16-BIT CMOS ERROR DETECTION AND CORRECTION UNIT

T-45-17
IDT39C60
IDT39C60-1
IDT39C60A
IDT39C60B

FEATURES

- Low-power CEMOS™
 - Military: 100mA (max.)
 - Commercial: 85mA (max.)
- Fast
 - Data in to Error Detect
IDT39C60B: 18ns (max.), IDT39C60A: 20ns (max.)
IDT39C60-1: 25ns (max.), IDT39C60: 32ns (max.)
 - Data in to Corrected Data out
IDT39C60B: 25ns (max.), IDT39C60A: 30ns (max.)
IDT39C60-1: 52ns (max.), IDT39C60: 65ns (max.)
- Improves system memory reliability
 - Corrects all single-bit errors, detects all double and some triple-bit errors
- Cascadable
 - Data words up to 64 bits
- Built-in diagnostics
 - Capable of verifying proper EDC operation via software control
- Simplified byte operations
 - Fast byte writes possible with separate byte enables
- Available in 48-pin DIP, 52-pin PLCC and LCC
- Pin-compatible to all versions of the AMD2960
- Military product available compliant to MIL-STD-883, Class B

- Standard Military Drawing #5962-88613 available for this function

DESCRIPTIONS

The IDT39C60 family are high-speed, low-power, 16-bit Error Detection and Correction Units which generate check-bits on a 16-bit data field according to a modified Hamming Code and correct the data word when checkbits are supplied. When performing a read operation from memory, the IDT39C60s will correct 100% of all single bit errors, will detect all double bit errors and some triple bit errors.

The IDT39C60s are easily cascadable from 16 bits up to 64 bits. Sixteen-bit systems use 6 check bits, 32-bit systems use 7 check bits and 64-bit systems use 8 check bits. For all three configurations, the error syndrome is made available.

All parts incorporate 2 built-in diagnostic modes. Both simplify testing by allowing for diagnostic data to be entered into the device and to execute system diagnostic functions.

The IDT39C60s are pin-compatible, performance-enhanced functional replacements for all versions of the 2960. They are fabricated using CEMOS, a CMOS technology designed for high-performance and high-reliability. The devices are packaged in either 48-pin DIPs and 52-pin PLCC and LCCs.

Military grade product is manufactured in compliance to the latest revision of MIL-STD-883, Class B.

PIN DESCRIPTIONS

Pin Name	I/O	Description
DATA ₀₋₁₅	I/O	16 bidirectional data lines provide input to the Data Input Latch and receive output from the Data Output Latch. DATA ₀ is the least significant bit; DATA ₁₅ the most significant.
CB ₀₋₆	I	Seven check bit input lines are used to input check bits for error detection. Also used to input syndrome bits for error correction in 32- and 64-bit configurations.
LE _{IN}	I	Latch Enable — Data Input Latch. Controls latching of the input data. When HIGH, the Data Input Latch and Check Bit Input Latch follow the input data and input check bits. When LOW, the Data Input Latch and Check Bit Input Latch are latched to their previous state.
GENERATE	I	Generate Check Bits input. When this input is LOW, the EDC is in the Check Bit Generate mode. When HIGH, the EDC is in the Detect mode or Correct mode. In the Generate mode, the circuit generates the check bits or partial check bits specific to the data in the Data Input Latch. The generated check bits are placed on the SC outputs. In the Detect or Correct modes the EDC detects single and multiple errors and generates syndrome bits based upon the contents of the Data Input Latch and Check Bit Input Latch. In Correct mode, single-bit errors are also automatically corrected — corrected data is placed at the input of the Data Output Latch. The syndrome result is placed on the SC outputs and indicates, in a coded form, the number of errors and the bit-in-error.
SC ₀₋₆	O	Syndrome/Check Bit outputs hold the check/partial check bits when the EDC is in Generate mode and will hold the syndrome/partial syndrome bits when the device is in Detect or Correct modes. These are 3-state outputs.
OE _{SC}	I	Output Enable — Syndrome/Check Bits. When LOW, the 3-state output lines SC ₀₋₆ are enabled. When HIGH, the SC outputs are in the high impedance state.
ERROR	O	Error Detected output. When the EDC is in Detect or Correct mode, this output will go LOW if one or more syndrome bits are asserted, meaning there are one or more bit errors in the data or check bits. If no syndrome bits are asserted, there are no errors detected and the output will be HIGH. In Generate mode, ERROR is forced HIGH. (In a 64-bit configuration, ERROR must be implemented externally.)
MULT ERROR	O	Multiple Errors Detected output. When the EDC is in Detect or Correct mode this output, if LOW, indicates that there are two or more bit errors that have been detected. If HIGH, this indicates that either one or no errors have been detected. In Generate mode, MULT ERROR is forced HIGH. (In a 64-bit configuration, MULT ERROR must be implemented externally.)
CORRECT	I	Correct input. When HIGH, this signal allows the correction network to correct any single-bit error in the Data Input Latch (by complementing the bit-in-error) before putting it into the Data Output Latch. When LOW, the EDC will drive data directly from the Data Input Latch to the Data Output Latch without correction.
LE _{OUT}	I	Latch Enable — Data Output Latch. Controls the latching of the Data Output Latch. When LOW, the Data Output Latch is latched to its previous state. When HIGH, the Data Output Latch follows the output of the Data Input Latch as modified by the correction logic network. In Correct mode, single-bit errors are corrected by the network before loading into the Data Output Latch. In Detect mode, the contents of the Data Input Latch are passed through the correction network unchanged into the Data Output Latch. The inputs to the Data Output Latch are disabled with its contents unchanged if the EDC is in Generate mode.
OE _{BYTE0} OE _{BYTE1}	I	Output Enable — Bytes 0 and 1, Data Output Latch controls the 3-state outputs for each of the two bytes of the Data Output Latch. When LOW, these lines enable the Data Output Latch and, when HIGH, these lines force the Data Output Latch into the high impedance state. The two enable lines can be separately activated to enable only one byte of the Data Output at a time.
PASSTHRU	I	PASSTHRU input, when HIGH, forces the contents of the Check Bit Input Latch onto the Syndrome/Check Bit outputs (SC ₀₋₆) and the unmodified contents of the Data Input Latch onto the inputs of the Data Output Latch.
DIAG MODE ₀₋₁ CODE ID ₀₋₂	I	Diagnostic Mode Select controls the initialization and diagnostic operation of the EDC. Code Identification inputs identify the size of the total data word to be processed and which 16-bit slice of larger data words a particular EDC is processing. The three allowable data word sizes are 16, 32, and 64 bits and their respective modified Hamming Codes are designated 16/22, 32/39 and 64/72. Special CODE ID input 001 (ID ₂ , ID ₁ , ID ₀) is also used to instruct the EDC that the signals CODE ID ₀₋₂ , DIAG MODE ₀₋₁ , CORRECT and PASSTHRU are to be taken from the diagnostic latch rather than the control lines.
LE _{DIAG}	I	Latch Enable — Diagnostic Latch. The Diagnostic Latch follows the 16-bit data on the input lines when HIGH. When LOW, the outputs of the Diagnostic Latch are latched to their previous states. The Diagnostic Latch holds diagnostic check bits and internal control signals for CODE ID ₀₋₂ , DIAG MODE ₀₋₁ , CORRECT and PASSTHRU.

16-BIT CMOS DETECTION AND CORRECTION UNIT

MILITARY AND COMMERCIAL TEMPERATURE RANGES

PRODUCT DESCRIPTION

The IDT39C60 EDC Unit is a powerful 16-bit cascaded slice used for check bit generation, error detection, error correction and diagnostics. As shown in the Functional Block Diagram, the device consists of the following:

- Data Input Latch
- Data Output Latch
- Diagnostic Latch
- Check Bit Input Latch
- Check Bit Generation Logic
- Syndrome Generation Logic
- Error Detection Logic
- Error Correction Logic
- Control Logic

DATA INPUT/OUTPUT/DIAGNOSTIC LATCHES

The LEIN, Latch Enable input, controls the Data Input which can load 16 bits of data from the bidirectional DATA lines. The input data is used for either check bit generation or error detection/correction.

The 16 bits of data from the DATA lines can be loaded into the Diagnostic Latch under control of the Diagnostic Latch Enable, LEDIAG, giving check bit information in one byte and control information in the other byte. The Diagnostic Latch is used when in Internal Control mode or in one of the Diagnostics modes.

The Data Output Latch is split into two bytes and enabled onto the DATA lines through separate byte control lines. The Data Output Latch stores the result of an error correction operation or is loaded directly from the Data Input Latch under control of the Latch Enable Out (LEOUT). The PASSTHRU control input determines which data is loaded.

CHECK BIT GENERATION LOGIC

This block of combinational logic generates 7 check bits using a modified Hamming Code from the 16 bits of data input from the Data Input Latch.

SYNDROME GENERATION LOGIC

This logic compares the check bits generated through the Check Bit Generator with either the check bits in the Check Bit Input Latch or 7 bits assigned in the Diagnostic Latch.

Syndrome bits are produced by an exclusive-OR of the two sets of bits. A match indicates no errors. If errors occur, the syndrome bits can be decoded to indicate the bit in error, whether 2 errors were detected or 3 or more errors.

ERROR DETECTION/CORRECTION LOGIC

The syndrome bits generated by the Syndrome Logic are decoded and used to control the ERROR and MULTERROR outputs. If one or more errors are detected,

ERROR goes low. If two or more errors are detected, both ERROR and MULTERROR go low. Both outputs remain high when there are no errors detected.

For single bit errors, the correction logic will complement (correct) the bit in error, which can then be loaded into the Data Out Latches under the LEOUT control. If check bit errors need to be corrected, then the device must be operated in the Generate mode.

CONTROL LOGIC

The control logic determines the specific mode of operation, usually from external control signals. However, the Internal Control mode allows these signals to be provided from the Diagnostic Latch.

DETAILED PRODUCT DESCRIPTION

The IDT39C60 EDC unit contains the logic necessary to generate check bits on a 16-bit data input according to a modified Hamming Code. The EDC can compare internally generated check bits against those read with the 16-bit data to allow correction of any single bit data error and detection of all double and some triple bit errors. The IDT39C60 can be used for 16-bit data words (6 check bits), 32-bit data words (7 check bits) or 64-bit data words (8 check bits).

CODE AND BYTE SELECTION

The 3 code identification pins, ID0-2, are used to determine the data word size from 16, 32 or 64 bits and the byte position of each 16-bit IDT39C60 EDC device.

Code 16/22 refers to a 16-bit data field with 6 check bits.

Code 32/39 refers to a 32-bit data field with 7 check bits.

Code 64/72 refers to a 64-bit data field with 8 check bits.

The ID0-2 of 001 is used to place the device in the Internal Control mode as described later in this section.

Table 1 defines all possible identification codes.

CHECK AND SYNDROME BITS

The IDT39C60 provides either check bits or syndrome bits on the three-state output pins, SCo-6. Check bits are generated from a combination of the Data Input bits, while syndrome bits are an Exclusive-OR of the check bits generated from read data with the read check bits stored with the data. Syndrome bits can be decoded to determine the single bit-in-error or that a double error was detected. Some triple bit errors are also detected. The check bits are labeled:

Co, C1, C2, C3, C4	for the 8-bit configuration
Co, C1, C2, C3, C4, C5	for the 16-bit configuration
Co, C1, C2, C3, C4, C5, C6	for the 32-bit configuration
Co, C1, C2, C3, C4, C5, C6, C7	for the 64-bit configuration

Syndrome bits are similarly labeled So through S7.

IDT39C60-1/A/B

16-BIT CMOS DETECTION AND CORRECTION UNIT

MILITARY AND COMMERCIAL TEMPERATURE RANGES

CONTROL MODE SELECTION

Tables 2 and 3 describe the 9 operating modes of the IDT39C60. The Diagnostic mode pins, DIAG MODE₀₋₁, define 4 basic areas of operation, with GENERATE, CORRECT and PASSTHRU, further dividing operation into 8 functions with the ID₀₋₂ defining the ninth mode as the Internal mode.

Generate mode is used to display the check bits on the outputs SC₀₋₆. The Diagnostic Generate mode displays check bits as stored in the Diagnostic Latch.

Detect mode provides an indication of errors or multiple errors on the outputs ERROR and MULTERROR. Single bit errors are not corrected in this mode. The syndrome bits are provided on the outputs SC₀₋₆. For the Diagnostic Detect mode, the syndrome bits are generated by comparing the internally generated check bits from the Data In Latch with check bits stored in the diagnostic latch rather than with the check bit latch contents.

Correct mode is similar to the Detect mode except that

single bit errors will be complemented (corrected) and made available as input to the Data Out Latch. Again, the Diagnostic Correct mode will correct single bit errors as determined by syndrome bits generated from the Data Input and contents of the Diagnostic Latch.

The Initialize mode provides check bits for all zero bit data. Data In Latch is set and latched to a logic zero and made available as input to the Data Out Latch.

The Internal mode disables the external control pins DIAG MODE₀₋₁, CORRECT, PASSTHRU and CODE ID to be defined by the Diagnostic Latch. When in the internal control mode, the data loaded into the diagnostic latch should have the CODE ID different from 001 as this would represent an invalid operation.

CODE ID ₂	CODE ID ₁	CODE ID ₀	Hamming Code and Slice Selected
0	0	0	Code 16/22
0	0	1	Internal Control Mode
0	1	0	Code 32/39, Byte 0 and 1
0	1	1	Code 32/39, Byte 2 and 3
1	0	0	Code 64/72, Byte 0 and 1
1	0	1	Code 64/72, Byte 2 and 3
1	1	0	Code 64/72, Byte 4 and 5
1	1	1	Code 64/72, Byte 6 and 7

2595 tbl 02

Table 1. Hamming Code and Slice Identification

DIAG MODE ₁	DIAG MODE ₂	Diagnostic Mode Selected
0	0	Non-diagnostic mode. The EDC functions normally in all modes.
0	1	Diagnostic Generate. The contents of the Diagnostic Latch are substituted for the normally generated check bits when in the Generate mode. The EDC functions normally in the Detect or Correct modes.
1	0	Diagnostic Detect/Correct. In the Detect or Correct mode, the contents of the Diagnostic Latch are substituted for the check bits normally read from the Check Bit Input Latch. The EDC functions normally in the Generate mode.
1	1	Initialize. The outputs of the Data Input Latch are forced to zeroes and the check bits generated correspond to the all zero data. The latch is not reset, a functional difference from the Am2960.

NOTE:

1. ERROR DEP (Error Dependent): ERROR will be low for single or multiple errors, with MULT ERROR low for double or multiple errors. Both signals are high for no errors.

2595 tbl 04

Table 3. IDT39C60 Operating Modes

16-BIT DATA WORD CONFIGURATION

Figure 1 indicates the 22-bit data format for two bytes of data and 6 check bits.

A single IDT39C60 EDC unit, connected as shown in Figure 2, provides all the logic needed for single bit error correction and double bit error detection of a 16-bit data field. The identification code 16/22 indicates 6 check bits are required. The CB₆ pin is, therefore, a "Don't Care" and ID₂, ID₁, ID₀ = 000.

2595 drw 04

Uses Modified Hamming Code 16/22
16 Data Bits with 6 Check Bits

Figure 1. 16-Bit Data Format

Figure 2. 16-Bit Configuration

Table 3 describes the operating modes available. The output pin SC₆ is forced high for either syndrome or check bits since only 6 check bits are used for the 16/22 code.

Table 4 indicates the data bits participating in the check bit generation. For example, check bit C₀ is the Exclusive-OR function of the 8 data input bits marked with an X. Check bits are generated and output in the Generate and Initialization Mode. Check bits are passed as stored in the PASSTHRU or Diagnostic Generate Mode.

Syndrome bits are generated by an Exclusive-OR of the generated check bits with the read check bits. For example, SX is the XOR of check bits CX from those read with those generated. Table 5 indicates the decoding of the six

syndrome bits to indicate the bit-in-error for a single bit error, or whether a double or triple bit error was detected. The all zero case indicates no errors detected.

In the Correct Mode, the syndrome bits are used to complement (correct) single bit errors in the data bits. For double or multiple error detection, the data available as input to the Data Out Latch is not defined.

Table 6 defines the bit definition for the Diagnostic Latch. As defined in Table 3, several modes will use the diagnostic check bits to determine syndrome bits or to pass as check bits to the SC₀₋₅ outputs. The Internal Mode substitutes the indicated bit position for the external control signals.

16-BIT CMOS DETECTION AND CORRECTION UNIT

MILITARY AND COMMERCIAL TEMPERATURE RANGES

32-BIT DATA WORD CONFIGURATION

Two IDT39C60 EDC units, connected as shown in Figure 5, provide all the logic needed for single bit error correction and double bit error detection of a 32-bit data field. The identification code 32/39 indicates 7 check bits are required. Table 1 gives the ID2, ID1, ID0 values needed for distinguishing the byte 0/1 from byte 2/3. Valid syndrome, check bits and the ERROR and MULTERROR signal come from the byte 2/3 unit. Control signals not indicated are connected to both units in parallel. The OEsc always enables the SCo-6 outputs of byte 0/1, but must be used to select data check bits or syndrome bits fed back from the byte 2/3 for data correction modes.

Data In bits 0 through 15 are connected to the same numbered inputs of the byte 0/1 EDC unit, while Data In bits 16 through 31 are connected to byte 2/3 Data Inputs 0 to 15, respectively.

Figure 4 indicates the 39-bit data format for 4 bytes of data and 7 check bits. Check bits are input to the byte 0/1 unit through a tri-state buffer unit such as the IDT74FCT244. Correction of single bit errors of the 32-bit configuration requires a feedback of syndrome bits from byte 2/3 into the byte 0/1 unit. The MUX shown on the functional block diagram is used to select the CBo-6 pins as the syndrome bits rather than internally generated syndrome bits.

Table 3 describes the operating mode available for the 32/39 configuration.

Syndrome bits are generated by an Exclusive-OR of the generated check bits with the read check bits. For example, S_n is the XOR of check bits C_n from those read with those generated. Table 7 indicates the decoding of the seven syndrome bits to determine the bit-in-error for a single bit error, or whether a double or triple bit error was detected. The all zero case indicates no errors detected.

In the Correct Mode, the syndrome bits are used to complement (correct) single bit errors in the data bits. For double or multiple error detection, the data available as input to the Data Out Latch is not defined.

Performance data is provided in Table 8 in relating a single IDT39C60 EDC with the two cascaded units of Figure 5. As indicated, a summation of propagation delays is required from the cascading arrangement of EDC units.

Table 9 defines the bit definition for the Diagnostic Latch. As defined in Table 3, several modes will use the Diagnostic check bits to determine syndrome bits or to pass as check bits to the SCo-6 outputs. The Internal Mode substitutes the indicated bit position for the external control signals.

Table 10 indicates the data bits participating in the check bit generation. For example, check bit C_0 is the Exclusive-OR function of the 16 data input bits marked with an X. Check bits are generated and output in the Generate and Initialization Mode. Check bits are passed as stored in the PASSTHRU or Diagnostic Generate Mode.

Table 10. 32-Bit Modified Hamming Code — Check Bit Encode Chart

64-BIT DATA WORD CONFIGURATION

The IDT39C60 EDC units connected with the MSI gates, as shown in Figure 7, provide all the logic needed for single bit error detection and double bit error detection of a 64-bit data field. The Identification code 64/72 is used, indicating 8 check bits are required. Check bits and Syndrome bits are generated external to the IDT39C60 EDC using Exclusive-OR gates. For error correction, the syndrome bits must be fed back to the CBo-6 inputs. Thus, external tri-state buffers are used to select between the check bits read in from memory and the syndrome bits being fed back.

The ERROR signal is low for one or more errors detected. From any of the 4 devices, MULTERROR is low for some double bit errors and for all three bit errors. Both are high otherwise. The DOUBLE ERROR signal is high only when a double bit error is detected.

Figure 6 indicates the 72-bit data format of 8 bytes of data and 8 check bits. Check bits are input to the various units through a tri-state buffer such as the IDT74FCT244. Correction of single bit errors of the 64-bit configuration requires a feedback of syndrome bits as generated external to the IDT39C60 EDC. The MUX shown on the functional block diagram is used to select the CBo-6 pins as the syndrome bits rather than internally generated syndrome bits.

Table 3 describes the operating modes available for the 64/72 configuration.

Syndrome bits are generated by an Exclusive-OR of the generated check bits with the read check bits. For example, S_n is the XOR of check bits C_n from those read with those generated. Table 11 indicates the decoding of the 8 syndrome bits to determine the bit-in-error for a single bit error or whether

a double or triple bit error was detected. The all zero case indicates no errors detected.

In the Correct Mode, the syndrome bits are used to complement (correct) single bit errors in the data bits. For double or multiple error detection, the data available as input to the Data Out Latch is not defined.

Performance data is provided in Table 12 in relating a single IDT39C60 EDC with the four units of Figure 7. Delay through the Exclusive-OR gates and the 3-state buffer must be included.

Table 13 indicates the Data Bits participating in the check bit generation. For example, check bit C_0 is the Exclusive-OR function of the 32 data input bits marked with an X. Check bits are generated and output in the Generate and Initialization mode. In the PASSTHRU mode, the contents of the check bit latch are passed through the external Exclusive-OR gates and appear inverted at the outputs C_0 to C_7 .

Table 14 defines the bit definition for the Diagnostic Latch. As defined in Table 3, several modes will use the Diagnostic Check Bits to determine syndrome bits or to pass as check bits to the SCo-6 outputs. The Internal Mode substitutes the indicated bit position for the external control signals.

Some multiple errors will cause a data bit to be inverted. For example, in the 16-bit mode where bits 8 and 13 are in error, the syndrome 111100 ($S_0, S_1, S_2, S_3, S_4, S_5$) is produced. The bit-in-error decoder receives the syndrome 111100 (S_0, S_1, S_2, S_3, S_4) which it decodes as a single error in data bit 0 and inverts that bit. Figure 8 indicates a method for inhibiting correction when a multiple error occurs.

Table 14. Diagnostic Latch Loading — 64-Bit Format

Some multiple errors will cause a data bit to be inverted. For example, in the 16-bit mode where bits 8 and 13 are in error, the syndrome 111100 (S₀, S₁, S₂, S₃, S₄, S₅) is produced. The bit-in-error decoder receives the syndrome 111100 (S₀, S₁, S₂, S₃, S₄) which it decodes as a single error in data bit 0 and inverts that bit. Figure 8 indicates a method for inhibiting correction when a multiple error occurs.

FUNCTIONAL EQUATIONS

The following equations and tables describe in detail how the output values of the IDT39C60 EDC are determined as a function of the value of the inputs and the internal states. Be sure to carefully read the following definitions of symbols before examining the tables.

DEFINITIONS

$D_i \leftarrow \text{DATA}_i$ if LEIN is HIGH or the output of bit i of the Data Input Latch if LEIN is LOW

$C_i \leftarrow \text{CB}_i$ if LEIN is HIGH or the output of bit i of the Check Bit Latch if LEIN is LOW

$DL_i \leftarrow \text{Output of bit } i \text{ of the Diagnostic Latch}$

$S_i \leftarrow \text{Internally generated syndromes (same as outputs of } SC_i \text{ if outputs enabled)}$

$PA \leftarrow D_0 \oplus D_1 \oplus D_2 \oplus D_4 \oplus D_6 \oplus D_8 \oplus D_{10} \oplus D_{12}$

$PB \leftarrow D_0 \oplus D_1 \oplus D_2 \oplus D_3 \oplus D_4 \oplus D_5 \oplus D_6 \oplus D_7$

$PC \leftarrow D_8 \oplus D_9 \oplus D_{10} \oplus D_{11} \oplus D_{12} \oplus D_{13} \oplus D_{14} \oplus D_{15}$

$PD \leftarrow D_0 \oplus D_3 \oplus D_4 \oplus D_7 \oplus D_9 \oplus D_{10} \oplus D_{13} \oplus D_{15}$

$PE \leftarrow D_0 \oplus D_1 \oplus D_5 \oplus D_6 \oplus D_7 \oplus D_{11} \oplus D_{12} \oplus D_{13}$

$PF \leftarrow D_2 \oplus D_3 \oplus D_4 \oplus D_5 \oplus D_6 \oplus D_{14} \oplus D_{15} \oplus D_7$

$PG_1 \leftarrow D_0 \oplus D_4 \oplus D_6 \oplus D_7$

$PG_2 \leftarrow D_1 \oplus D_2 \oplus D_3 \oplus D_5$

$PG_3 \leftarrow D_8 \oplus D_9 \oplus D_{11} \oplus D_{14}$

$PG_4 \leftarrow D_{10} \oplus D_{12} \oplus D_{13} \oplus D_{15}$

Error Signals

$\text{ERROR} \leftarrow (S_6 \cdot (ID_1 + ID_2)) \cdot S_5 \cdot S_4 \cdot S_3 \cdot S_2 \cdot S_1 \cdot S_0 + \text{GENERATE} + \text{INITIALIZE} + \text{PASSTHRU}$

MULT ERROR:

(16 and 32-Bit Modes) $\leftarrow ((S_6 \cdot ID_1) \oplus S_5 \oplus S_4 \oplus S_3 \oplus S_2 \oplus S_1 \oplus S_0) (\text{ERROR}) + \text{TOME} + \text{GENERATE} + \text{PASSTHRU} + \text{INITIALIZE}$

MULT ERROR: (64-Bit Modes) $\leftarrow \text{TOME} + \text{GENERATE} + \text{PASSTHRU} + \text{INITIALIZE}$

Hex	S ₂	S ₁	S ₀	Hex		0		1		2		3		4		5		6		7

			I _{OL} = 8mA MIL.	—	0.3	0.5	
			I _{OL} = 8mA COM'L.	—	0.3	0.5	
I _{OZ}	Off State (High Impedance) Output Current	Vcc = Max.	V _O = 0V	—	-0.1	-20	μA
			V _O = Vcc (Max.)	—	0.1	20	
I _{OS}	Output Short Circuit Current	Vcc = Max., VOUT = 0V ⁽³⁾		-20	—	—	mA

NOTES:

2595 tbl 36

- For conditions shown as Max. or Min. use appropriate value specified under DC Electrical Characteristics.
- Typical values are at Vcc = 5.0V, +25°C ambient and maximum loading.
- Not more than one output should be shorted at one time. Duration of the short circuit test should not exceed one second.
- These input levels should only be static tested in a noise-free environment. Guaranteed by design.

DC ELECTRICAL CHARACTERISTICS (Cont'd.)Commercial: $T_A = 0^\circ\text{C}$ to $+70^\circ\text{C}$, $V_{CC} = 5.0\text{V} \pm 5\%$; Military: $T_A = -55^\circ\text{C}$ to $+125^\circ\text{C}$, $V_{CC} = 5.0\text{V} \pm 10\%$ $V_{LC} = 2.0\text{V}$; $V_{HC} = V_{CC} - 0.2\text{V}$

Symbol	Parameter	Test Conditions ⁽¹⁾	Min.	Typ. ⁽²⁾	Max.	Unit
I _{CCQ}	Quiescent Power Supply Current (CMOS) Inputs	$V_{CC} = \text{Max.}$ $V_{IN} = V_{CC}$ or GND $f_{OP} = 0$	—	3.0	5.0	mA
I _{CCCT}	Quiescent Input Power Supply Current (per Input @ TTL High) ⁽³⁾	$V_{CC} = \text{Max.}$, $V_{IN} = 3.4\text{V}$, $f_{OP} = 0$	—	0.3	2.0	mA/ Input
I _{CCD}	Dynamic Power Supply Current	$V_{CC} = \text{Max.}$ $V_{IN} = V_{CC}$ or GND Outputs Open, $\overline{OE} = L$	MIL.	—	5.0	8.5
			COM'L.	—	5.0	7.0
I _{CC}	Total Power Supply Current ⁽⁴⁾	$V_{CC} = \text{Max.}$, $f_{OP} = 10\text{MHz}$ Outputs Open, $\overline{OE} = L$ 50% Duty Cycle $V_{IN} = V_{CC}$ or GND	MIL.	—	53	90
			COM'L.	—	53	75
		$V_{CC} = \text{Max.}$, $f_{OP} = 10\text{MHz}$ Outputs Open, $\overline{OE} = L$ 50% Duty Cycle	MIL.	—	60	100
		$V_{IN} = 3.4\text{V}$, $V_{IL} = 0.4\text{V}$	COM'L.	—	60	85

2595 tbl 37

NOTES:

- For conditions shown as Max. or Min. use appropriate value specified under DC Electrical Characteristics.
- Typical values are at $V_{CC} = 5.0\text{V}$, $+25^\circ\text{C}$ ambient and maximum loading.
- I_{CCCT} is derived by measuring the total current with all the inputs tied together at 3.4V, subtracting out I_{CCQ}, then dividing by the total number of inputs.
- Total Supply Current is the sum of the Quiescent Current and the Dynamic Current (at either CMOS or TTL input levels). For all conditions, the Total Supply Current can be calculated by using the following equation:

$$I_{CC} = I_{CCQ} + I_{CCCT} (N_T \times D_H) + I_{CCD} (f_{OP})$$

$$D_H = \text{Data duty cycle TTL high period } (V_{IN} = 3.4\text{V})$$

$$N_T = \text{Number of dynamic inputs driven at TTL levels}$$

$$f_{OP} = \text{Operating frequency}$$

CMOS TESTING CONSIDERATIONS

Special test board considerations must be taken into account when applying high-speed CMOS products to the automatic test environment. Large output currents are being switched in very short periods and proper testing demands that test set-ups have minimized inductance and guaranteed zero voltage grounds. The techniques listed below will assist the user in obtaining accurate testing results:

- All input pins should be connected to a voltage potential during testing. If left floating, the device may oscillate, causing improper device operation and possible latchup.
- Placement and value of decoupling capacitors is critical. Each physical set-up has different electrical characteristics and it is recommended that various decoupling capacitor sizes be experimented with. Capacitors should be positioned using the minimum lead lengths. They should also be distributed to decouple power supply lines and be placed as close as possible to the DUT power pins.

- Device grounding is extremely critical for proper device testing. The use of multi-layer performance boards with radial decoupling between power and ground planes is necessary. The ground plane must be sustained from the performance board to the DUT interface board and wiring unused interconnect pins to the ground plane is recommended. Heavy gauge stranded wire should be used for power wiring, with twisted pairs being recommended for minimized inductance.
- To guarantee data sheet compliance, the input thresholds should be tested per input pin in a static environment. To allow for testing and hardware-induced noise, IDT recommends using $V_{IL} \leq 0\text{V}$ and $V_{IH} \geq 3\text{V}$ for AC tests.

DEFINITIONS:

CL = Load capacitance: includes jig and probe capacitance

RL = Termination resistance: should be equal to ZOUT of the Pulse Generator

Figure 12.
