

ISO²-CMOS **MT9160B/61B** 5 Volt Multi-Featured Codec (MFC)

SEMICONDUCTOR

Advance Information

Features

- Improved idle channel noise over MT9160
- MT9161 version features a delayed framing pulse in SSI and ST-BUS modes to facilitate cascaded devices
- Programmable μ-Law/A-Law Codec and Filters
- Programmable ITU-T G.711/sign-magnitude coding
- Programmable transmit, receive and side-tone gains
- Fully differential interface to handset transducers including 300 ohm receiver driver
- Flexible digital interface including ST-BUS/SSI
- Serial microport or default controllerless mode
- Single 5 volt supply
- Low power operation
- ITU-T G.714 compliant

Applications

- Digital telephone sets
- Cellular radio sets
- Local area communications stations

Description

The MT9160B/61B 5V Multi-featured Codec incorporates a built-in Filter/Codec, gain control and programmable sidetone path as well as on-chip anti-alias filters, reference voltage and bias source. The device supports both ITU-T and sign-magnitude A-Law and μ -Law requirements.

Complete telephony interfaces are provided for connection to handset transducers. Internal register access is provided through a serial microport compatible with various industry standard micro-controllers. The device also supports controllerless operation utilizing the default register conditions.

The MT9160B/61B is fabricated in Mitel's ISO²-CMOS technology ensuring low power consumption and high reliability.

Figure 1 - Functional Block Diagram

Pin Description

	Pin # 24 Pin	Name	Description
1	1	V _{Bias}	Bias Voltage (Output). (V _{DD} /2) volts is available at this pin for biasing external amplifiers. Connect 0.1 μ F capacitor to V _{SSA} ,Connect 1 μ F capacitor to Vref.
2	2	V _{Ref}	Reference Voltage for Codec (Output). Nominally [(V_{DD} /2)-1.9] volts. Used internally. Connect 0.1 μ F capacitor to V_{SSA} ,Connect 1 μ F capacitor to VBias.
3	4	PWRST	Power-up Reset (Input). CMOS compatible input with Schmitt Trigger (active low). Resets internal state of device.
4	5	IC	Internal Connection. Tie externally to V _{SSD} for normal operation.
5	6	Α/μ/IRQ	$A\sqrt{\mu}$ - When internal control bit DEn = 0 this CMOS level compatible input pin governs the companding law used by the filter/Codec; μ -Law when tied to V _{SSD} and A-Law when tied to V _{DD} . Logically OR'ed with A/ μ register bit. IRQ - When internal control bit DEn = 1 this pin becomes an open-drain interrupt output signalling valid access to the D-Channel registers in ST-BUS mode.
6	7	V _{SSD}	Digital Ground. Nominally 0 volts.
7	8	CS	Chip Select (Input). This input signal is used to select the device for microport data transfers. Active low. CMOS level compatible.
8	10	SCLK	Serial Port Synchronous Clock (Input). Data clock for microport. CMOS level compatible.
9	11	DATA 1	Bidirectional Serial Data. Port for microprocessor serial data transfer. In Motorola/ National mode of operation, this pin becomes the data transmit pin only and data receive is performed on the DATA 2 pin. Input CMOS level compatible.
10	12	DATA 2	Serial Data Receive. In Motorola/National mode of operation, this pin is used for data receive. In Intel mode, serial data transmit and receive are performed on the DATA 1 pin and DATA 2 is disconnected. Input CMOS level compatible.
11	13	D _{out}	Data Output. A high impedance three-state digital output for 8 bit wide channel data being sent to the Layer 1 transceiver. Data is shifted out via this pin concurrent with the rising edge of the bit clock during the timeslot defined by STB, or according to standard ST-BUS timing.
12	14	D _{in}	Data Input. A digital input for 8 bit wide channel data received from the Layer 1 transceiver. Data is sampled on the falling edge of the bit clock during the timeslot defined by STB, or according to standard ST-BUS timing. Input level is CMOS compatible.

Pin Description (continued)

Pin # 20 Pin	Pin # 24 Pin	Name	Description
13	15	STB/F0i	Data Strobe/Frame Pulse (Input). For SSI mode this input determines the 8 bit timeslot used by the device for both transmit and receive data. This active high signal has a repetition rate of 8 kHz. Standard frame pulse definitions apply in ST-BUS mode (refer to figure 11). CMOS level compatible input.
	16 (MT9161B only)	STBd/ FOod	Delayed Frame Pulse Output . In SSI mode, an 8 bit wide strobe is output after the first strobe goes low. In ST-BUS mode, a frame pulse is output 4 channel time slots after /F0i.
14	17	CLOCKin	Clock (Input). The clock provided to this input pin is used for the internal device functions. For SSI mode connect the bit clock to this pin when it is 512 kHz or greater. Connect a 4096 kHz clock to this input when the available bit clock is 128 kHz or 256 kHz. For ST-BUS mode connect $\overline{C4i}$ to this pin. CMOS level compatible.
15	18	V _{DD}	Positive Power Supply (Input). Nominally 5 volts.
16	19	HSPKR-	Inverting Handset Speaker (Output). Output to the handset speaker (balanced).
17	20	HSPKR+	Non-Inverting Handset Speaker (Output). Output to the handset speaker (balanced).
18	22	V _{SSA}	Analog Ground (Input). Nominally 0 volts.
19	23	M-	Inverting Microphone (Input). Inverting input to microphone amplifier from the handset microphone.
20	24	M+	Non-Inverting Microphone (Input). Non-inverting input to microphone amplifier from the handset microphone.
	3,9, 16,21	NC	No Connect. (24 Pin Packages only). Pin 16 is NC for MT9160B.

Overview

The 5V Multi-featured Codec (MFC) features complete Analog/Digital and Digital/Analog conversion of audio signals (Filter/Codec) and an analog interface to a standard handset transmitter and receiver (Transducer Interface). The receiver amplifier is capable of driving a 300 ohm load.

Each of the programmable parameters within the functional blocks is accessed through a serial microcontroller port compatible with Intel MCS-51[®], Motorola SPI[®] and National Semiconductor Microwire[®] specifications. These parameters include: gain control, power down, mute, B-Channel select (ST-BUS mode), C&D channel control/access, law control, digital interface programming and loopback. Optionally the device may be used in a controllerless mode utilizing the power-on default settings.

Functional Description

Filter/Codec

The Filter/Codec block implements conversion of the analog 0-3.3 kHz speech signals to/from the digital domain compatible with 64 kb/s PCM B-Channels. Selection of companding curves and digital code assignment are programmable. These are ITU-T G.711 A-law or μ -Law, with true-sign/Alternate Digit Inversion or true-sign/Inverted Magnitude coding, respectively. Optionally, sign-magnitude coding may also be selected for proprietary applications.

The Filter/Codec block also implements transmit and receive audio path gains in the analog domain. A programmable gain, voice side-tone path is also included to provide proportional transmit speech feedback to the handset receiver. This side tone path feature is disabled by default. Figure 3 depicts the nominal half-channel and side-tone gains for the MT9160B/61B.

In the event of \overline{PWRST} , the MT9160B/61B defaults such that the side-tone path is off, all programmable gains are set to 0dB and ITU-T μ -Law is selected. Further, the digital port is set to SSI mode operation at 2048 kb/s and the FDI and driver sections are powered up. (See Microport section)

The internal architecture is fully differential to provide the best possible noise rejection as well as to allow a wide dynamic range from a single 5 volt supply design. This fully differential architecture is continued into the Transducer Interface section to provide full chip realization of these capabilities for the handset functions.

A reference voltage (V_{Ref}), for the conversion requirements of the Codec section, and a bias voltage (V_{Bias}), for biasing the internal analog sections, are both generated on-chip. V_{Bias} is also brought to an external pin so that it may be used for biasing external gain setting amplifiers. A 0.1µF capacitor must be connected from V_{Bias} to analog ground at all times. Although V_{Ref} may only be used internally, a 0.1µF capacitor must be connected from V_{Bias} and V_{Ref} to ground. The analog ground reference point for these two capacitors must be physically the same point. Connect a 1µF capacitor between V_{Bias} and V_{Ref} to ensure a quiet reference voltage. To facilitate this the V_{Ref} and V_{Bias} pins are situated on adjacent pins.

The transmit filter is designed to meet ITU-T G.714 specifications. The nominal gain for this filter is 0 dB (gain control = 0 dB). Gain control allows the output signal to be increased up to 7 dB. An anti-aliasing filter is included. This is a second order lowpass implementation with a corner frequency at 25 kHz.

The receive filter is designed to meet ITU-T G.714 specifications. The nominal gain for this filter is 0 dB (gain control = 0dB). Gain control allows the output signal to be attenuated up to 7 dB. Filter response is peaked to compensate for the sinx/x attenuation caused by the 8 kHz sampling rate.

Side-tone is derived from the input of the Tx filter and is not subject to the gain control of the Tx filter section. Side-tone is summed into the receive handset transducer driver path after the Rx filter gain control section so that Rx gain adjustment will not affect side-tone levels. The side-tone path may be enabled/disabled with the gain control bits located in Gain Control Register 2 (address 01h).

Transmit and receive filter gains are controlled by the $TxFG_0$ - $TxFG_2$ and $RxFG_0$ - $RxFG_2$ control bits, respectively. These are located in Gain Control

Register 1 (address 00h). Transmit filter gain is adjustable from 0 dB to +7 dB and receive filter gain from 0dB to -7 dB, both in 1 dB increments.

Side-tone filter gain is controlled by the STG_0-STG_2 control bits located in Gain Control Register 2 (address 01h). Side-tone gain is adjustable from -9.96 dB to +9.96 dB in 3.32 dB increments.

Companding law selection for the Filter/Codec is provided by the A/ μ companding control bit while the coding scheme is controlled by the Smag/ITU-T control bit. The A/ μ control bit is logically OR'ed with the A/ μ pin providing access in both controller and controllerless modes. Both A/ μ and Smag/ITU-T reside in Control Register 2 (address 04h). Table 1 illustrates these choices.

Code	Sign/	ITU-T (G.711)					
Code	Magnitude		A-Law				
+ Full Scale	1111 1111	1000 0000	1010 1010

- Full Scale	0111 1111	0000 0000	0010 1010				

Table 1 - PCM Coding

Transducer Interfaces

Standard handset transducer interfaces are provided by the MT9160B/61B. These are:

- The handset microphone inputs (transmitter), pins M+/M-. The transmit path gain path may be adjusted to either 6.0 dB or 15.3 dB. Control of this gain is provided by the TxINC control bit (Gain Control register 1, address 00h).
- The handset speaker outputs (receiver), pins HSPKR+/HSPKR-. This internally compensated fully differential output driver is capable of driving the load shown in Figure 3. The nominal receive path gain may be adjusted to either 0 dB, -6 dB or -12 dB. Control of this gain is provided by the RxINC control bit (Gain Control register 1, address 00h). This gain adjustment is in addition to the programmable gain provided by the receive filter.

The serial microport, compatible with Intel MCS-51 (mode 0), Motorola SPI (CPOL=0,CPHA=0) and National Semiconductor Microwire specifications provides access to all MT9160B/61B internal read and write registers. This microport consists of a transmit/receive data pin (DATA1), a receive data pin

Figure 3 - Audio Gain Partitioning

(DATA2), a chip select pin (\overline{CS}) and a synchronous data clock pin (SCLK). For D-channel contention control, in ST-BUS mode, this interface provides an open-drain interrupt output (\overline{IRQ}).

The microport dynamically senses the state of the serial clock (SCLK) each time chip select becomes active. The device then automatically adjusts its internal timing and pin configuration to conform to Intel or Motorola/National requirements. If SCLK is high during chip select activation then Intel mode 0 timing is assumed. The DATA1 pin is defined as a bi-directional (transmit/receive) serial port and DATA2 is internally disconnected. If SCLK is low during chip select activation then Motorola/National timing is assumed. Motorola processor mode CPOL=0, CPHA=0 must be used. DATA1 is defined as the data transmit pin while DATA2 becomes the data receive pin. Although the dual port Motorola controller configuration usually supports full-duplex communication, only half-duplex communication is possible in the MT9160B/61B. The micro must discard non-valid data which it clocks in during a valid write transfer to the MT9160B/61B. During a valid read transfer from the MT9160B/61B data simultaneously clocked out by the micro is ignored by the MT9160B/61B.

All data transfers through the microport are two-byte transfers requiring the transmission of a Command/ Address byte followed by the data byte written or read from the addressed register. CS must remain asserted for the duration of this two-byte transfer. As shown in Figures 5 and 6 the falling edge of \overline{CS} indicates to the MT9160B/61B that a microport transfer is about to begin. The first 8 clock cycles of SCLK after the falling edge of \overline{CS} are always used to receive the Command/Address byte from the microcontroller. Command/Address byte The contains information detailing whether the second byte transfer will be a read or a write operation and at what address. The next 8 clock cycles are used to transfer the data byte between the MT9160B/61B and the microcontroller. At the end of the two-byte transfer \overline{CS} is brought high again to terminate the session. The rising edge of \overline{CS} will tri-state the output driver of DATA1 which will remain tri-stated as long as \overline{CS} is high.

Intel processors utilize least significant bit first transmission while Motorola/National processors employ most significant bit first transmission. The MT9160B/61B microport automatically accommodates these two schemes for normal data bytes. However, to ensure decoding of the R/W and address information, the Command/Address byte is defined differently for Intel operation than it is for

MT9160B/61B

Motorola/National operation. Refer to the relative timing diagrams of Figures 5 and 6.

Receive data is sampled on the rising edge of SCLK while transmit data is made available concurrent with the falling edge of SCLK.

Flexible Digital Interface

A serial link is required to transport data between the MT9160B/61B and an external digital transmission device. The MT9160B/61B utilizes the ST-BUS architecture defined by Mitel Semiconductor but also

supports a strobed data interface found on many standard Codec devices. This interface is commonly referred to as Simple Serial Interface (SSI). The combination of ST-BUS and SSI provides a Flexible Digital Interface (FDI) capable of supporting all Mitel basic rate transmission devices as well as many other 2B+D transceivers.

The required mode of operation is selected via the CSL2-0 control bits (Control Register 2, address 04h). Pin definitions alter dependent upon the operational mode selected, as described in the following subsections as well as in the Pin Description tables.

Quiet Code

The FDI can be made to send quiet code to the decoder and receive filter path by setting the RxMute bit high. Likewise, the FDI will send quiet code in the transmit path when the TxMute bit is high. Both of these control bits reside in Control Register 1 at address 03h. When either of these bits are low their respective paths function normally. The -Zero entry of Table 1 is used for the quiet code definition.

ST-BUS Mode

The ST-BUS consists of output (DSTo) and input (DSTi) serial data streams, in FDI these are named Dout and Din respectively, a synchronous clock input signal CLOCKin ($\overline{C4i}$), and a framing pulse input ($\overline{F0i}$). These signals are direct connections to the corresponding pins of Mitel basic rate devices. The CSL2, CSL1 and CSL0 bits are set to 1 for ST-BUS operation.

The data streams operate at 2048 kb/s and are Time Division Multiplexed into 32 identical channels of 64 kb/s bandwidth. A frame pulse (a 244 nSec low going pulse) is used to separate the continuous serial data streams into the 32 channel TDM frames. Each frame has a 125 μ Second period translating into an 8 kHz frame rate. A valid frame begins when F0i is

logic low coincident with a falling edge of $\overline{C4i}$. Refer to figure 11 for detailed ST-BUS timing. $\overline{C4i}$ has a frequency (4096 kHz) which is twice the data rate. This clock is used to sample the data at the 3/4 bit-cell position on DSTi and to make data available on DSTo at the start of the bit-cell. $\overline{C4i}$ is also used to clock the MT9160B/61B internal functions (i.e., Filter/Codec, Digital gain and tone generation) and to provide the channel timing requirements.

The MT9160B/61B uses only the first four channels of the 32 channel frame. These channels are always defined, beginning with Channel 0 after the frame pulse, as shown in Figure 6 (ST-BUS channel assignments). The MT9161B provides a delayed frame pulse (F0od), 4 channels after the input frame pulse.

The first two (D & C) Channels are enabled for use by the DEN and CEN bits respectively, (Control Register 2, address 04h). ISDN basic rate service (2B+D) defines a 16 kb/s signalling (D) Channel. The MT9160B/61B supports transparent access to this signalling channel. ST-BUS basic rate transmission devices, which may not employ a microport, provide access to their internal control/status registers through the ST-BUS Control (C) Channel. The MT9160B/61B supports microport access to this C-Channel.

DEN - D-Channel

In ST-BUS mode access to the D-Channel (transmit and receive) data is provided through an 8-bit read/ write register (address 06h). D-Channel data is accumulated in, or transmitted from this register at the rate of 2 bits/frame for 16 kb/s operation (1 bit/ frame for 8 kb/s operation). Since the ST-BUS is asynchronous, with respect to the microport, valid access to this register is controlled through the use of an interrupt (IRQ) output. D-Channel access is enabled via the (DEn) bit.

<u>DEN:</u>

When 1, ST-BUS D-channel data (1 or 2 bits/frame depending on the state of the D8 bit) is shifted into/ out of the D-channel (READ/WRITE) register.

When 0, the receive D-channel data (READ) is still shifted into the proper register while the DSTo D-channel timeslot and IRQ outputs are tri-stated (default).

<u>D8:</u>

When 1, D-Channel data is shifted at the rate of 1 bit/ frame (8 kb/s).

When 0, D-Channel data is shifted at the rate of 2 bits/frame (16 kb/s default).

16 kb/s D-Channel operation is the default mode which allows the microprocessor access to a full byte of D-Channel information every fourth ST-BUS frame. By arbitrarily assigning ST-BUS frame n as the reference frame, during which the microprocessor D-Channel read and write operations are performed, then:

(a) A microport read of address 04 hex will result in a byte of data being extracted which is composed of four di-bits (designated by roman numerals I,II,III,IV). These di-bits are composed of the two D-Channel bits received during each of frames n, n-1, n-2 and n-3. Referring to Fig. 7a: di-bit I is mapped from frame n-3, di-bit II is mapped from frame n-2, di-bit III is mapped from frame n-1 and di-bit IV is mapped from frame n.

The D-Channel read register is not preset to any particular value on power-up (PWRST) or software reset (RST).

(b) A microport write to Address 04 hex will result in a byte of data being loaded which is composed of four di-bits (designated by roman numerals I, II, III, IV). These di-bits are destined for the two D-Channel bits transmitted during each of frames n+1, n+2, n+3, n+4. Referring to Fig. 7a: di-bit I is mapped to frame n+1, di-bit II is mapped to frame n+2, di bit III is mapped to frame n+3 and di bit IV is mapped to frame n+4.

If no new data is written to address 04 hex, the current D-channel register contents will be continuously re-transmitted. The D-Channel write register is preset to all ones on power-up (PWRST) or software reset (RST).

An interrupt output is provided (\overline{IRQ}) to synchronize microprocessor access to the D-Channel register during valid ST-BUS periods only. IRQ will occur every fourth (eighth in 8 kb/s mode) ST-BUS frame at the beginning of the third (second in 8 kb/s mode) ST-BUS bit cell period. The interrupt will be removed following a microprocessor Read or Write of Address 04 hex or upon encountering the following frames F0i input, whichever occurs first. To ensure D-Channel data integrity, microport read/write access to Address 04 hex must occur before the following frame pulse. See Figure 7b for timing.

8 kb/s operation expands the interrupt to every eight frames and processes data one-bit-per-frame. D-Channel register data is mapped according to Figure 7c.

<u>Cen - C-Channe</u>l

Channel 1 conveys the control/status information for the Layer 1 transceiver. C-Channel data is transferred MSB first on the ST-BUS by the MT9160B/61B. The full 64 kb/s bandwidth is available and is assigned according to which transceiver is being used. Consult the data sheet for the selected transceiver for its C-Channel bit definitions and order of bit transfer.

When CEN is high, data written to the C-Channel register (address 05h) is transmitted, most significant bit first, on DSTo. On power-up reset (PWRST) or software reset (Rst, address 03h) all C-Channel bits default to logic high. Receive C-Channel data (DSTi) is always routed to the read register regardless of this control bit's logic state.

When low, data transmission is halted and this timeslot is tri-stated on DSTo.

B1-Channel and B2-Channel

Channels 2 and 3 are the B1 and B2 channels, respectively. B-channel PCM associated with the Filter/Codec and transducer audio paths is selected on an independent basis for the transmit and receive paths. TxBSel and RxBSel (Control Register 1, address 03h) are used for this purpose.

If no valid transmit path has been selected then the timeslot output on DSTo is tri-stated (see PDFDI and PDDR control bits, Control Register 1 address 03h).

Figure 7b - IRQ Timing Diagram

Figure 7c - D-Channel 8 kb/s Operation

SSI Mode

The SSI BUS consists of input and output serial data streams named Din and Dout respectively, a Clock input signal (CLOCKin), a framing strobe input (STB) and the MT9161B provides a delayed framing strobe output (STBd). The frame strobe must be synchronous with, and eight cycles of, the bit clock. A 4.096 MHz master clock is also required for SSI operation if the bit clock is less than 512 kHz. The timing requirements for SSI are shown in Figures 12 & 13.

In SSI mode the MT9160B/61B supports only B-Channel operation. The internal C and D Channel registers used in ST-BUS mode are not functional for SSI operation. The control bits TxBSel and RxBSel, as described in the ST-BUS section, are ignored since the B-Channel timeslot is defined by the input STB strobe. Hence, in SSI mode transmit and receive B-Channel data are always in the channel defined by the STB input.

The data strobe input STB determines the 8-bit timeslot used by the device for both transmit and receive data. This is an active high signal with an 8 kHz repetition rate. The MT9161B provides a delayed strobe pulse (STBd) which occurs 4 frames after the initial strobe goes low and is held high for the duration of 8 pcm bits.

SSI operation is separated into two categories based upon the data rate of the available bit clock. If the bit clock is 512 kHz or greater then it is used directly by the internal MT9160B/61B functions allowing synchronous operation. If the available bit clock is 128 kHz or 256 kHz, then a 4096 kHz master clock is required to derive clocks for the internal MT9160B/ 61B functions.

Applications where Bit Clock (BCL) is below 512 kHz are designated as asynchronous. The MT9160B/61B will re-align its internal clocks to allow operation when the external master and bit clocks are asynchronous. Control bits CSL2, CSL1 and CSL0 in Control Register 2 (address 04h) are used to program the bit rates.

For synchronous operation data is sampled, from Din, on the falling edge of BCL during the time slot defined by the STB input. Data is made available, on Dout, on the rising edge of BCL during the time slot defined by the STB input. Dout is tri-stated at all times when STB is not true. If STB is valid and PDDR is set, then quiet code will be transmitted on Dout during the valid strobe period. There is no frame delay through the FDI circuit for synchronous operation.

For asynchronous operation Dout and Din are as defined for synchronous operation except that the allowed output jitter on Dout is larger. This is due to the resynchronization circuitry activity and will not affect operation since the bit cell period at 128 kb/s and 256 kb/s is relatively large. There is a one frame delay through the FDI circuit for asynchronous operation. Refer to the specifications of Figures 13& 14 for both synchronous and asynchronous SSI timing.

PWRST/Software Reset (Rst)

While the MT9160B/61B is held in PWRST no device control or functionality is possible. While in software reset (Rst=1, address 03h) only the microport is functional. Software reset can only be removed by writing the Rst bit low or by performing a hardware PWRST. While the Rst bit is high, the other bits in Control Register 1 are held low and cannot be reprogrammed. Therefore to modify Control Register 1 the Rst bit must first be written low, followed by a 2nd write operation which writes the desired data. This avoids a race condition between clearing the reset bit and the writing of the other bits in Control Register 1.

After a Power-up reset (\overline{PWRST}) or software reset (Rst) all control bits assume their "Power Reset Value" default states; μ -Law coding, 0 dB Rx and 6dB Tx gains and the device powered up in SSI mode 2048 kb/s operation with Dout tri-stated while there is no strobe active on STB. If a valid strobe is supplied to STB, then Dout will be active, during the defined channel.

To attain complete power-down from a normal operating condition, write PDFDI = 1 and PDDR = 1 (Control Register 1, address 03h) or set the \overline{PWRST} pin low.

Preliminary and Advance Data: Some data sheets carry the designation "Preliminary" or "Advance". Preliminary Information represents the design objective for a device type in development and may be revised without notice before the device reaches production. Advance Information is intended for design guidance purposes and refers to a device type in early production where device characterization is ongoing and information is still subject to change without notice. Current information on the status of Preliminary or Advance programs may be obtained from Mitel Sales Offices, Representatives or Distributors.

Information relating to products and circuits ("Product") furnished herein by Mitel Corporation or its subsidiaries ('Mitel") is believed to be reliable. However, Mitel assumes no liability for errors that may appear in this document, or for liability otherwise arising from the application or use of any such information or Product or for any infringement of patents or other intellectual property rights owned by third parties which may result from such application or use. Neither the supply of such information or the purchase of Product conveys any license, either expressed or implied, under patents or other intellectual property rights owned by Mitel or licensed from third parties by Mitel, whatsoever. Purchasers of Product are also hereby notified that the use of Product in certain ways or in combination with Mitel or non-Mitel furnished goods or services may infringe patents or other intellectual property rights owned by Mitel. The Products, their specifications and the information appearing in the document are subject to change by Mitel without notice.
