S3C72K8/P72K8 PRODUCT OVERVIEW

1

PRODUCT OVERVIEW

OVERVIEW

The S3C72K8 singl-chip CMOS microcontroller has been designed for high performance using Samsung's newest 4-bit CPU core, SAM48 (Samsung Arrageable Microcontrollers). With a two-channel comparator, up-to-320-dot LCD direct drive capability, 8-bit timer/counter, watchdog timer and serial I/O, the S3C72K8 offers an excellent design solution for a wide variety of applications which require LCD functions.

Up to 27 pins of the 80-pin QFP package can be dedicated to I/O. Seven vectored interrupts provide fast response to internal and external events. In addition, the S3C72K8's advanced CMOS technology provides for low power consumption and a wide operating voltage range.

OTP

The S3C72K8 microcontroller is also available is OTP (one time programmable) version, S3P72K8. S3P72K8 microcontroller has an one-chop 8 Kbyte one time programmable EPROM instead of masked ROM. The S3P72K8 is comparable to S3C72K8, both in function and in pin configuration.

PRODUCT OVERVIEW S3C72K8/P72K8

FEATURES

Memory

- 8 K × 8-bit RAM
- 1.024 × 4-bit ROM

27 I/O Pins

- Input only: 4 pins
- I/O: 15 pins
- Output: maximum 8 pins for 1-bit level output (sharing with segment driver outputs)

Comparator

- Two channel mode: internal reference (4-bit resolution)
- One channel mode: external reference

LCD Controller/Driver

- 40 segments and 8 common terminals
- 3, 4 and 8 common selectable
- Internal resistor circuit for LCD bias
- All dot can be switched on/off

8-Bit Basic Timer

- 4 interval timer functions
- Watchdog timer

8-Bit Timer/Counter

- Programmable 8-bit timer
- External event counter
- Arbitrary clock frequency output
- External clock signal divider
- Serial I/O interface clock generator

8-Bit Serial I/O Interface

- 8-bit transmit/receive mode
- 8-bit receive only mode
- LSB-first or MSB-first transmission selectable
- Internal or external clock source

Bit Sequential Carrier

Support 16-bit serial data transfer in arbitrary format

Watch Timer

- Timer interval generation:
 0.5 s, 3.9 ms at 32,768 Hz
- Four frequency outputs to BUZ pin
- Clock source generation for LCD

Interrupts

- Three internal vectored interrupts: INTB, INTTO, INTS
- Four external vectored interrupts: INT0, INT1, INT4, INTK
- Two quasi-interrupts: INT2, INTW

Memory-Mapped I/O Structure

Data memory bank 15

Two Power-Down Modes

- Idle mode (only CPU clock stops)
- Stop mode (main system oscillation stops)
- Subsystem clock stop mode

Oscillation Sources

- Crystal, ceramic, or External RC for system clock
- Main system clock frequency: 0.4 MHz–6 MHz
- Subsystem clock frequency: 32,768 kHz
- CPU clock divider circuit (by 4, 8, or 64)

Instruction Execution Times

- 0.67 us at 6 MHz (minimum)
- 0.95 μs at 4.19 MHz (minimum)
- 122 μs at 32,768 kHz (minimum)

Operating Temperature

- -40 °C to 85 °C

Operating Voltage Range

— 2.0 V to 5.5 V

Package Type

- 80-pin QFP

PIN DESCRIPTIONS

Table 1-1. S3C72K8 Pin Descriptions

Pin Name	Pin Type	Description	Circuit Type	Pin Number	Share Pin
P0.0 P0.1 P0.2 P0.3	I/O	4-bit I/O port. 1-bit or 4-bit read/write and test is possible. Individual pins are software configurable as input or output. Individual pins are software configurable as opendrain or push-pull output. 4-bit pull-up resistors are software assignable; pull-up resistors are automatically disabled for output pins.	E-2	8 9 10 11	K0/SCK K1/SO K2/SI K3/BUZ
P1.0 P1.1 P1.2 P1.3	I	4-bit input port. 1-bit or 4-bit read and test are possible. The 1-bit unit pull-up resistors are assigned to input pins by software. An interrupt is generated by digital input at P1.0, P1.1.	F–4 F–4 A–3 A–3	20 21 22 23	INTO/CINO INT1/CIN1 INT2 INT4
P2.0-P2.3	I/O	Same as port 0 except that 8-bit read/write and test is possible.	E-2	24–27	_
P3.0 P3.1 P3.2 P3.3				28 29 30 31	- LCDSY LCDCK
P4.0 P4.1 P4.2	I/O	Same as port 0 except that port 4 is 3-bit I/O port.	E-2	32 33 34	CLO TCL0 TCLO0
P5.0-P5.7	0	Output port for 1-bit data	H–11	75– 80,1,2	SEG32- SEG39
SCK	I/O	Serial I/O interface clock signal	E-2	8	P0.0/K0
SO	I/O	Serial data output	E-2	9	P0.1/K1
SI	I/O	Serial data input	E-2	10	P0.2/K2
BUZ	I/O	2 KHz, 4 KHz, 8 KHz or 16 KHz frequency output at the watch timer clock frequency of 32.768 kHz.	E-2	11	P0.3/K3
K0-K3	I/O	External interrupt. The triggering edge is selectable.	E-2	8–11	P0.0-P0.3
INT0 INT1	I	External interrupts. The triggering edge for INT0 and INT1 is selectable.	F–4	20 21	P1.0/CIN0 P1.1/CIN1
INT2	I	Quasi-interrupt with detection of rising or falling edges	A–3	22	P1.2
INT4	I	External interrupts with detection of rising and falling edges	A–3	23	P1.3

PRODUCT OVERVIEW S3C72K8/P72K8

Table 1-1. S3C72K8 Pin Descriptions (Continued)

Pin Name	Pin Type	Description	Circuit Type	Pin Number	Share Pin
CIN0 CIN1	I	2-channel comparator input. CIN0: comparator input or external reference input CIN1: comparator input only.	F-4	20 21	P1.0/INT0 P1.1/INT1
LCDSY	I/O	LCD synchronization clock output for display expansion	E-2	30	P3.2
LCDCK	I/O	LCD clock output for display expansion	E-2	31	P3.3
CLO	I/O	Clock output	E-2	32	P4.0
TCL0	I/O	External clock input for timer/counter 0	E-2	33	P4.1
TCLO0	I/O	Timer/counter 0 clock output	E-2	34	P4.2
SEG32- SEG39	0	LCD segment signal output	H–11	75– 80,1,2	P5.0-P5.7
SEG0- SEG31	0	LCD segment signal output	H–6	43–74	-
COM0- COM7	0	LCD common signal output	H–6	35–42	_
V _{LC1} -V _{LC5}	-	LCD power supply. Voltage dividing resistors are assignable by mask option.	_	3–7	_
X _{IN} , X _{OUT}	-	Crystal, ceramic or RC oscillator pins for system clock.	_	15, 14	_
XT _{IN,} XT _{OUT}	_	Crystal oscillator pins for subsystem clock.	_	17, 18	_
V _{DD}	_	Main power supply		12	_
V _{SS}	_	Ground	-	13	_
RESET	I	Chip reset signal input	В	19	-
TEST	I	Chip test signal input (must be connected to V _{SS})	_	16	_

NOTE: Pull-up resistors for all I/O ports are automatically disabled if they are configured to output mode

ADDRESS SPACES

PROGRAM MEMORY (ROM)

OVERVIEW

ROM maps for S3C72K8 devices are mask programmable at the factory. In its standard configuration, the device's $8,192 \times 8$ -bit program memory has three areas that are directly addressable by the program counter (PC):

- 16-byte area for vector addresses
- 96-byte instruction reference area
- 16-byte general-purpose area
- 8,064-byte general-purpose area

General-Purpose Program Memory

Two program memory areas are allocated for general-purpose use: One area is 16 bytes in size and the other is 8,064 bytes.

Vector Addresses

A 16-byte vector address area is used to store the vector addresses required to execute system resets and interrupts. Start addresses for interrupt service routines are stored in this area, along with the values of the enable memory bank (EMB) and enable register bank (ERB) flags that are used to set their initial value for the corresponding service routines. The 16-byte area can be used alternately as general-purpose ROM.

REF Instructions

Locations 0020H–007FH are used as a reference area (look-up table) for 1-byte REF instructions. The REF instruction reduces the byte size of instruction operands. REF can reference one 2-byte instruction, two 1-byte instructions, and 3-byte instructions which are stored in the look-up table. Unused look-up table addresses can be used as general-purpose ROM.

Table 2-1. Program Memory Address Ranges

ROM Area Function	Address Ranges	Area Size (in Bytes)
Vector address area	0000H-000FH	16
General-purpose program memory	0010H-001FH	16
REF instruction look-up table area	0020H-007FH	96
General-purpose program memory	0080H-1FFFH	8,064

GENERAL-PURPOSE MEMORY AREAS

The 16-byte area at ROM locations 000CH–001FH and the 8,064-byte area at ROM locations 0080H–1FFFH are used as general-purpose program memory. Unused locations in the vector address area and REF instruction look-up table areas can be used as general-purpose program memory. However, care must be taken not to overwrite live data when writing programs that use special-purpose areas of the ROM.

VECTOR ADDRESS AREA

The 16-byte vector address area of the ROM is used to store the vector addresses for executing system resets and interrupts. The starting addresses of interrupt service routines are stored in this area, along with the enable memory bank (EMB) and enable register bank (ERB) flag values that are needed to initialize the service routines. 16-byte vector addresses are organized as follows:

EMB	ERB	0	PC12	PC11	PC10	PC9	PC8
PC7	PC6	PC5	PC4	PC3	PC2	PC1	PC0

To set up the vector address area for specific programs, use the instruction VENTn. The programming tips on the next page explain how to do this.

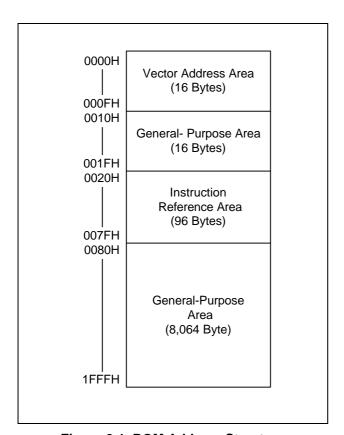

Figure 2-1. ROM Address Structure

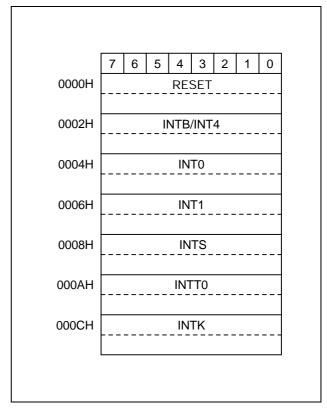

Figure 2-2. Vector Address Structure

PROGRAMMING TIP — Defining Vectored Interrupts

The following examples show you several ways you can define the vectored interrupt and instruction reference areas in program memory:

1. When all vector interrupts are used:

```
ORG
              0000H
                                           ; EMB \leftarrow 1, ERB \leftarrow 0; Jump to RESET address
VENT0
              1,0,RESET
VENT1
                                           ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INTB address
              0,0,INTB
                                          ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INT0 address
VENT2
              0.0,INT0
VENT3
              0,0,INT1
                                          ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INT1 address
VENT4
              0,0,INTS
                                           ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INTS address
                                           ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INTT0 address
VENT5
              0,0,INTT0
VENT6
              0,0,INTK
                                           ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INTK address
```

2. When a specific vectored interrupt such as INT0, and INTT0 is not used, the unused vector interrupt locations must be skipped with the assembly instruction ORG so that jumps will address the correct locations:

```
ORG
             0000H
VENT0
                                         ; EMB \leftarrow 1, ERB \leftarrow 0; Jump to RESET address
             1.0.RESET
                                         ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INTB address
VENT1
             0,0,INTB
                                         ; INT0 interrupt not used
ORG
             0006H
                                         ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INT1 address
VENT3
             0.0.INT1
                                         ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INTS address
VENT4
             0,0,INTS
ORG
             000CH
                                         ; INTT0 interrupt not used
VENT6
             0,0,INTK
                                          ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INTK address
```

3. If an INT0 interrupt is not used and if its corresponding vector interrupt area is not fully utilized, or if it is not written by a ORG instruction as in Example 2, a CPU malfunction will occur:

```
ORG
              0000H
                                          ; EMB \leftarrow 1, ERB \leftarrow 0; Jump to RESET address
VENT0
              1,0,RESET
                                          ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INTB address
VENT1
              0,0,INTB
                                          ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INT0 address
VENT3
              0,0,INT1
                                          ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INT1 address
VENT4
              0,0,INTS
                                          ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INTS address
VENT5
              0,0,INTT0
VENT6
              0,0,INTK
                                          ; EMB \leftarrow 0, ERB \leftarrow 0; Jump to INTT0 address
ORG
              0010H
```

General-purpose ROM area

In this example, when an INTS interrupt is generated, the corresponding vector area is not VENT4 INTS, but VENT5 INTT0. This causes an INTS interrupt to jump incorrectly to the INTT0 address and causes a CPU malfunction to occur.

INSTRUCTION REFERENCE AREA

Using 1-byte REF instructions, you can easily reference instructions with larger byte sizes that are stored in addresses 0020H–007FH of program memory. This 96-byte area is called the REF instruction reference area, or look-up table. Locations in the REF look-up table may contain two one-byte instructions, a single two-byte instruction, or three-byte instruction such as a JP (jump) or CALL. The starting address of the instruction you are referencing must always be an even number. To reference a JP or CALL instruction, it must be written to the reference area in a two-byte format: for JP, this format is TJP; for CALL, it is TCALL. In summary, there are three ways to the REF instruction:

By using REF instructions to execute instructions larger than one byte, you can improve program execution time considerably by reducing the number of program steps. In summary, there are three ways you can use the REF instruction:

- Using the 1-byte REF instruction to execute one 2-byte or two 1-byte instructions,
- Branching to any location by referencing a branch instruction stored in the look-up table,
- Calling subroutines at any location by referencing a call instruction stored in the look-up table.

PROGRAMMING TIP — Using the REF Look-Up Table

Here is one example of how to use the REF instruction look-up table:

```
ORG
                      0020H
           TJP
JMAIN
                      MAIN
                                            ; 0, MAIN
                                             1, KEYFG CHECK
           BTSF
KEYCK
                      KEYFG
WATCH
           TCALL
                      CLOCK
                                            ; 2, CALL CLOCK
INCHL
           LD
                      @HL,A
                                            ; 3, (HL) \leftarrow A
           INCS
                      HL
ABC
           LD
                      EA,#00H
                                            : EA ← #00H
           ORG
                      H0800
MAIN
           NOP
           NOP
                                            ; BTSF KEYFG (1-byte instruction)
                      KEYCK
           REF
                                            ; KEYFG = 1, jump to MAIN (1-byte instruction)
           REF
                      JMAIN
                      WATCH
                                            ; KEYFG = 0, CALL CLOCK (1-byte instruction)
           REF
           REF
                      INCHL
                                            ; LD @HL,A
                                              INCS HL
           REF
                      ABC
                                            ; LD EA,#00H (1-byte instruction)
```

DATA MEMORY (RAM)

OVERVIEW

In its standard configuration, the 1,024 x 4-bit data memory has three areas:

- 32 × 4-bit working register area in bank 0
- 224 × 4-bit general-purpose area in bank 0 which is also used as the stack area
- 176 × 4-bit general-purpose area in bank 1
- 80 × 4-bit area for LCD data in bank 1
- 256 × 4-bit general-purpose area in bank 2
- 256 × 4-bit general-purpose area in bank 3
- 128 × 4-bit area in bank 15 for memory-mapped I/O addresses

To make it easier to reference, the data memory area has five memory banks — bank 0, bank 1, bank 2, babk 3, and bank 15. The select memory bank instruction (SMB) is used to select the bank you want to select as working data memory. Data stored in RAM locations are 1-, 4-, and 8-bit addressable.

Initialization values for the data memory area are not defined by hardware and must therefore be initialized by program software following power RESET. However, when RESET signal is generated in power-down mode, the data memory contents are held.

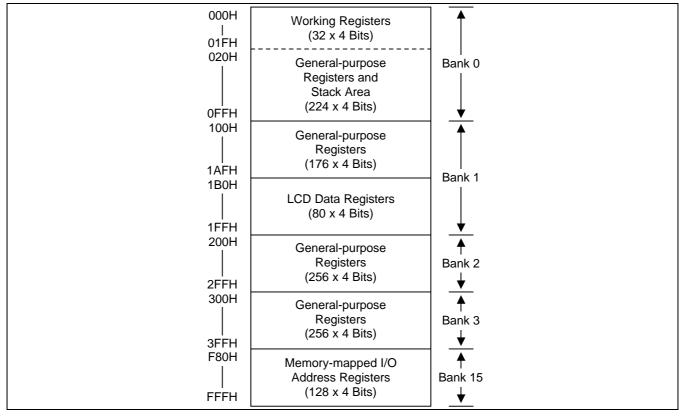

Figure 2-3. Data Memory (RAM) Map

Memory Banks 0, 1, and 15

Bank 0	(000H-0FFH)	The lowest 32 nibbles of bank 0 (000H–01FH) are used as working registers; the next 224 nibbles (020H–0FFH) can be used both as stack area and as general-purpose data memory. Use the stack area for implementing subroutine calls and returns, and for interrupt processing.
Bank 1	(1E0H-1FFH)	The lowest 176 nibbles of bank 1 (100H–1AFH) are for general-purpose use; use the ramaining of 80 nibbles (1B0H–1FFH) as display registers or as general purpose memory.
Bank 2	(200H-2FFH)	256 nibbles of bank 2 (200H–2FFH) are for general-purpose used
Bank 3	(300H-3FFH)	256 nibbles of bank 3 (300H–3FFH) are for general-purpose used
Bank 15	(F80H–FFFH)	The microcontroller uses bank 15 for memory-mapped peripheral I/O. Fixed RAM locations for each peripheral hardware address are mapped into this area.

Data Memory Addressing Modes

The enable memory bank (EMB) flag controls the addressing mode for data memory banks 0, 1, 2, 3 or 15. When the EMB flag is logic zero, the addressable area is restricted to specific locations, depending on whether direct or indirect addressing is used. With direct addressing, you can access locations 000H–07FH of bank 0 and bank 15. With indirect addressing, only bank 0 (000H–0FFH) can be accessed. When the EMB flag is set to logic one, all three data memory banks can be accessed according to the current SMB value.

For 8-bit addressing, two 4-bit registers are addressed as a register pair. Also, when using 8-bit instructions to address RAM locations, remember to use the even-numbered register address as the instruction operand.

Working Registers

The RAM working register area in data memory bank 0 is further divided into four *register* banks (bank 0, 1, 2, and 3). Each register bank has eight 4-bit registers and paired 4-bit registers are 8-bit addressable.

Register A is used as a 4-bit accumulator and register pair EA as an 8-bit extended accumulator. The carry flag bit can also be used as a 1-bit accumulator. Register pairs WX, WL, and HL are used as address pointers for indirect addressing. To limit the possibility of data corruption due to incorrect register addressing, it is advisable to use register bank 0 for the main program and banks 1, 2, and 3 for interrupt service routines.

LCD Data Register Area

Bit values for LCD segment data are stored in data memory bank 1. Register locations in this area that are not used to store LCD data can be assigned to general-purpose use.

Table 2-2. Data Memory Organization and Addressing

Addresses	Register Areas	Bank	EMB Value	SMB Value
000H-01FH	Working registers	0	0, 1	0
020H-0FFH	Stack and general-purpose registers			
100H-1AFH	General-purpose registers	1	1	1
1B0H-1FFH	LCD Data registers			
200H-2FFH	General-purpose registers	2	1	2
300H-3FFH	General-purpose registers	3	1	3
F80H-FFFH	I/O- mapped hardware registers	15	0, 1	15

PROGRAMMING TIP — Clearing Data Memory Banks 0 and 1

Clear banks 0 and 1 of the data memory area:

RAMCLR RMCL1	SMB LD LD LD INCS JR	1 HL, #00H A, #0H @HL, A HL RMCL1	;	RAM (100H–1FFH) clear
; RMCL0	SMB LD LD INCS JR	0 HL, #20H @HL, A HL RMCL0	;	RAM (020H–0FFH) clear

WORKING REGISTERS

Working registers, mapped to RAM address 000H–01FH in data memory bank 0, are used to temporarily store intermediate results during program execution, as well as pointer values used for indirect addressing. Unused registers may be used as general-purpose memory. Working register data can be manipulated as 1-bit units, 4-bit units or, using paired registers, as 8-bit units.

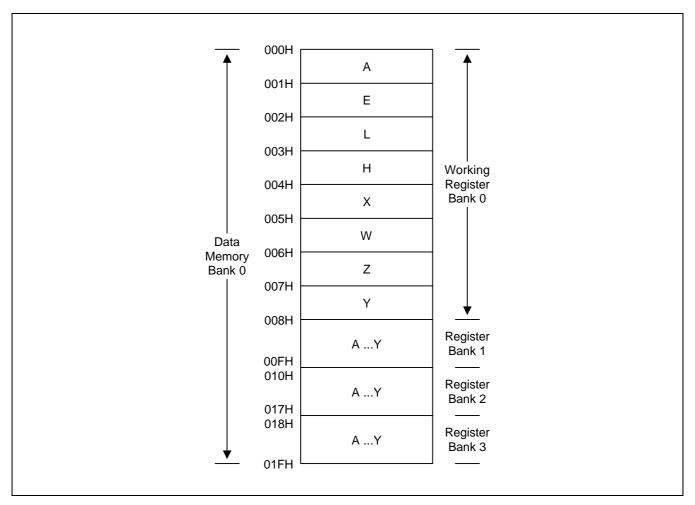

Figure 2-4. Working Register Map

Working Register Banks

For addressing purposes, the working register area is divided into four register banks — bank 0, bank 1, bank 2, and bank 3. Any one of these banks can be selected as the working register bank by the register bank selection instruction (SRB n) and by setting the status of the register bank enable flag (ERB).

Generally, working register bank 0 is used for the main program, and banks 1, 2, and 3 for interrupt service routines. Following this convention helps to prevent possible data corruption during program execution due to contention in register bank addressing.

ERB	SRB Settings			Selected Register Bank	
Setting	3	2	1	0	
0	0	0	-	_	Always set to bank 0
			0	0	Bank 0
1	0	0	0	1	Bank 1
			1	0	Bank 2
			1	1	Bank 3

Table 2-3. Working Register Organization and Addressing

NOTE: 'x' means don't care.

Paired Working Registers

Each of the register banks is subdivided into eight 4-bit registers. These registers, named Y, Z, W, X, H, L, E, and A, can either be manipulated individually using 4-bit instructions, or together as register pairs for 8-bit data manipulation.

The names of the 8-bit register pairs in each register bank are EA, HL, WX, YZ, and WL. Registers A, L, X, and Z always become the lower nibble when registers are addressed as 8-bit pairs. This makes a total of eight 4-bit registers or four 8-bit double registers in each of the four working register banks.

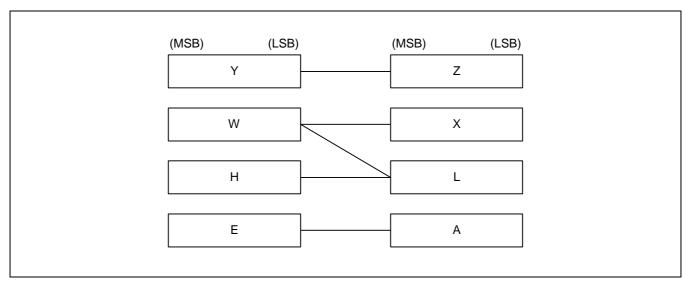

Figure 2-5. Register Pair Configuration

Special-Purpose Working Registers

Register A is used as a 4-bit accumulator and double register EA as an 8-bit accumulator. The carry flag can also be used as a 1-bit accumulator.

8-bit double registers WX, WL, and HL are used as data pointers for indirect addressing. When the HL register serves as a data pointer, the instructions LDI, LDD, XCHI, and XCHD can make very efficient use of working registers as program loop counters by letting you transfer a value to the L register and increment or decrement it using a single instruction.

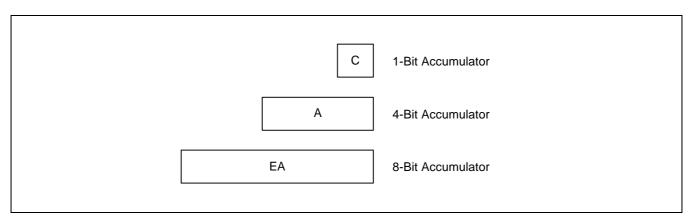

Figure 2-6. 1-Bit, 4-Bit, and 8-Bit Accumulator

Recommendation for Multiple Interrupt Processing

If more than four interrupts are being processed at one time, you can avoid possible loss of working register data by using the PUSH RR instruction to save register contents to the stack before the service routines are executed in the same register bank. When the routines have executed successfully, you can restore the register contents from the stack to working memory using the POP instruction.

PROGRAMMING TIP — Selecting the Working Register Area

The following examples show the correct programming method for selecting working register area:

1. When ERB = "0":

```
VENT2
            1,0,INT0
                                                 ; EMB \leftarrow 1, ERB \leftarrow 0, Jump to INT0 address
INT<sub>0</sub>
            PUSH
                        SB
                                                    PUSH current SMB, SRB
            SRB
                        2
                                                    Instruction does not execute because ERB = "0"
            PUSH
                        HL
                                                    PUSH HL register contents to stack
            PUSH
                        WX
                                                 ; PUSH WX register contents to stack
            PUSH
                        YΖ
                                                 ; PUSH YZ register contents to stack
            PUSH
                        EΑ
                                                 ; PUSH EA register contents to stack
            SMB
                        0
            LD
                        EA,#00H
            LD
                        80H,EA
            LD
                        HL,#40H
            INCS
                        HL
            LD
                        WX,EA
            LD
                        YZ,EA
            POP
                                                 ; POP EA register contents from stack
                        EΑ
            POP
                        YΖ
                                                    POP YZ register contents from stack
            POP
                        WX
                                                    POP WX register contents from stack
            POP
                        HL
                                                    POP HL register contents from stack
            POP
                        SB
                                                    POP current SMB, SRB
            IRET
```

The POP instructions execute alternately with the PUSH instructions. If an SMB n instruction is used in an interrupt service routine, a PUSH and POP SB instruction must be used to store and restore the current SMB and SRB values, as shown in Example 2 below.

2. When ERB = "1":

```
VENT2
                                                 ; EMB \leftarrow 1, ERB \leftarrow 1, Jump to INT0 address
          1,1,INT0
INT<sub>0</sub>
          PUSH
                       SB
                                                   Store current SMB, SRB
          SRB
                       2
                                                   Select register bank 2 because of ERB = "1"
          SMB
                       0
                       EA,#00H
          LD
          LD
                       80H,EA
          LD
                       HL,#40H
          INCS
                       HL
          LD
                       WX,EA
          LD
                       YZ,EA
          POP
                       SB
                                                 ; Restore SMB, SRB
          IRET
```

STACK OPERATIONS

STACK POINTER (SP)

The stack pointer (SP) is an 8-bit register that stores the address used to access the stack, an area of data memory set aside for temporary storage of data and addresses. The SP can be read or written by 8-bit control instructions. When addressing the SP, bit 0 must always remain cleared to logic zero.

F80H	SP3	SP2	SP1	"0"
F81H	SP7	SP6	SP5	SP4

There are two basic stack operations: writing to the top of the stack (push), and reading from the top of the stack (pop). A push decrements the SP and a pop increments it so that the SP always points to the top address of the last data to be written to the stack.

The program counter contents and program status word (PSW) are stored in the stack area prior to the execution of a CALL or a PUSH instruction, or during interrupt service routines. Stack operation is a LIFO (Last In-First Out) type. The stack area is located in general-purpose data memory bank 0.

During an interrupt or a subroutine, the PC value and the PSW are saved to the stack area. When the routine has completed, the stack pointer is referenced to restore the PC and PSW, and the next instruction is executed.

The SP can address stack registers in bank 0 (addresses 000H–0FFH) regardless of the current value of the enable memory bank (EMB) flag and the select memory bank (SMB) flag. Although general-purpose register areas can be used for stack operations, be careful to avoid data loss due to simultaneous use of the same register(s).

Since the RESET value of the stack pointer is not defined in firmware, we recommend that you initialize the stack pointer by program code to location 00H. This sets the first register of the stack area to 0FFH.

NOTE

A subroutine call occupies six nibbles in the stack; an interrupt requires six. When subroutine nesting or interrupt routines are used continuously, the stack area should be set in accordance with the maximum number of subroutine levels. To do this, estimate the number of nibbles that will be used for the subroutines or interrupts and set the stack area correspondingly.

PROGRAMMING TIP — Initializing the Stack Pointer

To initialize the stack pointer (SP):

1. When EMB = "1":

SMB 15 ; Select memory bank 15

LD EA,#00H ; Bit 0 of SP is always cleared to "0"

LD SP,EA; Stack area initial address (0FFH) \leftarrow (SP) -1

2. When EMB = "0":

LD EA,#00H

LD SP,EA ; Memory addressing area (00H–7FH, F80H–FFFH)

PUSH OPERATIONS

Three kinds of push operations reference the stack pointer (SP) to write data from the source register to the stack: PUSH instructions, CALL instructions, and interrupts. In each case, the SP is *decreased* by a number determined by the type of push operation and then points to the next available stack location.

PUSH Instructions

A PUSH instruction references the SP to write two 4-bit data nibbles to the stack. Two 4-bit stack addresses are referenced by the stack pointer: one for the upper register value and another for the lower register. After the PUSH has executed, the SP is decreased *by two* and points to the next available stack location.

CALL Instructions

When a subroutine call is issued, the CALL instruction references the SP to write the PC's contents to six 4-bit stack locations. Current values for the enable memory bank (EMB) flag and the enable register bank (ERB) flag are also pushed to the stack. Since six 4-bit stack locations are used per CALL, you may nest subroutine calls up to the number of levels permitted in the stack.

Interrupt Routines

An interrupt routine references the SP to push the contents of the PC and the program status word (PSW) to the stack. Six 4-bit stack locations are used to store this data. After the interrupt has executed, the SP is decreased *by six* and points to the next available stack location. During an interrupt sequence, subroutines may be nested up to the number of levels which are permitted in the stack area.

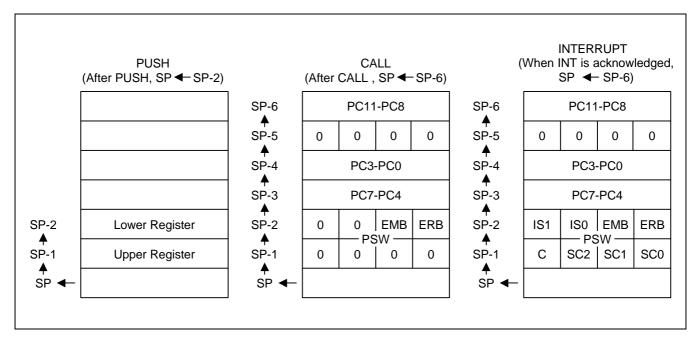

Figure 2-7. Push-Type Stack Operations

POP OPERATIONS

For each push operation there is a corresponding pop operation to write data from the stack back to the source register or registers: for the PUSH instruction it is the POP instruction; for CALL, the instruction RET or SRET; for interrupts, the instruction IRET. When a pop operation occurs, the SP is *incremented* by a number determined by the type of operation and points to the next free stack location.

POP Instructions

A POP instruction references the SP to write data stored in two 4-bit stack locations back to the register pairs and SB register. The value of the lower 4-bit register is popped first, followed by the value of the upper 4-bit register. After the POP has executed, the SP is incremented *by two* and points to the next free stack location.

RET and SRET Instructions

The end of a subroutine call is signaled by the return instruction, RET or SRET. The RET or SRET uses the SP to reference the six 4-bit stack locations used for the CALL and to write this data back to the PC, the EMB, and the ERB. After the RET or SRET has executed, the SP is incremented *by six* and points to the next free stack location.

IRET Instructions

The end of an interrupt sequence is signaled by the instruction IRET. IRET references the SP to locate the six 4-bit stack addresses used for the interrupt and to write this data back to the PC and the PSW. After the IRET has executed, the SP is incremented *by six* and points to the next free stack location.

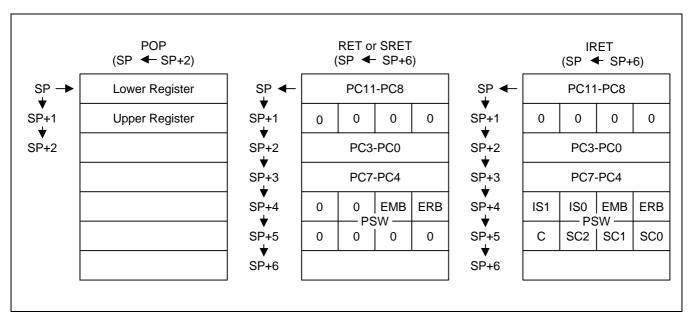

Figure 2-8. Pop-Type Stack Operations

BIT SEQUENTIAL CARRIER (BSC)

The bit sequential carrier (BSC) is a 16-bit general register that can be manipulated using 1-, 4-, and 8-bit RAM control instructions. RESET clears all BSC bit values to logic zero.

Using the BSC, you can specify sequential addresses and bit locations using 1-bit indirect addressing (memb.@L). (Bit addressing is independent of the current EMB value.) In this way, programs can process 16-bit data by moving the bit location sequentially and then incrementing or decreasing the value of the L register.

BSC data can also be manipulated using direct addressing. For 8-bit manipulations, the 4-bit register names BSC0 and BSC2 must be specified and the upper and lower 8 bits manipulated separately.

If the values of the L register are 0H at BSC0.@L, the address and bit location assignment is FC0H.0. If the L register content is FH at BSC0.@L, the address and bit location assignment is FC3H.3.

Name	Address	Bit 3	Bit 2	Bit 1	Bit 0
BSC0	FC0H	BSC0.3	BSC0.2	BSC0.1	BSC0.0
BSC1	FC1H	BSC1.3	BSC1.2	BSC1.1	BSC1.0
BSC2	FC2H	BSC2.3	BSC2.2	BSC2.1	BSC2.0
BSC3	FC3H	BSC3.3	BSC3.2	BSC3.1	BSC3.0

Table 2-4. BSC Register Organization

PROGRAMMING TIP — Using the BSC Register to Output 16-Bit Data

To use the bit sequential carrier (BSC) register to output 16-bit data (5937H) to the P3.0 pin:

	BITS SMB	EMB 15	
	LD	EA,#37H	
	LD	BSC0,EA	$BSC0 \leftarrow A, BSC1 \leftarrow E$
	LD	EA,#59H	
	LD	BSC2,EA	$BSC2 \leftarrow A, BSC3 \leftarrow E$
	SMB	0	
	LD	L,#0H	
AGN	LDB	C,BSC0.@L	
	LDB	P3.0,C	; P3.0 ← C
	INCS	L	
	JR	AGN	
	RET		

PROGRAM COUNTER (PC)

A 12-bit program counter (PC) stores addresses for instruction fetches during program execution. Whenever a reset operation or an interrupt occurs, bits PC11 through PC0 are set to the vector address.

Usually, the PC is incremented by the number of bytes of the instruction being fetched. One exception is the 1-byte REF instruction which is used to reference instructions stored in the ROM.

PROGRAM STATUS WORD (PSW)

The program status word (PSW) is an 8-bit word that defines system status and program execution status and which permits an interrupted process to resume operation after an interrupt request has been serviced. PSW values are mapped as follows:

	(MSB)			(LSB)
FB0H	IS1	IS0	EMB	ERB
FB1H	С	SC2	SC1	SC0

The PSW can be manipulated by 1-bit or 4-bit read/write and by 8-bit read instructions, depending on the specific bit or bits being addressed. The PSW can be addressed during program execution regardless of the current value of the enable memory bank (EMB) flag.

Part or all of the PSW is saved to stack prior to execution of a subroutine call or hardware interrupt. After the interrupt has been processed, the PSW values are popped from the stack back to the PSW address.

When a RESET is generated, the EMB and ERB values are set according to the RESET vector address, and the carry flag is left undefined (or the current value is retained). PSW bits IS0, IS1, SC0, SC1, and SC2 are all cleared to logical zero.

Table 2-5. Program Status Word Bit Descriptions

PSW Bit Identifier	Description	Bit Addressing	Read/Write
IS1, IS0	Interrupt status flags	1, 4	R/W
EMB	Enable memory bank flag	1	R/W
ERB	Enable register bank flag	1	R/W
С	Carry flag	1	R/W
SC2, SC1, SC0	Program skip flags	8	R

INTERRUPT STATUS FLAGS (ISO, IS1)

PSW bits IS0 and IS1 contain the current interrupt execution status values. You can manipulate IS0 and IS1 flags directly using 1-bit RAM control instructions

By manipulating interrupt status flags in conjunction with the interrupt priority register (IPR), you can process multiple interrupts by anticipating the next interrupt in an execution sequence. The interrupt priority control circuit determines the ISO and IS1 settings in order to control multiple interrupt processing. When both interrupt status flags are set to "0", all interrupts are allowed. The priority with which interrupts are processed is then determined by the IPR.

When an interrupt occurs, ISO and IS1 are pushed to the stack as part of the PSW and are automatically incremented to the next higher priority level. Then, when the interrupt service routine ends with an IRET instruction, ISO and IS1 values are restored to the PSW. Table 2-6 shows the effects of ISO and IS1 flag settings.

IS1 Value	IS0 Value	Status of Currently Executing Process	Effect of IS0 and IS1 Settings on Interrupt Request Control
0	0	0	All interrupt requests are serviced
0	1	1	Only high-priority interrupt(s) as determined in the interrupt priority register (IPR) are serviced
1	0	2	No more interrupt requests are serviced
1	1	_	Not applicable; these bit settings are undefined

Table 2-6. Interrupt Status Flag Bit Settings

Since interrupt status flags can be addressed by write instructions, programs can exert direct control over interrupt processing status. Before interrupt status flags can be addressed, however, you must first execute a DI instruction to inhibit additional interrupt routines. When the bit manipulation has been completed, execute an EI instruction to re-enable interrupt processing.

PROGRAMMING TIP — Setting ISx Flags for Interrupt Processing

The following instruction sequence shows how to use the IS0 and IS1 flags to control interrupt processing:

INTB DI ; Disable interrupt **BITR** IS1 ; IS1 \leftarrow 0

> **BITS** IS0 ; Allow interrupts according to IPR priority level

FI ; Enable interrupt

IRET

EMB FLAG (EMB)

The EMB flag is used to allocate specific address locations in the RAM by modifying the upper 4 bits of 12-bit data memory addresses. In this way, it controls the addressing mode for data memory banks 0, 1, or 15.

When the EMB flag is "0", the data memory address space is restricted to bank 15 and addresses 000H–07FH of memory bank 0, regardless of the SMB register contents. When the EMB flag is set to "1", the general-purpose areas of bank 0, 1, and 15 can be accessed by using the appropriate SMB value.

PROGRAMMING TIP — Using the EMB Flag to Select Memory Banks

EMB flag settings for memory bank selection:

1. When EMB = "0":

```
SMB
                                      : Non-essential instruction since EMB = "0"
            1
LD
            A,#9H
LD
            90H,A
                                     ; (F90H) ← A, bank 15 is selected
LD
            34H,A
                                      ; (034H) ← A, bank 0 is selected
SMB
                                     : Non-essential instruction since EMB = "0"
            90H.A
                                        (F90H) ← A, bank 15 is selected
LD
LD
            34H.A
                                        (034H) ← A, bank 0 is selected
SMB
                                     ; Non-essential instruction, since EMB = "0"
            15
            20H,A
                                     ; (020H) \leftarrow A, bank 0 is selected
LD
LD
            90H,A
                                     ; (F90H) ← A, bank 15 is selected
```

2. When EMB = "1":

```
SMB
                                     ; Select memory bank 1
LD
            A,#9H
LD
            90H,A
                                       (190H) \leftarrow A, bank 1 is selected
                                       (1340H) ← A, bank 1 is selected
LD
            34H,A
SMB
                                       Select memory bank 0
            0
LD
                                     ; (090H) ← A, bank 0 is selected
            90H,A
LD
            34H,A
                                     ; (034H) ← A, bank 0 is selected
SMB
                                     Select memory bank 15
            15
LD
            20H.A
                                     ; Program error, but assembler does not detect it
LD
            90H,A
                                       (F90H) ← A, bank 15 is selected
```

ERB FLAG (ERB)

The 1-bit register bank enable flag (ERB) determines the range of addressable working register area. When the ERB flag is "1", the working register area from register banks 0 to 3 is selected according to the register bank selection register (SRB). When the ERB flag is "0", register bank 0 is the selected working register area, regardless of the current value of the register bank selection register (SRB).

When an internal RESET is generated, bit 6 of program memory address 0000H is written to the ERB flag. This automatically initializes the flag. When a vectored interrupt is generated, bit 6 of the respective address table in program memory is written to the ERB flag, setting the correct flag status before the interrupt service routine is executed.

During the interrupt routine, the ERB value is automatically pushed to the stack area along with the other PSW bits. Afterwards, it is popped back to the FB0H.0 bit location. The initial ERB flag settings for each vectored interrupt are defined using VENTn instructions.

PROGRAMMING TIP — Using the ERB Flag to Select Register Banks

ERB flag settings for register bank selection:

1. When ERB = "0":

```
SRB
                                     ; Register bank 0 is selected (since ERB = "0", the
                                     ; SRB is configured to bank 0)
LD
            EA,#34H
                                     ; Bank 0 EA ← #34H
                                     ; Bank 0 HL \leftarrow EA
LD
            HL,EA

SKIP CONDITION FLAGS (SC2, SC1, SC0)

The skip condition flags SC2, SC1, and SC0 in the PSW indicate the current program skip conditions and are set and reset automatically during program execution. Skip condition flags can only be addressed by 8-bit read instructions. Direct manipulation of the SC2, SC1, and SC0 bits is not allowed.

CARRY FLAG (C)

The carry flag is used to save the result of an overflow or borrow when executing arithmetic instructions involving a carry (ADC, SBC). The carry flag can also be used as a 1-bit accumulator for performing Boolean operations involving bit-addressed data memory.

If an overflow or borrow condition occurs when executing arithmetic instructions with carry (ADC, SBC), the carry flag is set to "1". Otherwise, its value is "0". When a RESET occurs, the current value of the carry flag is retained during power-down mode, but when normal operating mode resumes, its value is undefined.

The carry flag can be directly manipulated by predefined set of 1-bit read/write instructions, independent of other bits in the PSW. Only the ADC and SBC instructions, and the instructions listed in Table 2-7, affect the carry flag.

Operation Type	Instructions	Carry Flag Manipulation
Direct manipulation	SCF	Set carry flag to "1"
	RCF	Clear carry flag to "0" (reset carry flag)
	CCF	Invert carry flag value (complement carry flag)
	BTST C	Test carry and skip if C = "1"
Bit transfer	LDB (operand) (1),C	Load carry flag value to the specified bit
	LDB C,(operand) (1)	Load contents of the specified bit to carry flag
Boolean manipulation	BAND C,(operand) (1)	AND the specified bit with contents of carry flag and save the result to the carry flag
	BOR C,(operand) (1)	OR the specified bit with contents of carry flag and save the result to the carry flag
	BXOR C,(operand) (1)	XOR the specified bit with contents of carry flag and save the result to the carry flag
Interrupt routine	INTn (2)	Save carry flag to stack with other PSW bits
Return from interrupt	IRET	Restore carry flag from stack with other PSW bits

Table 2-7. Valid Carry Flag Manipulation Instructions

NOTES:

- The operand has three bit addressing formats: mema.a, memb.@L, and @H + DA.b.
- 2. 'INTn' refers to the specific interrupt being executed and is not an instruction.

PROGRAMMING TIP — Using the Carry Flag as a 1-Bit Accumulator

1. Set the carry flag to logic one:

SCF ; $C \leftarrow 1$

LD EA,#0C3H ; EA \leftarrow #0C3H LD HL,#0AAH ; HL \leftarrow #0AAH

ADC EA,HL ; EA \leftarrow #0C3H + #0AAH + #1H, C \leftarrow 1

2. Logical-AND bit 3 of address 3FH with P3.3 and output the result to P5.0:

LD H,#3H ; Set the upper four bits of the address to the H register

; value

LDB C,@H+0FH.3 ; $C \leftarrow bit \ 3 \ of \ 3FH$ BAND C,P3.3 ; $C \leftarrow C \ AND \ P3.3$

LDB P4.0,C ; Output result from carry flag to P4.0

S3C72K8/P72K8 ADDRESSING MODES

3

ADDRESSING MODES

OVERVIEW

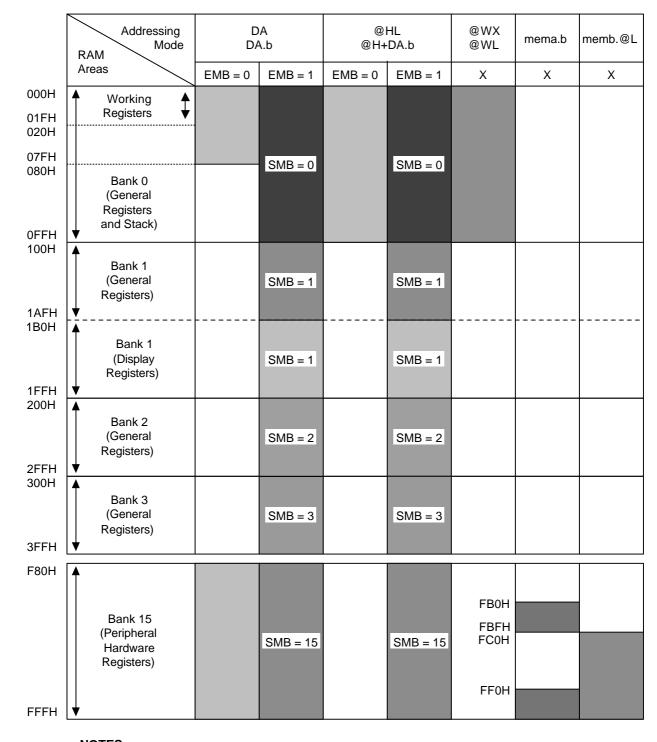

The enable memory bank flag, EMB, controls the two addressing modes for data memory. When the EMB flag is set to logic one, you can address the entire RAM area; when the EMB flag is cleared to logic zero, the addressable area in the RAM is restricted to specific locations.

The EMB flag works in connection with the select memory bank instruction, SMBn. You will recall that the SMBn instruction is used to select RAM bank 0, 1, 2, 3 or 15. The SMB setting is always contained in the upper four bits of a 12-bit RAM address. For this reason, both addressing modes (EMB = "0" and EMB = "1") apply specifically to the memory bank indicated by the SMB instruction, and any restrictions to the addressable area within banks 0, 1, 2, 3 or 15. Direct and indirect 1-bit, 4-bit, and 8-bit addressing methods can be used. Several RAM locations are addressable at all times, regardless of the current EMB flag setting.

Here are a few guidelines to keep in mind regarding data memory addressing:

- When you address peripheral hardware locations in bank 15, the mnemonic for the memory-mapped hardware component can be used as the operand in place of the actual address location.
- Always use an even-numbered RAM address as the operand in 8-bit direct and indirect addressing.
- With direct addressing, use the RAM address as the instruction operand; with indirect addressing, the instruction specifies a register which contains the operand's address.

ADDRESSING MODES S3C72K8/P72K8

NOTES:

- 1. 'X' means don't care.
- 2. Blank columns indicate RAM areas that are not addressable, given the addressing method and enable memory bank (EMB) flag setting shown in the column headers.

Figure 3-1. RAM Address Structure

S3C72K8/P72K8 ADDRESSING MODES

EMB AND ERB INITIALIZATION VALUES

The EMB and ERB flag bits are set automatically by the values of the RESET vector address and the interrupt vector address. When a RESET is generated internally, bit 7 of program memory address 0000H is written to the EMB flag, initializing it automatically. When a vectored interrupt is generated, bit 7 of the respective vector address table is written to the EMB. This automatically sets the EMB flag status for the interrupt service routine. When the interrupt is serviced, the EMB value is automatically saved to stack and then restored when the interrupt routine has completed.

At the beginning of a program, the initial EMB and ERB flag values for each vectored interrupt must be set by using VENT instruction. The EMB and ERB can be set or reset by bit manipulation instructions (BITS, BITR) despite the current SMB setting.

PROGRAMMING TIP — Initializing the EMB and ERB Flags

EMB

The following assembly instructions show how to initialize the EMB and ERB flag settings:

```
; ROM address assignment
ORG
               H0000
VENT0
               1,0,RESET
                                             ; EMB \leftarrow 1, ERB \leftarrow 0, branch RESET
VENT1
               0,1,INTB
                                             ; EMB \leftarrow 0, ERB \leftarrow 1, branch INTB
                                             ; EMB \leftarrow 0, ERB \leftarrow 1, branch INT0
VENT2
               0,1,INT0
VENT3
               0,1,INT1
                                             ; EMB \leftarrow 0, ERB \leftarrow 1, branch INT1
                                             ; EMB \leftarrow 0, ERB \leftarrow 1, branch INTS
VENT4
               0,1,INTS
VENT5
               0,1,INTT0
                                             ; EMB \leftarrow 0, ERB \leftarrow 1, branch INTT0
VENT6
                                             ; EMB \leftarrow 0, ERB \leftarrow 1, branch INTK
               0,1,INTK
```

RESET

BITR

ADDRESSING MODES S3C72K8/P72K8

ENABLE MEMORY BANK SETTINGS

EMB = "1"

When the enable memory bank flag EMB is set to logic one, you can address the data memory bank specified by the select memory bank (SMB) value (0, 1, 2, 3 or 15) using 1-, 4-, or 8-bit instructions. You can use both direct and indirect addressing modes. The addressable RAM areas when EMB = "1" are as follows:

If $SMB = 0$,	000H-0FFH
If $SMB = 1$,	100H-1FFH
If $SMB = 2$,	200H-2FFH
If $SMB = 3$,	300H-3FFH
If $SMB = 15$,	F80H-FFFH

EMB = "0"

When the enable memory bank flag EMB is set to logic zero, the addressable area is defined independently of the SMB value, and is restricted to specific locations depending on whether a direct or indirect address mode is used.

If EMB = "0", the addressable area is restricted to locations 000H–07FH in bank 0 and to locations F80H–FFFH in bank 15 for direct addressing. For indirect addressing, only locations 000H–0FFH in bank 0 are addressable, regardless of SMB value.

To address the peripheral hardware register (bank 15) using indirect addressing, the EMB flag must first be set to "1" and the SMB value to "15". When a RESET occurs, the EMB flag is set to the value contained in bit 7 of ROM address 0000H.

EMB-Independent Addressing

At any time, several areas of the data memory can be addressed independent of the current status of the EMB flag. These exceptions are described in Table 3-1.

Table 3-1. RAM Addressing Not Affected by the EMB Value

Address	Addressing Method	Affected Hardware	Program Examples
000H-0FFH	4-bit indirect addressing using WX and WL register pairs; 8-bit indirect addressing using SP	Not applicable	LD A,@WX PUSH EA POP EA
FB0H–FBFH FF0H–FFFH	1-bit direct addressing	PSW, SCMOD, IEx, IRQx, I/O	BITS EMB BITR IE4
FC0H-FFFH	1-bit indirect addressing using the L register	BSC, I/O	BTST FC3H.@L BAND C,P3.@L

S3C72K8/P72K8 ADDRESSING MODES

SELECT BANK REGISTER (SB)

The select bank register (SB) is used to assign the memory bank and register bank. The 8-bit SB register consists of the 4-bit select register bank register (SRB) and the 4-bit select memory bank register (SMB), as shown in Figure 3-2.

During interrupts and subroutine calls, SB register contents can be saved to stack in 8-bit units by the PUSH SB instruction. You later restore the value to the SB using the POP SB instruction.

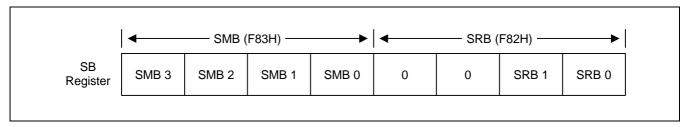

Figure 3-2. SMB and SRB Values in the SB Register

Select Register Bank (SRB) Instruction

The select register bank (SRB) value specifies which register bank is to be used as a working register bank. The SRB value is set by the 'SRB n' instruction, where n = 0, 1, 2, 3.

One of the four register banks is selected by the combination of ERB flag status and the SRB value that is set using the 'SRB n' instruction. The current SRB value is retained until another register is requested by program software. PUSH SB and POP SB instructions are used to save and restore the contents of SRB during interrupts and subroutine calls. RESET clears the 4-bit SRB value to logic zero.

Select Memory Bank (SMB) Instruction

To select one of the four available data memory banks, you must execute an SMB n instruction specifying the number of the memory bank you want (0, 1, 2, 3 or 15). For example, the instruction 'SMB 1' selects bank 1 and 'SMB 15' selects bank 15. (And remember to enable the selected memory bank by making the appropriate EMB flag setting.)

The upper four bits of the 12-bit data memory address are stored in the SMB register. If the SMB value is not specified by software (or if a RESET does not occur) the current value is retained. RESET clears the 4-bit SMB value to logic zero.

The PUSH SB and POP SB instructions save and restore the contents of the SMB register to and from the stack area during interrupts and subroutine calls.

ADDRESSING MODES S3C72K8/P72K8

DIRECT AND INDIRECT ADDRESSING

1-bit, 4-bit, and 8-bit data stored in data memory locations can be addressed directly using a specific register or bit address as the instruction operand.

Indirect addressing specifies a memory location that contains the required direct address. The S3C7 instruction set supports 1-bit, 4-bit, and 8-bit indirect addressing. For 8-bit indirect addressing, an even-numbered RAM address must always be used as the instruction operand.

1-BIT ADDRESSING

Table 3-2. 1-Bit Direct and Indirect RAM Addressing

Operand Notation	Addressing Mode Description	EMB Flag Setting	Addressable Area	Memory Bank	Hardware I/O Mapping
			000H-07FH	Bank 0	_
DA.b	Direct: bit is indicated by the RAM address (DA), memory bank selection, and specified bit number (b).	0	F80H-FFFH	Bank 15	All 1-bit addressable peripherals (SMB = 15)
		1	000H-FFFH	SMB = 0-3,15	
mema.b	Direct: bit is indicated by addressable area (mema) and bit number (b).	х	FB0H–FBFH FF0H–FFFH	Bank 15	ISO, IS1, EMB, ERB, IEx, IRQx, Pn.n
memb.@L	Indirect: lower two bits of register L as indicated by the upper 10 bits of RAM area (memb) and the upper two bits of register L.	Х	FC0H-FFFH	Bank 15	BSCn.x Pn.n
@H + DA.b	Indirect: bit indicated by the lower four bits of the address (DA), memory bank selection, and the H register identifier.	0	000H-0FFH	Bank 0	-
		1	000H-FFFH	SMB = 0-3,15	All 1-bit addressable peripherals (SMB = 15)

NOTE: 'x' means don't care.

MEMORY MAP

OVERVIEW

To support program control of peripheral hardware, I/O addresses for peripherals are memory-mapped to bank 15 of the RAM. Memory mapping lets you use a mnemonic as the operand of an instruction in place of the specific memory location.

Access to bank 15 is controlled by the select memory bank (SMB) instruction and by the enable memory bank flag (EMB) setting. If the EMB flag is "0", bank 15 can be addressed using direct addressing, regardless of the current SMB value. 1-bit direct and indirect addressing can be used for specific locations in bank 15, regardless of the current EMB value.

I/O MAP FOR HARDWARE REGISTERS

Table 4-1 contains detailed information about I/O mapping for peripheral hardware in bank 15 (register locations F80H–FFFH). Use the I/O map as a quick-reference source when writing application programs. The I/O map gives you the following information:

- Register address
- Register name (mnemonic for program addressing)
- Bit values (both addressable and non-manipulable)
- Read-only, write-only, or read and write addressability
- 1-bit, 4-bit, or 8-bit data manipulation characteristics

Table 4-1. I/O Map for Memory Bank 15

Addressing	Symbol	Description	Affected Memory mapped I/O
1-bit direct addressing	DA.b	The bit indicated by memory bank, DA and bit. (EMB=0, or EMB=1 and SMB 15)	All peripheral hardware that can be manipulated in 1 bit.
4-bit direct addressing	DA	The address indicated by memory bank and DA. (EMB=0, or EMB=1 and SMB 15)	All peripheral hardware that can be manipulated in 4 bits.
8-bit direct addressing	DA	The address (DA specifies an even address) indicated by memory bank and DA. (EMB=0, or EMB=1 and SMB 15)	All peripheral hardware that can be manipulated in 8 bits.
4-bit indirect addressing	@HL	The address indicated by memory bank and HL register. (EMB=1 and SMB 15)	All peripheral hardware that can be manipulated in 4 bits.
8-bit indirect addressing	@HL	The address indicated by memory bank and HL (the contents of the L register are even). (EMB=1 and SMB 15)	All peripheral hardware that can be manipulated in 8 bit.
1-bit manipulating addressing	mema.b	The bit indicated by mema and bit. (regardless of the status of EMB and SMB)	IS0, IS1, EMB, ERB, IEx, IRQx, Pn.m
	memb.@ L	The bit indicated by the lower 2 bits of the L register of the address indicated by the upper 10 bits of memb and the upper 2 bits of the L reigster. (regardless of the status of EMB and SMB)	Pn.m
	@H+DA.b	The bit of the address indicated by memory bank, H register and the lower 4 bits of DA. (EMB=1 and SMB=15)	All peripheral hardware that can be manipulated in 1 bit.

NOTES:

- 1. The carry flag can be read or written by specific bit manipulation instructions only.
- 2. P5 is mapped at RAM locations 1F0H-1FFH. (Refer to 12-13 page)

REGISTER DESCRIPTIONS

In this section, register descriptions are presented in a consistent format to familiarize you with the memory-mapped I/O locations in bank 15 of the RAM. Figure 4-1 describes features of the register description format. Register descriptions are arranged in alphabetical order. Programmers can use this section as a quick-reference source when writing application programs.

Counter registers, buffer registers, and reference registers, as well as the stack pointer and port I/O latches, are not included in these descriptions. More detailed information about how these registers are used is included in Part II of this manual, "Hardware Descriptions", in the context of the corresponding peripheral hardware module descriptions.

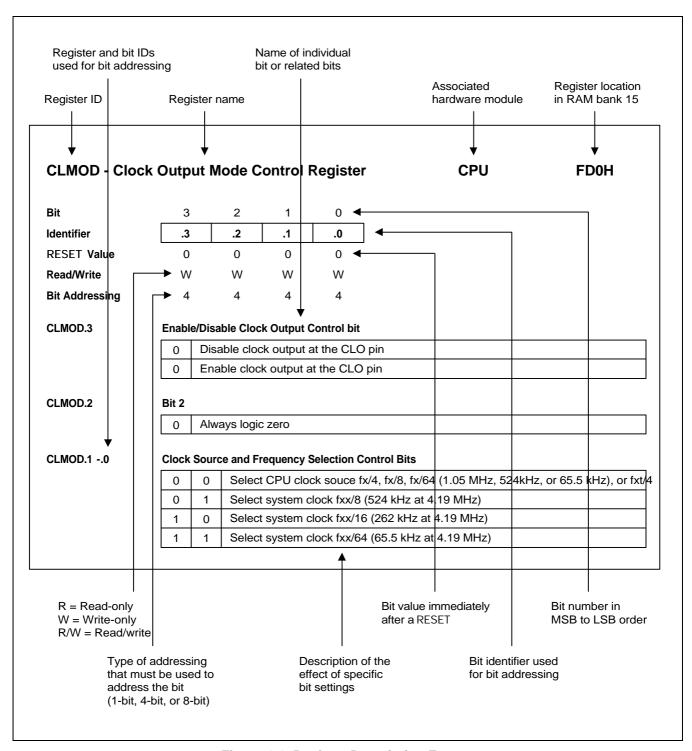

Figure 4-1. Register Description Format

BMOD — Basic Timer Mode Register

BT

F85H

Bit 3
Identifier .3
RESET Value 0
Read/Write W
Bit Addressing 1/4

3	2	1	0
.3	.2	.1	.0
0	0	0	0
W	W	W	W
1/4	4	4	4

BMOD.3

Basic Timer Restart Bit

1 Restart basic timer, then clear IRQB flag, BCNT and BMOD.3 to logic zero

BMOD.2-.0

Input Clock Frequency and Signal Stabilization Interval Control Bits

0	0	0	Input clock frequency: Interrupt interval time (wait time):	fxx/2 ¹² (1.02 kHz) 2 ²⁰ /fxx (250 ms)
0	1	1	Input clock frequency: Interrupt interval time (wait time):	fxx/2 ⁹ (8.18 kHz) 2 ¹⁷ /fxx (31.3 ms)
1	0	1	Input clock frequency: Interrupt interval time (wait time):	fxx/2 ⁷ (32.7 kHz) 2 ^{15/} fxx (7.82 ms)
1	1	1	Input clock frequency: Interrupt interval time (wait time):	fxx/2 ⁵ (131 kHz) 2 ¹³ /fxx (1.95 ms)

NOTES:

- 1. When a RESET occurs, the oscillation stabilization time is 31.3 ms (2¹⁷/fxx) at 4.19 MHz..
- 2. 'fxx' is the system clock rate given a clock frequency of 4.19 MHz.

CLMOD — Clock Output Mode Register

CPU

FD0H

Bit	3	2	1	0
Identifier	.3	"0"	.1	.0
RESET Value	0	0	0	0
Read/Write	W	W	W	W
Bit Addressing	4	4	4	4

CLMOD.3 Enable/Disable Clock Output Control Bit

0	Disable clock output at the CLO pin
1	Enable clock output at the CLO pin

CLMOD.2 Bit 2

0 Always logic zero

CLMOD.1–.0 Clock Source and Frequency Selection Control Bits

0	0	Select CPU clock source fxx/4, fxx/8 or fxx/64 (1.05 MHz, 524 kHz or 65.5 kHz); Refer to PCON
0	1	Select clock fxx/8 (524 kHz)
1	0	Select clock fxx/16 (262 kHz)
1	1	Select clock fxx/64 (65.5 kHz)

NOTE: "fx" is the main clock, given a clock frequency of 4.19 MHz.

CMOD — Comparator Mode Register

COMPARATOR

FD7H, FD6H

Bit Identifier RESET Value Read/Write Bit Addressing

7	6	5	4	3	2	1	0
.7	.6	.5	"0"	.3	.2	.1	.0
0	0	0	0	0	0	0	0
R/W							
8	8	8	8	8	8	8	8

.7 Comparator Enable/Disable Bit

0	Comparator operation disable
1	Comparator operation enable

.6 Conversion Timer Control Bit

0	4×2^8 /fx, 244.4 µs at 4.19 MHz
1	4×2^{5} /fx, 30.5 µs at 4.19 MHz

.5 External/Internal Reference Selection Bit

0	Internal reference, CIN0-1; analog input
1	External reference at CIN0, CIN1; analog input

.4 Bit 4

.3-.0 Reference Voltage Selection Bits

Selected
$$V_{REF} = V_{DD} \times \frac{(N+0.5)}{16}$$
, N = 0 to 15

.3-.2

Bits 3-2

_			
0	Alwavs	logic	zero

IET0

INTTO Interrupt Enable Flag

0	Disable INTT0 interrupt requests
1	Enable INTT0 interrupt requests

IRQT0

INTTO Interrupt Request Flag

 Generate INTT0 interrupt (This bit is set and cleared automatically by hardware when contents of TCNT0 and TREF0 registers match.)

IEK, IRQK — INTK Interrupt Enable/Request Flags

CPU

FBBH

Bit	3	2	1	0
Identifier	"0"	"0"	IEK	IRQK
RESET Value	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W
Bit Addressing	1/4	1/4	1/4	1/4

IEK INTK Interrupt Enable Flag

0	Disable interrupt requests at the K0–K3 pins
1	Enable interrupt requests at the K0–K3 pins

IRQK INTK Interrupt Request Flag

 Generate INTK interrupt (This bit is set and cleared automatically by hardware when rising or falling edge detected at K0–K3 pins.)

IEW, IRQW — INTW Interrupt Enable/Request Flags CPU

0 Bit 3 2 1 "0" "0" Identifier **IEW IRQW** 0 0 0 0 **RESET Value** Read/Write R/W R/W R/W R/W **Bit Addressing** 1/4 1/4 1/4 1/4

.3-.2 Bits 3-2

0 Always logic zero

IEW INTW Interrupt Enable Flag

0	Disable INTW interrupt requests
1	Enable INTW interrupt requests

IRQW INTW Interrupt Request Flag

Generate INTW interrupt (This bit is set when the timer interval is set to 0.5 seconds or 3.91 milliseconds.)

NOTE: Since INTW is a quasi-interrupt, the IRQW flag must be cleared by software.

1	Turn on the internal LCD bias TR	1

NOTES:

- 1. In case of LCON.0, you can turn on/off internal LCD bias TR.
- 2. In case of internal LCD bias

When LCON.1–.0 = #00B, LCD display is turned off. When LCON.1–.0 = #11B, LCD display is turned on.

- 3. In case of external LCD bias
 - When LCON.1–.0 = #00B and V_{LC5} = "High", LCD display is turned off.
 - When LCON.1–.0 = #10B and V_{LC5} = "Low", LCD display is turned on.
- 4. To select LCD bias, you must use both the LCON.3 setting and an external LCD bias circuit connection.

0	Enable sub system clock
1	Disable sub system clock

SCMOD.1 Bit 1

0 Always logic zero

SCMOD.0 Bit 0

0	Select main system clock
1	Select sub system clock

NOTES:

- 1. Sub-oscillation goes into stop mode only by SCMOD.2. PCON which revokes stop mode cannot stop the sub-oscillation.
- You can use SCMOD.2 as follows (ex; after data bank was used, a few minutes have passed):
 Main operation → sub-operation → sub-idle (LCD on, after a few minutes later without any external input) → sub-operation → main operation → SCMOD.2 = 1 → main stop mode (LCD off).
- 3. SCMOD bits 3–0 cannot be modified simultaneously by a 4-bit instruction; they can only be modified by separate 1-bit instructions.

1	Select subsystem clock as the watch timer clock Select subsystem clock as the LCD clock source

NOTE: RESET sets WMOD.3 to the current input level of the subsystem clock, XT_{IN}. If the input level is high, WMOD.3 is set to logic one; if low, WMOD.3 is cleared to zero along with all the other bits in the WMOD register.

S3C72K8/P72K8 OSCILLATOR CIRCUITS

6

OSCILLATOR CIRCUITS

OVERVIEW

The S3C72K8 microcontroller have two oscillator circuits: a main system clock circuit, and a subsystem clock circuit. The CPU and peripheral hardware operate on the system clock frequency supplied through these circuits. Specifically, a clock pulse is required by the following peripheral modules:

- LCD controller
- Basic timer
- Timer/counter 0
- Watch timer
- Serial I/O interface
- Clock output circuit

CPU Clock Notation

In this document, the following notation is used for descriptions of the CPU clock:

- fx Main-system clock
- fxt Sub-system clock
- fxx Selected system clock

Clock Control Registers

When the system clock mode register, SCMOD, and the power control register, PCON, are both cleared to zero after RESET, the normal CPU operating mode is enabled, a main system clock is selected as fx/64, and main system clock oscillation is initiated.

The PCON is used to select normal CPU operating mode or one of two power down mode-stop or idle. Bits 3 and 2 of the PCON register can be manipulated by STOP or IDLE instruction to engage stop or idle power down mode.

The SCMOD, lets you select the main system clock (fx) or a subsystem clock (fxt) as the CPU clock and start (or stop) main/sub system clock oscillation. The resulting clock source, either main system clock or subsystem clock, is referred to the selected system clock (fxx).

The main system clock is selected and oscillation started when all SCMOD bits are cleared to "0". By setting SCMOD.3, SCMOD.2 and SCMOD.0 to different values, you can select a subsystem clock source and start or stop main/sub system clock oscillation. To stop main system clock oscillation, you must use the STOP instruction (assuming the main system clock is selected) or manipulate SCMOD.3 to (assuming the sub system clock is selected).

The main system clock frequencies can be divided by 4, 8, or 64 and a subsystem clock frequencies can only be divided by 4. By manipulating PCON bits 1 and 0, you select one of the following frequencies as the CPU clock.

fx/4, fxt/4, fx/8, fx/64

OSCILLATOR CIRCUITS S3C72K8/P72K8

Using a Subsystem Clock

If a subsystem clock is being used as the selected system clock, the idle power-down mode can be initiated by executing an IDLE instruction.

The watch timer, buzzer and LCD display operate normally with a subsystem clock source, since they operate at very low speed (as low as $122 \,\mu s$ at $32.768 \,kHz$) and with very low power consumption. Other hardware such as the basic timer, timer/counter 0 and the serial I/O interface should not be driven using the subsystem clock, since they require higher operating speeds for normal performance.

POWER CONTROL REGISTER (PCON)

The power control register, PCON, is a 4-bit register that is used to select the CPU clock frequency and to control CPU operating and power-down modes. PCON can be addressed directly by 4-bit write instructions or indirectly by the instructions IDLE and STOP.

FB3H	PCON.3	PCON.2	PCON.1	PCON.0

PCON bits 3 and 2 are addressed by the STOP and IDLE instructions, respectively, to engage the idle and stop power-down modes. Idle and stop modes can be initiated by these instruction despite the current value of the enable memory bank flag (EMB). PCON bits 1 and 0 are used to select a specific system clock frequency. There are two basic choices:

- Main system clock (fx) or subsystem clock (fxt);
- Divided fx/4, 8, 64 or fxt/4 clock frequency.

PCON.1 and PCON.0 settings are also connected with the system clock mode control register, SCMOD. If SCMOD.0 = "0" the main system clock is always selected by the PCON.1 and PCON.0 setting; if SCMOD.0 = "1" the subsystem clock is selected.

RESET sets PCON register values (and SCMOD) to logic zero: SCMOD.3 and SCMOD.0 select the main system clock (fx) and start clock oscillation; PCON.1 and PCON.0 divide the selected fx frequency by 64, and PCON.3 and PCON.2 enable normal CPU operating mode.

Table 6-1. Power Control Register (PCON) Organization

PCON Bit Settings		Resulting CPU Operating Mode	
PCON.3 PCON.2			
0	0	Normal CPU operating mode	
0	1	Idle power-down mode	
1	0	Stop power-down mode	

PCON Bit Settings		Resulting CPU Clock Frequency	
PCON.1	PCON.0	If SCMOD.0 = "0"	If SCMOD.0 = "1"
0	0	fx/64	fxt/4
1	0	fx/8	
1	1	fx/4

LD PCON,A

S3C72K8/P72K8 OSCILLATOR CIRCUITS

INSTRUCTION CYCLE TIMES

The unit of time that equals one machine cycle varies depending on whether the main system clock (fx) or a subsystem clock (fxt) is used, and on how the oscillator clock signal is divided (by 4, 8, or 64). Table 6-2 shows corresponding cycle times in microseconds.

Table 6-2. Instruction Cycle Times for CPU Clock Rates

Selected CPU Clock	Resulting Frequency	Oscillation Source	Cycle Time (μsec)
fx/64	65.5 kHz	fx = 4.19 MHz	15.3
fx/8	524.0 kHz		1.91
fx/4	1.05 MHz		0.95
fxt/4	8.19 kHz	fxt = 32,768 kHz	122.0

OSCILLATOR CIRCUITS S3C72K8/P72K8

SYSTEM CLOCK MODE REGISTER (SCMOD)

The system clock mode register, SCMOD, is a 4-bit register that is used to select the CPU clock and to control main and sub-system clock oscillation. The SCMOD is mapped to the RAM address FB7H.

The main clock oscillation is stopped by setting SCMOD.3 when the clock source is subsystem clock and subsystem clock can be stopped by setting SCMOD.2 when the clock source is main system clock. SCMOD.0, SCMOD.3 cannot be simultaneously modified.

The subsystem clock is stopped only by setting SCMOD.2, and PCON which revokes stop mode cannot stop the subsystem clock. The stop of subsystem clock is released by RESET when the selected system clock is main system clock or subsystem clock and is released by setting SCMOD.2 when the selected system clock is main system clock.

RESET clears all SCMOD values to logic zero, selecting the main system clock (fx) as the CPU clock and starting clock oscillation. The reset value of the SCMOD is "0".

SCMOD.0, SCMOD.2, and SCMOD.3 bits can be manipulated by 1-bit write instructions (In other words, SCMOD.0, SCMOD.2, and SCMOD.3 cannot be modified simultaneously by a 4-bit write). Bit 1 is always logic zero.

FB7H SCMOD.3 SCMOD.2 "0" SCMOD

A subsystem clock (fxt) can be selected as the system clock by manipulating the SCMOD.3 and SCMOD.0 bit settings. If SCMOD.3 = "0" and SCMOD.0 = "1", the subsystem clock is selected and main system clock oscillation continues. If SCMOD.3 = "1" and SCMOD.0 = "1", fxt is selected, but main system clock oscillation stops.

Even if you have selected fx as the CPU clock, setting SCMOD.3 to "1" will stop main system clock oscillation, and malfunction may be occurred. To operate safely, main system clock should be stopped by a stop instruction is main system clock mode.

SCMOD Register Bit Settings		Resulting Clock Selection	
SCMOD.3	SCMOD.0	CPU Clock	fx Oscillation
0	0	fx	On
0	1	fxt	On
1	1	fyt	Off

Table 6-3. System Clock Mode Register (SCMOD) Organization

Table 6-4. SCMOD.2 for Sub-oscillation On/Off

SCMOD.2	Sub-oscillation on/off
0	Enable sub system clock
1	Disable sub system clock

NOTE: You can use SCMOD.2 as follows (ex; after data bank was used, a few minutes have passed): Main operation \rightarrow sub-operation \rightarrow sub-idle (LCD on, after a few minutes later without any external input) \rightarrow sub-operation \rightarrow main operation \rightarrow SCMOD.2 = 1 \rightarrow main stop mode (LCD off).

S3C72K8/P72K8 OSCILLATOR CIRCUITS

Table 6-5. Main/Sub Oscillation Stop Mode

Mode	Condition	Method to issue OSC Stop	OSC Stop Release Source (2)
Main Oscillation STOP Mode	Main oscillator runs. Sub oscillator runs (stops). System clock is the main oscillation clock.	STOP instruction: Main oscillator stops. CPU is in idle mode. Sub oscillator still runs (stops).	Interrupt and RESET: After releasing stop mode, main oscillation starts and oscillation stabilization time is elapsed. And then the CPU operates. Oscillation stabilization time is 1/[256 x BT clock (fx)]
		When SCMOD.3 is set to "1" (1), main oscillator stops, halting the CPU operation. Sub oscillator still runs (stops).	RESET: Interrupt can't start the main oscillation. Therefore, the CPU operation can never be restarted.
	Main oscillator runs. Sub oscillator runs. System clock is the sub oscillation clock.	STOP instruction ⁽¹⁾ : Main oscillator stops. CPU is in idle mode. Sub oscillator still runs (stops). Sub oscillator still runs.	BT overflow, interrupt, and RESET: After the overflow of basic timer [1/(256 x BT clock (fxt))], CPU operation and main oscillation automatically start.
		When SCMOD.3 is set to "1", main oscillator stops. The CPU, however, would still operate. Sub oscillator still runs.	Set SCMOD.3 to "0" or RESET
Sub Oscillation STOP Mode	Main oscillator runs. Sub oscillator runs. System clock is the main oscillation clock.	When SCMOD.2 to "1", sub oscillator stops, while main oscillator and the CPU would still operate.	Set SCMOD.2 to "0" or RESET
	Main oscillator runs (stops). Sub oscillator runs. System clock is the sub oscillation clock.	When SCMOD.2 to "1", sub oscillator stops, halting the CPU operation. Main oscillator still runs (stops).	RESET

NOTES:

- 1. This mode must not be used.
- 2. Oscillation stabilization time by interrupt is 1/(256 x BT clocks). Oscillation stabilization time by a reset is 31.3 ms at 4.19 MHz, main oscillation clock.

OSCILLATOR CIRCUITS S3C72K8/P72K8

SWITCHING THE CPU CLOCK

Together, bit settings in the power control register, PCON, and the system clock mode register, SCMOD, determine whether a main system or a subsystem clock is selected as the CPU clock, and also how this frequency is to be divided. This makes it possible to switch dynamically between main and subsystem clocks and to modify operating frequencies.

SCMOD.3, SCMOD.2, and SCMOD.0 select the main system clock (fx) or a subsystem clock (fxt) and start or stop main system clock oscillation. PCON.1 and PCON.0 control the frequency divider circuit, and divide the selected fx clock by 4, 8, or 64, or fxt clock by 4.

NOTE

A clock switch operation does not go into effect immediately when you make the SCMOD and PCON register modifications — the previously selected clock continues to run for a certain number of machine cycles.

For example, you are using the default CPU clock (normal operating mode and a main system clock of fx/64) and you want to switch from the fx clock to a subsystem clock and to stop the main system clock. To do this, you first need to set SCMOD.0 to "1". This switches the clock from fx to fxt but allows main system clock oscillation to continue. Before the switch actually goes into effect, a certain number of machine cycles must elapse. After this time interval, you can then disable main system clock oscillation by setting SCMOD.3 to "1".

This same 'stepped' approach must be taken to switch from a subsystem clock to the main system clock: first, clear SCMOD.3 to "0" to enable main system clock oscillation. Then, after a certain number of machine cycles has elapsed, select the main system clock by clearing all SCMOD values to logic zero.

Following a RESET, CPU operation starts with the lowest main system clock frequency of 15.3 μ s at 4.19 MHz after the standard oscillation stabilization interval of 31.3 ms has elapsed. Table 6-4 details the number of machine cycles that must elapse before a CPU clock switch modification goes into effect.

	AFTER	SCMOD.0 = 0			SCMOD.0 = 1			
BEFORE		PCON.1 = 0	PCON.0 = 0	PCON.1 = 1	PCON.0 = 0	PCON.1 = 1	PCON.0 = 1	
	PCON.1 = 0	N	/A	1 Machi	ne Cycle	1 Machi	ne Cycle	N/A
	PCON.0 = 0							
SCMOD.0 = 0	PCON.1 = 1	8 Machin	ne Cycles	N	/A	1 Machi	ne Cycle	N/A
	PCON.0 = 0							
	PCON.1 = 1	16 Machi	ne Cycles	1 Machi	ne Cycle	N	/A	fx / 4fxt
	PCON.0 = 1							
SCMOD.0 = 1	·	N	/A	N	/A	1 Machi	ne Cycle	N/A

Table 6-6. Elapsed Machine Cycles During CPU Clock Switch

NOTES:

- 1. Even if oscillation is stopped by setting SCMOD.3 during main system clock operation, the stop mode is not entered.
- 2. Since the X_{IN} input is connected internally to V_{SS} to avoid current leakage due to the crystal oscillator in stop mode, do not set SCMOD.3 to "1" or do not use stop instruction when an external clock is used as the main system clock.
- 3. When the system clock is switched to the subsystem clock, it is necessary to disable any interrupts which may occur during the time intervals shown in Table 6-6.
- 4. 'N/A' means 'not available'.
- 5. fx: Main-system clock, fxt: Sub-system clock. When fx is 4.19 MHz, and fxt is 32.768 kHz.

CLOCK OUTPUT MODE REGISTERS (CLMOD)

The clock output mode register, CLMOD, is a 4-bit register that is used to enable or disable clock output to the CLO pin and to select the CPU clock source and frequency. CLMOD is addressable by 4-bit write instructions only.

FD0H CLMOD.3 "0" CLMOD.1 C	D.0
----------------------------	-----

RESET clears CLMOD to logic zero, which automatically selects the CPU clock as the clock source (without initiating clock oscillation), and disables clock output.

CLMOD.3 is the enable/disable clock output control bit; CLMOD.1 and CLMOD.0 are used to select one of four possible clock sources and frequencies: normal CPU clock, fxx/8, fxx/16, or fxx/64.

Table 6-7. Clock Output Mode Register (CLMOD) Organization

CLMOD Bit Settings		Resulting Clock Output		
CLMOD.1	CLMOD.0	Clock Source	Frequency	
0	0	CPU clock (fx/4, fx/8, fx/64, fxt/4)	1.05 MHz, 524 kHz, 65.5 kHz, 8.2 kHz	
0	1	fxx/8	524 kHz	
1	0	fxx/16	262 kHz	
1	1	fxx/64	65.5 kHz	

CLMOD1.3	MOD1.3 Result of CLMOD1.3 Setting	
0	Clock output is disabled (CLO1, CLO2)	
1	Clock output is enabled (CLO1, CLO2)	

NOTE: Frequencies assume that fxx, fx = 4.19 MHz and fxt is 32,768 kHz.

S3C72K8/P72K8 OSCILLATOR CIRCUITS

CLOCK OUTPUT CIRCUIT

The clock output circuit, used to output clock pulses to the CLO pin, has the following components:

- 4-bit clock output mode register (CLMOD)
- Clock selector
- Output latch
- Port mode flag
- CLO output pin (P4.0)

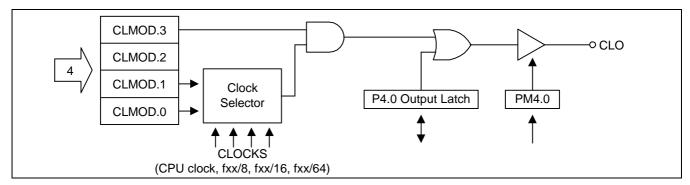

Figure 6-7. CLO Output Pin Circuit Diagram

CLOCK OUTPUT PROCEDURE

The procedure for outputting clock pulses to the CLO pin may be summarized as follows:

- 1. Disable clock output by clearing CLMOD.3 to logic zero.
- 2. Set the clock output frequency (CLMOD.1, CLMOD.0).
- 3. Load a "0" to the output latch of the CLO pin (P4.0).
- 4. Set the P4.0 mode flag (PM4.0) to output mode.
- 5. Enable clock output by setting CLMOD.3 to logic one.

S3C72K9/P72K8 INTERRUPTS

7 INTERRUPTS

OVERVIEW

The S3C72K8 interrupt control circuit has five functional components:

- Interrupt enable flags (IEx)
- Interrupt request flags (IRQx)
- Interrupt master enable register (IME)
- Interrupt priority register (IPR)
- Power-down release signal circuit

Three kinds of interrupts are supported:

- Internal interrupts generated by on-chip processes
- External interrupts generated by external peripheral devices
- Quasi-interrupts used for edge detection and as clock sources

Table 7-1. Interrupt Types and Corresponding Port Pin(s)

Interrupt Type	Interrupt Name	Corresponding Port Pins
External interrupts	INT0, INT1, INT4, INTK	P1.0, P1.1, P1.3, K0–K3
Internal interrupts	INTB, INTTO, INTS	Not applicable
Quasi-interrupts	INT2	P1.2
	INTW	Not applicable

INTERRUPTS S3C72K9/P72K8

Vectored Interrupts

Interrupt requests may be processed as vectored interrupts in hardware, or they can be generated by program software. A vectored interrupt is generated when the following flags and register settings, corresponding to the specific interrupt (INTn) are set to logic one:

- Interrupt enable flag (IEx)
- Interrupt master enable flag (IME)
- Interrupt request flag (IRQx)
- Interrupt status flags (IS0, IS1)
- Interrupt priority register (IPR)

If all conditions are satisfied for the execution of a requested service routine, the start address of the interrupt is loaded into the program counter and the program starts executing the service routine from this address.

EMB and ERB flags for RAM memory banks and registers are stored in the vector address area of the ROM during interrupt service routines. The flags are stored at the beginning of the program with the VENT instruction. The initial flag values determine the vectors for resets and interrupts. Enable flag values are saved during the main routine, as well as during service routines. Any changes that are made to enable flag values during a service routine are not stored in the vector address.

When an interrupt occurs, the enable flag values before the interrupt is initiated are saved along with the program status word (PSW), and the enable flag values for the interrupt is fetched from the respective vector address. Then, if necessary, you can modify the enable flags during the interrupt service routine. When the interrupt service routine is returned to the main routine by the IRET instruction, the original values saved in the stack are restored and the main program continues program execution with these values.

Software-Generated Interrupts

To generate an interrupt request from software, the program manipulates the appropriate IRQx flag. When the interrupt request flag value is set, it is retained until all other conditions for the vectored interrupt have been met, and the service routine can be initiated.

Multiple Interrupts

By manipulating the two interrupt status flags (ISO and IS1), you can control service routine initialization and thereby process multiple interrupts simultaneously.

If more than four interrupts are being processed at one time, you can avoid possible loss of working register data by using the PUSH RR instruction to save register contents to the stack before the service routines are executed in the same register bank. When the routines have executed successfully, you can restore the register contents from the stack to working memory using the POP instruction.

Power-Down Mode Release

An interrupt (with the exception of INT0) can be used to release power-down mode (stop or idle). Interrupts for power-down mode release are initiated by setting the corresponding interrupt enable flag. Even if the IME flag is cleared to zero, power-down mode will be released by an interrupt request signal when the interrupt enable flag has been set. In such cases, the interrupt routine will not be executed since IME = "0".

S3C72K9/P72K8 INTERRUPTS

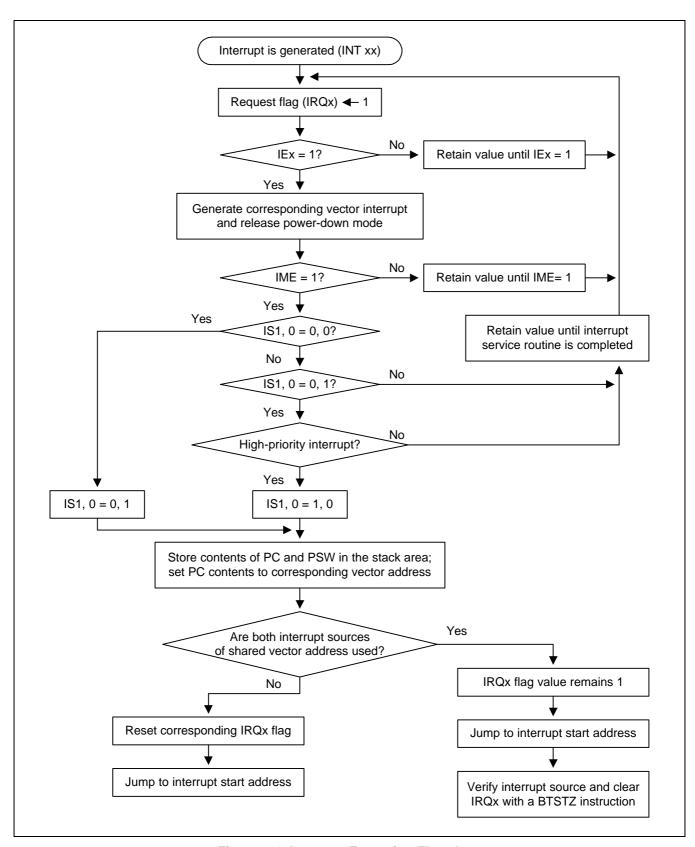

Figure 7-1. Interrupt Execution Flowchart

INTERRUPTS S3C72K9/P72K8

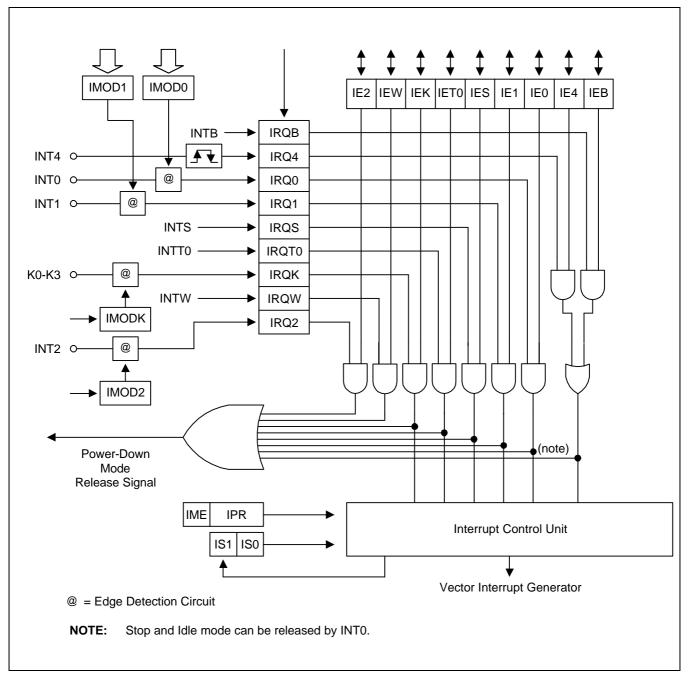

Figure 7-2. Interrupt Control Circuit Diagram

S3C72K9/P72K8 INTERRUPTS

MULTIPLE INTERRUPTS

The interrupt controller can service multiple interrupts in two ways: as two-level interrupts, where either all interrupt requests or only those of highest priority are serviced, or as multi-level interrupts, when the interrupt service routine for a lower-priority request is accepted during the execution of a higher priority routine.

Two-Level Interrupt Handling

Two-level interrupt handling is the standard method for processing multiple interrupts. When the IS1 and IS0 bits of the PSW (FB0H.3 and FB0H.2, respectively) are both logic zero, program execution mode is normal and all interrupt requests are serviced (see Figure 7-3).

Whenever an interrupt request is accepted, IS1 and IS0 are incremented by one ("0" \rightarrow "1" or "1" \rightarrow "0"), and the values are stored in the stack along with the other PSW bits. After the interrupt routine has been serviced, the modified IS1 and IS0 values are automatically restored from the stack by an IRET instruction.

ISO and IS1 can be manipulated directly by 1-bit write instructions, regardless of the current value of the enable memory bank flag (EMB). Before you can modify an interrupt service flag, however, you must first disable interrupt processing with a DI instruction.

When IS1 = "0" and IS0 = "1", all interrupt service routines are inhibited except for the highest priority interrupt currently defined by the interrupt priority register (IPR).

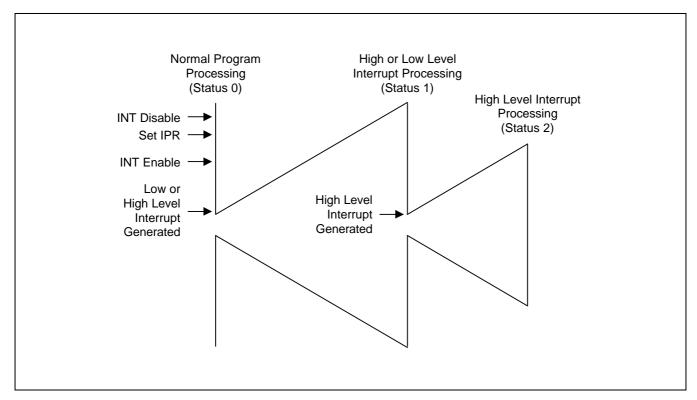

Figure 7-3. Two-Level Interrupt Handling

INTERRUPTS S3C72K9/P72K8

Multi-Level Interrupt Handling

With multi-level interrupt handling, a lower-priority interrupt request can be executed while a high-priority interrupt is being serviced. This is done by manipulating the interrupt status flags, ISO and IS1 (see Table 7-2).

When an interrupt is requested during normal program execution, interrupt status flags ISO and IS1 are set to "1" and "0", respectively. This setting allows only highest-priority interrupts to be serviced. When a high-priority request is accepted, both interrupt status flags are then cleared to "0" by software so that a request of any priority level can be serviced. In this way, the high- and low-priority requests can be serviced in parallel (see Figure 7-4).

Process Status Before INT		re INT	Effect of ISx Bit Setting	After INT ACK	
	IS1	IS0		IS1	IS0
0	0	0	All interrupt requests are serviced.		1
1	0	1	Only high-priority interrupts as determined by the current settings in the IPR register are serviced.		0
2	1	0	No additional interrupt requests will be serviced.	_	_
_	1	1	Value undefined	_	_

Table 7-2. IS1 and IS0 Bit Manipulation for Multi-Level Interrupt Handling

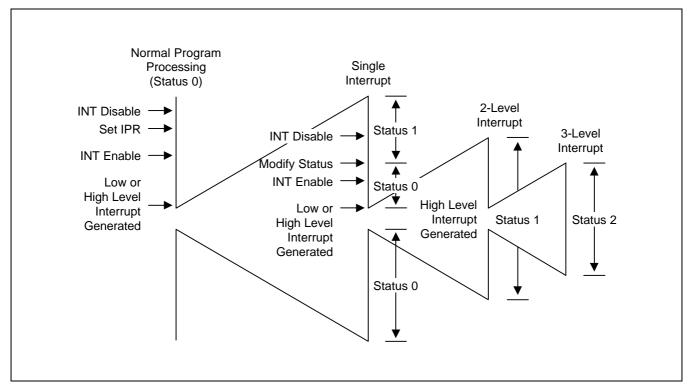

Figure 7-4. Multi-Level Interrupt Handling

S3C72K9/P72K8 INTERRUPTS

INTERRUPT PRIORITY REGISTER (IPR)

The 4-bit interrupt priority register (IPR) is used to control multi-level interrupt handling. Its reset value is logic zero. Before the IPR can be modified by 4-bit write instructions, all interrupts must first be disabled by a DI instruction.

FB2H	IME	IPR.2	IPR.1	IPR.0

By manipulating the IPR settings, you can choose to process all interrupt requests with the same priority level, or you can select one type of interrupt for high-priority processing. A low-priority interrupt can itself be interrupted by a high-priority interrupt, but not by another low-priority interrupt. A high-priority interrupt cannot be interrupted by any other interrupt source.

 Interrupt
 Default Priority

 INTB, INT4
 1

 INT0
 2

 INT1
 3

 INTS
 4

 INTT0
 5

 INTK
 6

Table 7-3. Standard Interrupt Priorities

The MSB of the IPR, the interrupt master enable flag (IME), enables and disables all interrupt processing. Even if an interrupt request flag and its corresponding enable flag are set, a service routine cannot be executed until the IME flag is set to logic one. The IME flag can be directly manipulated by EI and DI instructions, regardless of the current enable memory bank (EMB) value.

IPR.2	IPR.1	IPR.0	Result of IPR Bit Setting		
0	0	0	Process all interrupt requests at low priority ^(note)		
0	0	1	Process INTB and INT4 interrupts only		
0	1	0	Process INT0 interrupts only		
0	1	1	Process INT1 interrupts only		
1	0	0	Process INTS interrupts only		
1	0	1	Process INTT0 interrupts only		
1	1	0	Process INTK interrupts only		

Table 7-4. Interrupt Priority Register Settings

NOTE: When all interrupts are low priority (the lower three bits of the IPR register are logic zero), the interrupt requested first will have high priority. Therefore, the first-request interrupt cannot be superceded by any other interrupt.

INTERRUPTS S3C72K9/P72K8

Programming Tip — Setting the INT Interrupt Priority

The following instruction sequence sets the INT1 interrupt to high priority:

BITS EMB SMB 15

DI ; IPR.3 (IME) \leftarrow 0

LD A,#3H LD IPR,A

EI ; IPR.3 (IME) \leftarrow 1

EXTERNAL INTERRUPT 0, 1 AND 2 MODE REGISTERS (IMOD0, IMOD1 AND IMOD2)

The following components are used to process external interrupts at the INT0, INT1 and INT2 pins:

- Edge detection circuit
- Three mode registers, IMOD0, IMOD1 and IMOD2

The mode registers are used to control the triggering edge of the input signal. IMOD0, IMOD1 and IMOD2 settings let you choose either the rising or falling edge of the incoming signal as the interrupt request trigger. The INT4 interrupt is an exception since its input signal generates an interrupt request on both rising and falling edges. Since INT2 is a quasi-interrupt, the interrupt request flag (IRQ2) must be cleared by software.

FB4H	"0"	"0"	IMOD0.1	IMOD0.0
FB5H	"0"	"0"	"0"	IMOD1.0

FDAH "0" "0" IMOD2.0

IMOD0, IMOD1 and IMOD2 are addressable by 4-bit write instructions. RESET clears all IMOD values to logic zero, selecting rising edges as the trigger for incoming interrupt requests.

Table 7-5. IMOD0, 1 and 2 Register Organization

IMOD0	IMOD0.3	0	IMOD0.1	IMOD0.0	Effect of IMOD0 Settings
			0	0	Rising edge detection
			0	0 1 Falling edge detection	
			1	0	Both rising and falling edge detection
			1	1	IRQ0 flag cannot be set to "1"

Falling edge detection

S3C72K9/P72K8 INTERRUPTS

EXTERNAL INTERRUPT 0, 1, and 2 MODE REGISTERS (Continued)

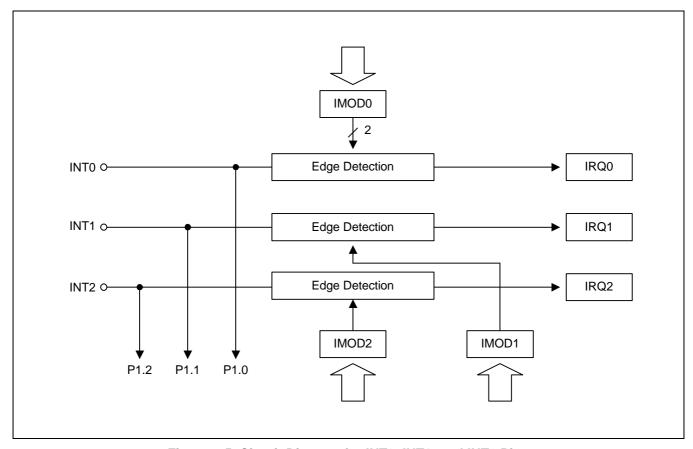

Figure 7-5. Circuit Diagram for INT0, INT1, and INT2 Pins

When modifying the IMOD registers, it is possible to accidentally set an interrupt request flag. To avoid unwanted interrupts, take these precautions when writing your programs:

- 1. Disable all interrupts with a DI instruction.
- 2. Modify the IMOD register.
- 3. Clear all relevant interrupt request flags.
- 4. Enable the interrupt by setting the appropriate IEx flag.
- 5. Enable all interrupts with an El instructions.

INTERRUPTS S3C72K9/P72K8

EXTERNAL KEY INTERRUPT MODE REGISTER (IMODK)

The mode register for external key interrupts at the K0–K3 pins, IMODK, is addressable only by 4-bit write instructions. RESET clears all IMODK bits to logic zero.

FB6H	"0"	IMODK.2	IMODK.1	IMODK.0
------	-----	---------	---------	---------

Rising or falling edge can be detected by bit IMODK.2 settings. If a rising or falling edge is detected at any one of the selected K pin by the IMODK register, the IRQK flag is set to logic one and a release signal for power-down mode is generated.

Table 7-6. IMODK Register Bit Settings

IMODK	0	IMODK.2	IMODK.1	IMODK.0	Effect of IMODK Settings	
		0, 1	0	0	Disable key interrupt	
			0	1	1 Enable edge detection at the K0–K1 pins	
			1	0	Enable edge detection at the K0–K2 pins	
			1	1	Enable edge detection at the K0–K3 pins	

IMODK.2	0	Falling edge detection
	1	Rising edge detection

NOTES:

- 1. To generate a key interrupt, the selected pins must be configured to input mode. If any one pin of the selected pins is configured to output mode, only falling edge can be detected.
- 2. To generate a key interrupt, first, configure pull-up resistors or external pull-down resistors. And then, select edge detection and pins by setting IMODK register.

S3C72K9/P72K8 INTERRUPTS

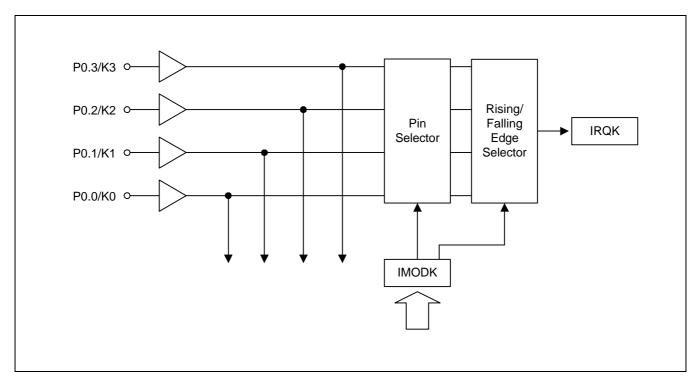

Figure 7-6. Circuit Diagram for INTK

PROGRAMMING TIP — Using INTK as a Key Input Interrupt

When the key interrupt is used, the selected key interrupt source pin must be set to input:

1. When K0–K3 are selected (four pins):

BITS EMB SMB 15 LD EA,#00H LD PMG1,EA ; P0, P4 ← input mode LD EA,#01H LD PUMOD1,EA ; Enable P0 pull-up resistors LD A,#3H

LD IMODK,A ; (IMODK) \leftarrow #3H, K0–K3 falling edge select

INTERRUPTS S3C72K9/P72K8

INTERRUPT FLAGS

There are three types of interrupt flags: interrupt request and interrupt enable flags that correspond to each interrupt, the interrupt master enable flag, which enables or disables all interrupt processing.

Interrupt Master Enable Flag (IME)

The interrupt master enable flag, IME, enables or disables all interrupt processing. Therefore, even when an IRQx flag is set and its corresponding IEx flag is enabled, the interrupt service routine is not executed until the IME flag is set to logic one.

The IME flag is located in the IPR register (IPR.3). It can be directly be manipulated by EI and DI instructions, regardless of the current value of the enable memory bank flag (EMB).

IME	IPR.2	IPR.1	IPR.0	Effect of Bit Settings
0				Inhibit all interrupts
1				Enable all interrupts

Interrupt Enable Flags (IEx)

IEx flags, when set to logical one, enable specific interrupt requests to be serviced. When the interrupt request flag is set to logical one, an interrupt will not be serviced until its corresponding IEx flag is also enabled.

Interrupt enable flags can be read, written, or tested directly by 1-bit instructions. IEx flags can be addressed directly at their specific RAM addresses, despite the current value of the enable memory bank (EMB) flag.

Address	Bit 3	Bit 2	Bit 1	Bit 0
FB8H	IE4	IRQ4	IEB	IRQB
FBAH	"0"	"0"	IEW	IRQW
FBBH	"0"	"0"	IEK	IRQK
FBCH	"0"	"0"	IET0	IRQT0
FBDH	"0"	"0"	IES	IRQS
FBEH	IE1	IRQ1	IE0	IRQ0
FBFH	"0"	"0"	IE2	IRQ2

Table 7-7. Interrupt Enable and Interrupt Request Flag Addresses

NOTES:

- 1. IEx refers generically to all interrupt enable flags.
- 2. IRQx refers generically to all interrupt request flags.
- 3. IEx = 0 is interrupt disable mode.
- 4. IEx = 1 is interrupt enable mode.

S3C72K9/P72K8 INTERRUPTS

Interrupt Request Flags (IRQx)

Interrupt request flags are read/write addressable by 1-bit or 4-bit instructions. IRQx flags can be addressed directly at their specific RAM addresses, regardless of the current value of the enable memory bank (EMB) flag.

When a specific IRQx flag is set to logic one, the corresponding interrupt request is generated. The flag is then automatically cleared to logic zero when the interrupt has been serviced. Exceptions are the watch timer interrupt request flags, IRQW, and the external interrupt 2 flag IRQ2, which must be cleared by software after the interrupt service routine has executed. IRQx flags are also used to execute interrupt requests from software. In summary, follow these guidelines for using IRQx flags:

- 1. IRQx is set to request an interrupt when an interrupt meets the set condition for interrupt generation.
- 2. IRQx is set to "1" by hardware and then cleared by hardware when the interrupt has been serviced (with the exception of IRQW and IRQ2).
- 3. When IRQx is set to "1" by software, an interrupt is generated.

When two interrupts share the same service routine start address, interrupt processing may occur in one of two ways:

- When only one interrupt is enabled, the IRQx flag is cleared automatically when the interrupt has been serviced.
- When two interrupts are enabled, the request flag is not automatically cleared so that the user has an
 opportunity to locate the source of the interrupt request. In this case, the IRQx setting must be cleared
 manually using a BTSTZ instruction.

Table 7-8. Interrupt Request Flag Conditions and Priorities

Interrupt Source	Internal / External	Pre-condition for IRQx Flag Setting	Interrupt Priority	IRQ Flag Name
INTB	I	Reference time interval signal from basic timer	1	IRQB
INT4	Е	Both rising and falling edges detected at INT4	1	IRQ4
INT0	E	Rising or falling edge detected at INT0 pin	2	IRQ0
INT1	E	Rising or falling edge detected at INT1 pin	3	IRQ1
INTS	I	Completion signal for serial transmit-and-receive or receive-only operation	4	IRQS
INTT0	I	Signals for TCNT0 and TREF0 registers match	5	IRQT0
INTK	E	When a rising or falling edge detected at any one of the K0–K3 pins	6	IRQK
INT2 (note)	E	Rising or falling edge detected at INT2	_	IRQ2
INTW	1	Time interval of 0.5 secs or 3.19 msecs	_	IRQW

NOTE: The quasi-interrupt INT2 is only used for testing incoming signals.

PROGRAMMING TIP — Enabling the INTB and INT4 Interrupts

To simultaneously enable INTB and INT4 interrupts:

S3C72K9/P72K8 POWER-DOWN

8

POWFR-DOWN

OVERVIEW

The S3C72K8 microcontroller has two power-down modes to reduce power consumption: idle and stop. Idle mode is initiated by the IDLE instruction and stop mode by the instruction STOP. (Several NOP instructions must always follow an IDLE or STOP instruction in a program.) In idle mode, the CPU clock stops while peripherals and the oscillation source continue to operate normally.

When RESET occurs during normal operation or during a power-down mode, a reset operation is initiated and the CPU enters idle mode. When the standard oscillation stabilization time interval (31.3 ms at 4.19 MHz) has elapsed, normal CPU operation resumes.

In stop mode, main system clock oscillation is halted (assuming it is currently operating), and peripheral hardware components are powered-down. The effect of stop mode on specific peripheral hardware components — CPU, basic timer, serial I/O, timer/ counters 0, watch timer, and LCD controller — and on external interrupt requests, is detailed in Table 8-1.

NOTE

Do not use stop mode if you are using an external clock source because X_{IN} input must be restricted internally to V_{SS} to reduce current leakage.

Idle or stop modes are terminated either by a RESET, or by an interrupt which is enabled by the corresponding interrupt enable flag, IEx. When power-down mode is terminated by RESET, a normal reset operation is executed. Assuming that both the interrupt enable flag and the interrupt request flag are set to "1", power-down mode is released immediately upon entering power-down mode.

When an interrupt is used to release power-down mode, the operation differs depending on the value of the interrupt master enable flag (IME):

- If the IME flag = "0", program execution starts immediately after the instruction which issues the request to enter power-down mode is executed. The interrupt request flag remains set to logical one.
- If the IME flag = "1", two instructions are executed after the power-down mode release and the vectored interrupt is then initiated. However, when the release signal is caused by INT2 or INTW, the operation is identical to the IME = "0" condition. Assuming that both interrupt enable flag and interrupt request flag are set to "1", the release signal is generated when power-down mode is entered.

POWER-DOWN S3C72K9/P72K8

Table 8-1. Hardware Operation During Power-Down Modes

Operation	Stop Mode (STOP)	Idle Mode (IDLE)
System clock status	Can be changed only if the main system clock is used	Can be changed if the main system clock or subsystem clock is used
Clock oscillator	Main system clock oscillation stops	CPU clock oscillation stops (main and subsystem clock oscillation continues)
Basic timer	Basic timer stops	Basic timer operates (with IRQB set at each reference interval)
Serial I/O interface	Operates only if external SCK input is selected as the serial I/O clock	Operates if a clock other than the CPU clock is selected as the serial I/O clock
Timer/counter 0	Operates only if TCL0 is selected as the counter clock	Timer/counter 0 operates
Watch timer	Operates only if subsystem clock (fxt) is selected as the counter clock	Watch timer operates
LCD controller	Operates only if a subsystem clock is selected as LCDCK	LCD controller operates
External interrupts	INT1, INT2, INT4, and INTK are acknowledged; INT0 is not serviced	INT0, INT1, INT2, INT4, and INTK are acknowledged ^(note)
CPU	All CPU operations are disabled	All CPU operations are disabled
Mode release signal	Interrupt request signals (except INT0) are enabled by an interrupt enable flag or by RESET input	Interrupt request signals are enabled by an interrupt enable flag or by RESET input (note)

NOTE: INTO can be operated in idle mode only when fxx/64 is selected as a sampling clock.

Table 8-2. System Operating Mode Comparison

Mode	Condition	STOP/IDLE Mode Start Method	Current Consumption
Main operating mode	Main oscillator runs Sub oscillator runs System clock is the main oscillation clock	_	А
Main Idle mode	Main oscillator runs Sub oscillator runs System clock is the main oscillation clock	IDLE instruction	В
Main Stop mode	Main oscillator runs Sub oscillator runs System clock is the main oscillation clock	STOP instruction	D
Sub operating mode	Main oscillator is stopped by SCMOD.3. Sub oscillator runs System clock is the sub oscillation clock	_	С
Sub Idle mode	Main oscillator is stopped by SCMOD.3. Sub oscillator runs System clock is the sub oscillation clock	IDLE instruction	D

NOTE: The current consumption is: A > B > C > D

- 2. Used as segment.

S3C72K8/P72K8 RESET

9

RESET

OVERVIEW

When a RESET signal is input during normal operation or power-down mode, a hardware reset operation is initiated and the CPU enters idle mode. Then, when the standard oscillation stabilization interval of 31.3 ms at 4.19 MHz has elapsed, normal system operation resumes.

Regardless of when the RESET occurs — during normal operating mode or during a power-down mode — most hardware register values are set to the reset values described in Table 9-1 below. The current status of several register values is, however, always retained when a RESET occurs during idle or stop mode; If a RESET occurs during normal operating mode, their values are undefined. Current values that are retained in this case are as follows:

- Carry flag
- Data memory values
- General-purpose registers E, A, L, H, X, W, Z, and Y
- Serial I/O buffer register (SBUF)

S3C72K8/P72K8 I/O PORTS

10 1/0 PORTS

OVERVIEW

The S3C72K8 has 6 ports. There are total of 4 input pins, 8 output pins (sharing with segment driver output) and 15 configurable I/O pins, for a maximum number of 27 pins.

Pin addresses for all ports are mapped to bank 15 of the RAM. The contents of I/O port pin latches can be read, written, or tested at the corresponding address using bit manipulation instructions.

Port Mode Flags

Port mode flags (PM) are used to configure I/O ports to input or output mode by setting or clearing the corresponding I/O buffer.

Port 1 Mode Register (P1MOD)

Port 1 (P1.0–P1.1) can be used for either digital or analog input. P1MOD register settings determine the input mode (digital or analog) for specific port 1 pins.

Pull-up Resistor Mode Register (PUMOD)

The pull-up mode registers (PUMOD1, 2) are used to assign internal pull-up resistors by software to specific ports. When a configurable I/O port pin is used as an output pin, its assigned pull-up resistor is automatically disabled, even though the pin's pull-up is enabled by a corresponding PUMOD bit setting.

N-Channel Open-Drain Mode Register (PNE)

The n-channel open-drain mode register (PNE) is used to configure outputs as n-channel, open-drain outputs or as push-pull outputs.

I/O PORTS S3C72K8/P72K8

Table 10-1. I/O Port Overview

Port	I/O	Pins	Pin Names	Address	Function Description
0	I/O	4	P0.0-P0.3	FF0H	4-bit I/O port. 1-bit and 4-bit read/write and test is possible. Individual pins are software configurable as input or output. Individual pins are software configurable as open-drain or push-pull output. 4-bit pull-up resistors are software assignable; pull-up resistors are automatically disabled for output pins.
1	I	4	P1.0-P1.3	FF1H	4-bit input port. 1-bit and 4-bit read and test is possible. The 1-bit unit pull-up resistors are assigned to input pins by software. An interrupt is generated by digital input at P1.0, P1.1.
2	I/O	4	P2.0-P2.3	FF2H	Same as port 0 except that 8-bit read/write and test possible.
3	I/O	4	P3.0-P3.3	FF3H	
4	I/O	3	P4.0-P4.2	FF4H	Same as port 0 except that port 4 is 3-bit I/O port and configurabled as analog input pin.
5	I/O	8	P5.0-P5.7	1FxH.0 ^(note)	Output port for 1-bit data

NOTE: "x" means an even-numbered value from "0H" to "FH".

Table 10-2. Port Pin Status During Instruction Execution

Instruction Type	Example		Input Mode Status	Output Mode Status
1-bit test 1-bit input 4-bit input 8-bit input	BTST LDB LD LD	P0.1 C,P1.3 A,P0 EA,P4	Input or test data at each pin	Input or test data at output latch
1-bit output	BITR	P2.3	Output latch contents undefined	Output pin status is modified
4-bit output 8-bit output	LD LD	P2,A P6,EA	Transfer accumulator data to the output latch	Transfer accumulator data to the output pin

S3C72K8/P72K8 I/O PORTS

PORT MODE FLAGS (PM FLAGS)

Port mode flags (PM) are used to configure I/O ports to input or output mode by setting or clearing the corresponding I/O buffer.

For convenient program reference, PM flags are organized into six groups — PMG1 and PMG2 as shown in Table 10-3. They are addressable by 8-bit write instructions only.

When a PM flag is "0", the port is set to input mode; when it is "1", the port is enabled for output. RESET clears all port mode flags to logical zero, automatically configuring the corresponding I/O ports to input mode.

PM Group ID Address Bit 3 Bit 2 Bit 1 Bit 0 PMG1 FE6H PM0.2 PM0.1 PM0.3 PM0.0 "O" FE7H PM4.2 PM4.1 PM4.0 PMG2 FE8H PM2.3 PM2.2 PM2.1 PM2.0 FE9H PM3.3 PM3.2 PM3.1 PM3.0

Table 10-3. Port Mode Group Flags

NOTE: If bit = "0", the corresponding I/O pin is set to input mode. If bit = "1", the pin is set to output mode: PM0.0 for P0.0, PM0.1 for P0.1, etc,. All flags are cleared to "0" following RESET.

PROGRAMMING TIP — Configuring I/O Ports to Input or Output

Configure ports 0 and 2 as an output port:

BITS EMB
SMB 15
LD EA,#7FH
LD PMG1,EA

: P0 and P4 ← Output

PORT 1 MODE REGISTER (P1MOD)

P1MOD register settings determine if port 1 is used for digital input or for analog input. The P1MOD register is a 4-bit write only register. P1MOD is mapped to address FE2H. A reset operation initializes all P1MOD values to logic zero, configuring port 1 as a analog input port.

When a P1MOD bit is "0", the corresponding pin is configured as a analog input pin. When set to "1", it is configured as an digital input pin: P1MOD.0 corresponds to P1.0, and P1MOD.1 to P1.1.

FE2H	"0"	"0"	P1MOD.1	P1MOD.0	P1MOD

NOTE

INT0 and INT1 can occur only when the port is configured to digital input. If you change the input mode from digital to analog using P1MOD settings, IRQ0 and IRQ1 will be set. When use analog input, you must clear the corresponding interrupt enable flag (IEx). That is, clear IE0 when P1.0 is an analog input and clear IE1 when P1.1 is an analog input.

I/O PORTS \$3C72K8/P72K8

PULL-UP RESISTOR MODE REGISTER (PUMOD)

The pull-up resistor mode registers (PUMOD1 and PUMOD2) are used to assign internal pull-up resistors by software to specific ports. When a configurable I/O port pin is used as an output pin, its assigned pull-up resistor is automatically disabled, even though the pin's pull-up is enabled by a corresponding PUMOD bit setting.

PUMOD1 is addressable by 8-bit write instructions only, and PUMOD2 by 4-bit write instruction only. RESET clears PUMOD register values to logic zero, automatically disconnecting all software-assignable port pull-up resistors.

Table 10-4. Pull-Up Resistor Mode Register (PUMOD) Organization

PUMOD ID	Address	Bit 3	Bit 2	Bit 1	Bit 0
PUMOD1	FDCH	PUR3	PUR2	"0"	PUR0
	FDDH	0	0	0	PUR4
PUMOD2	FDEH	PUR1.3	PUR1.2	PUR1.1	PUR1.0

NOTE: When bit = "1", a pull-up resistor is assigned to the corresponding I/O port: PUR3 for port 3, PUR2 for port 2, and so on.

PROGRAMMING TIP — Enabling and Disabling I/O Port Pull-Up Resistors

P6 and P7 enable pull-up resistors.

BITS EMB SMB 15 LD EA,#0CH

LD PUMOD1,EA ; P2 and P3 enable

N-CHANNEL OPEN-DRAIN MODE REGISTER (PNE)

The n-channel open-drain mode register (PNE) is used to configure ports 0, 2, 3 and 4 to n-channel, open-drain or as push-pull outputs. When a bit in the PNE register is set to "1", the corresponding output pin is configured to n-channel, open-drain; when set to "0", the output pin is configured to push-pull. The all PNE registers consist of an 8-bit register and a 4-bit register; PNE1 and PNE3 can be addressed by 4-bit write instruction only and PNE2 by 8-bit write instructions only.

FA6H	P0.3	P0.2	P0.1	P0.0	PNE1
FA8H	P2.3	P2.2	P2.1	P2.0	PNE2
FA9H	P3.3	P3.2	P3.1	P3.0

TIMERS and TIMER/COUNTERS

OVERVIEW

The S3C72K8 microcontroller has four timer and timer/counter modules:

- 8-bit basic timer (BT)
- 8-bit timer/counter (TC0)
- Watch timer (WT)

The 8-bit basic timer (BT) is the microcontroller's main interval timer and watchdog timer. It generates an interrupt request at a fixed time interval when the appropriate modification is made to its mode register. The basic timer is also used to determine clock oscillation stabilization time when stop mode is released by an interrupt and after a RESET.

The 8-bit timer/counter (TC0) is programmable timer/counter that is used primarily for event counting and for clock frequency modification and output. In addition, TC0 generates a clock signal that can be used by the serial I/O interface.

The watch timer (WT) module consists of an 8-bit watch timer mode register, a clock selector, and a frequency divider circuit. Watch timer functions include real-time and watch-time measurement, main and subsystem clock interval timing, buzzer output generation. It also generates a clock signal for the LCD controller.

BASIC TIMER (BT)

OVERVIEW

The 8-bit basic timer (BT) has five functional components:

- Clock selector logic
- 4-bit mode register (BMOD)
- 8-bit counter register (BCNT)
- 8-bit watchdog timer mode register (WDMOD)
- Watchdog timer counter clear flag (WDTCF)

The basic timer generates interrupt requests at precise intervals, based on the frequency of the system clock. You can use the basic timer as a "watchdog" timer for monitoring system events or use BT output to stabilize clock oscillation when stop mode is released by an interrupt and following RESET. Bit settings in the basic timer mode register BMOD turns the BT module on and off, selects the input clock frequency, and controls interrupt or stabilization intervals.

Interval Timer Function

The basic timer's primary function is to measure elapsed time intervals. The standard time interval is equal to 256 basic timer clock pulses.

To restart the basic timer, one bit setting is required: bit 3 of the mode register BMOD should be set to logic one. The input clock frequency and the interrupt and stabilization interval are selected by loading the appropriate bit values to BMOD.2-BMOD.0.

The 8-bit counter register, BCNT, is incremented each time a clock signal is detected that corresponds to the frequency selected by BMOD. BCNT continues incrementing as it counts BT clocks until an overflow occurs (≥ 255). An overflow causes the BT interrupt request flag (IRQB) to be set to logic one to signal that the designated time interval has elapsed. An interrupt request is than generated, BCNT is cleared to logic zero, and counting continues from 00H.

Watchdog Timer Function

The basic timer can also be used as a "watchdog" timer to signal the occurrence of system or program operation error. For this purpose, instruction that clear the watchdog timer (BITS WDTCF) should be executed at proper points in a program within given period. If an instruction that clears the watchdog timer is not executed within the given period and the watchdog timer overflows, reset signal is generated and the system restarts with reset status. An operation of watchdog timer is as follows:

- Write some values (except #5AH) to watchdog timer mode register, WDMOD.
- If WDCNT overflows, system reset is generated.

Oscillation Stabilization Interval Control

Bits 2–0 of the BMOD register are used to select the input clock frequency for the basic timer. This setting also determines the time interval (also referred to as 'wait time') required to stabilize clock signal oscillation when stop mode is released by an interrupt. When a RESET signal is inputted, the standard stabilization interval for system clock oscillation following the RESET is 31.3 ms at 4.19 MHz.

Table 11-1. Basic Timer Register Overview

Register Name	Туре	Description	Size	RAM Address	Addressing Mode	Reset Value
BMOD	Control	Controls the clock frequency (mode) of the basic timer; also, the oscillation stabilization interval after stop mode release or RESET	4-bit	F85H	4-bit write-only; BMOD.3: 1-bit writeable	"0"
BCNT	Counter	Counts clock pulses matching the BMOD frequency setting	8-bit	F86H-F87H	8-bit read-only	U (note)
WDMOD	Control	Controls watchdog timer operation.	8-bit	F98H-F99H	8-bit write-only	A5H
WDTCF	Control	Clears the watchdog timer's counter.	1-bit	F9AH.3	1-, 4-bit write	"0"

NOTE: 'U' means the value is undetermined after a RESET.

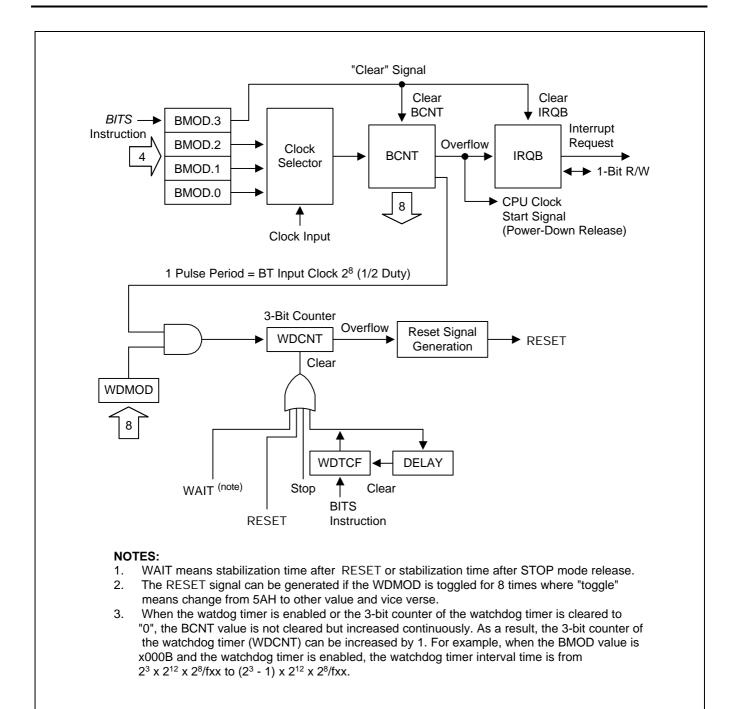

Figure 11-1. Basic Timer Circuit Diagram

BASIC TIMER MODE REGISTER (BMOD)

The basic timer mode register, BMOD, is a 4-bit write-only register. Bit 3, the basic timer start control bit, is also 1-bit addressable. All BMOD values are set to logic zero following RESET and interrupt request signal generation is set to the longest interval. (BT counter operation cannot be stopped.) BMOD settings have the following effects:

- Restart the basic timer:
- Control the frequency of clock signal input to the basic timer;
- Determine time interval required for clock oscillation to stabilize following the release of stop mode by an interrupt.

By loading different values into the BMOD register, you can dynamically modify the basic timer clock frequency during program execution. Four BT frequencies, ranging from fxx/2¹² to fxx/2⁵, are selectable. Since BMOD's reset value is logic zero, the default clock frequency setting is fxx/2¹².

The most significant bit of the BMOD register, BMOD.3, is used to restart the basic timer. When BMOD.3 is set to logic one (ebable) by a 1-bit write instruction, the contents of the BT counter register (BCNT) and the BT interrupt request flag (IRQB) are both cleared to logic zero, and timer operation restarts.

The combination of bit settings in the remaining three registers — BMOD.2, BMOD.1, and BMOD.0 — determine the clock input frequency and oscillation stabilization interval.

Table 11-2. Basic Timer Mode Register (BMOD) Organization

BMOD.3	Basic Timer Start Control Bit
1	Start basic timer; clear IRQB, BCNT, and BMOD.3 to "0"

BMOD.2	BMOD.1	BMOD.0
0	0	0
0	1	1
1	0	1
1	1	1

Basic Timer Input Clock	Interrupt Interval Time (Wait time when STOP mode is released)
fxx/2 ¹² (1.02 kHz)	2 ²⁰ /fxx (250 ms)
fxx/2 ⁹ (8.18 kHz)	2 ¹⁷ /fxx (31.3 ms)
fxx/2 ⁷ (32.7 kHz)	2 ¹⁵ /fxx (7.82 ms)
fxx/2 ⁵ (131 kHz)	2 ¹³ /fxx (1.95 ms)

NOTES:

- 1. Clock frequencies and oscillation stabilization assume a system oscillator clock frequency (fxx) of 4.19 MHz.
- 2. fxx = system clock frequency.
- 3. Oscillation stabilization time is the time required to stabilize clock signal oscillation after stop mode is released. The data in the table column 'Oscillation Stabilization' can also be interpreted as "Interrupt Interval Time".
- 4. The standard stabilization time for system clock oscillation following a RESET is 31.3 ms at 4.19 MHz.

BASIC TIMER COUNTER (BCNT)

BCNT is an 8-bit counter for the basic timer. It can be addressed by 8-bit read instructions.

RESET leaves the BCNT counter value undetermined. BCNT is automatically cleared to logic zero whenever the BMOD register control bit (BMOD.3) is set to "1" to restart the basic timer. It is incremented each time a clock pulse of the frequency determined by the current BMOD bit settings is detected.

When BCNT has incrementing to hexadecimal 'FFH' (≥ 255 clock pulses), it is cleared to '00H' and an overflow is generated. The overflow causes the interrupt request flag, IRQB, to be set to logic one. When the interrupt request is generated, BCNT immediately resumes counting incoming clock signals.

NOTE

Always execute a BCNT read operation twice to eliminate the possibility of reading unstable data while the counter is incrementing. If, after two consecutive reads, the BCNT values match, you can select the latter value as valid data. Until the results of the consecutive reads match, however, the read operation must be repeated until the validation condition is met.

BASIC TIMER OPERATION SEQUENCE

The basic timer's sequence of operations may be summarized as follows:

- 1. Set BMOD.3 to logic one to restart the basic timer
- 2. BCNT is then incremented by one after each clock pulse corresponding to BMOD selection
- 3. BCNT overflows if BCNT = 255 (BCNT = FFH)
- 4. When an overflow occurs, the IRQB flag is set by hardware to logic one
- 5. The interrupt request is generated
- 6. BCNT is then cleared by hardware to logic zero
- 7. Basic timer resumes counting clock pulses

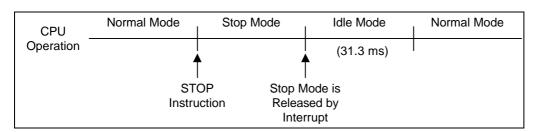

PROGRAMMING TIP — Using the Basic Timer

1. To read the basic timer count register (BCNT):

	BITS	EMB
	SMB	15
BCNTR	LD	EA,BCNT
	LD	YZ,EA
	LD	EA,BCNT
	CPSE	EA,YZ
	JR	BCNTR

2. When stop mode is released by an interrupt, set the oscillation stabilization interval to 31.3 ms:

```
BITS EMB
SMB 15
LD A,#0BH
LD BMOD,A ; Wait time is 31.3 ms
STOP ; Set stop power-down mode
NOP
NOP
NOP
```

3. To set the basic timer interrupt interval time to 1.95 ms (at 4.19 MHz):

BITS	EMB	
SMB	15	
LD	A,#0FH	
LD	BMOD,A	
El		
BITS	IEB	: Basic timer interrupt enable flag is set to "1"

4. Clear BCNT and the IRQB flag and restart the basic timer:

BITS	EMB
SMB	15
BITS	BMOD.3

WATCHDOG TIMER MODE REGISTER (WDMOD)

The watchdog timer mode register, WDMOD, is a 8-bit write-only register. WDMOD register controls to enable or disable the watchdog function. WDMOD values are set to logic "A5H" following RESET and this value enables the watchdog timer. Watchdog timer is set to the longest interval because BT overflow signal is generated with the longest interval.

WDMOD	Watchdog Timer Enable/Disable Control		
5AH	Disable watchdog timer function		
Any other value	Enable watchdog timer function		

WATCHDOG TIMER COUNTER (WDCNT)

The watchdog timer counter, WDCNT, is a 3-bit counter. WDCNT is automatically cleared to logic zero, and restarts whenever the WDTCF register control bit is set to "1". RESET, stop, and wait signal clears the WDCNT to logic zero also.

WDCNT increments each time a clock pulse of the overflow frequency determined by the current BMOD bit setting is generated. When WDCNT has incremented to hexadecimal '07H', it is cleared to '00H' and an overflow is generated. The overflow causes the system RESET. When the interrupt request is generated, BCNT immediately resumes counting incoming clock signals.

WATCHDOG TIMER COUNTER CLEAR FLAG (WDTCF)

The watchdog timer counter clear flag, WDTCF, is a 1-bit write instruction. When WDTCF is set to one, it clears the WDCNT to zero and restarts the WDCNT. WDTCF register bits 2-0 are always logic zero.

BMOD	BT Input Clock	WDT Interval Time (3)	
x000b	fxx/2 ¹²	$2^3 \times 2^{12} \times 2^8 / \text{fxx} - (2^3 - 1) \times 2^{12} \times 2^8 / \text{fxx}$	1.75–2.0 sec
x011b	fxx/2 ⁹	$2^3 \times 2^9 \times 2^8 / \text{fxx} - (2^3 - 1) \times 2^9 \times 2^8 / \text{fxx}$	218.7–250 ms
x101b	fxx/2 ⁷	$2^3 \times 2^7 \times 2^8 / \text{fxx} - (2^3 - 1) \times 2^7 \times 2^8 / \text{fxx}$	54.6-62.5ms
x111b	fxx/2 ⁵	$2^3 \times 2^5 \times 2^8 / \text{fxx} - (2^3 - 1) \times 2^5 \times 2^8 / \text{fxx}$	13.6–15.6 ms

Table 11-3. Watchdog Timer Interval Time

NOTES:

- 1. Clock frequencies assume a system oscillator clock frequency (fx) of 4.19 MHz
- 2. fxx = system clock frequency.
- 3. When the watchdog timer is enabled or the 3-bit counter of the watchdog timer is cleared to "0", the BCNT value is not cleared but increased continuously. As a result, the 3-bit counter of the watchdog timer (WDCNT) can be increased by 1. For example, when the BMOD value is x000b and the watchdog timer is enabled, the watchdog timer interval time is from $2^3 \times 2^{12} \times 2^8$ /fxx to $(2^3-1) \times 2^{12} \times 2^8$ /fxx.

8-BIT TIMER/COUNTER 0 (TC0)

OVERVIEW

Timer/counter 0 (TC0) is used to count system 'events' by identifying the transition (high-to-low or low-to-high) of incoming square wave signals. To indicate that an event has occurred, or that a specified time interval has elapsed, TC0 generates an interrupt request. By counting signal transitions and comparing the current counter value with the reference register value, TC0 can be used to measure specific time intervals.

TC0 has a reloadable counter that consists of two parts: an 8-bit reference register (TREF0) into which you write the counter reference value, and an 8-bit counter register (TCNT0) whose value is automatically incremented by counter logic.

An 8-bit mode register, TMOD0, is used to activate the timer/counter and to select the basic clock frequency to be used for timer/counter operations. To dynamically modify the basic frequency, new values can be loaded into the TMOD0 register during program execution.

Timer/counter 0 can supply a clock signal to the clock selector circuit of the serial I/O interface for data shifter and clock counter operations. (These internal SIO operations are controlled in turn by the SIO mode register, SMOD). This clock generation function enables you to adjust data transmission rates across the serial interface.

TC0 FUNCTION SUMMARY

8-bit programmable timer	Generates interrupts at specific time intervals based on the selected clock frequency.
External event counter	Counts various system "events" based on edge detection of external clock signals at the TC0 input pin, TCL0. To start the event counting operation, TMOD0.2 is set to "1" and TMOD0.6 is cleared to "0".
Arbitrary frequency output	Outputs selectable clock frequencies to the TC0 output pin, TCLO0.
External signal divider	Divides the frequency of an incoming external clock signal according to a modifiable reference value (TREF0), and outputs the modified frequency to the TCLO0 pin.
Serial I/O clock source	Outputs a modifiable clock signal for use as the SCK clock source.

TC0 COMPONENT SUMMARY

Mode register (TMOD0) Activates the timer/counter and selects the internal clock frequency or the

external clock source at the TCL0 pin.

Reference register (TREF0) Stores the reference value for the desired number of clock pulses between

interrupt requests.

Counter register (TCNT0) Counts internal or external clock pulses based on the bit settings in TMOD0

and TREF0.

Clock selector circuit Together with the mode register (TMOD0), lets you select one of four internal

clock frequencies or an external clock.

8-bit comparator Determines when to generate an interrupt by comparing the current value of

the counter register (TCNT0) with the reference value previously programmed

into the reference register (TREF0).

Output latch (TOL0) Where a clock pulse is stored pending output to the I/O circuit or to the TC0

output pin, TCLO0.

When the contents of the TCNT0 and TREF0 registers coincide, the

timer/counter interrupt request flag (IRQT0) is set to "1", the status of TOL0 is

inverted, and an interrupt is generated.

Output enable flag (TOE0) Must be set to logic one before the contents of the TOL0 latch can be output to

TCLO0.

Interrupt request flag (IRQT0) Cleared when TC0 operation starts and the TC0 interrupt service routine is

executed and set to 1 whenever the counter value and reference value

coincide.

Interrupt enable flag (IET0) Must be set to logic one before the interrupt requests generated by

timer/counter 0 can be processed.

Table 11-4. TC0 Register Overview

Register Name	Туре	Description	Size	RAM Address	Addressing Mode	Reset Value
TMOD0	Control	Controls TC0 enable/disable (bit 2); clears and resumes counting operation (bit 3); sets input clock and clock frequency (bits 6–4)	8-bit	F90H–F91H	8-bit write-only; (TMOD0.3 is also 1-bit writeable)	"0"
TCNT0	Counter	Counts clock pulses matching the TMOD0 frequency setting	8-bit	F94H–F95H	8-bit read-only	"0"
TREF0	Reference	Stores reference value for the timer/counter 0 interval setting	8-bit	F96H-F97H	8-bit write-only	FFH
TOE0	Flag	Controls timer/counter 0 output to the TCLO0 pin	1-bit	F92H.2	1-bit write-only	"0"

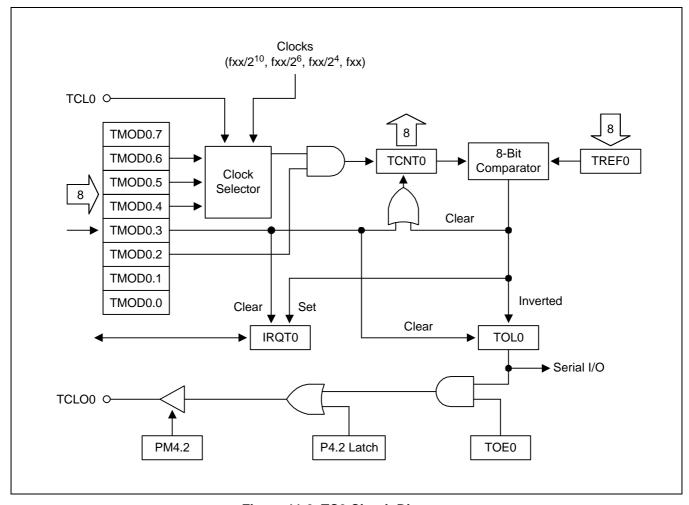

Figure 11-2. TC0 Circuit Diagram

TC0 ENABLE/DISABLE PROCEDURE

Enable Timer/Counter 0

- Set TMOD0.2 to logic one
- Set the TC0 interrupt enable flag IET0 to logic one
- Set TMOD0.3 to logic one

TCNT0, IRQT0, and TOL0 are cleared to logic zero, and timer/counter operation starts.

Disable Timer/Counter 0

Set TMOD0.2 to logic zero

Clock signal input to the counter register TCNT0 is halted. The current TCNT0 value is retained and can be read if necessary.

TC0 PROGRAMMABLE TIMER/COUNTER FUNCTION

Timer/counter 0 can be programmed to generate interrupt requests at various intervals based on the selected system clock frequency. Its 8-bit TC0 mode register TMOD0 is used to activate the timer/counter and to select the clock frequency.

The reference register TREF0 stores the value for the number of clock pulses to be generated between interrupt requests. The counter register, TCNT0, counts the incoming clock pulses, which are compared to the TREF0 value as TCNT0 is incremented. When there is a match (TREF0 = TCNT0), an interrupt request is generated.

To generate an interrupt request, the TC0 interrupt request flag (IRQT0) is set to logic one, the status of TOL0 is inverted, and the interrupt is generated. The content of TCNT0 is then cleared to 00H and TC0 continues counting. The interrupt request mechanism for TC0 includes an interrupt enable flag (IET0) and an interrupt request flag (IRQT0).

TC0 OPERATION SEQUENCE

The general sequence of operations for using TC0 can be summarized as follows:

- 1. Set TMOD0.2 to "1" to enable TC0.
- 2. Set TMOD0.6 to "1" to enable the system clock (fxx) input.
- 3. Set TMOD0.5 and TMOD0.4 bits to desired internal frequency (fxx/2ⁿ).
- 4. Load a value to TREF0 to specify the interval between interrupt requests.
- 5. Set the TC0 interrupt enable flag (IET0) to "1".
- 6. Set TMOD0.3 bit to "1" to clear TCNT0, IRQT0, and TOL0, and start counting.
- 7. TCNT0 increments with each internal clock pulse.
- 8. When the comparator shows TCNT0 = TREF0, the IRQT0 flag is set to "1" and an interrupt request is generated.
- 9. Output latch (TOL0) logic toggles high or low.
- 10. TCNT0 is cleared to 00H and counting resumes.
- 11. Programmable timer/counter operation continues until TMOD0.2 is cleared to "0".

TC0 EVENT COUNTER FUNCTION

Timer/counter 0 can monitor or detect system 'events' by using the external clock input at the TCL0 pin as the counter source. The TC0 mode register selects rising or falling edge detection for incoming clock signals. The counter register TCNT0 is incremented each time the selected state transition of the external clock signal occurs.

With the exception of the different TMOD0.4–TMOD0.6 settings, the operation sequence for TC0's event counter function is identical to its programmable timer/counter function. To activate the TC0 event counter function,

- Set TMOD0.2 to "1" to enable TC0;
- Clear TMOD0.6 to "0" to select the external clock source at the TCL0 pin;
- Select TCL0 edge detection for rising or falling signal edges by loading the appropriate values to TMOD0.5 and TMOD0.4.
- P4.2 must be set to input mode.

Table 11-5. TMOD0 Settings for TCL0 Edge Detection

TMOD0.5	TMOD0.4	TCL0 Edge Detection
0	0	Rising edges
0	1	Falling edges

TC0 CLOCK FREQUENCY OUTPUT

Using timer/counter 0, a modifiable clock frequency can be output to the TC0 clock output pin, TCLO0. To select the clock frequency, load the appropriate values to the TC0 mode register, TMOD0. The clock interval is selected by loading the desired reference value into the reference register TREFO. To enable the output to the TCLO0 pin, the following conditions must be met:

- TC0 output enable flag TOE0 must be set to "1"
- I/O mode flag for P4.2 must be set to output mode ("1")
- Output latch value for P4.2 must be set to "0"

In summary, the operational sequence required to output a TC0-generated clock signal to the TCLO0 pin is as follows:

- Load a reference value to TREF0.
- Set the internal clock frequency in TMOD0.
- Initiate TC0 clock output to TCLO0 (TMOD0.2 = "1").
- Set P4.2 mode flag to "1". 4.
- Set P4.2 output latch to "0".
- Set TOE0 flag to "1".

Each time TCNT0 overflows and an interrupt request is generated, the state of the output latch TOL0 is inverted and the TC0-generated clock signal is output to the TCLO0 pin.

PROGRAMMING TIP — TC0 Signal Output to the TCLO0 Pin

Output a 30 ms pulse width signal to the TCLO0 pin:

BITS	EMB

LD	EA,#4CH
LD	TMOD0,EA
LD	EA,#40H
LD	PMG1,EA
BITR	P4.2

; P4.2 ← output mode ; P4.2 clear

BITS TOE0

TC0 SERIAL I/O CLOCK GENERATION

Timer/count 0 can supply a clock signal to the clock selector circuit of the serial I/O interface for data shifter and clock counter operations. (These internal SIO operations are controlled in turn by the SIO mode register, SMOD). This clock generation function enables you to adjust data transmission rates across the serial interface.

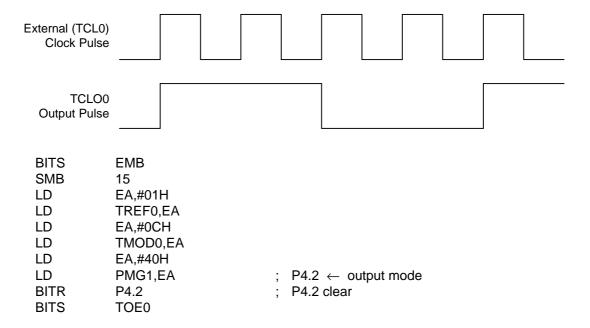

TC0 EXTERNAL INPUT SIGNAL DIVIDER

By selecting an external clock source and loading a reference value into the TC0 reference register, TREF0, you can divide the incoming clock signal by the TREF0 value and then output this modified clock frequency to the TCLO0 pin. The sequence of operations used to divide external clock input can be summarized as follows:

- 1. Load a signal divider value to the TREF0 register.
- 2. Clear TMOD0.6 to "0" to enable external clock input at the TCL0 pin.
- 3. Set TMOD0.5 and TMOD0.4 to desired TCL0 signal edge detection.
- 4. Set port 3.0 mode flag (PM3.0) to output ("1").
- 5. Set P3.0 output latch to "0".
- 6. Set TOE0 flag to "1" to enable output of the divided frequency to the TCLO0 pin. TC0 Mode Register (TMOD0)

PROGRAMMING TIP — External TCL0 Clock Output to the TCL00 Pin

Output external TCL0 clock pulse to the TCLO0 pin (divided by four):

TC0 MODE REGISTER (TMOD0)

TMOD0 is the 8-bit mode control register for timer/counter 0. It is addressable by 8-bit write instructions. One bit, TMOD0.3, is also 1-bit writeable. RESET clears all TMOD0 bits to logic zero and disables TC0 operations.

F90H	TMOD0.3	TMOD0.2	"0"	"0"
F91H	"0"	TMOD0.6	TMOD0.5	TMOD0.4

TMOD0.2 is the enable/disable bit for timer/counter 0. When TMOD0.3 is set to "1", the contents of TCNT0, IRQT0, and TOL0 are cleared, counting starts from 00H, and TMOD0.3 is automatically reset to "0" for normal TC0 operation. When TC0 operation stops (TMOD0.2 = "0"), the contents of the TC0 counter register TCNT0 are retained until TC0 is re-enabled.

The TMOD0.6, TMOD0.5, and TMOD0.4 bit settings are used together to select the TC0 clock source. This selection involves two variables:

- Synchronization of timer/counter operations with either the rising edge or the falling edge of the clock signal input at the TCL0 pin, and
- Selection of one of four frequencies, based on division of the incoming system clock frequency, for use in internal TC0 operation.

Bit Name Setting **Resulting TC0 Function Address** TMOD0.7 0 Always logic zero F91H TMOD0.6 TMOD0.5 0,1 Specify input clock edge and internal frequency TMOD_{0.4} Clear TCNT0, IRQT0, and TOL0 and resume counting 1 TMOD0.3 immediately (This bit is automatically cleared to logic zero immediately after counting resumes.) TMOD_{0.2} 0 Disable timer/counter 0; retain TCNT0 contents F90H 1 Enable timer/counter 0 TMOD0.1 0 Always logic zero TMOD0.0 0 Always logic zero

Table 11-6. TC0 Mode Register (TMOD0) Organization

Table 11-7. TMOD0.6, TMOD0.5, and TMOD0.4 Bit Settings

TMOD0.6	TMOD0.5	TMOD0.4	Resulting Counter Source and Clock Frequency
0	0	0	External clock input (TCL0) on rising edges
0	0	1	External clock input (TCL0) on falling edges
1	0	0	fxx/2 ¹⁰ (4.09 kHz)
1	0	1	fxx /2 ⁶ (65.5 kHz)
1	1	0	fxx/2 ⁴ (262 kHz)
1	1	1	fxx = 4.19 MHz

NOTE: 'fxx' = selected system clock of 4.19 MHz.

PROGRAMMING TIP — Restarting TC0 Counting Operation

1. Set TC0 timer interval to 4.09 kHz:

BITS EMB
SMB 15
LD EA,#4CH
LD TMOD0,EA

ΕI

BITS IET0

2. Clear TCNT0, IRQT0, and TOL0 and restart TC0 counting operation:

BITS EMB SMB 15

BITS TMOD0.3

TC0 COUNTER REGISTER (TCNT0)

The 8-bit counter register for timer/counter 0, TCNT0, is read-only and can be addressed by 8-bit RAM control instructions. RESET sets all TCNT0 register values to logic zero (00H).

Whenever TMOD0.3 is enabled, TCNT0 is cleared to logic zero and counting resumes. The TCNT0 register value is incremented each time an incoming clock signal is detected that matches the signal edge and frequency setting of the TMOD0 register (specifically, TMOD0.6, TMOD0.5, and TMOD0.4).

Each time TCNT0 is incremented, the new value is compared to the reference value stored in the TC0 reference buffer, TREF0. When TCNT0 = TREF0, an overflow occurs in the TCNT0 register, the interrupt request flag, IRQT0, is set to logic one, and an interrupt request is generated to indicate that the specified timer/counter interval has elapsed.

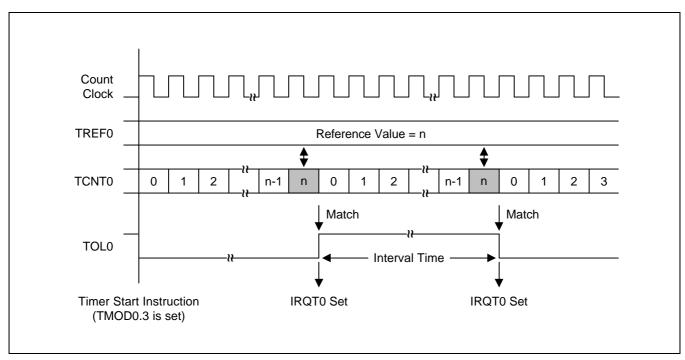

Figure 11-3. TC0 Timing Diagram

TC0 REFERENCE REGISTER (TREF0)

The TC0 reference register TREF0 is an 8-bit write-only register. It is addressable by 8-bit RAM control instructions. RESET initializes the TREF0 value to 'FFH'.

TREF0 is used to store a reference value to be compared to the incrementing TCNT0 register in order to identify an elapsed time interval. Reference values will differ depending upon the specific function that TC0 is being used to perform — as a programmable timer/counter, event counter, clock signal divider, or arbitrary frequency output source.

During timer/counter operation, the value loaded into the reference register is compared to the TCNT0 value. When TCNT0 = TREF0, the TC0 output latch (TOL0) is inverted and an interrupt request is generated to signal the interval or event. The TREF0 value, together with the TMOD0 clock frequency selection, determines the specific TC0 timer interval. Use the following formula to calculate the correct value to load to the TREF0 reference register:

TC0 timer interval = (TREF0 value + 1)
$$\times \frac{1}{\text{TMOD0 frequency setting}}$$
(TREF0 value $\neq 0$)

TC0 OUTPUT ENABLE FLAG (TOE0)

The 1-bit timer/counter 0 output enable flag TOE0 controls output from timer/counter 0 to the TCLO0 pin. TOE0 is addressable by 1-bit read and write instructions.

		(LSB)		
F92H	"0"	TOE0	"0"	"0"

When you set the TOE0 flag to "1", the contents of TOL0 can be output to the TCLO0 pin. Whenever a RESET occurs, TOE0 is automatically set to logic zero, disabling all TC0 output. Even when the TOE0 flag is disabled, timer/counter 0 can continue to output an internally-generated clock frequency, via TOL0, to the serial I/O clock selector circuit.

TC0 OUTPUT LATCH (TOL0)

TOL0 is the output latch for timer/counter 0. When the 8-bit comparator detects a correspondence between the value of the counter register TCNT0 and the reference value stored in the TREF0 register, the TOL0 value is inverted — the latch toggles high-to-low or low-to-high. Whenever the state of TOL0 is switched, the TC0 signal is output. TC0 output may be directed to the TCLO0 pin, or it can be output directly to the serial I/O clock selector circuit as the SCK signal.

Assuming TC0 is enabled, when bit 3 of the TMOD0 register is set to "1", the TOL0 latch is cleared to logic zero, along with the counter register TCNT0 and the interrupt request flag, IRQT0, and counting resumes immediately. When TC0 is disabled (TMOD0.2 = "0"), the contents of the TOL0 latch are retained and can be read, if necessary.

PROGRAMMING TIP — Setting a TC0 Timer Interval

To set a 30 ms timer interval for TC0, given fxx = 4.19 MHz, follow these steps.

- 1. Select the timer/counter 0 mode register with a maximum setup time of 62.5 ms (assume the TC0 counter clock = $fxx/2^{10}$, and TREF0 is set to FFH):
- 2. Calculate the TREF0 value:

$$30 \text{ ms} = \frac{\text{TREF0 value} + 1}{4.09 \text{ kHz}}$$

TREF0 + 1 =
$$\frac{30 \text{ ms}}{244 \text{ µs}}$$
 = 122.9 = 7AH

TREF0 value =
$$7AH - 1 = 79H$$

3. Load the value 79H to the TREF0 register:

BITS	EMB
SMB	15
LD	EA,#79H
LD	TREF0,EA
LD	EA,#4CH
LD	TMOD0,EA
LU	TIVIODU,EA

WATCH TIMER

OVERVIEW

The watch timer is a multi-purpose timer which consists of three basic components:

- 8-bit watch timer mode register (WMOD)
- Clock selector
- Frequency divider circuit

Watch timer functions include real-time and watch-time measurement and interval timing for the main and subsystem clock. It is also used as a clock source for the LCD controller and for generating buzzer (BUZ) output.

Real-Time and Watch-Time Measurement

To start watch timer operation, set bit 2 of the watch timer mode register (WMOD.2) to logic one. The watch timer starts, the interrupt request flag IRQW is automatically set to logic one, and interrupt requests commence in 0.5-second intervals.

Since the watch timer functions as a quasi-interrupt instead of a vectored interrupt, the IRQW flag should be cleared to logic zero by program software as soon as a requested interrupt service routine has been executed.

Using a Main System or Subsystem Clock Source

The watch timer can generate interrupts based on the main system clock frequency or on the subsystem clock. When the zero bit of the WMOD register is set to "1", the watch timer uses the subsystem clock signal (fxt) as its source; if WMOD.0 = "0", the main system clock (fx) is used as the signal source, according to the following formula:

Watch timer clock (fw) =
$$\frac{\text{Main system clock (fx)}}{128}$$
 = 32.768 kHz (fx = 4.19 MHz)

This feature is useful for controlling timer-related operations during stop mode. When stop mode is engaged, the main system clock (fx) is halted, but the subsystem clock continues to oscillate. By using the subsystem clock as the oscillation source during stop mode, the watch timer can set the interrupt request flag IRQW to "1", thereby releasing stop mode.

Clock Source Generation for LCD Controller

The watch timer supplies the clock frequency for the LCD controller (f_{LCD}). Therefore, if the watch timer is disabled, the LCD controller does not operate.

Buzzer Output Frequency Generator

The watch timer can generate a steady 2 kHz, 4 kHz, 8 kHz, or 16 kHz signal to the BUZ pin. To select the desired BUZ frequency, load the appropriate value to the WMOD register. This output can then be used to actuate an external buzzer sound. To generate a BUZ signal, three conditions must be met:

- The WMOD.7 register bit is set to "1"
- The output latch for I/O port 0.3 is cleared to "0"
- The port 0.3 output mode flag (PM0.3) set to 'output' mode

Timing Tests in High-Speed Mode

By setting WMOD.1 to "1", the watch timer will function in high-speed mode, generating an interrupt every 3.91 ms. At its normal speed (WMOD.1 = '0'), the watch timer generates an interrupt request every 0.5 seconds. High-speed mode is useful for timing events for program debugging sequences.

Check Subsystem Clock Level Feature

The watch timer can also check the input level of the subsystem clock by testing WMOD.3. If WMOD.3 is "1", the input level at the XT_{IN} pin is high; if WMOD.3 is "0", the input level at the XT_{IN} pin is low.

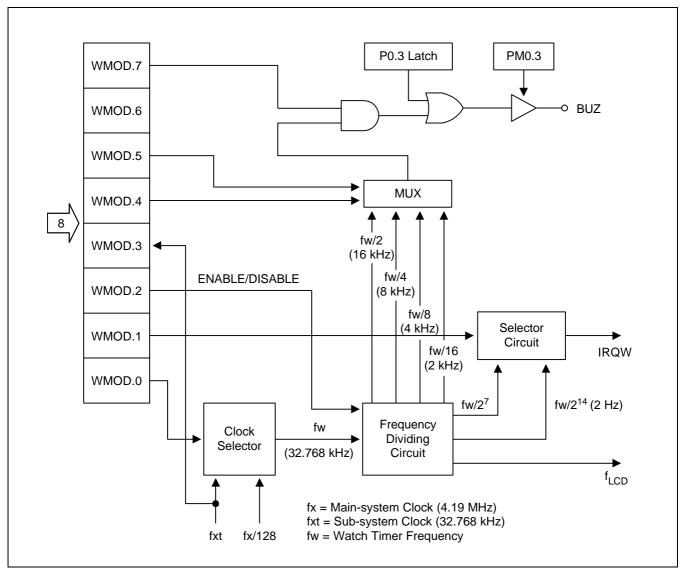

Figure 11-4. Watch Timer Circuit Diagram

WATCH TIMER MODE REGISTER (WMOD)

The watch timer mode register WMOD is used to select specific watch timer operations. It is 8-bit write-only addressable. An exception is WMOD bit 3 (the XT_{IN} input level control bit) which is 1-bit read-only addressable.

A RESET automatically sets WMOD.3 to the current input level of the subsystem clock, XT_{IN} (high, if logic one; low, if logic zero), and all other WMOD bits to logic zero.

F88H	WMOD.3	WMOD.2	WMOD.1	WMOD.0
F89H	WMOD.7	"0"	WMOD.5	WMOD.4

In summary, WMOD settings control the following watch timer functions:

Watch timer clock selection (WMOD.0)
 Watch timer speed control (WMOD.1)
 Enable/disable watch timer (WMOD.2)
 XT_{IN} input level control (WMOD.3)

Buzzer frequency selection (WMOD.4 and WMOD.5)

Enable/disable buzzer output (WMOD.7)

Table 11-8. Watch Timer Mode Register (WMOD) Organization

Bit Name	Values		Function	Address		
WMOD.7	0		Disable buzzer (BUZ) signal output	F89H		
	Ì	1	Enable buzzer (BUZ) signal output			
WMOD.6	()	Always logic zero			
WMOD.54	0	0	2 kHz buzzer (BUZ) signal output			
	0	1	4 kHz buzzer (BUZ) signal output			
	1	0	8 kHz buzzer (BUZ) signal output			
	1	1	16 kHz buzzer (BUZ) signal output			
WMOD.3	()	Input level to XT _{IN} pin is low	F88H		
	1		Input level to XT _{IN} pin is high			
WMOD.2	()	Disable watch timer; clear frequency dividing circuits			
	1		Enable watch timer			
WMOD.1	0		0		Normal mode; sets IRQW to 0.5 seconds	
	1		High-speed mode; sets IRQW to 3.91 ms			
WMOD.0	0		Select (fx/128) as the watch timer clock (fw)			
	•	1	Select subsystem clock as watch timer clock (fw)			

NOTE: Main system clock frequency (fx) is assumed to be 4.19 MHz; subsystem clock (fxt) is assumed to be 32.768 kHz.

PROGRAMMING TIP — Using the Watch Timer

1. Select a subsystem clock as the LCD display clock, a 0.5 second interrupt, and 2 kHz buzzer enable:

BITS EMB
SMB 15
LD EA,#8H
LD PMG1,EA

; P0.3 ← output mode

BITR P0.3 LD EA,#85H LD WMOD,EA BITS IEW

12 LCD CONTROLLER/DRIVER

OVERVIEW

The S3C72K8 microcontroller can directly drive an up-to-320-dot (40 segments x 8 commons) LCD panel. Its LCD block has the following components:

- LCD controller/driver
- Display RAM for storing display data
- 40 segment output pins (SEG0–SEG35)
- 8 common output pins (COM0–COM7)
- Five LCD operating power supply pins ($V_{LC1}-V_{LC5}$)
- $-\ \ V_{LC5}$ pin for controlling the driver and bias voltage

The frame frequency, duty and bias, and the segment pins used for display output, are determined by bit settings in the LCD mode register, LMOD.

The LCD control register, LCON, is used to turn the LCD display on and off, to switch current to the dividing resistors for the LCD display, and to output LCD clock (LCDCK) and synchronizing signal (LCDSY) for LCD display expansion. Data written to the LCD display RAM can be transferred to the segment signal pins automatically without program control.

When a subsystem clock is selected as the LCD clock source, the LCD display is enabled even during main clock stop and idle modes.

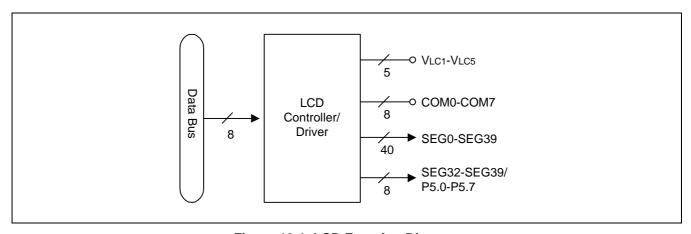

Figure 12-1. LCD Function Diagram

LCD CIRCUIT DIAGRAM

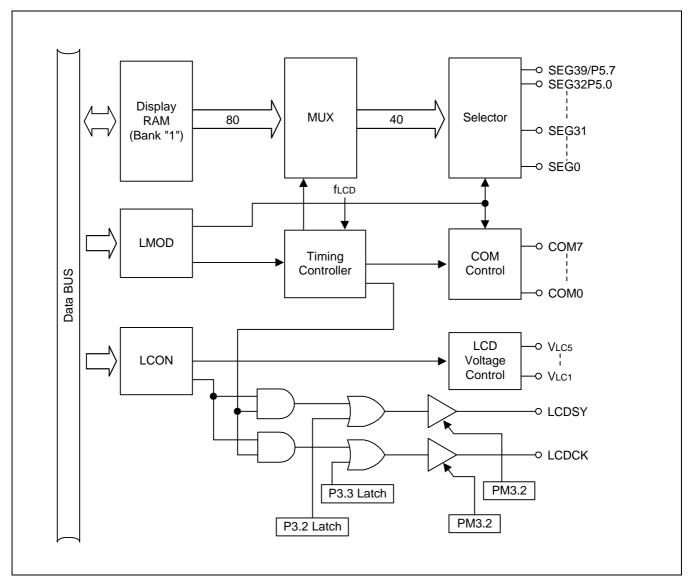

Figure 12-2. LCD Circuit Diagram

LCD RAM ADDRESS AREA

RAM addresses of bank 1 are used as LCD data memory. These locations can be addressed by 1-bit, 4-bit, or 8-bit instructions. When the bit value of a display segment is "1", the LCD display is turned on; when the bit value is "0", the display is turned off.

Display RAM data are sent out through segment pins SEG0–SEG40 using a direct memory access (DMA) method that is synchronized with the f_{LCD} signal. RAM addresses in this location that are not used for LCD display can be allocated to general-purpose use.

Figure 12-3. LCD Display Data RAM Organization

1-Bit Output

The eight pins (P5.0-P5.7) of the 40 segment output can be set in 4-bits for 1-bit level output by LMOD.6 and LMOD.7. The 1F0H.0 in LCD display RAM is used as the output latch for P5.0, 1F2H.0 is for 5, 1, and 1FEH.0 is for P5.7.

Table 12-1. Common and Segment Pins per Duty Cycle

Duty	Common Pins	Segment Pins	Dot Number
1/8	COM0-COM7	32–40 pins	256 dots-320 dots
1/4	COM0-COM3		128 dots-160 dots
1/3	COM0-COM2		96 dots-120 dots

LCD CONTROL REGISTER (LCON)

The LCD control register (LCON) is used to turn the LCD display on and off, to select duty, to output LCD SEG expand signal for LCD display expansion, and to control the flow of current to dividing resistors in the LCD circuit. Following a RESET, all LCON values are cleared to "0". This turns the LCD display off and stops the flow of current to the dividing resistors.

LCON	LCON.3	LCON.2	LCON.1	LCON.0	F8EH
------	--------	--------	--------	--------	------

Table 12-2. LCD Control Register (LCON) Organization

LCON Bit	Setting	Description	
LCON.3	0	1/4 bias select	
	1	1/3 bias select	
LCON.2	0	Disable LCDCK andLCDSY signal outputs	
	1	Enable LCDCK andLCDSY signal outputs	
LCON.1	0	LCD display off (All COM/SEG pins are high output)	
	1	LCD display on	
LCON.0	0	Turn off the internal LCD bias TR	
	1	Turn on the internal LCD bias TR	

NOTES:

- 1. In case of LCON.0, you can turn on/off internal LCD bias TR.
- 2. In case of internal LCD bias
 - When LCON.1-.0 = #00B, LCD display is turned off. When LCON.1-.0 = #11B, LCD display is turned on.
- 3. In case of external LCD bias
 - When LCON.1–.0 = #00B and VLC5 = #High, LCD display is turned off.
 - When LCON.1-.0 = #10B and VLC5 = "Low", LCD display is turned on
- 4. To select LCD bias, you must use both the LCON.3 setting and an external LCD bias circuit connection.

S3C72K8/P72K8 LCD CONTROLLER/DRIVER

LCD MODE REGISTER (LMOD)

The LCD mode control register LMOD is used to control display mode; LCD clock, segment or port output, and display on/off. LMOD can be manipulated using 8-bit write instructions.

The LCD clock signal, LCDCK, determines the frequency of COM signal scanning of each segment output. This is also referred to as the 'frame frequency. Since LCDCK is generated by dividing the watch timer clock (fw), the watch timer must be enabled when the LCD display is turned on.

The LCD display can continue to operate during idle and stop modes if a subsystem clock is used as the watch timer source. The LCD mode register LMOD controls the output mode of the 8 pins used for normal outputs (P5.0–P5.7). Bits LMOD.7–5 define the segment output and normal bit output configuration.

LCDCK 256 Hz 2048 Hz 1024 Hz 128 Hz 512 Hz

Table 12-4. LCD Clock Signal (LCDCK) Frame Frequency

4096 Hz **Display Duty Cycle** 1/8 64 128 256 512 1/4 128 512 64 256 1/3 42.7 85.3 341.3 170.7

NOTE: fw = 32.768 kHz

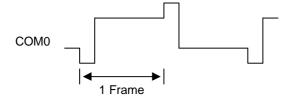

Table 12-5. LCD Mode Register (LMOD) Organization

Segment /Output Port Selection Bits

LMOD.7	LMOD.6	SEG39-36	SEG35-32	Total Number of Segment
0	0	SEG port	SEG port	40
0	1	SEG port	Output port	36
1	0	Output port	SEG port	36
1	1	Output port	Output port	32

LCD Clock Selection Bits

LMOD.5	LMOD.4	LCD Clock (LCDCK)		
		1/8 duty (COM0-COM7)	1/4 duty (COM0-COM3)	1/3 duty (COM0-COM2)
0	0	fxx/2 ⁶ (512 Hz)	fxx/2 ⁷ (256 Hz)	fxx/2 ⁸ (128 Hz)
0	1	fxx/2 ⁵ (1024 Hz)	fxx/2 ⁶ (512 Hz)	fxx/2 ⁷ (256 Hz)
1	0	fxx/2 ⁴ (2048 Hz)	fxx/2 ⁵ (1024 Hz)	fxx/2 ⁶ (512 Hz)
1	1	fxx/2 ³ (4096 Hz)	fxx/2 ⁴ (2048 Hz)	fxx/2 ⁵ (1024 Hz)

NOTE: LCDCK is supplied only when the watch timer operates. To use the LCD controller, bit-2 in the watch mode register WMOD should be set to 1.

Display Mode Selection Bits

LMOD.3	LMOD.2	Duty
0	0	1/8 duty (COM0–COM7 select)
1	0	1/4 duty (COM0–COM3 select)
1	1	1/3 duty (COM0–COM2 select)

0	0	All LCD dots off
0	1	All LCD dots on
1	0	Normal display

S3C72K8/P72K8 LCD CONTROLLER/DRIVER

LCD VOLTAGE DIVIDING METHOD

Power can be supplied without an external dividing resistor. Figure 12-4 shows the bias connections for the S3C72K8 LCD drive power supply.

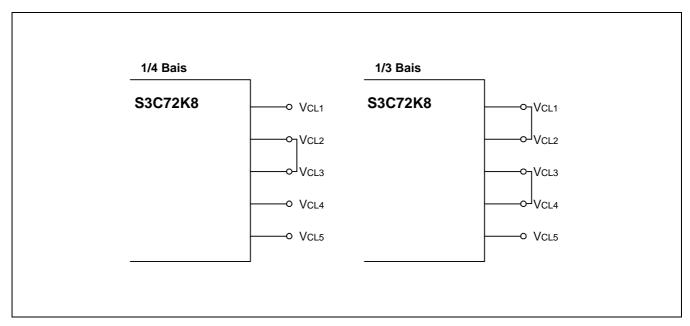

Figure 12-4. LCD Bias Circuit Connection

APPLICATION WITHOUT CONTRAST CONTROL

If you use an internal transistor (LCON.0) to turn on/off 'LCD display', you can get a merit that peripheral circuits are simple. But in that case, you can't control LCD contrast.

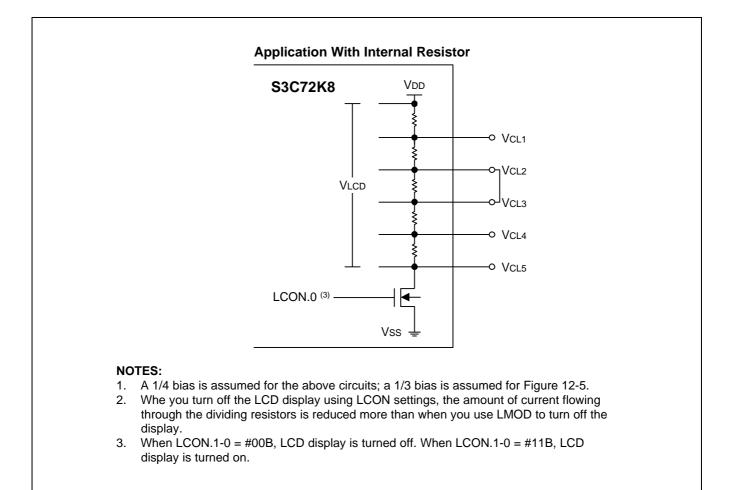

Figure 12-5. Connection For LCD On/Off Using Internal Transistor

S3C72K8/P72K8 LCD CONTROLLER/DRIVER

APPLICATION WITH CONTRAST CONTROL

If only turn on/off 'LCD display' using external output pin, you can control LCD contrast using variable resistor.

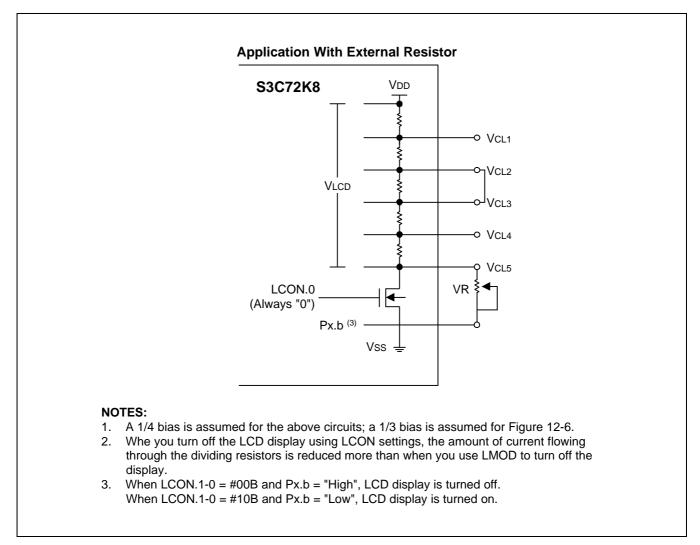

Figure 12-6. Connection For LCD On/Off Using External Output Pin

COMMON (COM) SIGNALS

The common signal output pin selection (COM pin selection) varies according to the selected duty cycle.

- In 1/8 duty mode, COM0–COM7 pins are selected
- In 1/4 duty mode, COM0–COM3 pins are selected
- In 1/3 duty mode, COM0–COM2 pins are selected

SEGMENT (SEG) SIGNALS

The 40 LCD segment signal pins are connected to corresponding display RAM locations at bank 1. Bits of the display RAM are synchronized with the common signal output pins.

When the bit value of a display RAM location is "1", a select signal is sent to the corresponding segment pin. When the display bit is "0", a 'no-select' signal is sent to the corresponding segment pin.

S3C72K8/P72K8 COMPARATOR

13 COMPARATOR

OVERVIEW

P1.0,and P1.1 can be used as a analog input port for a comparator. The reference voltage for the 2-channel comparator can be supplied either internally or externally at P1.0. When an internal reference voltage is used, two channels (P1.0–P1.1) are used for analog inputs and the internal reference voltage is varied in 16 levels. If an external reference voltage is input at P1.0, the other P1.1 pins are used for analog input.

When a conversion is completed, the result is saved in the comparison result register CMPREG. The initial values of the CMPREG are undefined and the comparator operation is disabled by a RESET. The comparator module has the following components:

- Comparator
- Internal reference voltage generator (4-bit resolution)
- External reference voltage source at P1.0
- Comparator mode register (CMOD)
- Comparison result register (CMPREG)

COMPARATOR S3C72K8/P72K8

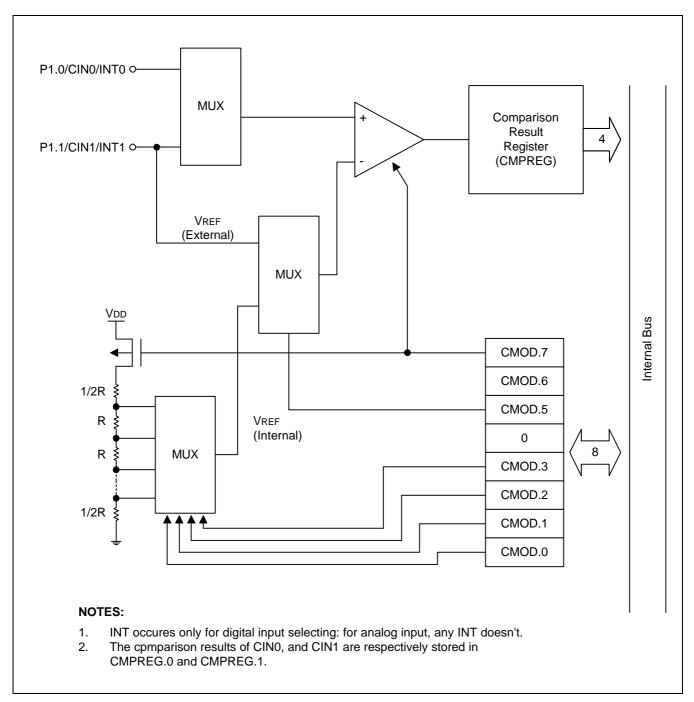

Figure 13-1. Comparator Circuit Diagram

S3C72K8/P72K8 COMPARATOR

COMPARATOR MODE REGISTER (CMOD)

The comparator mode register CMOD is an 8-bit register that is used to select the operation mode of the comparator. It is mapped to addresses FD2H–FD3H and can be manipulated using 8-bit memory instructions. Based on the CMOD.5 bit setting, an internal or an external reference voltage is input for the comparator, as follows:

When CMOD.5 is set to logic zero:

- A reference voltage is selected by the CMOD.0 to CMOD.3 bit settings.
- P1.0 to P1.1 are used as analog input pins.
- The internal digital to analog converter generates 16 reference voltages.
- The comparator can detect 150 mV differences between the reference voltage and the analog input voltages.
- Comparator results are written into bit-0 to bit-2 of the comparison result register (CMPREG).

When CMOD.5 is set to logic one:

- An external reference voltage is supplied from P1.0/CIN0.
- P1.1 is used as the analog input pins.
- The comparator can detect 150 mV differences between the reference voltage and the analog input voltages.
- Bits 0 and 1 in the CMPREG register contain the results.

Bit 6 in the CMOD register controls conversion time while bit 7 enables or disables comparator operation to reduce power consumption. A RESET signal clears all bits to logic zero, causing the comparator to enter stop mode.

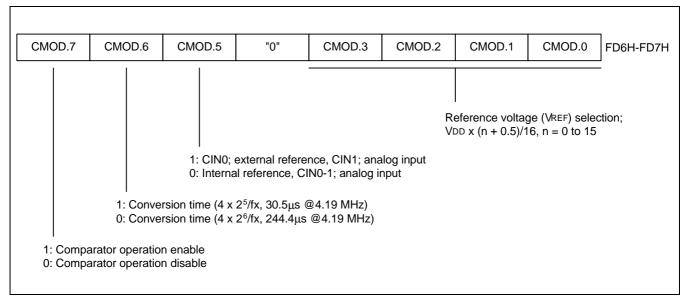

Figure 13-2. Comparator Mode Register (CMOD) Organization

COMPARATOR S3C72K8/P72K8

PORT 1 MODE REGISTER (P1MOD)

P1MOD register settings determine if P1.0 and P1.1 are used for analog or digital input. The P1MOD register is 4-bit write-only register. P1MOD is mapped to address FE2H. A reset operation initializes all P1MOD register values to zero, configuring P1.0 and P1.1 as a digital input port.

When a P1MOD bit is set to "0", the corresponding pin is configured as a digital input pin. When set to "1", it is configured as an analog input pin: P1MOD.0 for P1.0, and P1MOD.1 for P1.1.

COMPARATOR OPERATION

The comparator compares analog voltage input at CIN0–CIN2 with an external or internal reference voltage (V_{REF}) that is selected by the CMOD register. The result is written to the comparison result register CMPREG at address FD4H. The comparison result at internal reference is calculated as follows:

If "1" Analog input voltage ≥ V_{RFF} + 150 mV

If "0" Analog input voltage $\leq V_{RFF} - 150 \text{ mV}$

To obtain a comparison result, the data must be read out from the CMPREG register after V_{REF} is updated by changing the CMOD value after a conversion time has elapsed.

S3C72K8/P72K8 SERIAL I/O INTERFACE

14 SERIAL I/O INTERFACE

OVERVIEW

The serial I/O interface (SIO) has the following functional components:

- 8-bit mode register (SMOD)
- Clock selector circuit
- 8-bit buffer register (SBUF)
- 3-bit serial clock counter

Using the serial I/O interface, 8-bit data can be exchanged with an external device. The transmission frequency is controlled by making the appropriate bit settings to the SMOD register.

The serial interface can run off an internal or an external clock source, or the TOL0 signal that is generated by the 8-bit timer/counter, TC0. If the TOL0 clock signal is used, you can modify its frequency to adjust the serial data transmission rate.

SERIAL I/O OPERATION SEQUENCE

The general operation sequence of the serial I/O interface can be summarized as follows:

- 1. Set SIO mode to transmit-and-receive or to receive-only.
- 2. Select MSB-first or LSB-first transmission mode.
- 3. Set the SCK clock signal in the mode register, SMOD.
- 4. Set SIO interrupt enable flag (IES) to "1".
- 5. Initiate SIO transmission by setting bit 3 of the SMOD to "1".
- 6. When the SIO operation is complete, IRQS flag is set and an interrupt is generated.

SERIAL I/O INTERFACE S3C72K8/P72K8

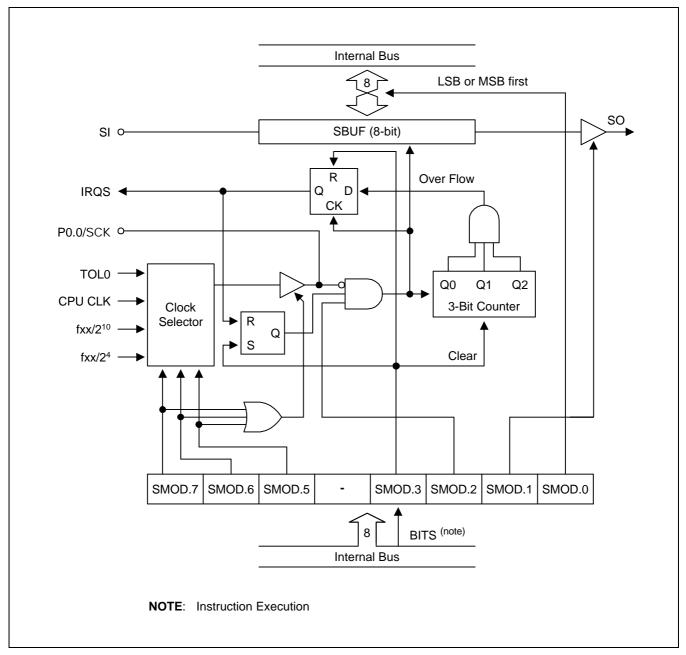

Figure 14-1. Serial I/O Interface Circuit Diagram

S3C72K8/P72K8 SERIAL I/O INTERFACE

SERIAL I/O MODE REGISTER (SMOD)

The serial I/O mode register, SMOD, is an 8-bit register that specifies the operation mode of the serial interface. Its reset value is logical zero. SMOD is organized in two 4-bit registers, as follows:

FE0H	SMOD.3	SMOD.2	SMOD.1	SMOD.0
FE1H	SMOD.7	SMOD.6	SMOD.5	0

SMOD register settings enable you to select either MSB-first or LSB-first serial transmission, and to operate in transmit-and-receive mode or receive-only mode. SMOD is a write-only register and can be addressed only by 8-bit RAM control instructions. One exception to this is SMOD.3, which can be written by a 1-bit RAM control instruction. When SMOD.3 is set to 1, the contents of the serial interface interrupt request flag, IRQS, and the 3-bit serial clock counter are cleared, and SIO operations are initiated. When the SIO transmission starts, SMOD.3 is cleared to logical zero.

Table 14-1. SIO Mode Register (SMOD) Organization

SMOD.0	0	Most significant bit (MSB) is transmitted first
	1	Least significant bit (LSB) is transmitted first
SMOD.1	0	Receive-only mode
	1	Transmit-and-receive mode
SMOD.2	0	Disable the data shifter and clock counter; retain contents of IRQS flag when serial transmission is halted
	1	Enable the data shifter and clock counter; set IRQS flag to "1" when serial transmission is halted
SMOD.3	1	Clear IRQS flag and 3-bit clock counter to "0"; initiate transmission and then reset this bit to logic zero
SMOD.4	0	Bit not used; value is always "0"

SMOD.7	SMOD.6	SMOD.5	Clock Selection	R/W Status of SBUF
0	0	0	External clock at SCK pin	SBUF is enabled when SIO operation is halted or when SCK goes high.
0	0	1	Use TOL0 clock from TC0	
0	1	Х	CPU clock: fxx/4, fxx/8, fxx/64	Enable SBUF read/write
1	0	0	4.09 kHz clock: fxx/2 ¹⁰	SBUF is enabled when SIO operation is halted or when SCK goes high.
1	1	1	262 kHz clock: fxx/2 ⁴	

NOTES:

- 1. 'fxx' = system clock; 'x' means 'don't care'.
- 2. kHz frequency ratings assume a system clock (fxx) running at 4.19 MHz.
- 3. The SIO clock selector circuit cannot select a fxx/2⁴ clock if the CPU clock is fxx/64.
- 4. It must be selected MSB-first or LSB-first transmission mode before loading a data to SBUF.

SERIAL I/O INTERFACE S3C72K8/P72K8

SERIAL I/O TIMING DIAGRAMS

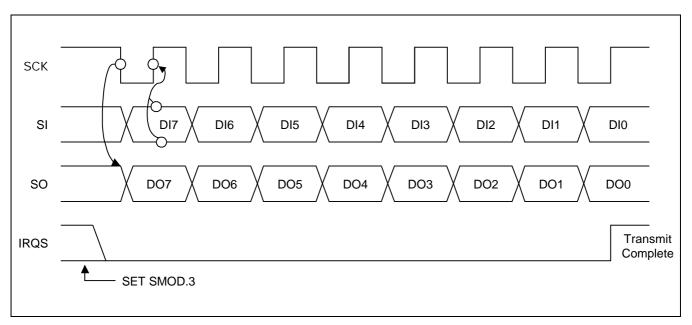

Figure 14-2. SIO Timing in Transmit/Receive Mode

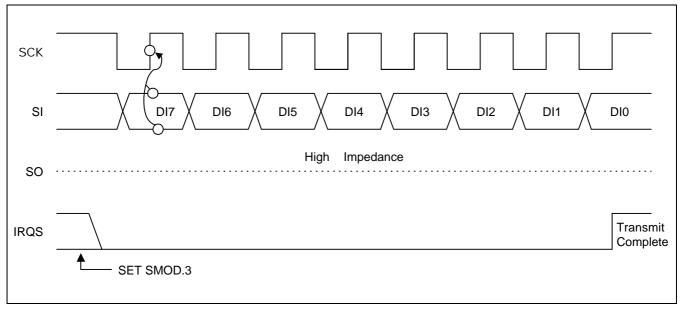

Figure 14-3. SIO Timing in Receive-Only Mode

S3C72K8/P72K8 SERIAL I/O INTERFACE

SERIAL I/O BUFFER REGISTER (SBUF)

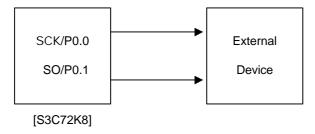

The serial I/O buffer register ,SBUF, can be read or written using 8-bit RAM control instructions. Following a RESET, the value of SBUF is undetermined.

When the serial interface operates in transmit-and-receive mode (SMOD.1 = "1"), transmit data in the SIO buffer register are output to the SO pin (P0.1) at the rate of one bit for each falling edge of the SIO clock. Receive data are simultaneously input from the SI pin (P0.2) to SBUF at the rate of one bit for each rising edge of the SIO clock. When receive-only mode is used, incoming data are input to the SIO buffer at the rate of one bit for each rising edge of the SIO clock.

S3C72K8/P72K8 ELECTRICAL DATA

15 ELECTRICAL DATA

OVERVIEW

In this section, information on S3C72K8 electrical characteristics is presented as tables and graphics. The information is arranged in the following order:

Standard Electrical Characteristics

- Absolute maximum ratings
- D.C. electrical characteristics
- Main system clock oscillator characteristics
- Subsystem clock oscillator characteristics
- I/O capacitance
- Comparator electrical characteristics
- A.C. electrical characteristics
- Operating voltage range

Stop Mode Characteristics and Timing Waveforms

- RAM data retention supply voltage in stop mode
- Stop mode release timing when initiated by RESET
- Stop mode release timing when initiated by an interrupt request

Miscellaneous Timing Waveforms

- A.C timing measurement points
- Clock timing measurement at X_{IN}
- Clock timing measurement at XT_{IN}
- TCL timing
- Input timing for RESET signal
- Input timing for external interrupts
- Serial data transfer timing

ELECTRICAL DATA S3C72K8/P72K8

Table 15-1. Absolute Maximum Ratings

 $(T_A = 25 \,^{\circ}C)$

Parameter	Symbol	Conditions	Rating	Units
Supply Voltage	V _{DD}	_	- 0.3 to + 6.5	V
Input Voltage	V _{I1}	All I/O pins active	-0.3 to $V_{DD} + 0.3$	V
Output Voltage	Vo	_	-0.3 to $V_{DD} + 0.3$	V
Output Current High	I _{OH}	One I/O pin active	– 15	mA
		All I/O pins active	- 35	
Output Current Low	I _{OL}	One I/O pin active	+ 30 (Peak value)	mA
			+ 15 ^(note)	
		All I/O port, total	+ 100 (Peak value)	
			+ 60 (note)	
Operating Temperature	T _A	_	- 40 to + 85	°C
Storage Temperature	T _{stg}	-	-65 to +150	°C

NOTE: The values for Output Current Low (I_{OL}) are calculated as Peak Value \times $\sqrt{\text{Duty}}$.

NOTES:

- 1. Currents in the following circuits are not included; on-chip pull-up resistors, internal LCD voltage dividing resistors, output port drive currents, comparator.
- 2. Data includes power consumption for subsystem clock oscillation.
- 3. When the system clock control register, SCMOD, is set to 1001B, main system clock oscillation stops and the subsystem clock is used.
- 4. Every values in this table is measured when the power control register (PCON) is set to "0011B".

Table 15-3. Main System Clock Oscillator Characteristics

 $(T_A = -40 \,^{\circ}\text{C} + 85 \,^{\circ}\text{C}, \, V_{DD} = 2.0 \,^{\circ}\text{V} \text{ to } 5.5 \,^{\circ}\text{V})$

S3C72K8/P72K8 MECHANICAL DATA

16 MECHANICAL DATA

OVERVIEW

The S3C72K8 microcontroller is currently available in a 80-pin QFP package.

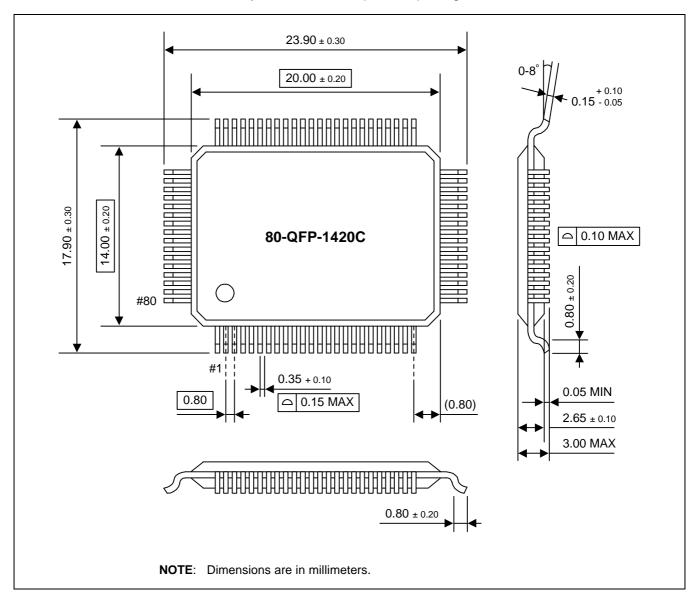

Figure 16-1. 80-QFP-1420C Package Dimensions

S3C72K8/P72K8 S3P72K8 OTP

17 S3P72K8 OTP

OVERVIEW

The S3P72K8 single-chip CMOS microcontroller is the OTP (One Time Programmable) version of the S3C72K8 microcontroller. It has an on-chip OTP ROM instead of masked ROM. The EPROM is accessed by serial data format.

The S3P72K8 is fully compatible with the S3C72K8, both in function and in pin configuration except ROM size. Because of its simple programming requirements, the S3P72K8 is ideal for use as an evaluation chip for the S3C72K8.

S3P72K8 OTP S3C72K8/P72K8

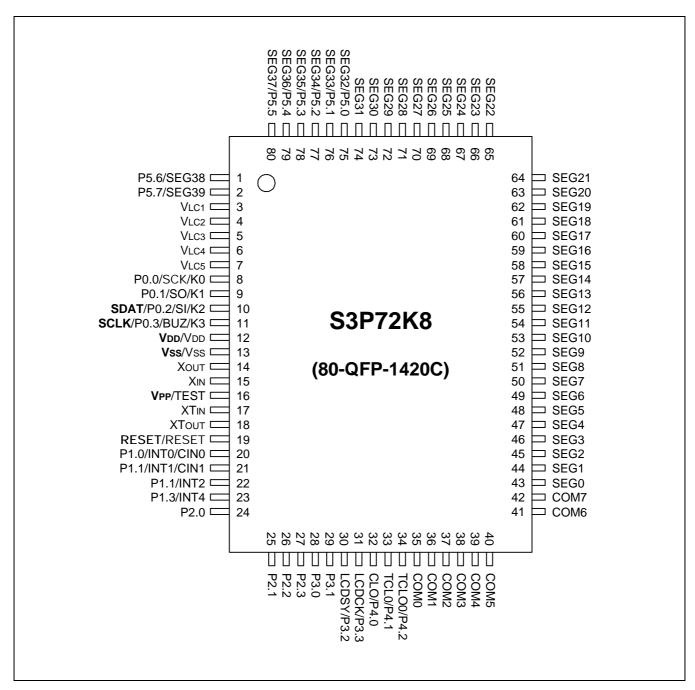

Figure 17-1. S3P72K8 Pin Assignments (80-QFP Package)

S3C72K8/P72K8 S3P72K8 OTP

Table 17-1. Descriptions of Pins Used to Read/Write the EPROM

Main Chip			During	Programming
Pin Name	Pin Name	Pin No.	I/O	Function
P0.2	SDAT	10	I/O	Serial data pin. Output port when reading and input port when writing. Can be assigned as a Input/push-pull output port.
P0.3	SCLK	11	I	Serial clock pin. Input only pin.
TEST	V_PP	16	I	Power supply pin for EPROM cell writing (indicates that OTP enters into the writing mode). When 12.5 V is applied, OTP is in writing mode and when 5 V is applied, OTP is in reading mode. (Option)
RESET	RESET	19	I	Chip Initialization
V _{DD} /V _{SS}	V _{DD} /V _{SS}	12/13	1	Logic power supply pin. V _{DD} should be tied to +5 V during programming.

Table 17-2. Comparison of S3P72K8 and S3C72K8 Features

Characteristic	S3P72K8	S3C72K8
Program Memory	8-Kbyte EPROM	8-Kbyte mask ROM
Operating Voltage (V _{DD})	2.0 V to 5.5 V	2.0 V to 5.5 V
OTP Programming Mode	V _{DD} = 5 V, V _{PP} (TEST) = 12.5V	
Pin Configuration	80 QFP	80 QFP
EPROM Programmability	User Program 1 time	Programmed at the factory

OPERATING MODE CHARACTERISTICS

When 12.5 V is supplied to the V_{PP} (TEST) pin of the S3P72K8, the EPROM programming mode is entered. The operating mode (read, write, or read protection) is selected according to the input signals to the pins listed in Table 17-3 below.

Table 17-3. Operating Mode Selection Criteria

V _{DD}	V _{PP} (TEST)	REG/ MEM	Address (A15-A0)	R/W	Mode
5 V	5 V	0	0000H	1	EPROM read
	12.5 V	0	0000H	0	EPROM program
	12.5 V	0	0000H	1	EPROM verify
	12.5 V	1	0E3FH	0	EPROM read protection

NOTE: "0" means Low level; "1" means High level.

S3C72K8/P72K8 DEVELOPMENT TOOLS

18 DEVELOPMENT TOOLS

OVERVIEW

Samsung provides a powerful and easy-to-use development support system in turnkey form. The development support system is configured with a host system, debugging tools, and support software. For the host system, any standard computer that operates with MS-DOS as its operating system can be used. One type of debugging tool including hardware and software is provided: the sophisticated and powerful in-circuit emulator, SMDS2+, for S3C7, S3C9, S3C8 families of microcontrollers. The SMDS2+ is a new and improved version of SMDS2. Samsung also offers support software that includes debugger, assembler, and a program for setting options.

SHINE

Samsung Host Interface for In-Circuit Emulator, SHINE, is a multi-window based debugger for SMDS2+. SHINE provides pull-down and pop-up menus, mouse support, function/hot keys, and context-sensitive hyper-linked help. It has an advanced, multiple-windowed user interface that emphasizes ease of use. Each window can be sized, moved, scrolled, highlighted, added, or removed completely.

SAMA ASSEMBLER

The Samsung Arrangeable Microcontroller (SAM) Assembler, SAMA, is a universal assembler, and generates object code in standard hexadecimal format. Assembled program code includes the object code that is used for ROM data and required SMDS program control data. To assemble programs, SAMA requires a source file and an auxiliary definition (DEF) file with device specific information.

SASM57

The SASM57 is an relocatable assembler for Samsung's S3C7-series microcontrollers. The SASM57 takes a source file containing assembly language statements and translates into a corresponding source code, object code and comments. The SASM57 supports macros and conditional assembly. It runs on the MS-DOS operating system. It produces the relocatable object code only, so the user should link object file. Object files can be linked with other object files and loaded into memory.

HEX2ROM

HEX2ROM file generates ROM code from HEX file which has been produced by assembler. ROM code must be needed to fabricate a microcontroller which has a mask ROM. When generating the ROM code (.OBJ file) by HEX2ROM, the value 'FF' is filled into the unused ROM area up to the maximum ROM size of the target device automatically.

TARGET BOARDS

Target boards are available for all S3C7-series microcontrollers. All required target system cables and adapters are included with the device-specific target board.

OTPs

One time programmable microcontroller (OTP) for the S3C72K8 microcontroller and OTP programmer (Gang) are now available.
