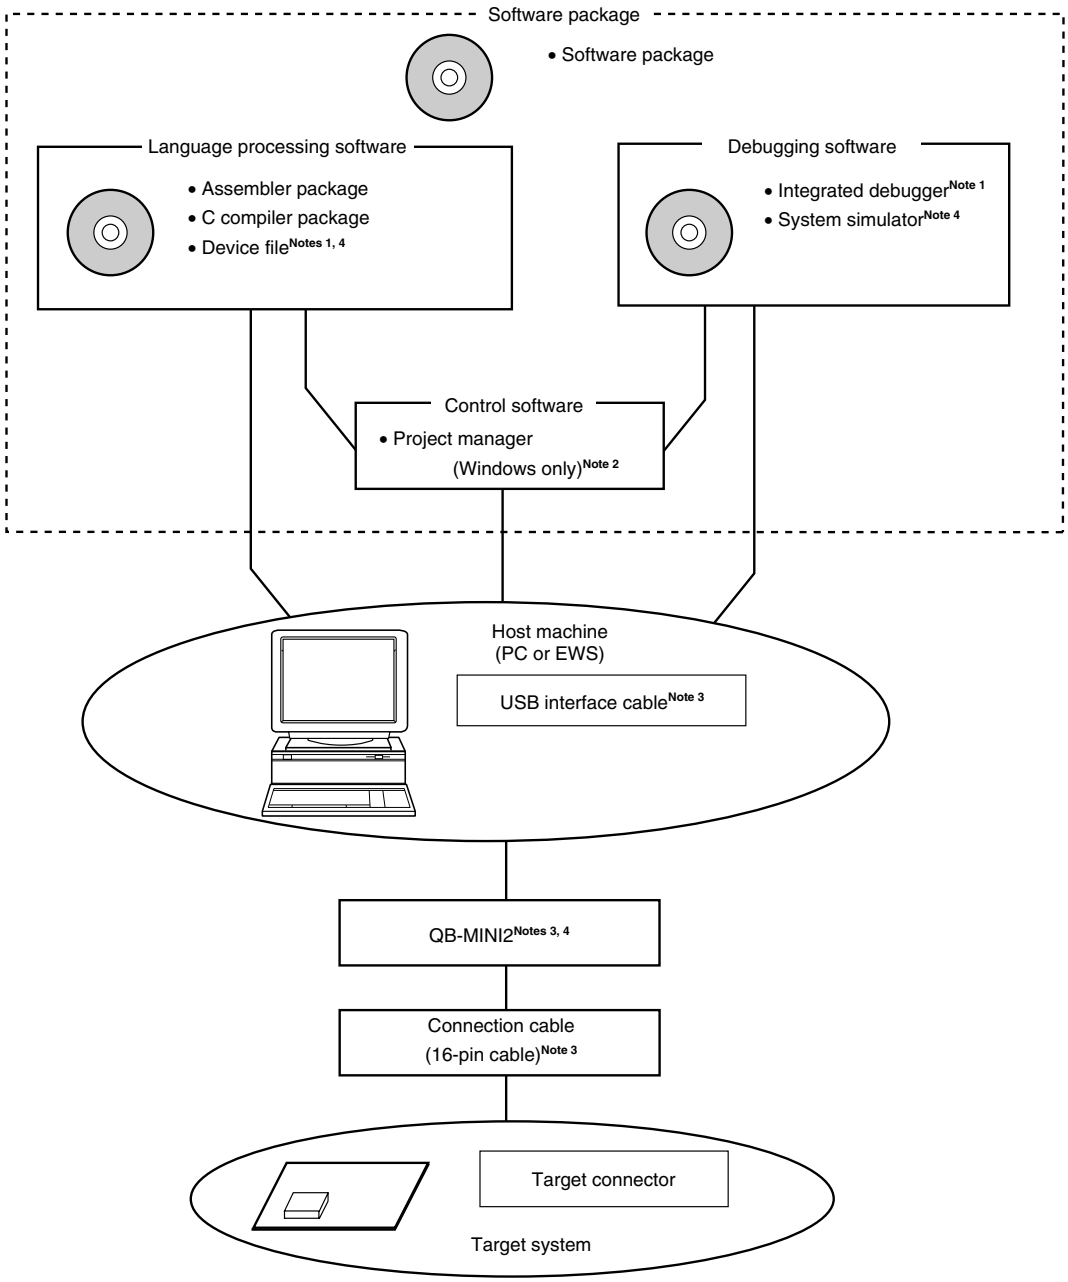
2. The project manager PM+ is included in the assembler package.
The PM+ is only used for Windows.

3. In-circuit emulator QB-78K0RIX3 is supplied with integrated debugger ID78K0R-QB, on-chip debug emulator with programming function QB-MINI2, power supply unit, and USB interface cable. Any other products are sold separately.

4. Under development

Figure A-1. Development Tool Configuration (2/2)

(2) When using the on-chip debug emulator with programming function QB-MINI2



Notes 1. Download the device file for 78K0R/Kx3-L (DF781009) and the integrated debugger (ID78K0R-QB) from the download site for development tools (http://www.necel.com/micro/ods/eng/index.html).

2. The project manager PM+ is included in the assembler package.
The PM+ is only used for Windows.

3. On-chip debug emulator QB-MINI2 is supplied with USB interface cable, connection cables (10-pin cable and 16-pin cable), and 78K0-OCD board. Any other products are sold separately. In addition, download the software for operating the QB-MINI2 from the download site for MINICUBE2 (http://www.necel.com/micro/en/development/asia/minicube2/minicube2.html).

4. Under development

A.1 Software Package

SP78K0R 78K0R Series software package	Development tools (software) common to the 78K0R microcontrollers are combined in this package.

A.2 Language Processing Software

RA78K0R Assembler package	This assembler converts programs written in mnemonics into object codes executable with a microcontroller. This assembler is also provided with functions capable of automatically creating symbol tables and branch instruction optimization. This assembler should be used in combination with a device file (DF781009). **<Precaution when using RA78K0R in PC environment>** This assembler package is a DOS-based application. It can also be used in Windows, however, by using the Project Manager (included in assembler package) on Windows.
CC78K0R C compiler package	This compiler converts programs written in C language into object codes executable with a microcontroller. This compiler should be used in combination with an assembler package and device file (both sold separately). **<Precaution when using CC78K0R in PC environment>** This C compiler package is a DOS-based application. It can also be used in Windows, however, by using the Project Manager (included in assembler package) on Windows.
DF781009Note s 1, 2 Device file	This file contains information peculiar to the device. This device file should be used in combination with a tool (RA78K0R, CC78K0R, SM+ for 78K0R, and ID78K0R-QB) (all sold separately). The corresponding OS and host machine differ depending on the tool to be used.

Notes 1. The DF781009 can be used in common with the RA78K0R, CC78K0R, SM+ for 78K0R, and ID78K0R-QB.

2. Under development

A.3 Flash Memory Programming Tools

A.3.1 When using flash memory programmer PG-FP5, FL-PR5, PG-FP4 and FL-PR4

PG-FP5, FL-PR5, PG-FP4, FL-PR4 Flash memory programmer	Flash memory programmer dedicated to microcontrollers with on-chip flash memory.
Flash memory programming adapter [Note]	Flash memory programming adapter used connected to the flash memory programmer for use.

Note Under development

Remarks 1. The FL-PR4 and FL-PR5 are a product of Naito Densei Machida Mfg. Co., Ltd.

2. Use the latest version of the flash memory programming adapter.

A.3.2 When using on-chip debug emulator with programming function QB-MINI2

QB-MINI2 On-chip debug emulator with programming function	This is a flash memory programmer dedicated to microcontrollers with on-chip flash memory. It is available also as on-chip debug emulator which serves to debug hardware and software when developing application systems using the 78K0R/Kx3-L microcontrollers. When using this as flash memory programmer, it should be used in combination with a connection cable (16-pin cable) and a USB interface cable that is used to connect the host machine.

Remark Download the software for operating the QB-MINI2 from the download site for MINICUBE2 (http://www.necel.com/micro/en/development/asia/minicube2/minicube2.html).

A.4 Debugging Tools (Hardware)

A.4.1 When using in-circuit emulator QB-78K0RIX3

QB-78K0RIX3[Notes 1, 2] In-circuit emulator	This in-circuit emulator serves to debug hardware and software when developing application systems using the 78K0R/Kx3-L microcontrollers. It supports to the integrated debugger (ID78K0R-QB). This emulator should be used in combination with a power supply unit and emulation probe, and the USB is used to connect this emulator to the host machine.
QB-144-CA-01 Check pin adapter	This check pin adapter is used in waveform monitoring using the oscilloscope, etc.
QB-80-EP-01T Emulation probe	This emulation probe is flexible type and used to connect the in-circuit emulator and target system.
QB-xxxx-EA-xxx[Notes 1, 2] Exchange adapter	This exchange adapter is used to perform pin conversion from the in-circuit emulator to target connector.
QB-xxxx-YS-xxxx[Notes 1, 2] Space adapter	This space adapter is used to adjust the height between the target system and in-circuit emulator.
QB-xxxx-YQ-xxx[Notes 1, 2] YQ connector	This YQ connector is used to connect the target connector and exchange adapter.
QB-xxxx-HQ-Xxx[Notes 1, 2] Mount adapter	This mount adapter is used to mount the target device with socket.
QB-xxxx-NQ-xxx[Notes 1, 2] Target connector	This target connector is used to mount on the target system.

Notes 1. Under development

2. The part numbers of the exchange adapter, space adapter, YQ connector, mount adapter, and target connector and the packages of the target device are described below.

Package		Exchange Adapter	Space Adapter	YQ Connector	Mount Adapter	Target Connector
78K0R/KC3-L	44-pin plastic LQFP (GB-GAF type)	QB-44GB-EA-04T	QB-44GB-YS-01T	QB-44GB-YQ-01T	QB-44GB-HQ-01T	QB-44GB-NQ-01T

	64-pin plastic FBGA (F1-AN1 type)	QB-64FC-EA-01T	None	None	None	QB-64FC-NQ-01T

(Remarks are listed on the next page or later.)

Remarks 1. The QB-78K0RIX3 is supplied with the integrated debugger ID78K0R-QB, a USB interface cable, a power supply unit, the on-chip debug emulator QB-MINI2, connection cables (10-pin and 16-pin cables), and the 78K0-OCD board.
Download the software for operating the QB-MINI2 from the download site for development tools (http://www.necel.com/micro/ods/eng/index.html) when using the QB-MINI2.

2. The packed contents differ depending on the part number, as follows.

A.4.2 When using on-chip debug emulator with programming function QB-MINI2

QB-MINI2 On-chip debug emulator with programming function	This on-chip debug emulator serves to debug hardware and software when developing application systems using the 78K0R/Kx3-L microcontrollers. It is available also as flash memory programmer dedicated to microcontrollers with on-chip flash memory. When using this as on-chip debug emulator, it should be used in combination with a connection cable (16-pin cable) and a USB interface cable that is used to connect the host machine.

Remark Download the software for operating the QB-MINI2 from the download site for MINICUBE2 (http://www.necel.com/micro/en/development/asia/minicube2/minicube2.html).

A.5 Debugging Tools (Software)

SM+ for 78K0R Note System simulator	SM+ for 78K0R is Windows-based software. It is used to perform debugging at the C source level or assembler level while simulating the operation of the target system on a host machine. Use of SM+ for 78K0R allows the execution of application logical testing and performance testing on an independent basis from hardware development, thereby providing higher development efficiency and software quality. SM+ for 78K0R should be used in combination with the device file (DF781009).
ID78K0R-QB Integrated debugger	This debugger supports the in-circuit emulators for the 78K0R microcontrollers. The ID78K0R-QB is Windows-based software. It has improved C-compatible debugging functions and can display the results of tracing with the source program using an integrating window function that associates the source program, disassemble display, and memory display with the trace result. It should be used in combination with the device file (DF781009).
