MOTOROLA intelligence everywhere™ | digital dna™

This document contains detailed information on power considerations, AC/DC electrical characteristics, and AC timing specifications for revision A,B, and C of the MPC850 Family.

This document contains the following topics:

Part I Overview

The MPC850 is a versatile, one-chip integrated microprocessor and peripheral combination that can be used in a variety of controller applications, excelling particularly in communications and networking products. The MPC850, which includes support for Ethernet, is specifically designed for cost-sensitive, remote-access, and telecommunications applications. It is provides functions similar to the MPC860, with system enhancements such as universal serial bus (USB) support and a larger (8-Kbyte) dual-port RAM.

In addition to a high-performance embedded MPC8xx core, the MPC850 integrates system functions, such as a versatile memory controller and a communications processor module (CPM) that incorporates a specialized, independent RISC communications processor (referred to as the CP). This separate processor off-loads peripheral tasks from the embedded MPC8xx core.

The CPM of the MPC850 supports up to seven serial channels, as follows:

- One or two serial communications controllers (SCCs). The SCCs support Ethernet, ATM (MPC850SR and MPC850DSL), HDLC and a number of other protocols, along with a transparent mode of operation.
- One USB channel
- Two serial management controllers (SMCs)
- One I^2C port
- One serial peripheral interface (SPI).

Table 1-1 shows the functionality supported by the members of the MPC850 family.

Part III Electrical and Thermal Characteristics

This section provides the AC and DC electrical specifications and thermal characteristics for the MPC850. Table 3-2 provides the maximum ratings.

Table 3-2. Maximum Ratings

(GND = 0V)

Rating	Symbol	Value	Unit
Supply voltage	VDDH	-0.3 to 4.0	V
	VDDL	-0.3 to 4.0	V
	KAPWR	-0.3 to 4.0	V
	VDDSYN	-0.3 to 4.0	V
Input voltage [1]	V_{in}	GND-0.3 to VDDH + 2.5 V	V
Junction temperature [2]	T_j	0 to 95 (standard) -40 to 95 (extended)	˚C
Storage temperature range	T_{stg}	-55 to +150	˚C

1 Functional operating conditions are provided with the DC electrical specifications in Table 4-5. Absolute maximum ratings are stress ratings only; functional operation at the maxima is not guaranteed. Stress beyond those listed may affect device reliability or cause permanent damage to the device.
CAUTION: All inputs that tolerate 5 V cannot be more than 2.5 V greater than the supply voltage. This restriction applies to power-up and normal operation (that is, if the MPC850 is unpowered, voltage greater than 2.5 V must not be applied to its inputs).

2 The MPC850, a high-frequency device in a BGA package, does not provide a guaranteed maximum ambient temperature. Only maximum junction temperature is guaranteed. It is the responsibility of the user to consider power dissipation and thermal management. Junction temperature ratings are the same regardless of frequency rating of the device.

This device contains circuitry protecting against damage due to high-static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level (for example, either GND or V_{CC}). Table 4-3 provides the package thermal characteristics for the MPC850.

Part V Power Considerations

The average chip-junction temperature, T_J, in °C can be obtained from the equation:

$$T_J = T_A + (P_D \bullet \theta_{JA}) \qquad (1)$$

where

T_A = Ambient temperature, °C

θ_{JA} = Package thermal resistance, junction to ambient, °C/W

$P_D = P_{INT} + P_{I/O}$

$P_{INT} = I_{DD} \times V_{DD}$, watts—chip internal power

$P_{I/O}$ = Power dissipation on input and output pins—user determined

For most applications $P_{I/O} < 0.3 \bullet P_{INT}$ and can be neglected. If $P_{I/O}$ is neglected, an approximate relationship between P_D and T_J is:

$$P_D = K \div (T_J + 273°C) \qquad (2)$$

Solving equations (1) and (2) for K gives:

$$K = P_D \bullet (T_A + 273°C) + \theta_{JA} \bullet P_D^2 \qquad (3)$$

where K is a constant pertaining to the particular part. K can be determined from equation (3) by measuring P_D (at equilibrium) for a known T_A. Using this value of K, the values of P_D and T_J can be obtained by solving equations (1) and (2) iteratively for any value of T_A.

5.1 Layout Practices

Each V_{CC} pin on the MPC850 should be provided with a low-impedance path to the board's supply. Each GND pin should likewise be provided with a low-impedance path to ground. The power supply pins drive distinct groups of logic on chip. The V_{CC} power supply should be bypassed to ground using at least four 0.1 µF by-pass capacitors located as close as possible to the four sides of the package. The capacitor leads and associated printed circuit traces connecting to chip V_{CC} and GND should be kept to less than half an inch per capacitor lead. A four-layer board is recommended, employing two inner layers as V_{CC} and GND planes.

All output pins on the MPC850 have fast rise and fall times. Printed circuit (PC) trace interconnection length should be minimized in order to minimize undershoot and reflections caused by these fast output switching times. This recommendation particularly applies to the address and data busses. Maximum PC trace lengths of six inches are recommended. Capacitance calculations should consider all device loads as well as parasitic capacitances due to the PC traces. Attention to proper PCB layout and bypassing becomes especially critical in systems with higher capacitive loads because these loads create higher transient currents in the V_{CC} and GND circuits. Pull up all unused inputs or signals that will be inputs during reset. Special care should be taken to minimize the noise levels on the PLL supply pins.

Part VI Bus Signal Timing

Table 6-6 provides the bus operation timing for the MPC850 at 50 MHz, 66 MHz, and 80 MHz. Timing information for other bus speeds can be interpolated by equation using the MPC850 Electrical Specifications Spreadsheet found at http://www.mot.com/netcomm.

The maximum bus speed supported by the MPC850 is 50 MHz. Higher-speed parts must be operated in half-speed bus mode (for example, an MPC850 used at 66 MHz must be configured for a 33 MHz bus).

The timing for the MPC850 bus shown assumes a 50-pF load. This timing can be derated by 1 ns per 10 pF. Derating calculations can also be performed using the MPC850 Electrical Specifications Spreadsheet.

[1] The minima provided assume a 0 pF load, whereas maxima assume a 50pF load. For frequencies not marked on the part, new bus timing must be calculated for all frequency-dependent AC parameters. Frequency-dependent AC parameters are those with an entry in the FFactor column. AC parameters without an FFactor entry do not need to be calculated and can be taken directly from the frequency column corresponding to the frequency marked on the part. The following equations should be used in these calculations.

For a frequency F, the following equations should be applied to each one of the above parameters:

For minima:

$$D = \frac{FFACTOR \times 1000}{F} + (D_{50} - 20 \times FFACTOR)$$

For maxima:

$$D = \frac{FFACTOR \times 1000}{F} + (D_{50} - 20 \times FFACTOR) + 1ns(CAP\ LOAD - 50) / 10$$

where:

D is the parameter value to the frequency required in ns

F is the operation frequency in MHz

D_{50} is the parameter value defined for 50 MHz

CAP LOAD is the capacitance load on the signal in question.

FFACTOR is the one defined for each of the parameters in the table.

[2] Phase and frequency jitter performance results are valid only if the input jitter is less than the prescribed value.

[3] If the rate of change of the frequency of EXTAL is slow (i.e. it does not jump between the minimum and maximum values in one cycle) or the frequency of the jitter is fast (i.e., it does not stay at an extreme value for a long time) then the maximum allowed jitter on EXTAL can be up to 2%.

[4] The timing for $\overline{BR}$ output is relevant when the MPC850 is selected to work with external bus arbiter. The timing for $\overline{BG}$ output is relevant when the MPC850 is selected to work with internal bus arbiter.

[5] The setup times required for $\overline{TA}$, $\overline{TEA}$, and $\overline{BI}$ are relevant only when they are supplied by an external device (and not when the memory controller or the PCMCIA interface drives them).

[6] The timing required for $\overline{BR}$ input is relevant when the MPC850 is selected to work with the internal bus arbiter. The timing for $\overline{BG}$ input is relevant when the MPC850 is selected to work with the external bus arbiter.

[7] The D[0–31] and DP[0–3] input timings B20 and B21 refer to the rising edge of the CLKOUT in which the $\overline{TA}$ input signal is asserted.

[8] The D[0:31] and DP[0:3] input timings B20 and B21 refer to the falling edge of CLKOUT. This timing is valid only for read accesses controlled by chip-selects controlled by the UPM in the memory controller, for data beats where DLT3 = 1 in the UPM RAM words. (This is only the case where data is latched on the falling edge of CLKOUT.

[9] The timing B30 refers to $\overline{CS}$ when ACS = '00' and to $\overline{WE[0:3]}$ when CSNT = '0'.

[10] The signal UPWAIT is considered asynchronous to CLKOUT and synchronized internally. The timings specified in B37 and B38 are specified to enable the freeze of the UPM output signals.

[11] The $\overline{AS}$ signal is considered asynchronous to CLKOUT.

The timings I41, I42, and I43 are specified to allow the correct function of the $\overline{IRQ}$ lines detection circuitry, and has no direct relation with the total system interrupt latency that the MPC850 is able to support

200	SCL clock frequency (slave)	fSCL	0	BRGCLK/48	Hz
200	SCL clock frequency (master) [1]	fSCL	BRGCLK/16512	BRGCLK/48	Hz
202	Bus free time between transmissions		1/(2.2 * fSCL)	—	s
203	Low period of SCL		1/(2.2 * fSCL)	—	s
204	High period of SCL		1/(2.2 * fSCL)	—	s
205	Start condition setup time		1/(2.2 * fSCL)	—	s
206	Start condition hold time		1/(2.2 * fSCL)	—	s
207	Data hold time		0	—	s
208	Data setup time		1/(40 * fSCL)	—	s
209	SDL/SCL rise time		—	1/(10 * fSCL)	s
210	SDL/SCL fall time		—	1/(33 * fSCL)	s
211	Stop condition setup time		1/2(2.2 * fSCL)	—	s

1 SCL frequency is given by SCL = BrgClk_frequency / ((BRG register + 3) * pre_scaler * 2). The ratio SyncClk/(Brg_Clk/pre_scaler) must be greater or equal to 4/1.

9.1 Pin Assignments and Mechanical Dimensions of the PBGA

The original pin numbering of the MPC850 conformed to a Motorola proprietary pin numbering scheme that has since been replaced by the JEDEC pin numbering standard for this package type. To support customers that are currently using the non-JEDEC pin numbering scheme, two sets of pinouts, JEDEC and non-JEDEC, are presented in this document.

Figure 9-62 shows the non-JEDEC pinout of the PBGA package as viewed from the top surface.

Figure 9-63 shows the JEDEC pinout of the PBGA package as viewed from the top surface.

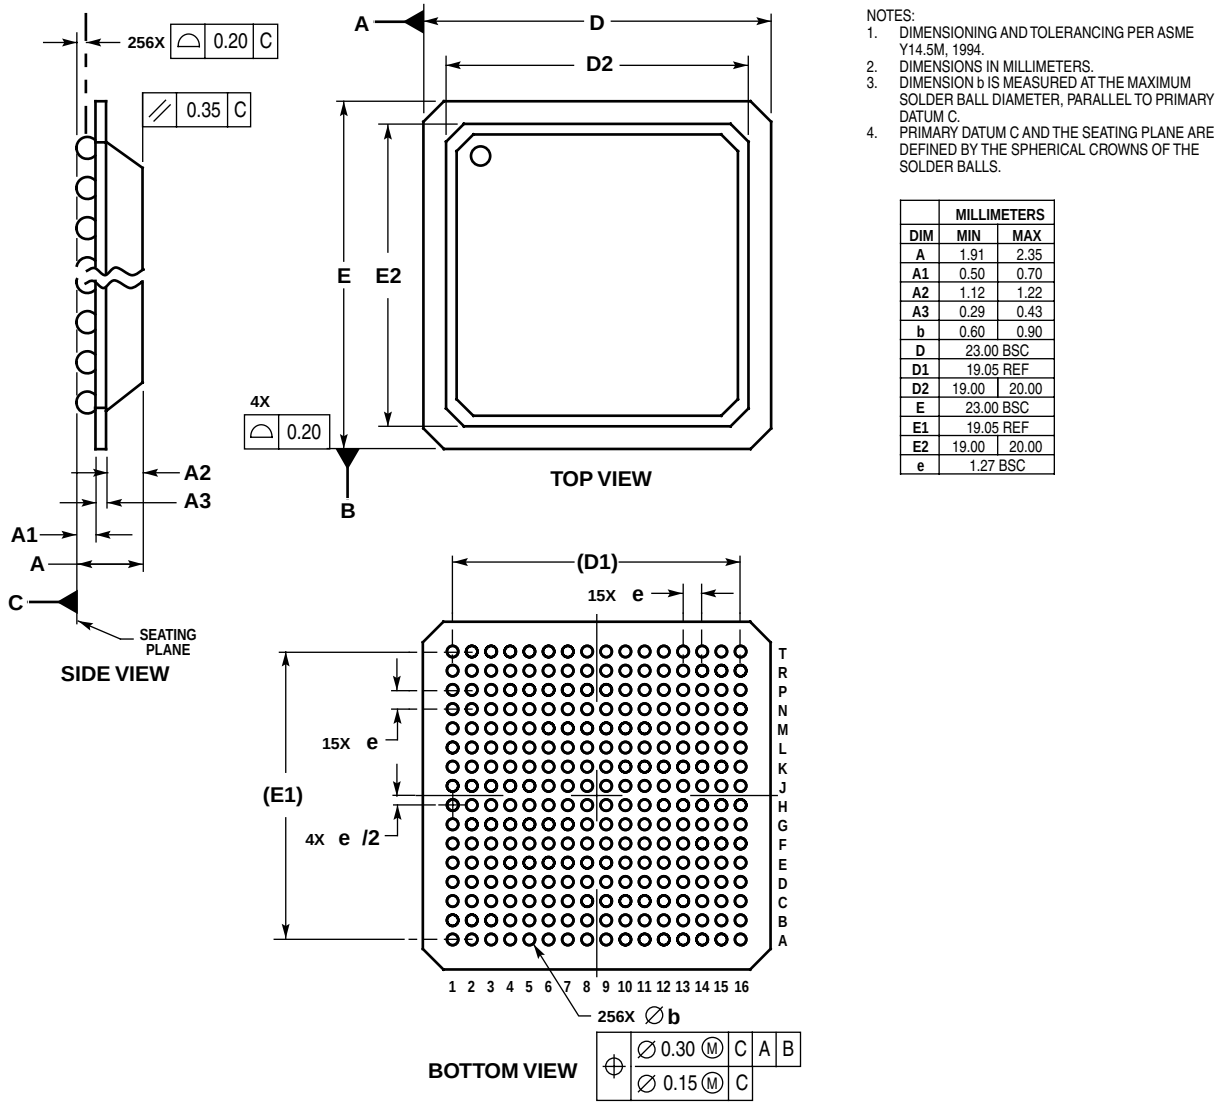
For more information on the printed circuit board layout of the PBGA package, including thermal via design and suggested pad layout, please refer to AN-1231/D, Plastic Ball Grid Array Application Note available from your local Motorola sales office.

Figure 9-64 shows the non-JEDEC package dimensions of the PBGA.



NOTES:
1. DIMENSIONING AND TOLERANCING PER ASME Y14.5M, 1994.
