

Audio Hub CODEC with Voice Processor DSP

DESCRIPTION

The WM5102^[1] is a highly-integrated low-power audio system for smartphones, tablets and other portable audio devices. It combines wideband telephony voice processing with a flexible, high-performance audio hub CODEC.

The WM5102 digital core provides a powerful combination of fixed-function signal processing blocks with a programmable DSP. These are supported by a fully-flexible, all-digital audio mixing and routing engine with sample rate converters, for wide use-case flexibility. The programmable DSP is optimised for Wolfson's wideband voice processing which includes multi-mic noise reduction and echo cancellation. Many other audio algorithms can also be implemented. Fixed-function signal processing blocks include filters, EQ, dynamics processors and sample rate converters.

A SLIMbus interface supports multi-channel audio paths and host control register access. Multiple sample rates are supported concurrently via the SLIMbus interface. Three further digital audio interfaces are provided, each supporting a wide range of standard audio sample rates and serial interface formats. Automatic sample rate detection enables seamless wideband/narrowband voice call handover.

Two stereo headphone drivers each provide stereo ground-referenced or mono BTL outputs, with noise levels as low as $2.3\mu\text{V}_{\text{RMS}}$ for hi-fi quality line or headphone output. The CODEC also features stereo 2W Class-D speaker outputs, a dedicated BTL earpiece output and PDM for external speaker amplifiers. A signal generator for controlling haptics devices is included; vibrate actuators can connect directly to the Class-D speaker output, or via an external driver on the PDM output interface. All inputs, outputs and system interfaces can function concurrently.

The WM5102 supports up to six microphone inputs, each either analogue or PDM digital. Microphone activity detection with interrupt is available. A smart accessory interface supports most standard 3.5mm accessories. Impedance sensing and measurement is provided for external accessory and push-button detection.

The WM5102 power, clocking and output driver architectures are all designed to maximise battery life in voice, music and standby modes. Low-power 'Sleep' is supported, with configurable wake-up events. The WM5102 is powered from a 1.8V external supply. A separate supply is required for the Class D speaker drivers (typically direct connection to 4.2V battery).

Two integrated FLLs provide support for a wide range of system clock frequencies. The WM5102 is configured using the I2C, SPI or SLIMbus interfaces. The fully-differential internal analogue architecture, minimal analogue signal paths and on-chip RF noise filters ensure a very high degree of noise immunity.

FEATURES

- Audio hub CODEC with integrated voice processor DSP
- Programmable audio effects and voice processing functions
 - Transmit-path noise reduction and echo cancellation
 - Receive-path enhancement and noise reduction
 - Wind noise, sidetone and other programmable filters
 - Dynamic Range Control, Fully parametric EQs
- Multi-channel asynchronous sample rate conversion
- Integrated 6/7 channel 24-bit hi-fi audio hub CODEC
 - 6 ADCs, 96dB SNR microphone input (48kHz)
 - 7 DACs, 113dB SNR headphone playback (48kHz)
- Audio inputs
 - Up to 6 analogue or digital microphone inputs
 - Single-ended or differential mic/line inputs
- Multi-purpose headphone / earpiece / line output drivers
 - 2 stereo output paths
 - 29mW into 32Ω load at 0.1% THD+N
 - 100mW into 32Ω BTL load at 5% THD+N
 - 6.5mW typical headphone playback power consumption
 - Pop suppression functions
 - $2.3\mu\text{V}_{\text{RMS}}$ noise floor (A-weighted)
- Mono BTL earpiece output driver
- 2 x 2W stereo Class D speaker output drivers
 - Direct drive of external haptics vibrate actuators
- Two-channel digital speaker (PDM) interface
- SLIMbus[®] audio and control interface
- 3 full digital audio interfaces
 - Standard sample rates from 4kHz up to 192kHz
 - Ultrasonic accessory function support
 - TDM support on all AIFs
 - 8 channel input and output on AIF1
- Flexible clocking, derived from MCLKn, BCLKn or SLIMbus
- 2 low-power FLLs support reference clocks down to 32kHz
- Advanced accessory detection functions
 - Low-power standby mode and configurable wake-up
- Configurable functions on 5 GPIO pins
- Integrated LDO regulators and charge pumps
- Support for single 1.8V supply operation
- Small W-CSP package, 0.4mm pitch

APPLICATIONS

- Smartphones and Multimedia handsets
- Tablets and Mobile Internet Devices (MID)
- General-purpose low-power audio CODEC hub

ORDERING INFORMATION

ORDER CODE	TEMPERATURE RANGE	PACKAGE	MOISTURE SENSITIVITY LEVEL	PEAK SOLDERING TEMPERATURE
WM5102ECS/R	-40°C to +85°C	W-CSP (Pb-free, Tape and reel)	MSL1	260°C

Note:

Reel quantity = 5000

PIN DESCRIPTION

A description of each pin on the WM5102 is provided below.

Note that a table detailing the associated power domain for every input and output pin is provided on the following page.

Note that, where multiple pins share a common name, these pins should be tied together on the PCB.

All Digital Output pins are CMOS outputs, unless otherwise stated.

PIN NO	NAME	TYPE	DESCRIPTION
B3, B4, B7, C3, C4, C5, C6, C7, C8, F2, F3, G3, H3, J3, L3	AGND	Supply	Analogue ground (Return path for AVDD)
J13	AIF1BCLK	Digital Input / Output	Audio interface 1 bit clock
J11	AIF1RXDAT	Digital Input	Audio interface 1 RX digital audio data
J12	AIF1LRCLK	Digital Input / Output	Audio interface 1 left / right clock
J8	AIF1TXDAT	Digital Output	Audio interface 1 TX digital audio data
K5	AIF2BCLK	Digital Input / Output	Audio interface 2 bit clock
M9	AIF2RXDAT	Digital Input	Audio interface 2 RX digital audio data
L8	AIF2LRCLK	Digital Input / Output	Audio interface 2 left / right clock
L6	AIF2TXDAT	Digital Output	Audio interface 2 TX digital audio data
L5	AIF3BCLK	Digital Input / Output	Audio interface 3 bit clock
K4	AIF3RXDAT	Digital Input	Audio interface 3 RX digital audio data
M5	AIF3LRCLK	Digital Input / Output	Audio interface 3 left / right clock
L4	AIF3TXDAT	Digital Output	Audio interface 3 TX digital audio data
A3, A7, M3	AVDD	Supply	Analogue supply
L13	CIF1ADDR	Digital Input	Control interface 1 (I2C) address select
K12	CIF1SCLK	Digital Input	Control interface 1 clock input
K11	CIF1SDA	Digital Input / Output	Control interface 1 data input and output / acknowledge output. The output function is implemented as an Open Drain circuit.
M13	CIF2MOSI	Digital Input	Control interface 2 Master Out / Slave In data
K9	CIF2MISO	Digital Output	Control interface 2 Master In / Slave Out data
L12	CIF2SCLK	Digital Input	Control interface 2 clock input
L11	CIF2SS	Digital Input	Control interface 2 Slave Select (SS)
B9	CP1CA	Analogue Output	Charge pump 1 fly-back capacitor pin
B10	CP1CB	Analogue Output	Charge pump 1 fly-back capacitor pin
A10	CP1VOUTN	Analogue Output	Charge pump 1 negative output decoupling pin
A9	CP1VOUTP	Analogue Output	Charge pump 1 positive output decoupling pin
C11	CP2CA	Analogue Output	Charge pump 2 fly-back capacitor pin
B11	CP2CB	Analogue Output	Charge pump 2 fly-back capacitor pin
A11	CP2VOUT	Analogue Output	Charge pump 2 output decoupling pin / Supply for LDO2
C10	CPGND	Supply	Charge pump 1 & 2 ground (Return path for CPVDD)
C9	CPVDD	Supply	Supply for Charge Pump 1 & 2
G13, M10	DBVDD1	Supply	Digital buffer (I/O) supply (core functions and Audio Interface 1)
M6	DBVDD2	Supply	Digital buffer (I/O) supply (for Audio Interface 2)
M4	DBVDD3	Supply	Digital buffer (I/O) supply (for Audio Interface 3)
G11, M8	DCVDD	Supply	Digital core supply
E5, E6, E7, E8, E9, F5, F6, F7, F8, F9, G5, G6, G7, G8, G9, G12, H5, H6, H7, H8, H9, M7	DGND	Supply	Digital ground (Return path for DCVDD, DBVDD1, DBVDD2 and DBVDD3)
A4	EPOUTP	Analogue Output	Earpiece positive output

PIN NO	NAME	TYPE	DESCRIPTION
A5	EPOUTN	Analogue Output	Earpiece negative output
K13	GPIO1	Digital Input / Output	General Purpose pin GPIO1. The output configuration is selectable CMOS or Open Drain.
L7	GPIO2	Digital Input / Output	General Purpose pin GPIO2. The output configuration is selectable CMOS or Open Drain.
K3	GPIO3	Digital Input / Output	General Purpose pin GPIO3. The output configuration is selectable CMOS or Open Drain.
K10	GPIO4	Digital Input / Output	General Purpose pin GPIO4. The output configuration is selectable CMOS or Open Drain.
G10	GPIO5	Digital Input / Output	General Purpose pin GPIO5. The output configuration is selectable CMOS or Open Drain.
B12	HPDETL	Analogue Input	Headphone left (HPOUT1L) sense input
A12	HPDETR	Analogue Input	Headphone right (HPOUT1R) sense input
A13	HPOUT1FB1/ MICDET2	Analogue Input	HPOUT1L and HPOUT1R ground feedback pin 1/ Microphone & accessory sense input 2
B8	HPOUT1L	Analogue Output	Left headphone 1 output
A8	HPOUT1R	Analogue Output	Right headphone 1 output
B6	HPOUT2FB	Analogue Input	HPOUT2L and HPOUT2R ground loop noise rejection feedback
A6	HPOUT2L	Analogue Output	Left headphone 2 output
B5	HPOUT2R	Analogue Output	Right headphone 2 output
E3	IN1LN/ DMICCLK1	Analogue Input / Digital Output	Left channel negative differential MIC input / Digital MIC clock output 1
D3	IN1LP	Analogue Input	Left channel single-ended MIC input / Left channel line input / Left channel positive differential MIC input
E1	IN1RN/ DMICDAT1	Analogue input / Digital Input	Right channel negative differential MIC input / Digital MIC data input 1
E2	IN1RP	Analogue Input	Right channel single-ended MIC input / Right channel line input / Right channel positive differential MIC input
C1	IN2LN/ DMICCLK2	Analogue Input / Digital Output	Left channel negative differential MIC input / Digital MIC clock output 2
C2	IN2LP	Analogue Input	Left channel single-ended MIC input / Left channel line input / Left channel positive differential MIC input
D1	IN2RN/ DMICDAT2	Analogue input / Digital Input	Right channel negative differential MIC input / Digital MIC data input 2
D2	IN2RP	Analogue Input	Right channel single-ended MIC input / Right channel line input / Right channel positive differential MIC input
A1	IN3LN/ DMICCLK3	Analogue Input / Digital Output	Left channel negative differential MIC input / Digital MIC clock output 3
A2	IN3LP	Analogue Input	Left channel single-ended MIC input / Left channel line input / Left channel positive differential MIC input
B1	IN3RN/ DMICDAT3	Analogue input / Digital Input	Right channel negative differential MIC input / Digital MIC data input 3
B2	IN3RP	Analogue Input	Right channel single-ended MIC input / Right channel line input / Right channel positive differential MIC input
F13	IRQ	Digital Output	Interrupt Request (IRQ) output (default is active low). The pin configuration is selectable CMOS or Open Drain.
E10	JACKDET	Analogue Input	Jack detect input

PIN NO	NAME	TYPE	DESCRIPTION
F11	LDOENA	Digital Input	Enable pin for LDO1
D13	LDOVDD	Supply	Supply for LDO1
E12	LDOVOUT	Analogue Output	LDO1 output
H13	MCLK1	Digital Input	Master clock 1
F12	MCLK2	Digital Input	Master clock 2
C12	MICBIAS1	Analogue Output	Microphone bias 1
D12	MICBIAS2	Analogue Output	Microphone bias 2
C13	MICBIAS3	Analogue Output	Microphone bias 3
B13	MICDET1/ HPOUT1FB2	Analogue Input	Microphone & accessory sense input 1/ HPOUT1L and HPOUT1R ground feedback pin 2
E11, F1	MICVDD	Analogue Output	LDO2 output decoupling pin (generated internally by WM5102)
E13	RESET	Digital Input	Digital Reset input (active low)
H12	SLIMCLK	Digital Input / Output	SLIM Bus Clock input / output
H11	SLIMDAT	Digital Input / Output	SLIM Bus Data input / output
L10	SPKCLK	Digital Output	Digital speaker (PDM) clock output
K8	SPKDAT	Digital Output	Digital speaker (PDM) data output
J1, J2	SPKGNDL	Supply	Left speaker driver ground (Return path for SPKVDDL)
K1, K2	SPKGNDR	Supply	Right speaker driver ground (Return path for SPKVDDR)
H2	SPKOUTLN	Analogue Output	Left speaker negative output
H1	SPKOUTLP	Analogue Output	Left speaker positive output
L2	SPKOUTRN	Analogue Output	Right speaker negative output
L1	SPKOUTRP	Analogue Output	Right speaker positive output
G1, G2	SPKVDDL	Supply	Left speaker driver supply
M1, M2	SPKVDDR	Supply	Right speaker driver supply
L9	TCK	Digital Input	JTAG clock input
M11	TDI	Digital Input	JTAG data input
K6	TDO	Digital Output	JTAG data output
K7	TMS	Digital Input	JTAG mode select input
M12	TRST	Digital Input	JTAG Test Access Port reset (active low, internal pull-down). This input should be logic 0 for normal WM5102 operation.
D11	VREFC	Analogue Output	Bandgap reference decoupling capacitor connection

The following table identifies the power domain and ground reference associated with each of the input / output pins.

PIN NO	NAME	POWER DOMAIN	GROUND DOMAIN
J13	AIF1BCLK	DBVDD1	DGND

ABSOLUTE MAXIMUM RATINGS

Absolute Maximum Ratings are stress ratings only. Permanent damage to the device may be caused by continuously operating at or beyond these limits. Device functional operating limits and guaranteed performance specifications are given under Electrical Characteristics at the test conditions specified.

ESD Sensitive Device. This device is manufactured on a CMOS process. It is therefore generically susceptible to damage from excessive static voltages. Proper ESD precautions must be taken during handling and storage of this device.

Wolfson tests its package types according to IPC/JEDEC J-STD-020 for Moisture Sensitivity to determine acceptable storage conditions prior to surface mount assembly. These levels are:

MSL1 = unlimited floor life at <30°C / 85% Relative Humidity. Not normally stored in moisture barrier bag.

MSL2 = out of bag storage for 1 year at <30°C / 60% Relative Humidity. Supplied in moisture barrier bag.

MSL3 = out of bag storage for 168 hours at <30°C / 60% Relative Humidity. Supplied in moisture barrier bag.

The Moisture Sensitivity Level for each package type is specified in Ordering Information.

CONDITION	MIN	MAX
Supply voltages (DBVDD1, LDOVDD, AVDD, DCVDD, CPVDD)	-0.3V	+2.0V
Supply voltages (DBVDD2, DBVDD3, MICVDD)	-0.3V	+4.0V
Supply voltages (SPKVDDL, SPKVDDR)	-0.3V	+6.0V
Voltage range digital inputs (DBVDD1 domain)	AGND - 0.3V	DBVDD1 + 0.3V
Voltage range digital inputs (DBVDD2 domain)	AGND - 0.3V	DBVDD2 + 0.3V
Voltage range digital inputs (DBVDD3 domain)	AGND - 0.3V	DBVDD3 + 0.3V
Voltage range digital inputs (DMICDATn)	AGND - 3.3V	MICVDD + 0.3V
Voltage range analogue inputs (INnLN)	AGND - 0.3V	MICVDD + 0.3V
Voltage range analogue inputs (INnLP, INnRN, INnRP)	AGND - 3.3V	MICVDD + 0.3V
Ground (DGND, CPGND, SPKGNL, SPKGND)	AGND - 0.3V	AGND + 0.3V
Operating temperature range, T _A	-40°C	+85°C
Operating junction temperature, T _J	-40°C	+125°C
Storage temperature after soldering	-65°C	+150°C

RECOMMENDED OPERATING CONDITIONS

PARAMETER	SYMBOL	MIN	TYP	MAX	UNIT
Digital supply range (Core) See notes 3, 4, 5	DCVDD (≤ 24.576 MHz clocking)	1.14	1.2	1.9	V
	DCVDD (> 24.576 MHz clocking)	1.71	1.8	1.9

Charge Pump supply range	CPVDD	1.7	1.8	1.9	V
Speaker supply range	SPKVDDL, SPKVDDR	2.4		5.5	V
Analogue supply range	AVDD	1.7	1.8	1.9	V
Microphone Bias supply See note 6	MICVDD	2.375	2.5	3.6	V
Ground	DGND, AGND, CPGND, SPKGNL, SPKGND		0		V
Power supply rise time See notes 7, 8, 9	All supplies	1			μ s
Operating temperature range	T_A	-40		85	$^{\circ}$ C

Notes:

1. The grounds must always be within 0.3V of AGND.
2. AVDD must be supplied before or simultaneously to DCVDD. DCVDD must not be powered if AVDD is not present. There are no other power sequencing requirements.
3. An internal LDO (powered by LDOVDD) can be used to provide the DCVDD supply.
4. 'Sleep' mode is supported when DCVDD is below the limits noted, provided AVDD and DBVDD1 are present.
5. Under default conditions, digital core clocking rates above 24.576MHz are inhibited. The register-controlled clocking limit should only be raised when the applicable DCVDD voltage is present.
6. An internal Charge Pump and LDO (powered by CPVDD) provide the Microphone Bias supply; the MICVDD pin should not be connected to an external supply.
7. DCVDD and MICVDD minimum rise times do not apply when these domains are powered using the internal LDOs.
8. The specified minimum power supply rise times assume a minimum decoupling capacitance of 100nF per pin. However, Wolfson strongly advises that the recommended decoupling capacitors are present on the PCB and that appropriate layout guidelines are observed.
9. The specified minimum power supply rise times also assume a maximum PCB inductance of 10nH between decoupling capacitor and pin.

ELECTRICAL CHARACTERISTICS

Test Conditions

AVDD = 1.8V,

With the exception of the condition(s) noted above, the following electrical characteristics are valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	TEST CONDITIONS	MIN	TYP	MAX	UNIT
Analogue Input Signal Level (IN1L, IN1R, IN2L, IN2R, IN3L, IN3R)						
Full-scale input signal level	V _{INFS}	Single-ended PGA input	0.5			V _{RMS}
			-6			dBV
		Differential PGA input	1			V _{RMS}
			0			dBV

Notes:

1. The full-scale input signal level changes in proportion with AVDD. For differential input, it is calculated as AVDD / 1.8.
2. A 1.0V_{RMS} differential signal equates to 0.5V_{RMS}/-6dBV per input.
3. A sinusoidal input signal is assumed.

Test Conditions

T_A = +25°C

With the exception of the condition(s) noted above, the following electrical characteristics are valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	TEST CONDITIONS	MIN	TYP	MAX	UNIT
Analogue Input Pin Characteristics (IN1L, IN1R, IN2L, IN2R, IN3L, IN3R)						
Input resistance	R _{IN}	Differential input, All PGA gain settings		24		kΩ
		Single-ended input, 0dB PGA gain		16		
Input capacitance	C _{IN}				5	pF

Test Conditions

The following electrical characteristics are valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	TEST CONDITIONS	MIN	TYP	MAX	UNIT
Input Programmable Gain Amplifiers (PGAs)						
Minimum programmable gain				0		dB
Maximum programmable gain				31		dB
Programmable gain step size		Guaranteed monotonic		1		dB

Test Conditions

The following electrical characteristics are valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	TEST CONDITIONS	MIN	TYP	MAX	UNIT
Line / Headphone / Earpiece Output Driver (HPOUTnL, HPOUTnR)						
Load resistance		Normal Mode	15			Ω
		Mono Mode (BTL)	30			
		Device survival with load applied indefinitely	0.1			
Load capacitance		Direct connection, Normal Mode			400	pF
		Direct connection, Mono Mode (BTL)			200	
		Connection via 16Ω series resistor			2	nF
DC offset at Load		Single-ended mode		0.1		mV
		Differential (BTL) mode		0.2

Test Conditions

The following electrical characteristics are valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	TEST CONDITIONS	MIN	TYP	MAX	UNIT
Digital Input / Output (except DMICDATn and DMICCLKn)						
Digital I/O is referenced to DBVDD1, DBVDD2 or DBVDD3. See "Pin Description" for the domain applicable to each pin. See "Recommended Operating Conditions" for the valid operating voltage range of each DBVDDn domain.						
Input HIGH Level	V_{IH}	$V_{DBVDDn} = 1.8V \pm 10\%$	$0.65 \times V_{DBVDDn}$			V
		$V_{DBVDDn} = 3.3V \pm 10\%$	$0.7 \times V_{DBVDDn}$			
Input LOW Level	V_{IL}	$V_{DBVDDn} = 1.8V \pm 10\%$			$0.35 \times V_{DBVDDn}$	V
		$V_{DBVDDn} = 3.3V \pm 10\%$			$0.3 \times V_{DBVDDn}$	
Note that digital input pins should not be left unconnected or floating.						
Output HIGH Level	V_{OH}	$I_{OH} = 1mA$	$0.9 \times V_{DBVDDn}$			V
Output LOW Level	V_{OL}	$I_{OL} = -1mA$			$0.1 \times V_{DBVDDn}$	V
Input capacitance				10		pF
Input leakage			-1		1	μA
Pull-up / pull-down resistance (where applicable)			28	36	45	k Ω
Digital Microphone Input / Output (DMICDATn and DMICCLKn)						
DMICDATn and DMICCLKn are each referenced to a selectable supply, V_{SUP}, according to the INN_DMIC_SUP registers						
DMICDATn input HIGH Level	V_{IH}		$0.65 \times V_{SUP}$			V
DMICDATn input LOW Level	V_{IL}				$0.35 \times V_{SUP}$	V
DMICCLKn output HIGH Level	V_{OH}	$I_{OH} = 1mA$	$0.8 \times V_{SUP}$			V
DMICCLKn output LOW Level	V_{OL}	$I_{OL} = -1mA$			$0.2 \times V_{SUP}$	V
Input capacitance				10		pF
Input leakage			-1		1	μA
SLIMbus Digital Input / Output (SLIMCLK and SLIMDAT)						
1.8V I/O Signalling (ie. $1.65V \leq DBVDD1 \leq 1.95V$)						
Input HIGH Level	V_{IH}		$0.65 \times V_{DBVDD1}$			V
Input LOW Level	V_{IL}				$0.35 \times V_{DBVDD1}$	V
Output HIGH Level	V_{OH}	$I_{OH} = 1mA$	$0.9 \times V_{DBVDD1}$			V
Output LOW Level	V_{OL}	$I_{OL} = -1mA$			$0.1 \times V_{DBVDD1}$	V
Pin capacitance					5	pF
General Purpose Input / Output (GPIO)						
Clock output frequency		GPIO pin configured as OPCLK or FLL output			26.5	MHz

Test Conditions

$f_s \leq 48\text{kHz}$

With the exception of the condition(s) noted above, the following electrical characteristics are valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	TEST CONDITIONS	MIN	TYP	MAX	UNIT
ADC Decimation Filters						
Passband		+/- 0.05dB	0		0.454 fs	
		-6dB		0.5 fs		
Passband ripple					+/- 0.05	dB
Stopband			0.546 fs			
Stopband attenuation		$f > 0.546 \text{ fs}$	85			dB
Signal path delay		Analogue input to Digital AIF output			2	ms
DAC Interpolation Filters						
Passband		+/- 0.05dB	0		0.454 fs	
		-6dB		0.5 fs		
Passband ripple					+/- 0.05	dB
Stopband			0.546 fs			
Stopband attenuation		$f > 0.546 \text{ fs}$	85			dB
Signal path delay		Digital AIF input to Analogue output			1.5	ms

Test Conditions

DBVDD1 = DBVDD2 = DBVDD3 = LDOVDD = CPVDD = AVDD = 1.8V,
 DCVDD = 1.2V (powered from LDO1), MICVDD = 3.0V (powered from LDO2), SPKVDDL = SPKVDDR = 4.2V,
 T_A = +25°C, 1kHz sinusoid signal, f_s = 48kHz, Input PGA gain = 0dB, 24-bit audio data unless otherwise stated.

PARAMETER	SYMBOL	TEST CONDITIONS	MIN	TYP	MAX	UNIT
voltage (JACKDET)		Jack removal		0.85 x AVDD		
MICVDD Charge Pump and Regulator (CP2 and LDO2)						
Output voltage	V _{MICVDD}		1.7	2.7	3.3	V
Programmable output voltage step size				50		mV
Maximum output current				8		mA
Start-up time		4.7μF on MICVDD, I _{MICBIASn} = 1mA		4.5		ms
Frequency Locked Loop (FLL1, FLL2)						
Output frequency		Normal operation, input reference supplied	13		52	MHz
		Free-running mode, no reference supplied				
Lock Time		F _{REF} = 32kHz, F _{OUT} = 24.576MHz		10		ms
		F _{REF} = 12MHz, F _{OUT} = 24.576MHz		1		
RESET pin Input						
RESET input pulse width (To trigger a Hardware Reset, the RESET input must be asserted for longer than this duration)			1			μs

Test Conditions

The following electrical characteristics are valid across the full range of recommended operating conditions.

Device Reset Thresholds						
AVDD Reset Threshold	V _{AVDD}		0.50		1.51	V
DCVDD Reset Threshold	V _{DCVDD}		0.59		0.81	V
DBVDD1 Reset Threshold	V _{DBVDD1}		0.50		1.51	V
Note that the reset thresholds are derived from simulations only, across all operational and process corners. Device performance is not assured outside the voltage ranges defined in the "Recommended Operating Conditions" section. Refer to this section for the WM5102 power-up sequencing requirements.						

TERMINOLOGY

1. Signal-to-Noise Ratio (dB) – SNR is a measure of the difference in level between the maximum full scale output signal and the output with no input signal applied. (Note that this is measured without any mute function enabled.)
2. Total Harmonic Distortion (dB) – THD is the ratio of the RMS sum of the harmonic distortion products in the specified bandwidth (see note below) relative to the RMS amplitude of the fundamental (ie. test frequency) output.
3. Total Harmonic Distortion plus Noise (dB) – THD+N is the ratio of the RMS sum of the harmonic distortion products plus noise in the specified bandwidth (see note below) relative to the RMS amplitude of the fundamental (ie. test frequency) output.
4. Power Supply Rejection Ratio (dB) - PSRR is the ratio of a specified power supply variation relative to the output signal that results from it. PSRR is measured under quiescent signal path conditions.
5. Common Mode Rejection Ratio (dB) – CMRR is the ratio of a specified input signal (applied to both sides of a differential input), relative to the output signal that results from it.
6. Channel Separation (L/R) (dB) – left-to-right and right-to-left channel separation is the difference in level between the active channel (driven to maximum full scale output) and the measured signal level in the idle channel at the test signal frequency. The active channel is configured and supplied with an appropriate input signal to drive a full scale output, with signal measured at the output of the associated idle channel.
7. Multi-Path Crosstalk (dB) – is the difference in level between the output of the active path and the measured signal level in the idle path at the test signal frequency. The active path is configured and supplied with an appropriate input signal to drive a full scale output, with signal measured at the output of the specified idle path.
8. Mute Attenuation – This is a measure of the difference in level between the full scale output signal and the output with mute applied.
9. All performance measurements are specified with a 20kHz low pass 'brick-wall' filter and, where noted, an A-weighted filter. Failure to use these filters will result in higher THD and lower SNR readings than are found in the Electrical Characteristics. The low pass filter removes out of band noise.

TYPICAL PERFORMANCE

TYPICAL POWER CONSUMPTION

Typical power consumption data is provided below for a number of different operating conditions.

Test Conditions:

DBVDD1 = DBVDD2 = DBVDD3 = LDOVDD = CPVDD = AVDD = 1.8V,

SPKVDDL = SPKVDDR = 4.2V,

DCVDD = 1.2V (powered from LDO1), MICVDD = 3.0V (powered from LDO2), T_A = +25°C

OPERATING MODE	TEST CONDITIONS	SUPPLY CURRENT (1.8V)	SUPPLY CURRENT (4.2V)	TOTAL POWER
Music Playback to Headphone				
AIF1 to DAC to HPOUT1 (stereo) fs=48kHz, 24-bit I2S, Slave mode Load = 32Ω	Quiescent	4.8mA	0.0mA	8.6mW
	1kHz sine wave, P _o =10mW	37.7mA	0.0mA	67.9mW
Music Playback to Line Output				
AIF1 to DAC to HPOUT2 (stereo) fs=48kHz, 24-bit I2S, Slave mode Load = 10kΩ, 50pF	Quiescent	4.4mA	0.0mA	7.9mW
Music Playback to Earpiece				
AIF1 to DAC to EPOUT (mono) fs=48kHz, 24-bit I2S, Slave mode Load = 32Ω, 22μH, BTL	Quiescent	5.3mA	0.0mA	9.5mW
	1kHz sine wave, P _o =30mW	59.7mA	0.0mA	107.5mW
Music Playback to Speaker				
AIF1 to DAC to SPKOUT (stereo) fs=48kHz, 24-bit I2S, Slave mode Load = 8Ω, 22μH, BTL	Quiescent	5.5mA	5.8mA	34.3mW
	1kHz sine wave, P _o =700mW	5.6mA	380mA	1606mW
Full Duplex Voice Call				
Analogue Mic to ADC to AIF1 (out) AIF (in) to DAC to EPOUT (mono) fs=8kHz, 16-bit I2S, Slave mode Low Power mode (INn_OSR=00) Load = 32Ω, 22μH, BTL	Quiescent	6.7mA	0.0mA	12mW
Stereo Line Record				
Analogue Line to ADC to AIF1 fs=48kHz, 24-bit I2S, Slave mode Low Power mode (INn_OSR=00)	1kHz sine wave, -1dBFS out	4.2mA	0.0mA	7.6mW
Sleep Mode				
Accessory detect enabled (JD1_ENA=1)		0.015mA	0.0mA	0.03mW

TYPICAL SIGNAL LATENCY

OPERATING MODE	TEST CONDITIONS			LATENCY
	INPUT	OUTPUT	DIGITAL CORE	
AIF to DAC Stereo Path				
Digital input (AIFn) to analogue output (EPOUT). Signal is routed via the digital core ASRC function in the asynchronous test cases only.	fs = 48kHz	fs = 48kHz	Synchronous	352µs
	fs = 44.1kHz	fs = 44.1kHz	Synchronous	362µs
	fs = 16kHz	fs = 16kHz	Synchronous	711µs
	fs = 8kHz	fs = 8kHz	Synchronous	3580µs
	fs = 8kHz	fs = 44.1kHz	Asynchronous	3750µs
	fs = 16kHz	fs = 44.1kHz	Asynchronous	848µs
ADC to AIF Stereo Path				
Analogue input (INn) to digital output (AIFn). Digital core High Pass filter included in signal path. Signal is routed via the digital core ASRC function in the asynchronous test cases only.	fs = 48kHz	fs = 48kHz	Synchronous	268µs
	fs = 44.1kHz	fs = 44.1kHz	Synchronous	292µs
	fs = 16kHz	fs = 16kHz	Synchronous	894µs
	fs = 8kHz	fs = 8kHz	Synchronous	1730µs
	fs = 44.1kHz	fs = 8kHz	Asynchronous	880µs
	fs = 44.1kHz	fs = 16kHz	Asynchronous	530µs

SIGNAL TIMING REQUIREMENTS

SYSTEM CLOCK & FREQUENCY LOCKED LOOP (FLL)

Figure 1 Master Clock Timing

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
Master Clock Timing (MCLK1, MCLK2)					
MCLK cycle time	MCLK as input to FLL, FLLn_REFCLK_DIV=00	74			ns
	MCLK as input to FLL, FLLn_REFCLK_DIV=01	37			
	MCLK as input to FLL, FLLn_REFCLK_DIV=10 or 11	25			
	MCLK as direct SYSCLK or ASYNCCLK source	40			
MCLK duty cycle	MCLK as input to FLL	80:20		20:80	%
	MCLK as direct SYSCLK or ASYNCCLK source	60:40		40:60	
Frequency Locked Loops (FLL1, FLL2)					
FLL input frequency	FLLn_REFCLK_DIV=00	0.032		13.5	MHz
	FLLn_REFCLK_DIV=01	0.064		27	
	FLLn_REFCLK_DIV=10	0.128		40	
	FLLn_REFCLK_DIV=11	0.256		40	
FLL synchroniser input frequency	FLLn_SYNCCLK_DIV=00	0.032		13.5	MHz
	FLLn_SYNCCLK_DIV=01	0.064		27	
	FLLn_SYNCCLK_DIV=10	0.128		40	
	FLLn_SYNCCLK_DIV=11	0.256		40	

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
Internal Clocking					
SYSCLK frequency	SYSCLK_FREQ=000, SYSCLK_FRAC=0	-1%	6.144	+1%	MHz
	SYSCLK_FREQ=000, SYSCLK_FRAC=1	-1%	5.6448	+1%	
	SYSCLK_FREQ=001, SYSCLK_FRAC=0	-1%	12.288	+1%	
	SYSCLK_FREQ=001, SYSCLK_FRAC=1	-1%	11.2896	+1%	
	SYSCLK_FREQ=010, SYSCLK_FRAC=0	-1%	24.576	+1%	
	SYSCLK_FREQ=010, SYSCLK_FRAC=1	-1%	22.5792	+1%	
	SYSCLK_FREQ=011, SYSCLK_FRAC=0	-1%	49.152	+1%	
	SYSCLK_FREQ=011, SYSCLK_FRAC=1	-1%	45.1584	+1%	
ASYNCCLK frequency	ASYNC_CLK_FREQ=000	-1%	6.144	+1%	MHz
		-1%	5.6448	+1%	
	ASYNC_CLK_FREQ=001	-1%	12.288	+1%	
		-1%	11.2896	+1%	
	ASYNC_CLK_FREQ=010	-1%	24.576	+1%	
		-1%	22.5792	+1%	
	ASYNC_CLK_FREQ=011	-1%	49.152	+1%	
		-1%	45.1584	+1%	

Note:

When MCLK1 or MCLK2 is selected as a source for SYSCLK or ASYNCCLK (either directly or via one of the FLLs), the frequency must be within 1% of the applicable SYSCLK_FREQ or ASYNCCLK_FREQ register setting.

AUDIO INTERFACE TIMING

DIGITAL MICROPHONE (DMIC) INTERFACE TIMING

Figure 2 Digital Microphone Interface Timing

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	MIN	TYP	MAX	UNIT
Digital Microphone Interface Timing					
DMICCLKn cycle time	t_{CY}	320	326	716	ns
DMICCLKn duty cycle		45		55	%
DMICCLKn rise/fall time (25pF load, 1.8V supply - see note)	t_r, t_f	5		30	ns
DMICDATn (Left) setup time to falling DMICCLK edge	t_{LSU}	15			ns
DMICDATn (Left) hold time from falling DMICCLK edge	t_{LH}	0			ns
DMICDATn (Right) setup time to rising DMICCLK edge	t_{RSU}	15			ns
DMICDATn (Right) hold time from rising DMICCLK edge	t_{RH}	0			ns

Notes:

DMICDATn and DMICCLKn are each referenced to a selectable supply, V_{SUP} .

The applicable supply is selected using the INn_DMIC_SUP registers.

DIGITAL SPEAKER (PDM) INTERFACE TIMING

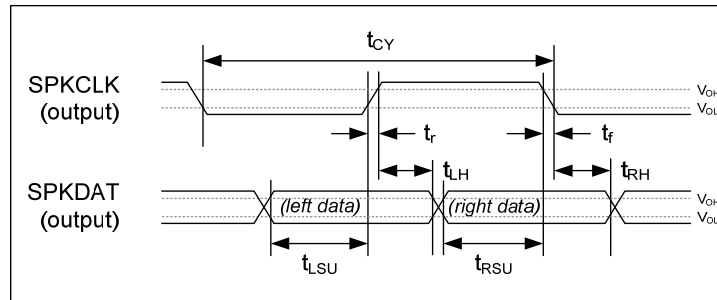

Figure 3 Digital Speaker (PDM) Interface Timing - Mode A

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	MIN	TYP	MAX	UNIT
PDM Audio Interface Timing					
SPKCLKn cycle time	t_{CY}	160	163	358	ns
SPKCLKn duty cycle		45		55	%
SPKCLKn rise/fall time (DBVDD=1.8V, 25pF load)	t_r, t_f	5		30	ns
SPKDATn set-up time to SPKCLKn rising edge (Left channel)	t_{LSU}	30			ns
SPKDATn hold time from SPKCLKn rising edge (Left channel)	t_{LH}	30			ns
SPKDATn set-up time to SPKCLKn falling edge (Right channel)	t_{RSU}	30			ns
SPKDATn hold time from SPKCLKn falling edge (Right channel)	t_{RH}	30			ns

Figure 4 Digital Speaker (PDM) Interface Timing - Mode B

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	MIN	TYP	MAX	UNIT
PDM Audio Interface Timing					
SPKCLKn cycle time	t_{CY}	160	163	358	ns
SPKCLKn duty cycle		45		55	%
SPKCLKn rise/fall time (DBVDD=1.8V, 25pF load)	t_r, t_f	5		30	ns
SPKDATn enable from SPKCLK rising edge (Right channel)	t_{REN}			15	ns
SPKDATn disable to SPKCLK falling edge (Right channel)	t_{RDIS}			5	ns
SPKDATn enable from SPKCLK falling edge (Left channel)	t_{LEN}			15	ns
SPKDATn disable to SPKCLK rising edge (Left channel)	t_{LDIS}			5	ns

DIGITAL AUDIO INTERFACE - MASTER MODE

Figure 5 Audio Interface Timing - Master Mode

Note that BCLK and LRCLK outputs can be inverted if required; Figure 5 shows the default, non-inverted polarity of these signals.

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	MIN	TYP	MAX	UNIT
Audio Interface Timing - Master Mode					
AIFnBCLK cycle time	t_{BCY}	80			ns
AIFn[TX/RX]LRCLK propagation delay from BCLK falling edge	t_{LRD}	0		12	ns
AIFnTXDAT propagation delay from BCLK falling edge	t_{DD}	0		12	ns
AIFnRXDAT setup time to BCLK rising edge	t_{DSU}	7			ns
AIFnRXDAT hold time from BCLK rising edge	t_{DH}	5			ns

Note:

The descriptions above assume non-inverted polarity of AIFnBCLK and AIFn[TX/RX]LRCLK.

DIGITAL AUDIO INTERFACE - SLAVE MODE

Figure 6 Audio Interface Timing - Slave Mode

Note that BCLK and LRCLK inputs can be inverted if required; Figure 6 shows the default, non-inverted polarity.

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	MIN	TYP	MAX	UNIT
Audio Interface Timing - Slave Mode					
AIFnBCLK cycle time	t_{BCY}	80			ns
AIFnBCLK pulse width high	t_{BCH}	12			ns
AIFnBCLK pulse width low	t_{BCL}	12			ns
AIFn[TX/RX]LRCLK set-up time to BCLK rising edge	t_{LRSU}	7			ns
AIFn[TX/RX]LRCLK hold time from BCLK rising edge	t_{LRH}	5			ns
AIFnRXDAT hold time from BCLK rising edge	t_{DH}	5			ns
AIFnTXDAT propagation delay from BCLK falling edge	t_{DD}	0		12	ns
AIFnRXDAT set-up time to BCLK rising edge	t_{DSU}	7			ns

Notes:

The descriptions above assume non-inverted polarity of AIFnBCLK and AIFn[TX/RX]LRCLK.

When AIFnBCLK is selected as a source for SYSCLK or ASYNCCLK (either directly or via one of the FLLs), the frequency must be within 1% of the applicable SYSCLK_FREQ or ASYNCCLK_FREQ register setting.

DIGITAL AUDIO INTERFACE - TDM MODE

When TDM operation is used on the AIFnTXDAT pins, it is important that two devices do not attempt to drive the AIFnTXDAT pin simultaneously. To support this requirement, the AIFnTXDAT pins can be configured to be tri-stated when not outputting data.

The timing of the AIFnTXDAT tri-stating at the start and end of the data transmission is described in Figure 7 below.

Figure 7 Audio Interface Timing - TDM Mode

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

PARAMETER	MIN	TYP	MAX	UNIT
TDM Timing - Master Mode				
AIFnTXDAT setup time from BCLK falling edge	0			ns
AIFnTXDAT release time from BCLK falling edge			15	ns
TDM Timing - Slave Mode				
AIFnTXDAT setup time from BCLK falling edge	5			ns
AIFnTXDAT release time from BCLK falling edge			32	ns

CONTROL INTERFACE TIMING

2-WIRE (I2C) CONTROL MODE

Figure 8 Control Interface Timing - 2-wire (I2C) Control Mode

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	MIN	TYP	MAX	UNIT
SCLK Frequency				1000	kHz
SCLK Low Pulse-Width	t_1	500			ns
SCLK High Pulse-Width	t_2	260			ns
Hold Time (Start Condition)	t_3	260			ns
Setup Time (Start Condition)	t_4	260			ns
SDA, SCLK Rise Time	t_6			120	ns
SDA, SCLK Fall Time	t_7			120	ns
Setup Time (Stop Condition)	t_8	260			ns
SDA Setup Time (data input)	t_5	50			ns
SDA Hold Time (input/output)	t_9	0			ns
SDA Valid Time (data/ACK output)	t_{10}			450	ns
Pulse width of spikes that will be suppressed	t_{ps}	0		50	ns

4-WIRE (SPI) CONTROL MODE

Figure 9 Control Interface Timing - 4-wire (SPI) Control Mode (Write Cycle)

Figure 10 Control Interface Timing - 4-wire (SPI) Control Mode (Read Cycle)

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

PARAMETER	SYMBOL	MIN	TYP	MAX	UNIT
SS falling edge to SCLK rising edge	t_{SSU}	2.6			ns
SCLK falling edge to SS rising edge	t_{SHO}	0			ns
SCLK pulse cycle time	t_{SCY}	38.4			ns
SCLK pulse width low	t_{SCL}	15.3			ns
SCLK pulse width high	t_{SCH}	15.3			ns
MOSI to SCLK set-up time	t_{DSU}	1.3			ns
MOSI to SCLK hold time	t_{DHO}	1.7			ns
SCLK falling edge to MISO transition	t_{DL}	0		7.8	ns

SLIMBUS INTERFACE TIMING

For details of the SLIMbus interface timing requirements, refer to the MIPI Alliance Specification for Serial Low-power Inter-chip Media Bus (SLIMbus).

DEVICE DESCRIPTION

INTRODUCTION

The WM5102 is a highly integrated low-power audio hub CODEC for mobile telephony and portable devices. It provides flexible, high-performance audio interfacing for handheld devices in a small and cost-effective package. It provides wideband voice processing for mobile telephony, ideally suited for multimedia phones and smartphones.

The WM5102 digital core provides an extensive capability for signal processing algorithms, including echo cancellation, wind noise, side-tone and other programmable filters. Parametric equalisation (EQ) and dynamic range control (DRC) are also supported. Highly flexible digital mixing, including stereo full-duplex asynchronous sample rate conversion, provides use-case flexibility across a broad range of system architectures. A signal generator for controlling haptics vibrate actuators is included.

The WM5102 provides multiple digital audio interfaces, including SLIMbus, in order to provide independent and fully asynchronous connections to different processors (eg. application processor, baseband processor and wireless transceiver).

A flexible clocking arrangement supports a wide variety of external clock references, including clocking derived from the digital audio interface. Two integrated Frequency Locked Loop (FLL) circuits provide additional flexibility.

Unused circuitry can be disabled under software control, in order to save power; low leakage currents enable extended standby/off time in portable battery-powered applications. Configurable 'Wake-Up' actions can be associated with the low-power standby (Sleep) mode.

Versatile GPIO functionality is provided, and support for external accessory / push-button detection inputs. Comprehensive Interrupt (IRQ) logic and status readback are also provided.

HI-FI AUDIO CODEC

The WM5102 is a high-performance low-power audio CODEC which uses a simple analogue architecture. 6 ADCs and 7 DACs are incorporated, providing a dedicated ADC for each input and a dedicated DAC for each output channel.

The analogue outputs comprise two 29mW (113dB SNR) stereo headphone amplifiers with ground-referenced output, a 100mW differential (BTL) earpiece driver, and a Class D stereo speaker driver capable of delivering 2W per channel into a 4Ω load. Six analogue inputs are provided, each supporting single-ended or differential input modes. In differential mode, the input path SNR is 96dB. The ADC input paths can be bypassed, supporting up to 6 channels of digital microphone input.

The audio CODEC is controlled directly via register access. The simple analogue architecture, combined with the integrated tone generator, enables simple device configuration and testing, minimising debug time and reducing software effort.

The WM5102 output drivers are designed to support as many different system architectures as possible. Each output has a dedicated DAC which allows mixing, equalisation, filtering, gain and other audio processing to be configured independently for each channel. This allows each signal path to be individually tailored for the load characteristics. All outputs have integrated pop and click suppression features.

The headphone output drivers are ground-referenced, powered from an integrated charge pump, enabling high quality, power efficient headphone playback without any requirement for DC blocking capacitors. Ground loop feedback is incorporated, providing rejection of noise on the ground connections. A mono mode is available on the headphone outputs; this configures the drivers as differential (BTL) outputs, suitable for an earpiece or hearing aid coil.

The Class D speaker drivers deliver excellent power efficiency. High PSRR, low leakage and optimised supply voltage ranges enable powering from switching regulators or directly from the battery. Battery current consumption is minimised across a wide variety of voice communication and multimedia playback use cases.

The WM5102 is cost-optimised for a wide range of mobile phone applications, and features two channels of Class D power amplification. For applications requiring more than two channels of power amplification (or when using the integrated Class D path to drive a haptics actuator), the PDM output channels can be used to drive two external PDM-input speaker drivers. In applications where stereo loudspeakers are physically widely separated, the PDM outputs can ease layout and EMC by avoiding the need to run the Class-D speaker outputs over long distances and interconnects.

DIGITAL AUDIO CORE

The WM5102 uses a core architecture based on all-digital signal routing, making digital audio effects available on all signal paths, regardless of whether the source data input is analogue or digital. The digital mixing desk allows different audio effects to be applied simultaneously on many independent paths, whilst also supporting a variety of sample rates concurrently. This helps support many new audio use-cases. Soft mute and un-mute control allows smooth transitions between use-cases without interrupting existing audio streams elsewhere.

The WM5102 digital core provides an extensive capability for programmable signal processing algorithms. The DSP can support functions such as echo cancellation, wind noise, side-tone and other programmable filters. The DSP is optimised for advanced voice processing, but a wide range of application-specific filters and audio enhancements can also be implemented.

Highly flexible digital mixing, including mixing between audio interfaces, is possible. The WM5102 performs stereo full-duplex asynchronous sample rate conversion, providing use-case flexibility across a broad range of system architectures. Automatic sample rate detection is provided, enabling seamless wideband/narrowband voice call handover.

Dynamic Range Controller (DRC) functions are available for optimising audio signal levels. In playback modes, the DRC can be used to maximise loudness, while limiting the signal level to avoid distortion, clipping or battery droop, in particular for high-power output drivers such as speaker amplifiers. In record modes, the DRC assists in applications where the signal level is unpredictable.

The 5-band parametric equaliser (EQ) functions can be used to compensate for the frequency characteristics of the output transducers. EQ functions can be cascaded to provide additional frequency control. Programmable high-pass and low-pass filters are also available for general filtering applications such as removal of wind and other low-frequency noise.

DIGITAL INTERFACES

Three serial digital audio interfaces (AIFs) each support PCM, TDM and I2S data formats for compatibility with most industry-standard chipsets. AIF1 supports eight input/output channels; AIF2 and AIF3 each support two input/output channels. Bidirectional operation at sample rates up to 192kHz is supported.

Six digital PDM input channels are available (three stereo interfaces); these are typically used for digital microphones, powered from the integrated MICBIAS power supply regulators. Two PDM output channels are also available (one stereo interface); these are typically used for external power amplifiers. Embedded mute codes provide a control mechanism for external PDM-input devices.

The WM5102 features a MIPI-compliant SLIMbus interface, providing eight channels of audio input/output. Mixed audio sample rates are supported on the SLIMbus interface. The SLIMbus interface also supports read/write access to the WM5102 control registers.

The WM5102 is equipped with an I2C slave port (at up to 1MHz), and an SPI port (at up to 26MHz). Full access to the register map is also provided via the SLIMbus port.

OTHER FEATURES

The WM5102 incorporates two 1kHz tone generators which can be used for 'beep' functions through any of the audio signal paths. The phase relationship between the two generators is configurable, providing flexibility in creating differential signals, or for test scenarios.

A white noise generator is provided, which can be routed within the digital core. The noise generator can provide 'comfort noise' in cases where silence (digital mute) is not desirable.

Two Pulse Width Modulation (PWM) signal generators are incorporated. The duty cycle of each PWM signal can be modulated by an audio source, or can be set to a fixed value using a control register setting. The PWM signal generators can be output directly on a GPIO pin.

The WM5102 provides 5 GPIO pins, supporting selectable input/output functions for interfacing, detection of external hardware, and to provide logic outputs to other devices. Comprehensive Interrupt (IRQ) functionality is also provided for monitoring internal and external event conditions.

A signal generator for controlling haptics devices is included, compatible with both Eccentric Rotating Mass (ERM) and Linear Resonant Actuator (LRA) haptic devices. The haptics signal generator is highly configurable, and can execute programmable drive event profiles, including reverse drive control. An external vibe actuator can be driven directly by the Class D speaker output.

The WM5102 can be powered from a 1.8V external supply. A separate supply (4.2V) is typically required for the Class D speaker driver. Integrated Charge Pump and LDO Regulators circuits are used to generate supply rails for internal functions and to support powering or biasing of external microphones.

A smart accessory interface is included, supporting most standard 3.5mm accessories. Jack detection, accessory sensing and impedance measurement is provided, for external accessory and push-button detection. Accessory detection can be used as a 'Wake-Up' trigger from low-power standby. Microphone activity detection with interrupt is also available.

System clocking can be derived from the MCLK1 or MCLK2 input pins. Alternatively, the SLIMbus interface, or the audio interfaces (configured in Slave mode), can be used to provide a clock reference. Two integrated Frequency Locked Loop (FLL) circuits provide support for a wide range of clocking configurations, including the use of a 32kHz input clock reference.

INPUT SIGNAL PATH

The WM5102 has six highly flexible input channels, configurable in a large number of combinations. Each of the six input channels supports analogue (mic or line) and digital input configurations.

The analogue input paths support single-ended and differential modes, programmable gain control and are digitised using a high performance 24-bit sigma-delta ADC.

The digital input paths interface directly with external digital microphones; a separate microphone interface clock is provided for 3 separate stereo pairs of digital microphones. Digital delay can be applied to any of the digital input paths; this can be used for phase adjustment of any digital input, including directional control of multiple microphones.

Three microphone bias (MICBIAS) generators are available, which provide a low noise reference for biasing electret condenser microphones (ECMs) or for use as a low noise supply for digital microphones.

Digital volume control is available on all inputs (analogue and digital), with programmable ramp control for smooth, glitch-free operation.

The IN1L and IN1R input signal paths and control registers are illustrated in Figure 11. The IN2 and IN3 signal paths are equivalent to the IN1 signal path.

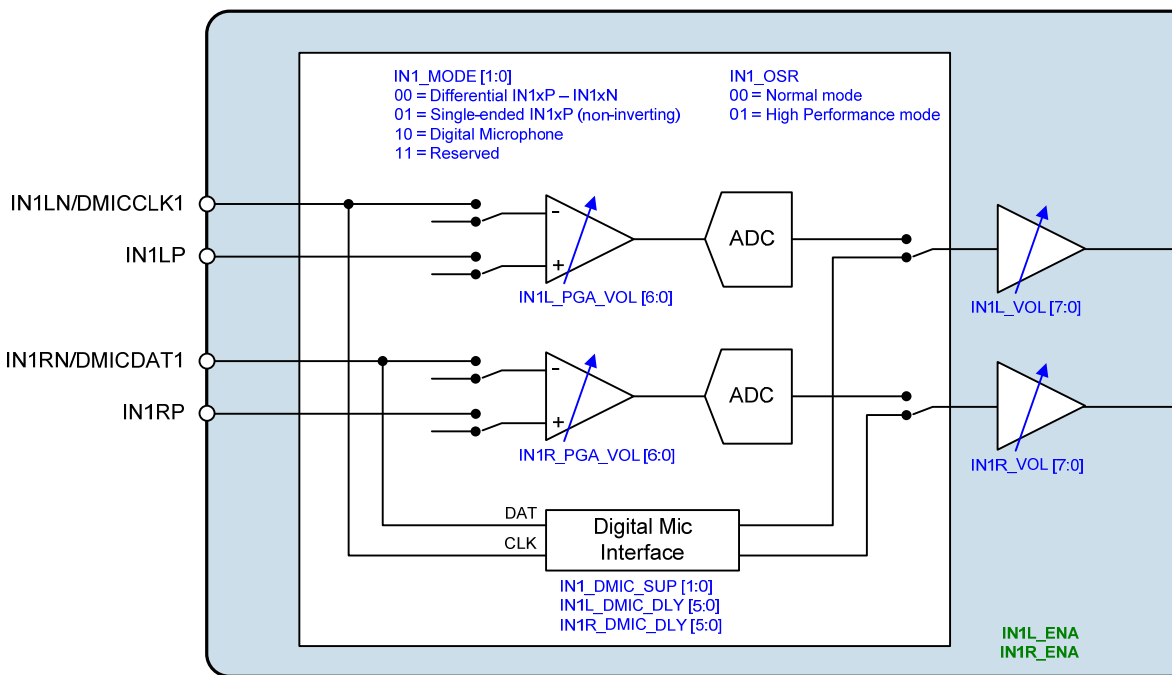

Figure 11 Input Signal Paths

ANALOGUE MICROPHONE INPUT

Up to six analogue microphones can be connected to the WM5102, either in single-ended or differential mode. The applicable mode is selected using the INn_MODE registers, as described later. Note that the mode is configurable for each stereo pair of inputs; the Left and Right channels of any pair of inputs are always in the same mode.

The WM5102 includes external accessory detection circuits, which can detect the presence of a microphone, and the status of a hookswitch or other push-buttons. When using this function, it is recommended to use one of the Right channel analogue microphone input paths, to ensure best immunity to electrical transients arising from the push-buttons.

For single-ended input, the microphone signal is connected to the non-inverting input of the PGAs ($INnLP$ or $INnRP$). The inverting inputs of the PGAs are connected to an internal reference in this configuration.

For differential input, the non-inverted microphone signal is connected to the non-inverting input of the PGAs ($INnLP$ or $INnRP$), whilst the inverted (or 'noisy ground') signal is connected to the inverting input pins ($INnLN$ or $INnRN$).

The gain of the input PGAs is controlled via register settings, as defined in Table 4. Note that the input impedance of the analogue input paths is fixed across all PGA gain settings.

The analogue microphone input configurations are illustrated in Figure 12 and Figure 13.

Figure 12 Single-Ended Microphone Input

Figure 13 Differential Microphone Input

ANALOGUE LINE INPUT

Line inputs can be connected to the WM5102 in a similar manner to the microphone inputs described above. Single-ended and differential modes are supported on each of the six input paths.

The applicable mode (single-ended or differential) is selected using the INn_MODE registers, as described later. Note that the mode is configurable for each stereo pair of inputs; the Left and Right channels of any pair of inputs are always in the same mode.

The analogue line input configurations are illustrated in Figure 14 and Figure 15. Note that the microphone bias (MICBIAS) is not used for line input connections.

Figure 14 Single-Ended Line Input

Figure 15 Differential Line Input

DIGITAL MICROPHONE INPUT

Up to six digital microphones can be connected to the WM5102. The digital microphone mode is selected using the IN_n_MODE registers, as described later. Note that the mode is configurable for each stereo pair of inputs; the Left and Right channels of any pair of inputs are always in the same mode.

In digital microphone mode, two channels of audio data are multiplexed on the DMICDAT1, DMICDAT2 or DMICDAT3 pins. Each of these stereo interfaces is clocked using the respective DMICCLK1, DMICCLK2 or DMICCLK3 pin.

When digital microphone input is enabled, the WM5102 outputs a clock signal on the applicable DMICCLK n pin(s). The DMICCLK n frequency is controlled by the respective IN_n_OSR register, as described in Table 1. See Table 3 for details of the IN_n_OSR registers.

Note that the DMICCLK n frequencies noted in Table 1 assume that the SYSCLK frequency is a multiple of 6.144MHz (SYSCLK_FRAC=0). If the SYSCLK frequency is a multiple of 5.6448MHz (SYSCLK_FRAC=1), then the DMICCLK n frequencies will be scaled accordingly.

CONDITION	DMICCLK n FREQUENCY
$IN_n_OSR = 00$	1.536MHz
$IN_n_OSR = 01$	3.072MHz

Table 1 DMICCLK Frequency

The voltage reference for each digital microphone interface is selectable, using the $IN_n_DMIC_SUP$ registers. Each interface may be referenced to MICVDD, or to the MICBIAS1, MICBIAS2 or MICBIAS3 levels.

A pair of digital microphones is connected as illustrated in Figure 16. The microphones must be configured to ensure that the Left mic transmits a data bit when DMICCLK is high, and the Right mic transmits a data bit when DMICCLK is low. The WM5102 samples the digital microphone data at the end of each DMICCLK phase. Each microphone must tri-state its data output when the other microphone is transmitting.

Note that the WM5102 provides integrated pull-down resistors on the DMICDAT1, DMICDAT2 and DMICDAT3 pins. This provides a flexible capability for interfacing with other devices.

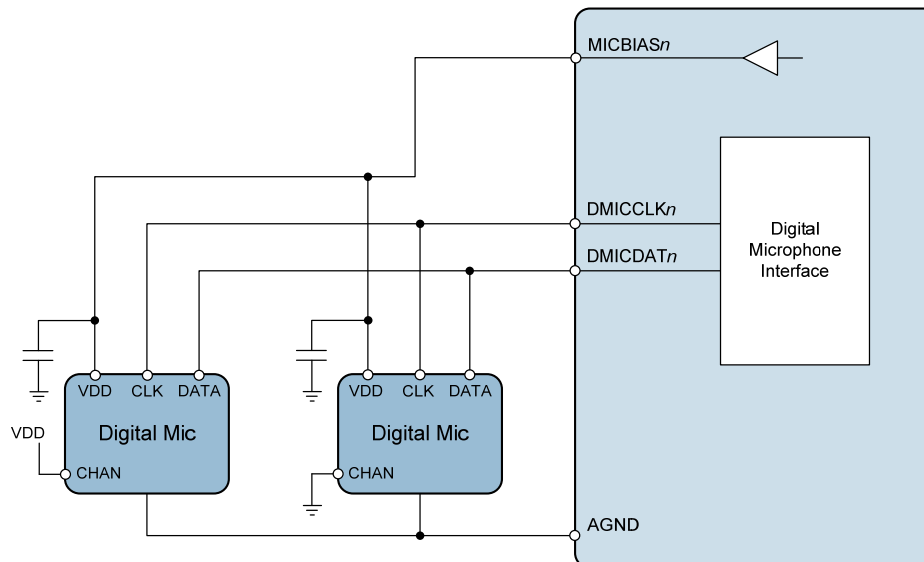

Figure 16 Digital Microphone Input

Two digital microphone channels are interleaved on DMICDAT n . The digital microphone interface timing is illustrated in Figure 17. Each microphone must tri-state its data output when the other microphone is transmitting.

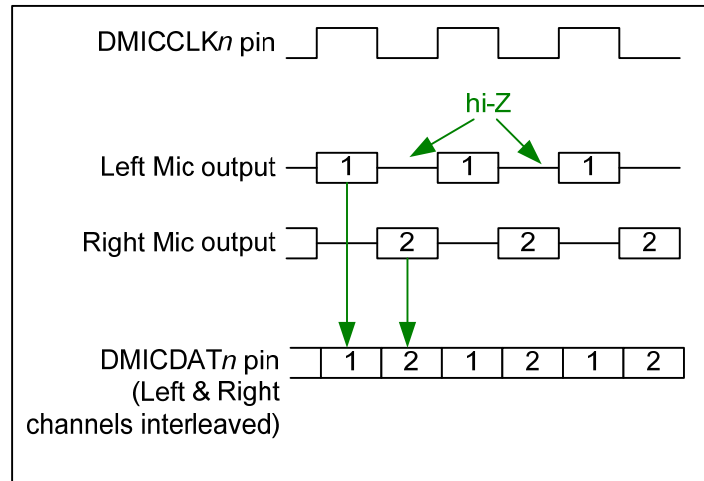

Figure 17 Digital Microphone Interface Timing

When digital microphone input is enabled, the WM5102 outputs a clock signal on the applicable DMICCLK pin(s). The DMICCLK frequency is selectable, as described in Table 1.

Note that SYSCLK must be present and enabled when using the Digital Microphone inputs; see “Clocking and Sample Rates” for details of SYSCLK and the associated register control fields.

INPUT SIGNAL PATH ENABLE

The input signal paths are enabled using the register bits described in Table 2. The respective bit(s) must be enabled for analogue or digital input on the respective input path(s).

The MICVDD power domain must be enabled when using the analogue input signal path(s). This power domain is provided using an internal Charge Pump (CP2) and LDO Regulator (LDO2). See “Charge Pumps, Regulators and Voltage Reference” for details of these circuits.

The system clock, SYSCLK, must be configured and enabled before any audio path is enabled. The ASYNCCLK and 32kHz clock may also be required, depending on the path configuration. See “Clocking and Sample Rates” for details of the system clocks.

The WM5102 performs automatic checks to confirm that the SYSCLK frequency is high enough to support the input signal paths and associated ADCs. If an attempt is made to enable an input signal path, and there are insufficient SYSCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error condition can be monitored using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

The status bits in Register R769 indicate the status of each of the input signal paths. If an Underclocked Error condition occurs, then these bits provide readback of which input signal path(s) have been successfully enabled.

Table 2 Input Signal Path Enable

INPUT SIGNAL PATH SAMPLE RATE CONTROL

The input signal paths may be selected as input to the digital mixers or signal processing functions within the WM5102 digital core. The sample rate for the input signal paths is configured using the IN_RATE register - see Table 20 within the "Digital Core" section.

Note that sample rate conversion is required when routing the input signal paths to any signal chain that is asynchronous and/or configured for a different sample rate.

INPUT SIGNAL PATH CONFIGURATION

The WM5102 supports six input signal paths. Each pair of inputs can be configured as single-ended, differential, or digital microphone configuration. Note that the mode is configurable for each stereo pair of inputs; the Left and Right channels of any pair of inputs are always in the same mode.

The input signal path configuration is selected using the IN_n_MODE registers (where 'n' identifies the associated input). The external circuit configurations are illustrated on the previous pages.

The analogue input signal paths (single-ended or differential) each incorporate a PGA to provide gain in the range 0dB to +31dB in 1dB steps. Note that these PGAs do not provide pop suppression functions; it is recommended that the gain should not be adjusted whilst the respective signal path is enabled.

The analogue input PGA gain is controlled using the $IN_nL_PGA_VOL$ and $IN_nR_PGA_VOL$ registers. Note that separate volume control is provided for the Left and Right channels of each stereo pair.

When the input signal path is configured for digital microphone input, the voltage reference for the associated input/output pins is selectable using the $IN_n_DMIC_SUP$ registers - each interface may be referenced to MICVDD, or to the MICBIAS1, MICBIAS2 or MICBIAS3 levels.

A digital delay may be applied to any of the digital microphone input channels. This feature can be used for phase adjustment of any digital input, including directional control of multiple microphones. The delay is controlled using the $IN_nL_DMIC_DLY$ and $IN_nR_DMIC_DLY$ registers.

The MICVDD voltage is generated by an internal Charge Pump and LDO Regulator. The MICBIAS1, MICBIAS2 and MICBIAS3 outputs are derived from MICVDD - see "Charge Pumps, Regulators and Voltage Reference".

Under default register conditions, the input signal paths are configured for highest performance. This can be adjusted using the IN_n_OSR registers, which provide control of the $DMICCLK_n$ frequency and the ADC oversample rate.

The input signal paths are configured using the register bits described in Table 3.

Table 3 Input Signal Path Configuration

INPUT SIGNAL PATH DIGITAL VOLUME CONTROL

A digital volume control is provided on each of the input signal paths, providing -64dB to +31.5dB gain control in 0.5dB steps. An independent mute control is also provided for each input signal path.

Whenever the gain or mute setting is changed, the signal path gain is ramped up or down to the new settings at a programmable rate. For increasing gain (or un-mute), the rate is controlled by the IN_VI_RAMP register. For decreasing gain (or mute), the rate is controlled by the IN_VD_RAMP register. Note that the IN_VI_RAMP and IN_VD_RAMP registers should not be changed while a volume ramp is in progress.

The IN_VU bits control the loading of the input signal path digital volume and mute controls. When IN_VU is set to 0, the digital volume and mute settings will be loaded into the respective control register, but will not actually change the signal path gain. The digital volume and mute settings on all of the input signal paths are updated when a 1 is written to IN_VU. This makes it possible to update the gain of multiple signal paths simultaneously.

For correct gain ramp behaviour, the IN_VU bits should not be written during the 0.75ms after any of the input path enable bits (see Table 2) have been asserted. It is recommended that the input path mute bit be set when the respective input path is enabled; the signal path can then be un-muted after the 0.75ms has elapsed.

Note that, although the digital volume control registers provide 0.5dB steps, the internal circuits provide signal gain adjustment in 0.125dB steps. This allows a very high degree of gain control, and smooth volume ramping under all operating conditions.

The digital volume control register fields are described in Table 4 and Table 5.

Table 5 Input Signal Path Digital Volume Range

DIGITAL MICROPHONE INTERFACE PULL-DOWN

The WM5102 provides integrated pull-down resistors on the DMICDAT1, DMICDAT2 and DMICDAT3 pins. This provides a flexible capability for interfacing with other devices.

Each of the pull-down resistors can be configured independently using the register bits described in Table 6. Note that, if the DMICDAT1, DMICDAT2 or DMICDAT3 digital microphone input paths are disabled, then the pull-down will be disabled on the respective pin.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION

	0	DMICDAT1_PD	0	DMICDAT1 Pull-Down Control 0 = Disabled 1 = Enabled

Table 6 Digital Microphone Interface Pull-Down Control

DIGITAL CORE

The WM5102 digital core provides extensive mixing and processing capabilities for multiple signal paths. The configuration is highly flexible, and virtually every conceivable input/output connection can be supported between the available processing blocks.

The digital core provides parametric equalisation (EQ) functions, dynamic range control (DRC), low-pass / high-pass filters (LHPF), and programmable DSP capability. The DSP can support functions such as wind noise, side-tone or other programmable filters, also dynamic range control and compression, or virtual surround sound and other audio enhancements.

The WM5102 supports multiple signal paths through the digital core. Stereo full-duplex sample rate conversion is provided to allow digital audio to be routed between input (ADC) paths, output (DAC) paths, Digital Audio Interfaces (AIF1, AIF2 and AIF3) and SLIMbus paths operating at different sample rates and/or referenced to asynchronous clock domains.

The DSP functions are highly programmable, using application-specific control sequences. It should be noted that the DSP configuration data is lost whenever the DCVDD power domain is removed; the DSP configuration data must be downloaded to the WM5102 each time the device is powered up.

The procedure for configuring the WM5102 DSP functions is tailored to each customer's application; please contact your local Wolfson representative for more details.

The WM5102 incorporates two 1kHz tone generators which can be used for 'beep' functions through any of the audio signal paths. A white noise generator is incorporated, to provide 'comfort noise' in cases where silence (digital mute) is not desirable.

A haptic signal generator is provided, for use with external haptic devices (eg. mechanical vibration actuators). Two Pulse Width Modulation (PWM) signal generators are also provided; the PWM waveforms can be modulated by an audio source within the digital core, and can be output on a GPIO pin.

An overview of the digital core processing and mixing functions is provided in Figure 18. An overview of the external digital interface paths is provided in Figure 19.

The control registers associated with the digital core signal paths are shown in Figure 20 through to Figure 37. The full list of digital mixer control registers is provided in the "Register Map" section (Register R1600 through to R2920). Generic register definitions are provided in Table 7.

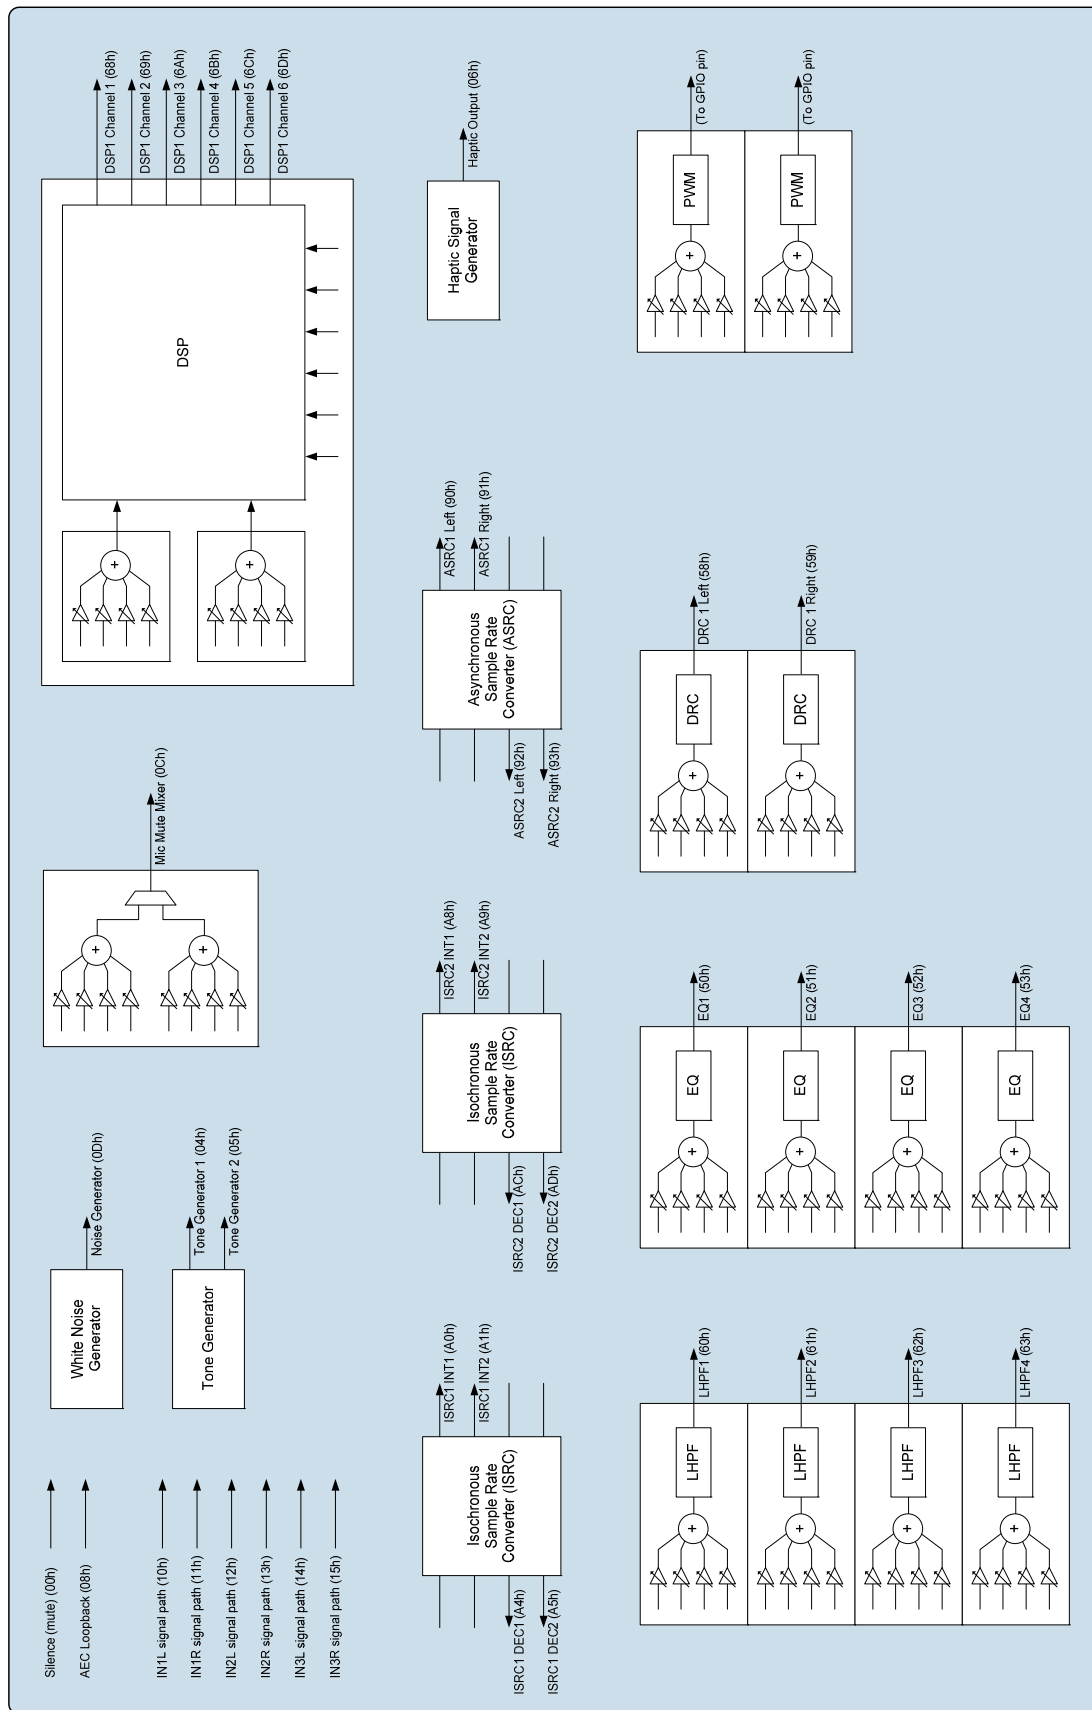

Figure 18 Digital Core - Internal Signal Processing

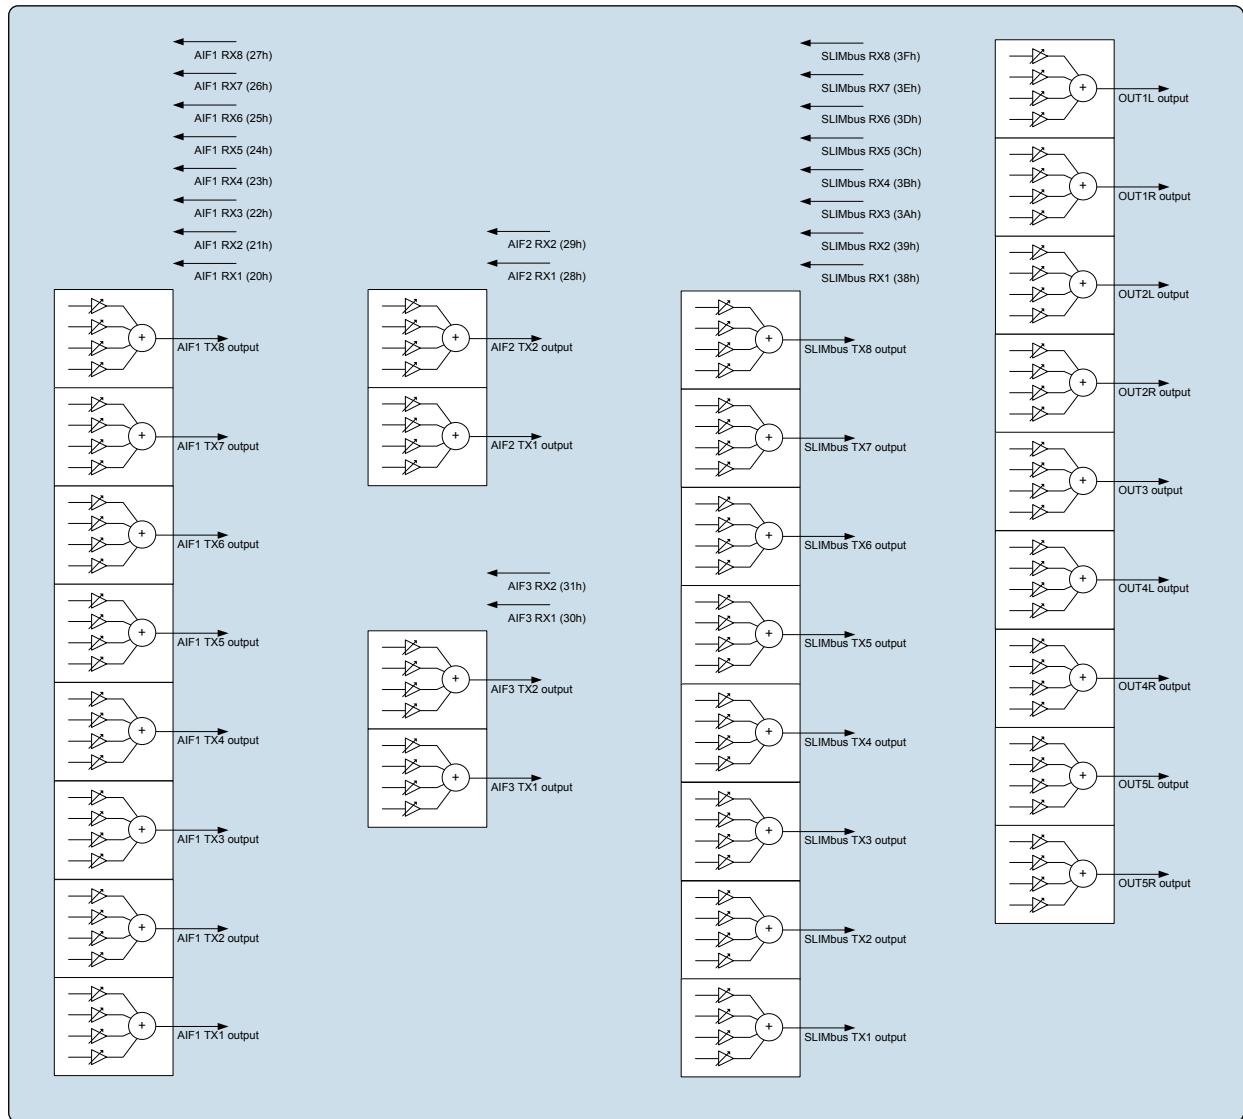

Figure 19 Digital Core - External Digital Interfaces

DIGITAL CORE MIXERS

The WM5102 provides an extensive digital mixing capability. The digital core signal processing blocks and audio interface paths are illustrated in Figure 18 and Figure 19.

A 4-input digital mixer is associated with many of these functions, as illustrated. The digital mixer circuit is identical in each instance, providing up to 4 selectable input sources, with independent volume control on each input.

The control registers associated with the digital core signal paths are shown in Figure 20 through to Figure 37. The full list of digital mixer control registers is provided in the “Register Map” section (Register R1600 through to R2920).

Further description of the associated control registers is provided below. Generic register definitions are provided in Table 7.

The digital mixer input sources are selected using the associated *_SRCn registers; the volume control is implemented via the associated *_VOLn registers.

The ASRC, ISRC, and DSP Aux Input functions support selectable input sources, but do not

incorporate any digital mixing. The respective input source (*_SRCn) registers are identical to those of the digital mixers.

The *_SRCn registers select the input source(s) for the respective mixer or signal processing block. Note that the selected input source(s) must be configured for the same sample rate as the block(s) to which they are connected. Sample rate conversion functions are available to support flexible interconnectivity - see "Asynchronous Sample Rate Converter (ASRC)" and "Isochronous Sample Rate Converter (ISRC)".

A status bit associated with each of the configurable input sources provides readback for the respective signal path. If an Underclocked Error condition occurs, then these bits provide readback of which signal path(s) have been successfully enabled.

The generic register definition for the digital mixers is provided in Table 7.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION

Table 7 Digital Core Mixer Control Registers

DIGITAL CORE INPUTS

The digital core comprises multiple input paths as illustrated in Figure 20. Any of these inputs may be selected as a source to the digital mixers or signal processing functions within the WM5102 digital core.

Note that the outputs from other blocks within the Digital Core may also be selected as input to the digital mixers or signal processing functions within the WM5102 digital core. Those input sources, which are not shown in Figure 20, are described separately in other sections of the "Digital Core" description.

The bracketed numbers in Figure 20, eg. "(10h)" indicate the corresponding *_SRCn register setting for selection of that signal as an input to another digital core function.

The sample rate for the input signal paths is configured using the applicable IN_RATE, AIFn_RATE or SLIMRXn_RATE register - see Table 20. Note that sample rate conversion is required when routing the input signal paths to any signal chain that is asynchronous and/or configured for a different sample rate.

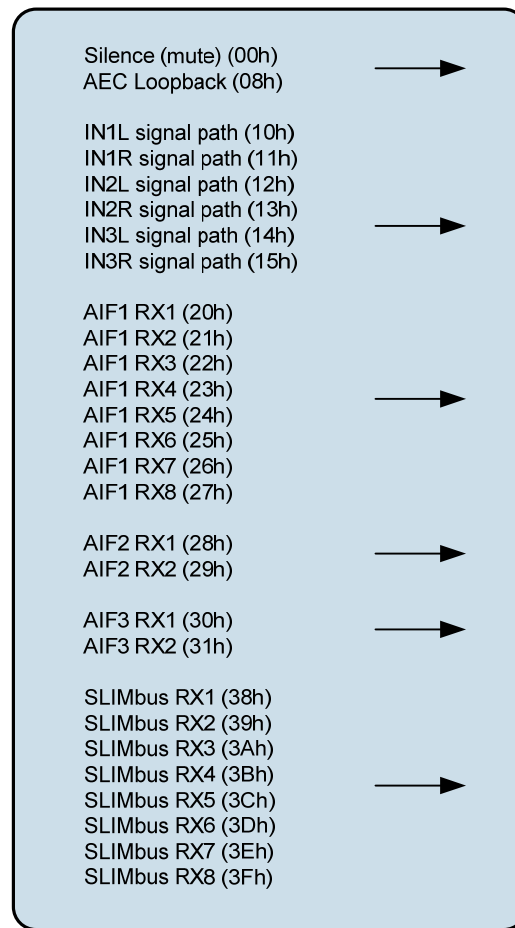

Figure 20 Digital Core Inputs

DIGITAL CORE OUTPUT MIXERS

The digital core comprises multiple output paths. The output paths associated with AIF1, AIF2 and AIF3 are illustrated in Figure 21. The output paths associated with OUT1, OUT2, OUT3, OUT4 and OUT5 are illustrated in Figure 22. The output paths associated with the SLIMbus interface are illustrated in Figure 23.

A 4-input mixer is associated with each output. The 4 input sources are selectable in each case, and independent volume control is provided for each path.

The AIF1, AIF2 and AIF3 output mixer control registers (see Figure 21) are located at register addresses R1792 (700h) through to R1935 (78Fh). The OUT1, OUT2, OUT3, OUT4 and OUT5 output mixer control registers (see Figure 22) are located at addresses R1664 (680h) through to R1743 (06CFh). The SLIMbus output mixer control registers (see Figure 23) are located at addresses R1984 (7C0h) through to R2047 (7FFh).

The full list of digital mixer control registers is provided in the "Register Map" section (Register R1600 through to R2920). Generic register definitions are provided in Table 7.

The *_SRCn registers select the input source(s) for the respective mixers. Note that the selected input source(s) must be configured for the same sample rate as the mixer to which they are connected. Sample rate conversion functions are available to support flexible interconnectivity - see "Asynchronous Sample Rate Converter (ASRC)" and "Isochronous Sample Rate Converter (ISRC)".

The sample rate for the output signal paths is configured using the applicable OUT_RATE, AIFn_RATE or SLIMTXn_RATE register - see Table 20. Note that sample rate conversion is required when routing the output signal paths to any signal chain that is asynchronous and/or configured for a different sample rate.

The WM5102 performs automatic checks to confirm that the SYSCLK frequency is high enough to support the output mixer paths. If an attempt is made to enable an output mixer path, and there are insufficient SYSCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error condition can be monitored using the GPIO and/or Interrupt functions. See "General Purpose Input / Output" and "Interrupts" for further details.

The status bits in Registers R1600 to R2920 indicate the status of each of the digital mixers. If an Underclocked Error condition occurs, then these bits provide readback of which mixer(s) have been successfully enabled.

Figure 21 Digital Core AIF Outputs

Figure 22 Digital Core OUTn Outputs

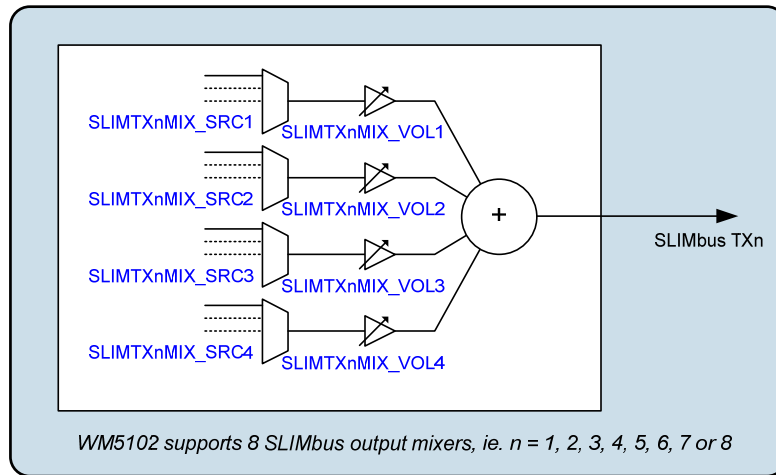

Figure 23 Digital Core SLIMbus Outputs

MIC MUTE MIXER

The Mic Mute mixer function supports applications where two signal paths are multiplexed into a single output. A typical use case is muting a microphone audio path and inserting a 'comfort noise' signal in place of the normal audio path.

The Mic Mute mixer function comprises two digital mixers (MICMIX and NOISEMIX), as illustrated in Figure 24. A multiplexer selects one or other mixer as the Mic Mute output signal. Up to 4 input sources can be selected for each mixer, and independent volume control is provided for each path.

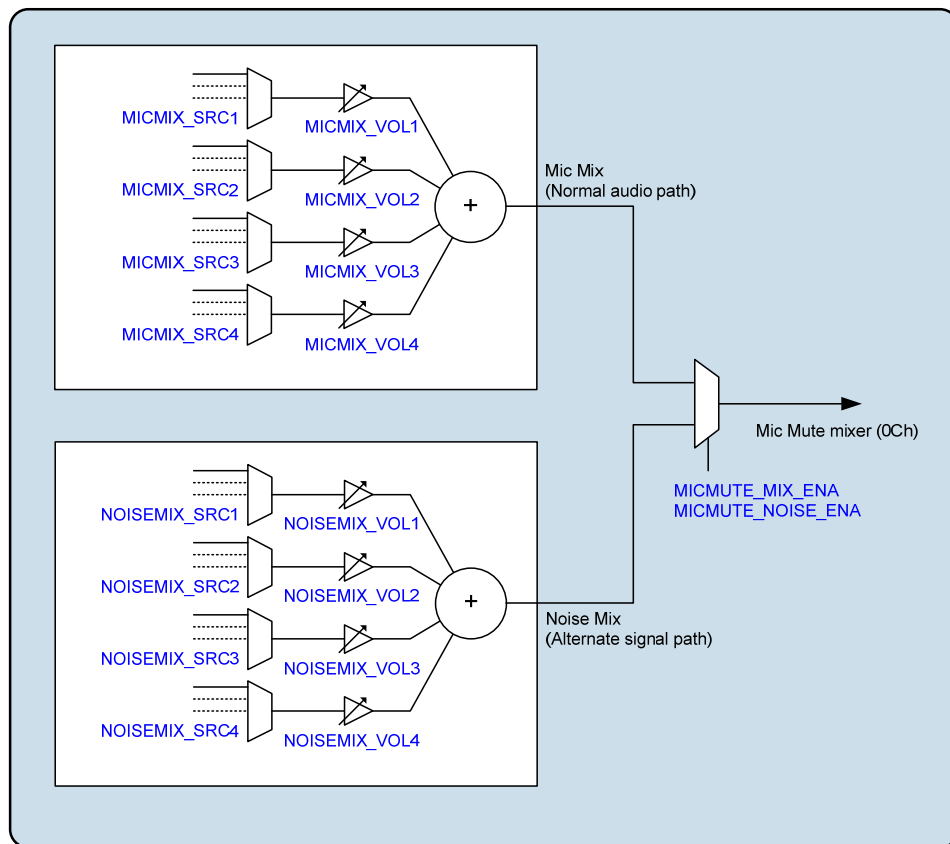

Figure 24 Mic Mute Digital Mixers

The MICMIX and NOISEMIX control registers (see Figure 24) are located at register addresses R1632 (0660h) through to R1647 (066Fh).

The full list of digital mixer control registers is provided in the “Register Map” section (Register R1600 through to R2920). Generic register definitions are provided in Table 7.

The Mic Mute mixer can be selected as input to any of the digital mixers or signal processing functions within the WM5102 digital core. The bracketed number (0Ch) in Figure 24 indicates the corresponding *_SRCn register setting for selection of the Mic Mute mixer as an input to another digital core function.

The sample rate for the Mic Mute mixer and multiplexer is configured using the MICMUTE_RATE register - see Table 20. Note that sample rate conversion is required when routing the Mic Mute mixer to any signal chain that is asynchronous and/or configured for a different sample rate.

The control registers associated with the Mic Mute mixer function are described in Table 8.

The output of the Mic Mute mixer and multiplexer is enabled using MICMUTE_MIX_ENA.

The multiplexer is controlled using the MICMUTE_NOISE_ENA register bit, selecting MICMIX or NOISEMIX as the output signal source.

Under recommended operating conditions, the MICMIX output is selected for normal (audio) conditions, and the NOISEMIX output is selected for mute (or ‘comfort noise’) conditions.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R707 (02C3h) Mic noise mix control 1	7	MICMUTE_NOIS E_ENA	0	Mic Mute Mixer Control 0 = Mic Mix 1 = Noise Mix
	6	MICMUTE_MIX_E NA	0	Mic Mute Mixer Enable 0 = Disabled 1 = Enabled

Table 8 Mic Mute Mixer Control Registers

The WM5102 performs automatic checks to confirm that the SYSCLK frequency is high enough to support the commanded digital mixing functions. If an attempt is made to enable a MICMIX or NOISEMIX signal path, and there are insufficient SYSCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error condition can be monitored using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

The status bits in Registers R1600 to R2920 indicate the status of each of the digital mixers. If an Underclocked Error condition occurs, then these bits provide readback of which mixer(s) have been successfully enabled, and which mixer(s) could not be enabled.

5-BAND PARAMETRIC EQUALISER (EQ)

The digital core provides four EQ processing blocks as illustrated in Figure 25. A 4-input mixer is associated with each EQ. The 4 input sources are selectable in each case, and independent volume control is provided for each path. Each EQ block supports 1 output.

The EQ provides selective control of 5 frequency bands as described below.

The low frequency band (Band 1) filter can be configured either as a peak filter or a shelving filter. When configured as a shelving filter, it provides adjustable gain below the Band 1 cut-off frequency. As a peak filter, it provides adjustable gain within a defined frequency band that is centred on the Band 1 frequency.

The mid frequency bands (Band 2, Band 3, Band 4) filters are peak filters, which provide adjustable gain around the respective centre frequency.

The high frequency band (Band 5) filter is a shelving filter, which provides adjustable gain above the Band 5 cut-off frequency.

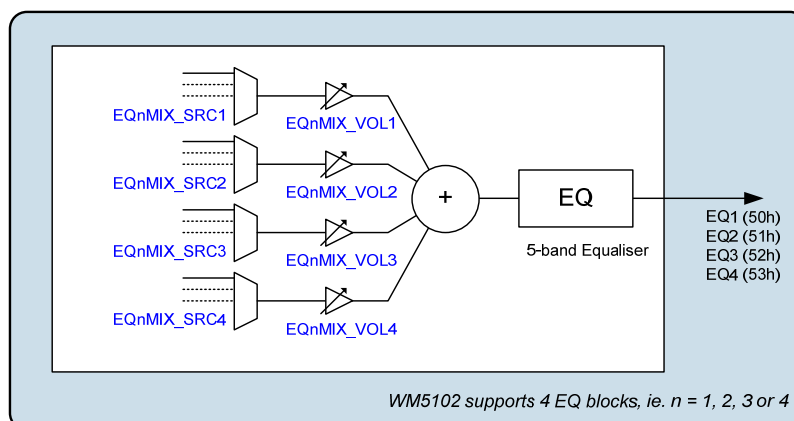

Figure 25 Digital Core EQ Blocks

The EQ1, EQ2, EQ3 and EQ4 mixer control registers (see Figure 25) are located at register addresses R2176 (880h) through to R2207 (89Fh).

The full list of digital mixer control registers is provided in the “Register Map” section (Register R1600 through to R2920). Generic register definitions are provided in Table 7.

The *_SRCn registers select the input source(s) for the respective EQ processing blocks. Note that the selected input source(s) must be configured for the same sample rate as the EQ to which they are connected. Sample rate conversion functions are available to support flexible interconnectivity - see “Asynchronous Sample Rate Converter (ASRC)” and “Isochronous Sample Rate Converter (ISRC)”.

The bracketed numbers in Figure 25, eg. “(50h)” indicate the corresponding *_SRCn register setting for selection of that signal as an input to another digital core function.

The sample rate for the EQ function is configured using the FX_RATE register - see Table 20. Note that the EQ, DRC and LHPF functions must all be configured for the same sample rate. Sample rate conversion is required when routing the EQ signal paths to any signal chain that is asynchronous and/or configured for a different sample rate.

The control registers associated with the EQ functions are described in Table 10.

The cut-off or centre frequencies for the 5-band EQ are set using the coefficients held in the registers identified in Table 9. These coefficients are derived using tools provided in Wolfson’s WISCE™ evaluation board control software; please contact your local Wolfson representative for more details.

Table 11 EQ Gain Control Range

The WM5102 performs automatic checks to confirm that the SYSCLK frequency is high enough to support the commanded EQ and digital mixing functions. If an attempt is made to enable an EQ signal path, and there are insufficient SYSCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error can be monitored using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

The FX_STS field in Register R3585 indicates the status of each of the EQ, DRC and LHPF signal paths. If an Underclocked Error condition occurs, then this register provides readback of which EQ, DRC or LHPF signal path(s) have been successfully enabled.

The status bits in Registers R1600 to R2920 indicate the status of each of the digital mixers. If an Underclocked Error condition occurs, then these bits provide readback of which mixer(s) have been successfully enabled.

DYNAMIC RANGE CONTROL (DRC)

The digital core provides a stereo Dynamic Range Control (DRC) processing block as illustrated in Figure 26. A 4-input mixer is associated with each DRC input channel. The 4 input sources are selectable in each case, and independent volume control is provided for each path.

The function of the DRC is to adjust the signal gain in conditions where the input amplitude is unknown or varies over a wide range, e.g. when recording from microphones built into a handheld system, or to restrict the dynamic range of an output signal path.

The DRC can apply Compression and Automatic Level Control to the signal path. It incorporates ‘anti-clip’ and ‘quick release’ features for handling transients in order to improve intelligibility in the presence of loud impulsive noises.

The DRC also incorporates a Noise Gate function, which provides additional attenuation of very low-level input signals. This means that the signal path is quiet when no signal is present, giving an improvement in background noise level under these conditions.

A Signal Detect function is provided within the DRC; this can be used to detect the presence of an audio signal, and used to trigger other events. The Signal Detect function can be used as an Interrupt event, or as a GPIO output, or used to trigger the Control Write Sequencer.

Figure 26 Dynamic Range Control (DRC) Block

The DRC1 mixer control registers (see Figure 26) are located at register addresses R2240 (8C0h) through to R2255 (08CFh).

The full list of digital mixer control registers is provided in the “Register Map” section (Register R1600 through to R2920). Generic register definitions are provided in Table 7.

The *_SRCn registers select the input source(s) for the respective DRC processing blocks. Note that the selected input source(s) must be configured for the same sample rate as the DRC to which they are connected. Sample rate conversion functions are available to support flexible interconnectivity - see “Asynchronous Sample Rate Converter (ASRC)” and “Isochronous Sample Rate Converter (ISRC)”.

The bracketed numbers in Figure 26, eg. “(58h)” indicate the corresponding *_SRCn register setting for selection of that signal as an input to another digital core function.

The sample rate for the DRC function is configured using the FX_RATE register - see Table 20. Note that the EQ, DRC and LHPF functions must all be configured for the same sample rate. Sample rate conversion is required when routing the DRC signal paths to any signal chain that is asynchronous and/or configured for a different sample rate.

The DRC functions are enabled using the control registers described in Table 12.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R3712 (0E80h) DRC1 ctrl1	1	DRC1L_ENA	0	DRC1 (Left) Enable 0 = Disabled 1 = Enabled
	0	DRC1R_ENA	0	DRC1 (Right) Enable 0 = Disabled 1 = Enabled

Table 12 DRC Enable

DRC Compression / Expansion / Limiting

The DRC supports two different compression regions, separated by a “Knee” at a specific input amplitude. In the region above the knee, the compression slope DRC1_HI_COMP applies; in the region below the knee, the compression slope DRC1_LO_COMP applies.

The DRC also supports a noise gate region, where low-level input signals are heavily attenuated. This function can be enabled or disabled according to the application requirements. The DRC response in this region is defined by the expansion slope DRC1_NG_EXP.

For additional attenuation of signals in the noise gate region, an additional “knee” can be defined (shown as “Knee2” in Figure 27). When this knee is enabled, this introduces an infinitely steep drop-off in the DRC response pattern between the DRC1_LO_COMP and DRC1_NG_EXP regions.

The overall DRC compression characteristic in “steady state” (i.e. where the input amplitude is near-constant) is illustrated in Figure 27.

Figure 27 DRC Response Characteristic

The slope of the DRC response is determined by register fields DRC1_HI_COMP and DRC1_LO_COMP. A slope of 1 indicates constant gain in this region. A slope less than 1 represents compression (i.e. a change in input amplitude produces only a smaller change in output amplitude). A slope of 0 indicates that the target output amplitude is the same across a range of input amplitudes; this is infinite compression.

When the noise gate is enabled, the DRC response in this region is determined by the DRC1_NG_EXP register. A slope of 1 indicates constant gain in this region. A slope greater than 1 represents expansion (ie. a change in input amplitude produces a larger change in output amplitude).

When the DRC1_KNEE2_OP knee is enabled (“Knee2” in Figure 27), this introduces the vertical line

in the response pattern illustrated, resulting in infinitely steep attenuation at this point in the response.

The DRC parameters are listed in Table 13.

REF	PARAMETER	DESCRIPTION
1	DRC1_KNEE_IP	Input level at Knee1 (dB)
2	DRC1_KNEE_OP	Output level at Knee2 (dB)
3	DRC1_HI_COMP	Compression ratio above Knee1
4	DRC1_LO_COMP	Compression ratio below Knee1
5	DRC1_KNEE2_IP	Input level at Knee2 (dB)
6	DRC1_NG_EXP	Expansion ratio below Knee2
7	DRC1_KNEE2_OP	Output level at Knee2 (dB)

Table 13 DRC Response Parameters

The noise gate is enabled when the DRC1_NG_ENA register is set. When the noise gate is not enabled, parameters 5, 6, 7 above are ignored, and the DRC1_LO_COMP slope applies to all input signal levels below Knee1.

The DRC1_KNEE2_OP knee is enabled when the DRC1_KNEE2_OP_ENA register is set. When this bit is not set, then parameter 7 above is ignored, and the Knee2 position always coincides with the low end of the DRC1_LO_COMP region.

The “Knee1” point in Figure 27 is determined by register fields DRC1_KNEE_IP and DRC1_KNEE_OP.

Parameter Y0, the output level for a 0dB input, is not specified directly, but can be calculated from the other parameters, using the equation:

$$Y0 = DRC1_KNEE_OP - (DRC1_KNEE_IP \times DRC1_HI_COMP)$$

Gain Limits

The minimum and maximum gain applied by the DRC is set by register fields DRC1_MINGAIN, DRC1_MAXGAIN and DRC1_NG_MINGAIN. These limits can be used to alter the DRC response from that illustrated in Figure 27. If the range between maximum and minimum gain is reduced, then the extent of the dynamic range control is reduced.

The minimum gain in the Compression regions of the DRC response is set by DRC1_MINGAIN. The minimum gain in the Noise Gate region is set by DRC1_NG_MINGAIN. The minimum gain limit prevents excessive attenuation of the signal path.

The maximum gain limit set by DRC1_MAXGAIN prevents quiet signals (or silence) from being excessively amplified.

Dynamic Characteristics

The dynamic behaviour determines how quickly the DRC responds to changing signal levels. Note that the DRC responds to the average (RMS) signal amplitude over a period of time.

The DRC1_ATK determines how quickly the DRC gain decreases when the signal amplitude is high. The DRC1_DCY determines how quickly the DRC gain increases when the signal amplitude is low.

These register fields are described in Table 14. Note that the register defaults are suitable for general purpose microphone use.

Anti-Clip Control

The DRC includes an Anti-Clip feature to avoid signal clipping when the input amplitude rises very quickly. This feature uses a feed-forward technique for early detection of a rising signal level. Signal clipping is avoided by dynamically increasing the gain attack rate when required. The Anti-Clip feature is enabled using the DRC1_ANTICLIP bit.

Note that the feed-forward processing increases the latency in the input signal path.

Note that the Anti-Clip feature operates entirely in the digital domain. It cannot be used to prevent signal clipping in the analogue domain nor in the source signal. Analogue clipping can only be prevented by reducing the analogue signal gain or by adjusting the source signal.

Quick Release Control

The DRC includes a Quick-Release feature to handle short transient peaks that are not related to the intended source signal. For example, in handheld microphone recording, transient signal peaks sometimes occur due to user handling, key presses or accidental tapping against the microphone. The Quick Release feature ensures that these transients do not cause the intended signal to be masked by the longer time constant of DRC1_DCY.

The Quick-Release feature is enabled by setting the DRC1_QR bit. When this bit is enabled, the DRC measures the crest factor (peak to RMS ratio) of the input signal. A high crest factor is indicative of a transient peak that may not be related to the intended source signal. If the crest factor exceeds the level set by DRC1_QR_THR, then the normal decay rate (DRC1_DCY) is ignored and a faster decay rate (DRC1_QR_DCY) is used instead.

Signal Activity Detect

The DRC incorporates a configurable signal detect function, allowing the signal level at the DRC input to be monitored and to be used to trigger other events. This can be used to detect the presence of a microphone signal on an ADC or digital mic channel, or can be used to detect an audio signal received over the digital audio interface.

The DRC Signal Detect function is enabled by setting DRC1_SIG_DET register bit. (Note that DRC1 must also be enabled.) The detection threshold is either a Peak level (Crest Factor) or an RMS level, depending on the DRC1_SIG_DET_MODE register bit. When Peak level is selected, the threshold is determined by DRC1_SIG_DET_PK, which defines the applicable Crest Factor (Peak to RMS ratio) threshold. If RMS level is selected, then the threshold is set using DRC1_SIG_DET_RMS.

The DRC Signal Detect function is an input to the Interrupt control circuit and can be used to trigger an Interrupt event - see "Interrupts".

The DRC Signal Detect signal can be output directly on a GPIO pin as an external indication of the Signal Detection. See "General Purpose Input / Output" to configure a GPIO pin for this function.

The Control Write Sequencer can be triggered by the DRC Signal Detect function. This is enabled using the DRC1_WSEQ_SIG_DET_ENA register bit. See "Control Write Sequencer" for further details.

GPIO Outputs from DRC

The Dynamic Range Control (DRC) circuit provides a number of status outputs, which can be output directly on a GPIO pin as an external indication of the DRC Status. See "General Purpose Input / Output" to configure a GPIO pin for these functions.

Each of the DRC status outputs is described below.

The DRC Signal Detect flag indicates that a signal is present on the respective signal path. The threshold level for signal detection is configurable using the register fields are described in Table 14.

The DRC Anti-Clip flag indicates that the DRC Anti-Clip function has been triggered. In this event, the DRC gain is decreasing in response to a rising signal level. The flag is asserted until the DRC gain stabilises.

The DRC Decay flag indicates that the DRC gain increasing in response to a low level signal input. The flag is asserted until the DRC gain stabilises.

The DRC Noise Gate flag indicates that the DRC Noise Gate function has been triggered, indicating that an idle condition has been detected in the signal path.

The DRC Quick Release flag indicates that the DRC Quick Release function has been triggered. In this event, the DRC gain is increasing rapidly following detection of a short transient peak. The flag is asserted until the DRC gain stabilises.

DRC Register Controls

The DRC control registers are described in Table 14.

Table 14 DRC1 Control Registers

The WM5102 performs automatic checks to confirm that the SYSCLK frequency is high enough to support the commanded DRC and digital mixing functions. If an attempt is made to enable a DRC signal path, and there are insufficient SYSCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error can be monitored using the GPIO and/or Interrupt functions. See "General Purpose Input / Output" and "Interrupts" for further details.

The FX_STS field in Register R3585 indicates the status of each of the EQ, DRC and LHPF signal paths. If an Underclocked Error condition occurs, then this register provides readback of which EQ, DRC or LHPF signal path(s) have been successfully enabled.

The status bits in Registers R1600 to R2920 indicate the status of each of the digital mixers. If an Underclocked Error condition occurs, then these bits provide readback of which mixer(s) have been successfully enabled.

LOW PASS / HIGH PASS DIGITAL FILTER (LHPF)

The digital core provides four Low Pass Filter (LPF) / High Pass Filter (HPF) processing blocks as illustrated in Figure 28. A 4-input mixer is associated with each filter. The 4 input sources are selectable in each case, and independent volume control is provided for each path. Each Low/High Pass Filter (LHPF) block supports 1 output.

The Low Pass Filter / High Pass Filter can be used to remove unwanted 'out of band' noise from a signal path. Each filter can be configured either as a Low Pass filter or High Pass filter.

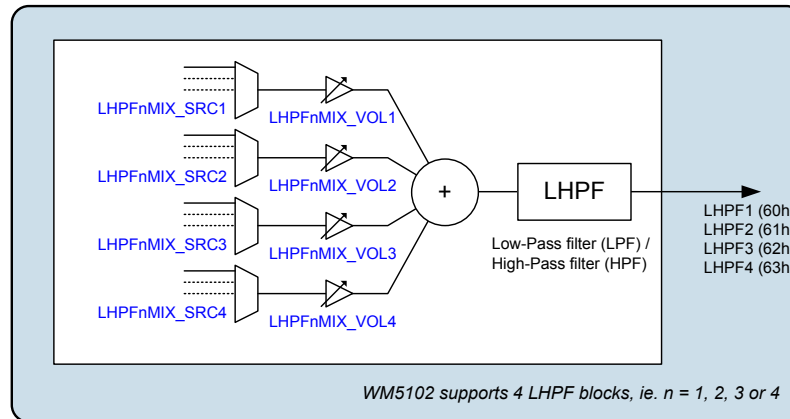

Figure 28 Digital Core LPF/HPF Blocks

The LHPF1, LHPF2, LHPF3 and LHPF4 mixer control registers (see Figure 28) are located at register addresses R2304 (900h) through to R2335 (91Fh).

The full list of digital mixer control registers is provided in the "Register Map" section (Register R1600 through to R2920). Generic register definitions are provided in Table 7.

The *_SRCn registers select the input source(s) for the respective LHPF processing blocks. Note that the selected input source(s) must be configured for the same sample rate as the LHPF to which they are connected. Sample rate conversion functions are available to support flexible interconnectivity - see "Asynchronous Sample Rate Converter (ASRC)" and "Isochronous Sample Rate Converter (ISRC)".

The bracketed numbers in Figure 28, eg. "(60h)" indicate the corresponding *_SRCn register setting for selection of that signal as an input to another digital core function.

The sample rate for the LHPF function is configured using the FX_RATE register - see Table 20. Note that the EQ, DRC and LHPF functions must all be configured for the same sample rate. Sample rate conversion is required when routing the LHPF signal paths to any signal chain that is asynchronous and/or configured for a different sample rate.

The control registers associated with the LHPF functions are described in Table 15.

The cut-off frequencies for the LHPF blocks are set using the coefficients held in registers R3777, R3781, R3785 and R3789 for LHPF1, LHPF2, LHPF3 and LHPF4 respectively. These coefficients are derived using tools provided in Wolfson's WISCE™ evaluation board control software; please contact your local Wolfson representative for more details.

Table 15 Low Pass Filter / High Pass Filter Control

The WM5102 performs automatic checks to confirm that the SYSCLK frequency is high enough to support the commanded LHPF and digital mixing functions. If an attempt is made to enable an LHPF signal path, and there are insufficient SYSCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error can be monitored using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

The FX_STS field in Register R3585 indicates the status of each of the EQ, DRC and LHPF signal paths. If an Underclocked Error condition occurs, then this register provides readback of which EQ, DRC or LHPF signal path(s) have been successfully enabled.

The status bits in Registers R1600 to R2920 indicate the status of each of the digital mixers. If an Underclocked Error condition occurs, then these bits provide readback of which mixer(s) have been successfully enabled.

DIGITAL CORE DSP

The digital core incorporates a programmable DSP block, as illustrated in Figure 29. The DSP supports 8 inputs (Left, Right, Aux1, Aux2, ... Aux6). A 4-input mixer is associated with the Left and Right inputs, providing further expansion of the number of input paths. Each of the input sources is selectable, and independent volume control is provided for Left and Right input mixer channels. The DSP block supports 6 outputs.

The functionality of the DSP is not fixed, and a wide range of audio enhancements algorithms may be performed. The procedure for configuring the WM5102 DSP functions is tailored to each customer's application; please contact your local Wolfson representative for more details.

For details of the DSP Firmware requirements relating to clocking, register access, and code execution, refer to the "DSP Firmware Control" section.

Figure 29 Digital Core DSP Block

The DSP1 mixer / input control registers (see Figure 29) are located at register addresses R2368 (940h) through to R2383 (094Fh).

The full list of digital mixer control registers is provided in the "Register Map" section (Register R1600 through to R2920). Generic register definitions are provided in Table 7.

The *_SRCn registers select the input source(s) for the DSP1 block. Note that the selected input source(s) must be configured for the same sample rate as the DSP to which they are connected. Sample rate conversion functions are available to support flexible interconnectivity - see "Asynchronous Sample Rate Converter (ASRC)" and "Isochronous Sample Rate Converter (ISRC)".

The bracketed numbers in Figure 29, eg. "(68h)" indicate the corresponding *_SRCn register setting for selection of that signal as an input to another digital core function.

The sample rate of the DSP input/output is configured using the respective DSP1_RATE register - see Table 20. Sample rate conversion is required when routing the DSP1 signal paths to any signal chain that is asynchronous and/or configured for a different sample rate.

The WM5102 performs automatic checks to confirm that the SYSCCLK frequency is high enough to support the commanded DSP mixing functions. If an attempt is made to enable a DSP mixer path, and there are insufficient SYSCCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error condition can be monitored using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

The status bits in Registers R1600 to R2920 indicate the status of each of the digital mixers. If an Underclocked Error condition occurs, then these bits provide readback of which mixer(s) have been successfully enabled.

The WM5102 supports two DSP Status flags as outputs from the DSP. These are configurable within the DSP to provide external indication of the required function(s). The DSP Status flags can be read using the DSP_IRQn_STS registers described in Table 86 (see “Interrupts”).

The DSP Status flags are inputs to the Interrupt control circuit and can be used to trigger an interrupt event - see “Interrupts”.

The DSP Status flags can be output directly on a GPIO pin as an external indication of the DSP Status. See “General Purpose Input / Output” to configure a GPIO pin for this function.

tone generator

The WM5102 incorporates two 1kHz tone generators which can be used for ‘beep’ functions through any of the audio signal paths. The phase relationship between the two generators is configurable, providing flexibility in creating differential signals, or for test scenarios.

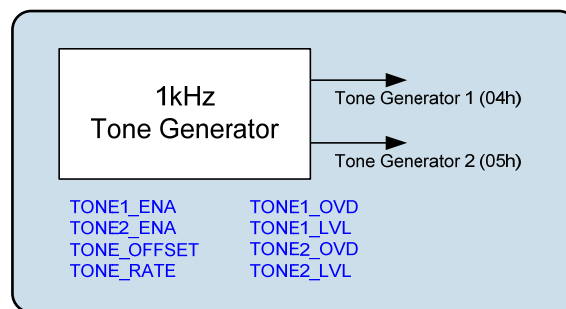

Figure 30 Digital Core Tone Generator

The tone generators can be selected as input to any of the digital mixers or signal processing functions within the WM5102 digital core. The bracketed numbers in Figure 30, eg. “(04h)” indicate the corresponding *_SRCn register setting for selection of that signal as an input to another digital core function.

The sample rate for the tone generators is configured using the TONE_RATE register - see Table 20. Note that sample rate conversion is required when routing the tone generator output(s) to any signal chain that is asynchronous and/or configured for a different sample rate.

The tone generators are enabled using the TONE1_ENA and TONE2_ENA register bits as described in Table 16. The phase relationship is configured using TONE_OFFSET.

The tone generators can also provide a configurable DC signal level, for use as a test signal. The DC output is selected using the TONEn_OVD register bits, and the DC signal amplitude is configured using the TONEn_LVL registers, as described in Table 16.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION

Table 16 Tone Generator Control

NOISE GENERATOR

The WM5102 incorporates a white noise generator, which can be routed within the digital core. The main purpose of the noise generator is to provide 'comfort noise' in cases where silence (digital mute) is not desirable.

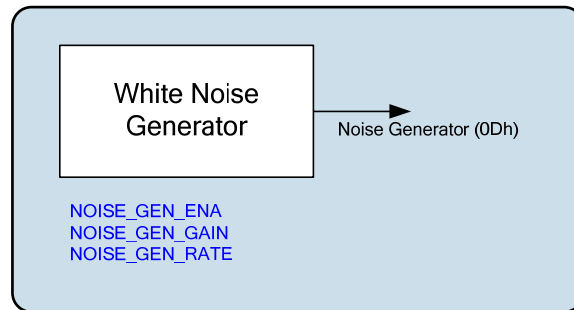

Figure 31 Digital Core Noise Generator

The noise generator can be selected as input to any of the digital mixers or signal processing functions within the WM5102 digital core. The bracketed number (0Dh) in Figure 31 indicates the corresponding *_SRCn register setting for selection of the noise generator as an input to another digital core function.

The sample rate for the noise generator is configured using the NOISE_GEN_RATE register - see Table 20. Note that sample rate conversion is required when routing the noise generator output to any signal chain that is asynchronous and/or configured for a different sample rate.

The noise generator is enabled using the NOISE_GEN_ENA register bit as described in Table 17. The signal level is configured using NOISE_GEN_GAIN.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION

Table 17 Noise Generator Control

HAPTIC SIGNAL GENERATOR

The WM5102 incorporates a signal generator for use with haptic devices (eg. mechanical vibration actuators). The haptic signal generator is compatible with both Eccentric Rotating Mass (ERM) and Linear Resonant Actuator (LRA) haptic devices.

The haptic signal generator is highly configurable, and includes the capability to execute a programmable event profile comprising three distinct operating phases.

The resonant frequency of the haptic signal output (for LRA devices) is selectable, providing support for many different actuator components.

The haptic signal generator is a digital signal generator which is incorporated within the digital core of the WM5102. The haptic signal may be routed, via one of the digital core output mixers, to a Class D speaker output for connection to the external haptic device, as illustrated in Figure 32. (Note that the digital PDM output paths may also be used for haptic signal output.)

Figure 32 Digital Core Haptic Signal Generator

The bracketed number (06h) in Figure 32 indicates the corresponding *_SRCn register setting for selection of the haptic signal generator as an input to another digital core function.

The haptic signal generator is selected as input to one of the digital core output mixers by setting the *_SRCn register of the applicable output mixer to (06h).

The sample rate for the haptic signal generator is configured using the HAP_RATE register - see Table 20. Note that sample rate conversion is required when routing the haptic signal generator output to any signal chain that is asynchronous and/or configured for a different sample rate.

The haptic signal generator is configured for an ERM or LRA actuator using the HAP_ACT register bit. The required resonant frequency is configured using the LRA_FREQ field. (Note that the resonant frequency is only applicable to LRA actuators.)

The signal generator can be enabled in Continuous mode or configured for One-Shot mode using the HAP_CTRL register, as described in Table 18. In One-Shot mode, the output is triggered by writing to the ONESHOT_TRIG bit.

In One-Shot mode, the signal generator profile comprises the distinct phases (1, 2, 3). The duration and intensity of each output phase is programmable.

In Continuous mode, the signal intensity is controlled using the PHASE2_INTENSITY field only.

In the case of an ERM actuator (HAP_ACT = 0), the haptic output is a DC signal level, which may be positive or negative, as selected by the *_INTENSITY registers.

For an LRA actuator (HAP_ACT = 1), the haptic output is an AC signal; selecting a negative signal level corresponds to a 180 degree phase inversion. In some applications, phase inversion may be desirable during the final phase, to halt the physical motion of the haptic device.

Table 18 Haptic Signal Generator Control

PWM GENERATOR

The WM5102 incorporates two Pulse Width Modulation (PWM) signal generators as illustrated in Figure 33. The duty cycle of each PWM signal can be modulated by an audio source, or can be set to a fixed value using a control register setting.

A 4-input mixer is associated with each PWM generator. The 4 input sources are selectable in each case, and independent volume control is provided for each path.

The PWM signal generators can be output directly on a GPIO pin. See “General Purpose Input / Output” to configure a GPIO pin for this function.

Note that the PWM signal generators cannot be selected as input to the digital mixers or signal processing functions within the WM5102 digital core.

Figure 33 Digital Core Pulse Width Modulation (PWM) Generator

The PWM1 and PWM2 mixer control registers (see Figure 33) are located at register addresses R1600 (640h) through to R1615 (64Fh).

The full list of digital mixer control registers is provided in the “Register Map” section (Register R1600 through to R2920). Generic register definitions are provided in Table 7.

The *_SRC_n registers select the input source(s) for the respective mixers. Note that the selected input source(s) must be configured for the same sample rate as the mixer to which they are connected. Sample rate conversion functions are available to support flexible interconnectivity - see “Asynchronous Sample Rate Converter (ASRC)” and “Isochronous Sample Rate Converter (ISRC)”.

The PWM sample rate (cycle time) is configured using the PWM_RATE register - see Table 20. Note that sample rate conversion is required when linking the PWM generators to any signal chain that is asynchronous and/or configured for a different sample rate.

The PWM generators are enabled using PWM1_ENA and PWM2_ENA respectively, as described in Table 19.

Under default conditions (PWMn_OVD = 0), the duty cycle of the PWM generators is controlled by an audio signal path; a 4-input mixer is associated with each PWM generator, as illustrated in Figure 33.

When the PWMn_OVD bit is set, the duty cycle of the respective PWM generator is set to a fixed ratio; in this case, the duty cycle ratio is configurable using the PWMn_LVL registers.

The PWM generator clock frequency is selected using PWM_CLK_SEL. For best performance, this register should be set to the highest available setting. Note that the PWM generator clock must not be set to a higher frequency than SYSCLK (if PWM_RATE < 1000) or ASYNCCLK (if PWM_RATE ≥ 1000).

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R48 (0030h) PWM Drive 1	10:8	PWM_CLK_SEL [2:0]	000	PWM Clock Select 000 = 6.144MHz (5.6448MHz) 001 = 12.288MHz (11.2896MHz) 010 = 24.576MHz (22.5792MHz) All other codes are Reserved The frequencies in brackets apply for 44.1kHz-related sample rates only. PWM_CLK_SEL controls the resolution of the PWM generator; higher settings correspond to higher resolution. The PWM Clock must be less than or equal to SYSCLK (if PWM_RATE < 1000) or less than or equal to ASYNCCLK (if PWM_RATE ≥ 1000).

	0	PWM1_ENA	0	PWM1 Generator Enable 0 = Disabled 1 = Enabled
R49 (0031h) PWM Drive 2	9:0	PWM1_LVL [9:0]	100h	PWM1 Override Level Sets the PWM1 duty cycle when PWM1_OVD=1. Coded as 2's complement. 000h = 50% duty cycle 100h = 0% duty cycle
R50 (0032h) PWM Drive 3	9:0	PWM2_LVL [9:0]	100h	PWM2 Override Level Sets the PWM2 duty cycle when PWM2_OVD=1. Coded as 2's complement. 000h = 50% duty cycle 100h = 0% duty cycle

Table 19 Pulse Width Modulation (PWM) Generator Control

The WM5102 performs automatic checks to confirm that the SYSCLK frequency is high enough to support the digital mixer paths. If an attempt is made to enable a PWM signal mixer path, and there are insufficient SYSCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error condition can be monitored using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

The status bits in Registers R1600 to R2920 indicate the status of each of the digital mixers. If an Underclocked Error condition occurs, then these bits provide readback of which mixer(s) have been successfully enabled.

SAMPLE RATE CONTROL

The WM5102 supports multiple signal paths through the digital core. Stereo full-duplex sample rate conversion is provided to allow digital audio to be routed between interfaces operating at different sample rates and/or referenced to asynchronous clock domains.

Two independent clock domains are supported, referenced to SYSCLK and ASYNCCLK respectively, as described in “Clocking and Sample Rates”. Every digital signal path must be synchronised either to SYSCLK or to ASYNCCLK.

Up to five different sample rates may be in use at any time on the WM5102. Three of these sample rates must be synchronised to SYSCLK; the remaining two, where required, must be synchronised to ASYNCCLK.

Sample rate conversion is required when routing any audio path between digital functions that are asynchronous and/or configured for different sample rates.

The Asynchronous Sample Rate Converter (ASRC) provides two stereo signal paths between the SYSCLK and ASYNCCLK domains. The ASRC is described later, and is illustrated in Figure 36.

There are two Isochronous Sample Rate Converters (ISRCs). These provide two signal paths each between sample rates on the SYSCLK domain, or between sample rates on the ASYNCCLK domain. The ISRCs are described later, and are illustrated in Figure 37.

The sample rate of different blocks within the WM5102 digital core are controlled as illustrated in Figure 34 and Figure 35 - the *_RATE registers select the applicable sample rate for each respective group of digital functions.

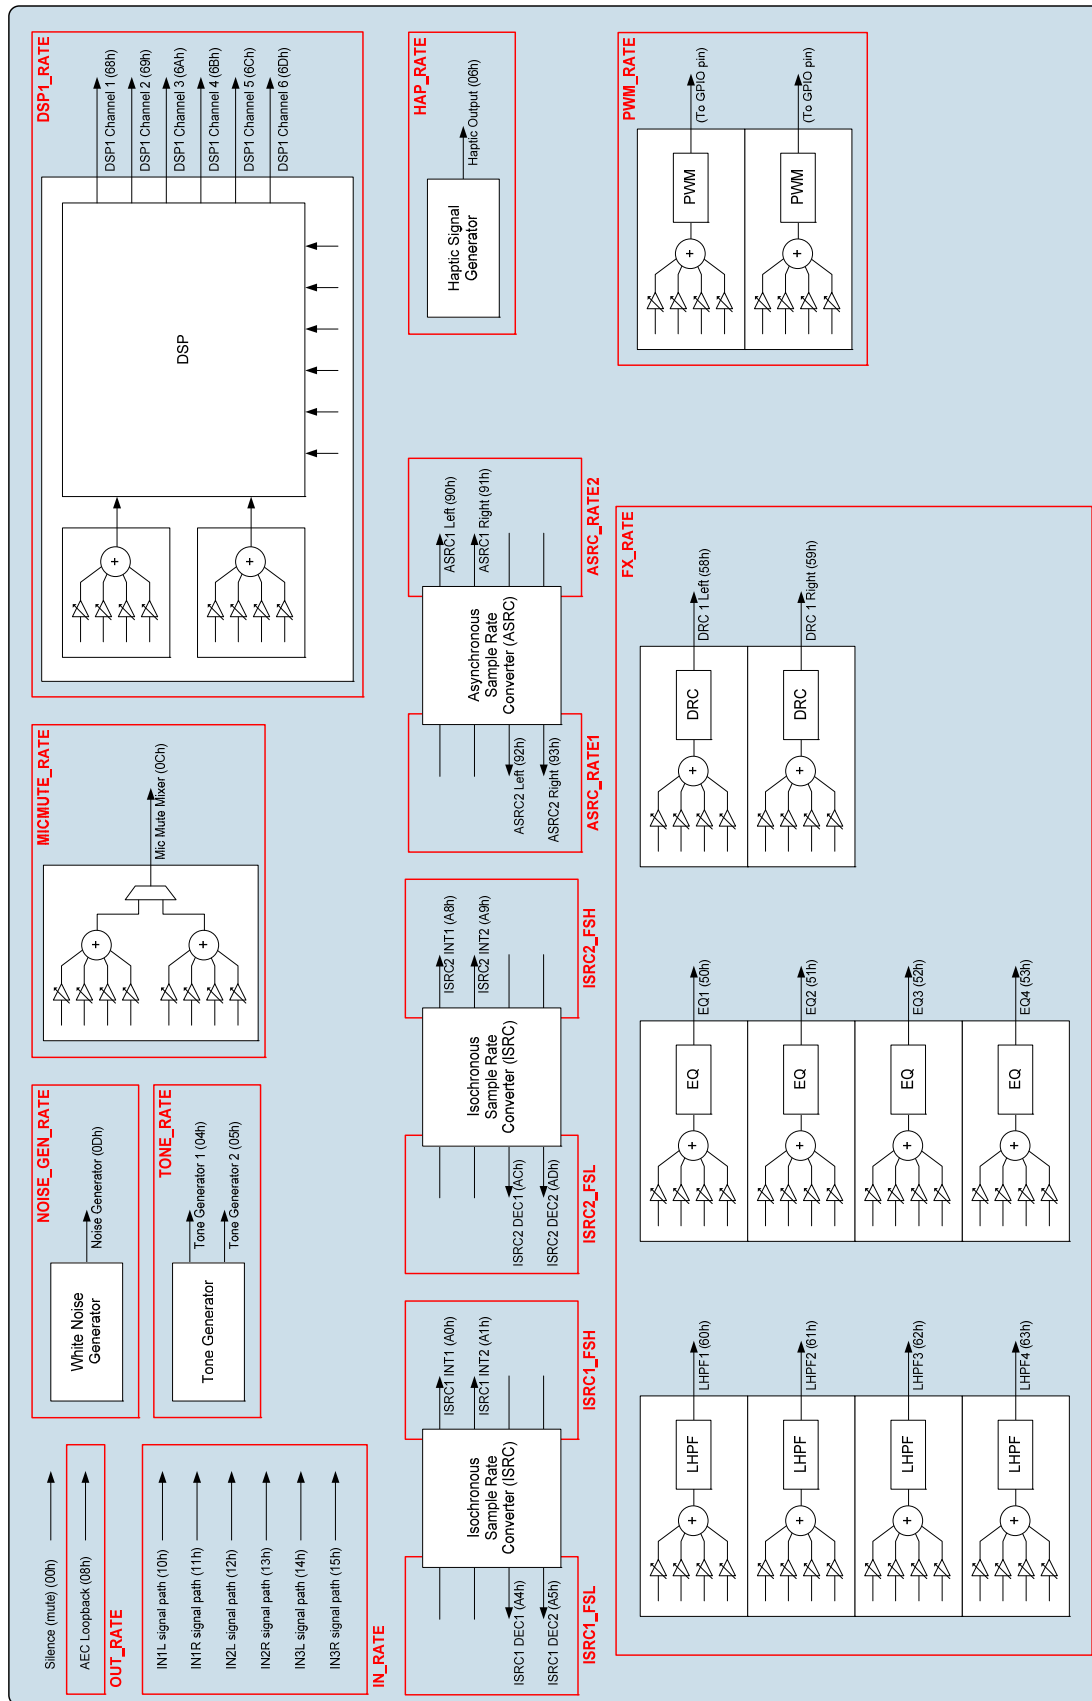

Figure 34 Digital Core Sample Rate Control (Internal Signal Processing)

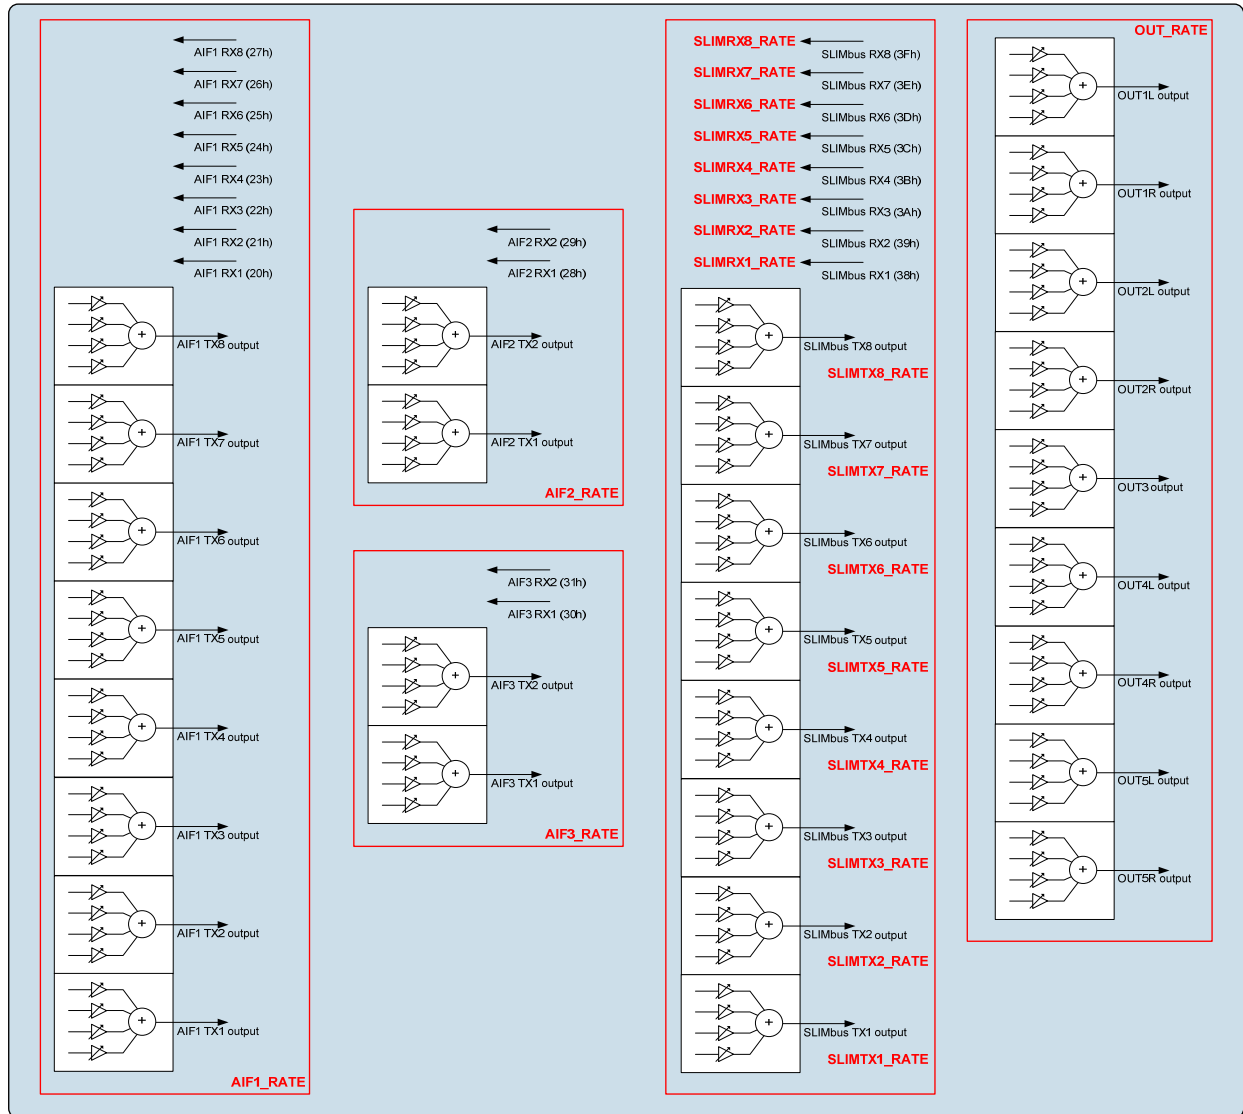

Figure 35 Digital Core Sample Rate Control (External Digital Interfaces)

The input signal paths may be selected as input to the digital mixers or signal processing functions. The sample rate for the input signal paths is configured using the IN_RATE register.

The output signal paths are derived from the respective output mixers. The sample rate for the output signal paths is configured using the OUT_RATE register. The sample rate of the AEC Loopback path is also set by the OUT_RATE register.

The AIFn RX inputs may be selected as input to the digital mixers or signal processing functions. The AIFn TX outputs are derived from the respective output mixers. The sample rates for digital audio interfaces (AIF1, AIF2 and AIF3) are configured using the AIF1_RATE, AIF2_RATE and AIF3_RATE registers respectively.

The SLIMbus interface supports up to 8 input channels and 8 output channels. The sample rate of each channel can be configured independently, using the SLIMTXn_RATE and SLIMRXn_RATE registers.

Note that the SLIMbus interface provides simultaneous support for SYSCCLK-referenced and ASYNCCCLK-referenced sample rates on different channels. For example, 48kHz and 44.1kHz SLIMbus audio paths can be simultaneously supported.

The EQ, LHPF and DRC functions can be enabled in any signal path within the digital core. The sample rate for these functions is configured using the FX_RATE register. Note that the EQ, DRC and LHPF functions must all be configured for the same sample rate.

The DSP functions can be enabled in any signal path within the digital core. The applicable sample rates are configured using the DSP1_RATE register.

The tone generators and noise generator can be selected as input to any of the digital mixers or signal processing functions. The sample rates for these sources are configured using the TONE_RATE and NOISE_GEN_RATE registers respectively.

The haptic signal generator can be used to control an external vibrate actuator, which can be driven directly by the Class D speaker output. The sample rate for the haptic signal generator is configured using the HAP_RATE register.

The PWM signal generators can be modulated by an audio source, derived from the associated signal mixers. The sample rate (cycle time) for the PWM signal generators is configured using the PWM_RATE register.

The sample rate control registers are described in Table 20. Refer to the register descriptions for details of the valid selections in each case. Note that the input (ADC) and output (DAC) signal paths must always be associated with the SYSCLK clocking domain and are therefore synchronous to each other.

The control registers associated with the ASRC and ISRCs are described in Table 21 and Table 22 respectively within the following sections.

Table 20 Digital Core Sample Rate Control

ASYNCHRONOUS SAMPLE RATE CONVERTER (ASRC)

The WM5102 supports multiple signal paths through the digital core. Two independent clock domains are supported, referenced to SYSCLK and ASYNCCLK respectively, as described in "Clocking and Sample Rates". Every digital signal path must be synchronised either to SYSCLK or to ASYNCCLK.

The Asynchronous Sample Rate Converter (ASRC) provides two stereo signal paths between the SYSCLK and ASYNCCLK domains, as illustrated in Figure 36.

The sample rate on the SYSCLK domain is selected using the ASRC_RATE1 register - the rate can be set equal to SAMPLE_RATE_1, SAMPLE_RATE_2 or SAMPLE_RATE_3.

The sample rate on the ASYNCCLK domain is selected using the ASRC_RATE2 register - the rate can be set equal to ASYNC_SAMPLE_RATE_1 or ASYNC_SAMPLE_RATE_2.

See "Clocking and Sample Rates" for details of the sample rate control registers.

The ASRC supports sample rates in the range 8kHz to 48kHz only. The applicable SAMPLE_RATE_n and ASYNC_SAMPLE_RATE_n registers must each select sample rates between 8kHz and 48kHz when any ASRC path is enabled.

The ASRC1 Left and ASRC1 Right paths convert from the SYSCLK domain to the ASYNCCLK domain. These paths are enabled using the ASRC1L_ENA and ASRC1R_ENA register bits respectively.

The ASRC2 Left and ASRC2 Right paths convert from the ASYNCCLK domain to the SYSCLK domain. These paths are enabled using the ASRC2L_ENA and ASRC2R_ENA register bits respectively.

Synchronisation (lock) between different clock domains is not instantaneous when the clocking or sample rate configurations are updated. The lock status of each ASRC path is an input to the Interrupt control circuit and can be used to trigger an Interrupt event - see "Interrupts".

The ASRC Lock status of each ASRC path can be output directly on a GPIO pin as an external indication of ASRC Lock. See "General Purpose Input / Output" to configure a GPIO pin for this function.

The WM5102 performs automatic checks to confirm that the SYSCLK or ASYNCCLK frequency is high enough to support the commanded ASRC and digital mixing functions. If an attempt is made to enable an ASRC signal path, and there are insufficient SYSCLK or ASYNCCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error can be monitored using the GPIO and/or Interrupt functions. See "General Purpose Input / Output" and "Interrupts" for further details.

The status bits in Register R3809 indicate the status of each of the ASRC signal paths. If an Underclocked Error condition occurs, then these bits provide readback of which ASRC signal path(s) have been successfully enabled.

The status bits in Registers R1600 to R2920 indicate the status of each of the digital mixers. If an Underclocked Error condition occurs, then these bits provide readback of which mixer(s) have been successfully enabled.

The Asynchronous Sample Rate Converter (ASRC) signal paths and control registers are illustrated in Figure 36.

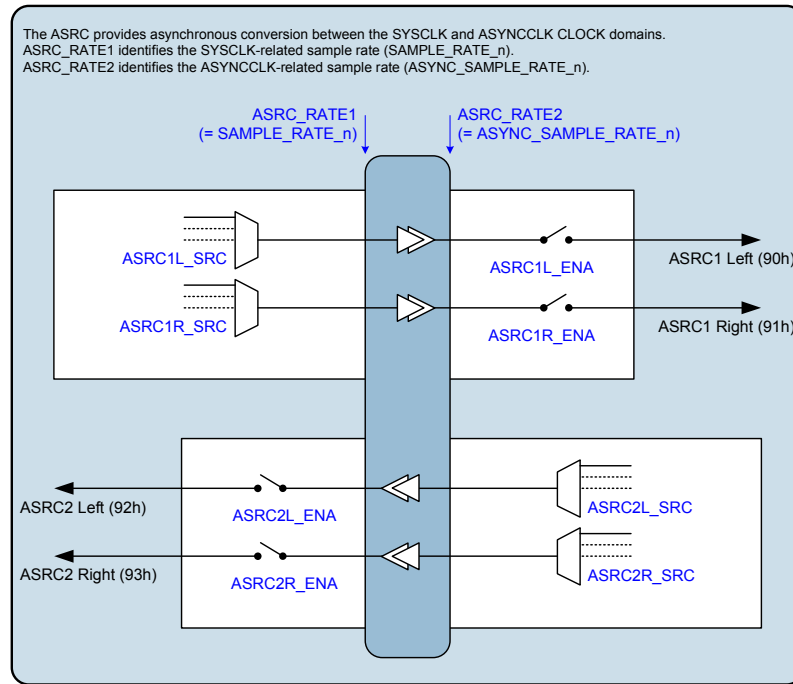

Figure 36 Asynchronous Sample Rate Converters (ASRCs)

The ASRC1 and ASRC2 input control registers (see Figure 36) are located at register addresses R2688 (A80h) through to R2712 (A98h).

The full list of digital mixer control registers is provided in the “Register Map” section (Register R1600 through to R2920). Generic register definitions are provided in Table 7.

The *_SRCn registers select the input source(s) for the respective ASRC processing blocks. Note that the selected input source(s) must be configured for the same sample rate as the ASRC to which they are connected.

The bracketed numbers in Figure 36, eg. “(90h)” indicate the corresponding *_SRCn register setting for selection of that signal as an input to another digital core function.

The register bits associated with the ASRCs are described in Table 21.

Table 21 Digital Core ASRC Control

ISOCRONOUS SAMPLE RATE CONVERTER (ISRC)

The WM5102 supports multiple signal paths through the digital core. The Isochronous Sample Rate Converters (ISRCs) provide sample rate conversion between synchronised sample rates on the SYSCLK clock domain, or between synchronised sample rates on the ASYNCCLK clock domain.

There are two Isochronous Sample Rate Converters (ISRCs). Each of these provides two signal paths between two different sample rates, as illustrated in Figure 37.

The sample rates associated with each ISRC can be set independently. Note that the two sample rates associated with any single ISRC must both be referenced to the same clock domain (SYSCLK or ASYNCCLK).

When an ISRC is used on the SYSCLK domain, then the associated sample rates may be selected from SAMPLE_RATE_1, SAMPLE_RATE_2 or SAMPLE_RATE_3.

When an ISRC is used on the ASYNCCLK domain, then the associated sample rates are ASYNC_SAMPLE_RATE_1 and ASYNC_SAMPLE_RATE_2.

See “Clocking and Sample Rates” for details of the sample rate control registers.

Each ISRC supports sample rates in the range 8kHz to 192kHz. The higher of the sample rates associated with each ISRC must be an integer multiple of the lower sample rate; integer ratios in the range 1 to 6 are supported.

Each ISRC converts between a sample rate selected by ISRCn_FSL and a sample rate selected by ISRCn_FSH, (where 'n' identifies the applicable ISRC 1 or 2). Note that, in each case, the higher of the two sample rates must be selected by ISRCn_FSH.

The ISRCn 'interpolation' paths (increasing sample rate) are enabled using the ISRCn_INT1_ENA and ISRCn_INT2_ENA register bits.

The ISRCn 'decimation' paths (decreasing sample rate) are enabled using the ISRCn_DEC1_ENA and ISRCn_DEC2_ENA register bits.

A notch filter is provided in each of the ISRC paths; these are enabled using the ISRCn_NOTCH_ENA bits. The filter is configured automatically according to the applicable sample rate(s). It is recommended to enable the filter for typical applications. Disabling the filter will provide maximum 'pass' bandwidth, at the expense of degraded stopband attenuation.

The WM5102 performs automatic checks to confirm that the SYSCLK frequency is high enough to support the commanded ISRC and digital mixing functions. If an attempt is made to enable an ISRC signal path, and there are insufficient SYSCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error condition can be monitored using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

The status bits in Registers R1600 to R2920 indicate the status of each of the digital mixers. If an Underclocked Error condition occurs, then these bits provide readback of which mixer(s) have been successfully enabled.

The Isochronous Sample Rate Converter (ISRC) signal paths and control registers are illustrated in Figure 37.

Figure 37 Isochronous Sample Rate Converters (ISRCs)

The ISRC input control registers (see Figure 37) are located at register addresses R2816 (B00h) through to R2920 (0B68h).

The full list of digital mixer control registers is provided in the “Register Map” section (Register R1600 through to R2920). Generic register definitions are provided in Table 7.

The *_SRC registers select the input source(s) for the respective ISRC processing blocks. Note that the selected input source(s) must be configured for the same sample rate as the ISRC to which they are connected.

The bracketed numbers in Figure 37, eg. “(A4h)” indicate the corresponding *_SRC register setting for selection of that signal as an input to another digital core function.

The register bits associated with the ISRCs are described in Table 22.

Table 22 Digital Core ISRC Control

DSP FIRMWARE CONTROL

The WM5102 digital core incorporates a programmable DSP block, capable of running a wide range of audio enhancement functions. Different firmware configurations can be loaded onto the DSP, enabling the WM5102 to be highly customised for specific application requirements.

Examples of the DSP functions include High Definition Bass (HDBass™), Virtual Surround Sound (VSS), Multiband Compressor (MBC). Note that it is possible to implement more than one type of audio enhancement function on the DSP; the precise combination(s) of functions will vary from one firmware configuration to another.

In order to use the DSP, the required firmware configuration must first be loaded onto the device by writing the appropriate files to the WM5102 register map. The firmware configuration will comprise Program, Coefficient and Data content. In some cases, the Coefficient content must be derived using tools provided in Wolfson's WISCE™ evaluation board control software.

Details of how to load the firmware configuration onto the WM5102 are described below. Note that the WISCE™ evaluation board control software provides support for easy loading of Program, Coefficient and Data content onto the WM5102. Please contact your local Wolfson representative for more details of the WISCE™ evaluation board control software.

After loading the DSP firmware, the DSP functions must be enabled using the associated register control fields.

The audio signal paths connecting to/from the DSP are configured as described in the "Digital Core" section. Note that the DSP firmware must be loaded and enabled before audio signal paths can be enabled.

DSP FIRMWARE MEMORY CONTROL

The DSP firmware memory is programmed by writing to the registers referenced in Table 23. Note that the DSP clock must be configured and enabled for the respective DSP block to support read/write access to these registers.

The WM5102 Program, Coefficient and Data memory space is described in Table 23. See "Register Map" for a definition of these register addresses.

The Program firmware parameters are formatted as 40-bit words. For this reason, 3 x 16-bit register addresses are required for each 40-bit word.

The Coefficient and Data firmware parameters are formatted as 24-bit words. For this reason, 2 x 16-bit register addresses are required for each 24-bit word.

	DESCRIPTION	REGISTER ADDRESS	DSP MEMORY SIZE
DSP1	Program memory	10_0000h to 10_5FFFh (24576 registers)	8192 x 40-bit words
	Coefficient memory	18_0000h to 18_07FFh (2048 registers)	1024 x 24-bit words
	X Data memory	19_0000h to 19_47FFh (18432 registers)	9216 x 24-bit words
	Y Data memory	1A_8000h to 1A_97FFh (6144 registers)	3072 x 24-bit words

Table 23 DSP Program, Coefficient and Data Registers

Clocking is required for any functionality of the DSP, including any register read/write operations associated with DSP firmware loading.

The clock source for the DSP is derived from SYSCLK, which must also be enabled. See "Clocking and Sample Rates" for details of how to configure SYSCLK.

The DSP clock frequency is selected using the DSP1_CLK_SEL register. The DSP clock frequency must be less than or equal to the SYSCLK frequency.

If the SUBSYS_MAX_FREQ bit is set to '0', then the DSP clock frequency is restricted to a maximum of 24.576MHz (or 22.5792MHz), even if a higher rate is selected. The SUBSYS_MAX_FREQ should only be set to '1' when the applicable DCVDD condition is satisfied, as described in Table 87.

The clock source for the DSP block is enabled using DSP1_SYS_ENA.

The DSP Memory must be enabled for any functionality of the DSP, including any register read/write operations associated with DSP firmware loading. The DSP Memory is controlled using DSP1_MEM_ENA; this bit is enabled by default.

The DSP1_RAM_RDY status bits indicate when the DSP firmware memory registers are ready for read/write access.

The DSP RAM Ready flags are inputs to the Interrupt control circuit and can be used to trigger an interrupt event - see "Interrupts".

The DSP RAM Ready flags can be output directly on a GPIO pin as an external indication of the DSP RAM Status. See "General Purpose Input / Output" to configure a GPIO pin for this function.

The DSP memory contents are retained during Hardware Reset and Software Reset. The DSP memory contents are cleared in Sleep mode, or if DCVDD falls below its Reset threshold.

Table 24 DSP Clocking Control

DSP FIRMWARE EXECUTION

After the DSP firmware has been loaded, and the clocks configured, the DSP blocks are enabled using the DSP1_CORE_ENA and DSP1_START register bits. Write '1' to both registers to enable and start the firmware execution.

The DSP1_CORE_ENA bit must be set to '1' to enable DSP firmware execution. Note that the usage of the DSP1_START bit may vary depending on the particular software that is being executed: in some applications, writing to the DSP1_START bit will not be required.

For read/write access to the DSP firmware memory registers, the respective firmware execution must be disabled by setting the DSP1_CORE_ENA bit to '0'.

After disabling the DSP (ie. writing DSP1_CORE_ENA=0), the associated DMA must be disabled by setting the DSP1_WDMA_BUFFER_LENGTH, DSP1_WDMA_CHANNEL_ENABLE, and DSP1_RDMA_CHANNEL_ENABLE fields to 0.

The audio signal paths connecting to/from the DSP processing blocks are configured as described in the "Digital Core" section. Note that the DSP firmware must be loaded and enabled before audio signal paths can be enabled.

Table 25 DSP Firmware Execution

DIGITAL AUDIO INTERFACE

The WM5102 provides three audio interfaces, AIF1, AIF2 and AIF3. Each of these is independently configurable on the respective transmit (TX) and receive (RX) paths. AIF1 supports up to 8 channels of input and output signal paths; AIF2 and AIF3 each support up to 2 channels of input and output signal paths.

The data source(s) for the audio interface transmit (TX) paths can be selected from any of the WM5102 input signal paths, or from the digital core processing functions. The audio interface receive (RX) paths can be selected as inputs to any of the digital core processing functions or digital core outputs. See “Digital Core” for details of the digital core routing options.

The digital audio interfaces provide flexible connectivity for multiple processors and other audio devices. Typical connections include Applications Processor, Baseband Processor and Wireless Transceiver. Note that the SLIMbus interface also provides digital audio input/output paths, providing options for additional interfaces. A typical configuration is illustrated in Figure 38.

The audio interfaces AIF1, AIF2 and AIF3 are referenced to DBVDD1, DBVDD2 and DBVDD3 respectively, allowing the WM5102 to connect between application sub-systems on different voltage domains.

Figure 38 Typical AIF Connections

In the general case, the digital audio interface uses four pins:

- TXDAT: Data output
- RXDAT: Data input
- BCLK: Bit clock, for synchronisation
- LRCLK: Left/Right data alignment clock

In master interface mode, the clock signals BCLK and LRCLK are outputs from the WM5102. In slave mode, these signals are inputs, as illustrated below.

As an option, a GPIO pin can be configured as TXLRCLK, ie. the Left/Right clock for the TXDAT output. In this case, the LRCLK pin is dedicated to the RXDAT input, allowing the two sides to be clocked independently.

Four different audio data formats are supported by the digital audio interface:

- DSP mode A
- DSP mode B
- I2S
- Left Justified

The Left Justified and DSP-B modes are valid in Master mode only (ie. BCLK and LRCLK are outputs from the WM5102). These modes cannot be supported in Slave mode.

All four of these modes are MSB first. Data words are encoded in 2's complement format. Each of the audio interface modes is described in the following sections. Refer to the "Signal Timing Requirements" section for timing information.

Two variants of DSP mode are supported - 'Mode A' and 'Mode B'. Mono PCM operation can be supported using the DSP modes.

MASTER AND SLAVE MODE OPERATION

The WM5102 digital audio interfaces can operate as a master or slave as shown in Figure 39 and Figure 40. The associated control bits are described in "Digital Audio Interface Control".

Figure 39 Master Mode

Figure 40 Slave Mode

AUDIO DATA FORMATS

The WM5102 digital audio interfaces can be configured to operate in I²S, Left-Justified, DSP-A or DSP-B interface modes. Note that Left-Justified and DSP-B modes are valid in Master mode only (ie. BCLK and LRCLK are outputs from the WM5102).

The digital audio interfaces also provide flexibility to support multiple 'slots' of audio data within each LRCLK frame. This flexibility allows multiple audio channels to be supported within a single LRCLK frame.

The data formats described in this section are generic descriptions, assuming only one stereo pair of audio samples per LRCLK frame. In these cases, the AIF is configured to transmit (or receive) in the first available position in each frame (ie. the Slot 0 position).

The options for multi-channel operation are described in the following section ("AIF Timeslot Configuration").

The audio data modes supported by the WM5102 are described below. Note that the polarity of the BCLK and LRCLK signals can be inverted if required; the following descriptions all assume the default, non-inverted polarity of these signals.

In DSP mode, the left channel MSB is available on either the 1st (mode B) or 2nd (mode A) rising edge of BCLK following a rising edge of LRCLK. Right channel data immediately follows left channel data. Depending on word length, BCLK frequency and sample rate, there may be unused BCLK cycles between the LSB of the right channel data and the next sample.

In master mode, the LRCLK output will resemble the frame pulse shown in Figure 41 and Figure 42. In slave mode, it is possible to use any length of frame pulse less than 1/fs, providing the falling edge of the frame pulse occurs at least one BCLK period before the rising edge of the next frame pulse.

Figure 41 DSP Mode A Data Format

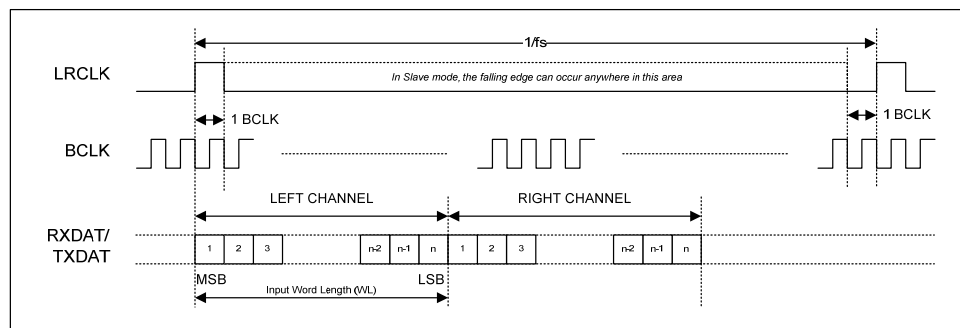

Figure 42 DSP Mode B Data Format

PCM operation is supported in DSP interface mode. WM5102 data that is output on the Left Channel will be read as mono PCM data by the receiving equipment. Mono PCM data received by the WM5102 will be treated as Left Channel data. This data may be routed to the Left/Right playback paths using the control fields described in the “Digital Core” section.

In I²S mode, the MSB is available on the second rising edge of BCLK following a LRCLK transition. The other bits up to the LSB are then transmitted in order. Depending on word length, BCLK frequency and sample rate, there may be unused BCLK cycles between the LSB of one sample and the MSB of the next.

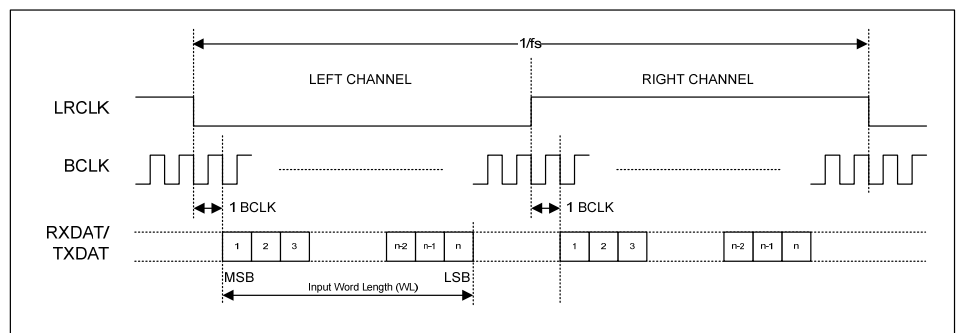

Figure 43 I2S Data Format (assuming n-bit word length)

In Left Justified mode, the MSB is available on the first rising edge of BCLK following a LRCLK transition. The other bits up to the LSB are then transmitted in order. Depending on word length, BCLK frequency and sample rate, there may be unused BCLK cycles before each LRCLK transition.

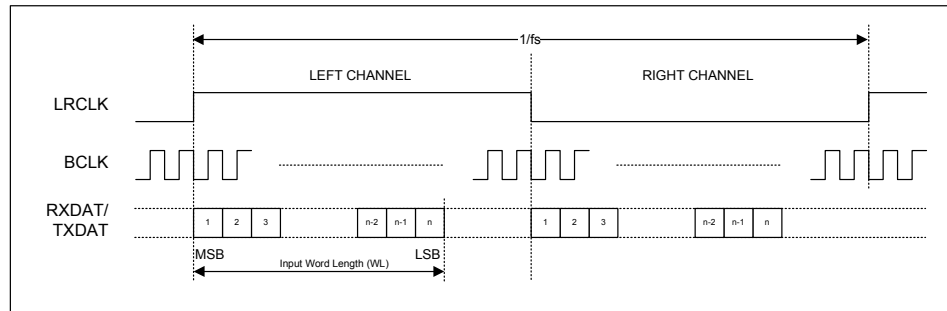

Figure 44 Left Justified Data Format (assuming n-bit word length)

AIF TIMESLOT CONFIGURATION

Digital audio interface AIF1 supports multi-channel operation; up to 8 input (RX) channels and 8 output (TX) channels can be supported simultaneously. A high degree of flexibility is provided to define the position of the audio samples within each LRCLK frame; the audio channel samples may be arranged in any order within the frame.

AIF2 and AIF3 also provide flexible configuration options, but support only 1 stereo input and 1 stereo output pair each.

Note that, on each interface, all input and output channels must operate at the same sample rate (f_s).

Each of the audio channels can be enabled or disabled independently on the transmit (TX) and receive (RX) signal paths. For each enabled channel, the audio samples are assigned to one timeslot within the LRCLK frame.

In DSP modes, the timeslots are ordered consecutively from the start of the LRCLK frame. In I2S and Left-Justified modes, the even-numbered timeslots are arranged in the first half of the LRCLK frame, and the odd-numbered timeslots are arranged in the second half of the frame.

The timeslots are assigned independently for the transmit (TX) and receive (RX) signal paths. There is no requirement to assign every available timeslot to an audio sample; some slots may be unused, if desired. Care is required, however, to ensure that no timeslot is allocated to more than one audio channel.

The number of BCLK cycles within a slot is configurable; this is the Slot Length. The number of valid data bits within a slot is also configurable; this is the Word Length. The number of BCLK cycles per LRCLK frame must be configured; it must be ensured that there are enough BCLK cycles within each LRCLK frame to transmit or receive all of the enabled audio channels.

Examples of the AIF Timeslot Configurations are illustrated in Figure 45 to Figure 48. One example is shown for each of the four possible data formats.

Figure 45 shows an example of DSP Mode A format. Four enabled audio channels are shown, allocated to timeslots 0 through to 3.

Figure 45 DSP Mode A Example

Figure 46 shows an example of DSP Mode B format. Six enabled audio channels are shown, with timeslots 4 and 5 unused.

Figure 46 DSP Mode B Example

Figure 47 shows an example of I2S format. Four enabled channels are shown, allocated to timeslots 0 through to 3.

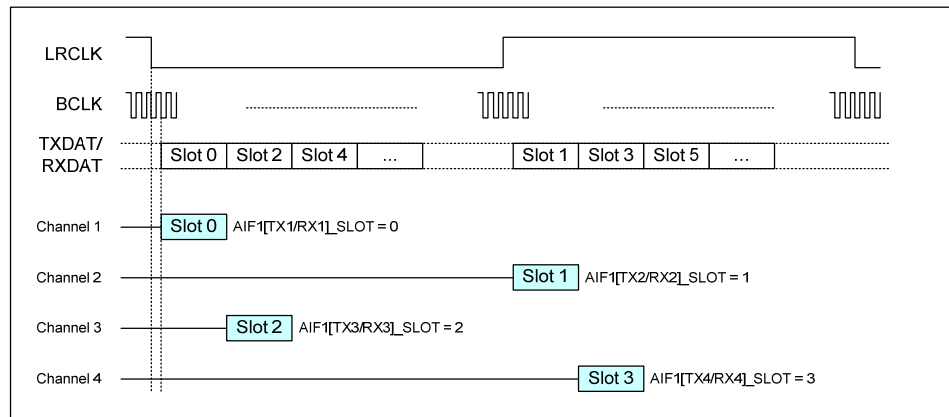

Figure 47 I2S Example

Figure 48 shows an example of Left Justified format. Six enabled channels are shown.

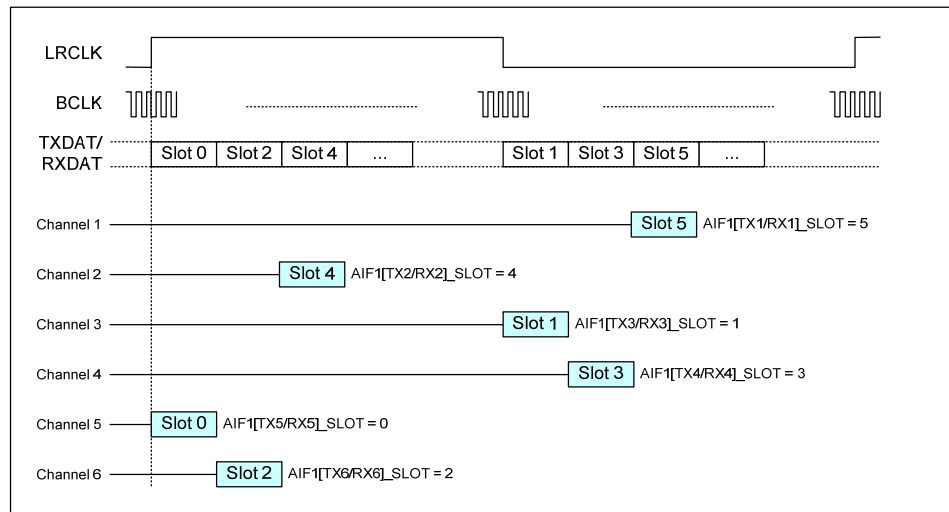

Figure 48 Left Justified Example

TDM OPERATION BETWEEN THREE OR MORE DEVICES

The AIF operation described above illustrates how multiple audio channels can be interleaved on a single TXDAT or RXDAT pin. The interface uses Time Division Multiplexing (TDM) to allocate time periods to each of the audio channels in turn.

This form of TDM is implemented between two devices, using the electrical connections illustrated in Figure 39 or Figure 40.

It is also possible to implement TDM between three or more devices. This allows one CODEC to receive audio data from two other devices simultaneously on a single audio interface, as illustrated in Figure 49, Figure 50 and Figure 51.

The WM5102 provides full support for TDM operation. The TXDAT pin can be tri-stated when not transmitting data, in order to allow other devices to transmit on the same wire. The behaviour of the TXDAT pin is configurable, to allow maximum flexibility to interface with other devices in this way.

Typical configurations of TDM operation between three devices are illustrated in Figure 49, Figure 50 and Figure 51.

Figure 49 TDM with WM5102 as Master

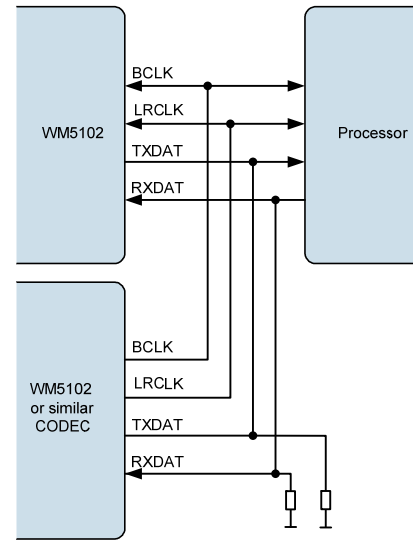

Figure 50 TDM with Other CODEC as Master

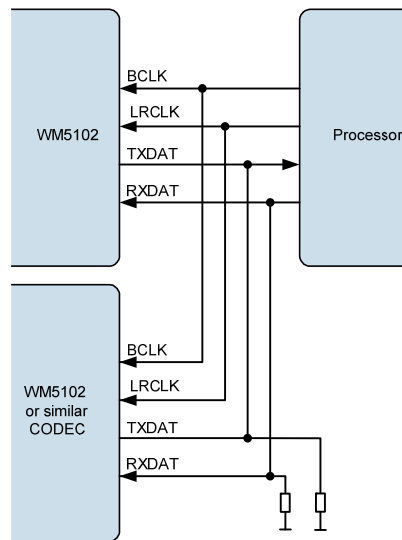

Figure 51 TDM with Processor as Master

Note:

The WM5102 is a 24-bit device. If the user operates the WM5102 in 32-bit mode then the 8 LSBs will be ignored on the receiving side and not driven on the transmitting side. It is therefore recommended to add a pull-down resistor if necessary to the RXDAT line and the TXDAT line in TDM mode.

DIGITAL AUDIO INTERFACE CONTROL

This section describes the configuration of the WM5102 digital audio interface paths.

AIF1 supports up to 8 input signal paths and up to 8 output signal paths. AIF2 and AIF3 support up to 2 input and output signal paths each. The digital audio interfaces AIF1, AIF2 and AIF3 can be configured as Master or Slave interfaces; mixed master/slave configurations are also possible.

Each input and output signal path can be independently enabled or disabled. The AIF output (TX) and AIF input (RX) paths can use a common LRCLK frame clock, or can use separate LRCLK signals if required.

The digital audio interface supports flexible data formats, selectable word-length, configurable timeslot allocations and TDM tri-state control.

AIF SAMPLE RATE CONTROL

The AIF RX inputs may be selected as input to the digital mixers or signal processing functions within the WM5102 digital core. The AIF TX outputs are derived from the respective output mixers.

The sample rate for each digital audio interface AIFn is configured using the respective AIFn_RATE register - see Table 20 within the "Digital Core" section.

Note that sample rate conversion is required when routing the AIF paths to any signal chain that is asynchronous and/or configured for a different sample rate.

AIF MASTER / SLAVE CONTROL

The digital audio interfaces can operate in Master or Slave modes and also in mixed master/slave configurations. In Master mode, the BCLK and LRCLK signals are generated by the WM5102 when any of the respective digital audio interface channels is enabled. In Slave mode, these outputs are disabled by default to allow another device to drive these pins.

Master mode is selected on the AIFnBCLK pin using the AIFn_BCLK_MSTR register bit. In Master mode, the AIFnBCLK signal is generated by the WM5102 when one or more AIFn channels is enabled.

When the AIFn_BCLK_FRC bit is set in BCLK master mode, the AIFnBCLK signal is output at all times, including when none of the AIFn channels is enabled.

The AIFnBCLK signal can be inverted in Master or Slave modes using the AIFn_BCLK_INV register.

Master mode is selected on the AIFnLRCLK pin using the AIFnRX_LRCLK_MSTR register bit. In Master mode, the AIFnRXLRCLK signal is generated by the WM5102 when one or more AIFn channels is enabled. (Note that, when GPIO is configured as AIFnTXLRCLK, then only the AIFn RX channels will cause AIFnRXLRCLK to be output.)

When the AIFnRX_LRCLK_FRC bit is set in LRCLK master mode, the AIFnRXLRCLK signal is output at all times, including when none of the AIFn channels is enabled. Note that AIFnRXLRCLK is derived from AIFnBCLK, and an internal or external AIFnBCLK signal must be present to generate AIFnRXLRCLK.

The AIFnRXLRCLK signal can be inverted in Master or Slave modes using the AIFnRX_LRCLK_INV register.

Under default conditions, the AIFn input (RX) and output (TX) paths both use the AIFnRXLRCLK signal as the frame synchronisation clock. The AIFn output (TX) interface can be configured to use a separate frame clock, AIFnTXLRCLK, using the AIFnTX_LRCLK_SRC bit.

The AIFnTXLRCLK function, when used, must be selected on the GPIO pin as described in the "General Purpose Input / Output" section.

The AIFnTXLRCLK function can operate in Master or Slave mode, and is controlled similarly to the AIFnRXLRCLK function using the register bits described in Table 26, Table 27 and Table 28 for AIF1, AIF2 and AIF3 respectively.

AIF SIGNAL PATH ENABLE

The AIF1 interface supports up to 8 input (RX) channels and up to 8 output (TX) channels. Each of these channels can be enabled or disabled using the register bits defined in Table 29.

The AIF2 and AIF3 interfaces support up to 2 input (RX) channels and up to 2 output (TX) channels. Each of these channels can be enabled or disabled using the register bits defined in Table 30 and Table 31.

The system clock, SYSCLK, must be configured and enabled before any audio path is enabled. The ASYNCCLK may also be required, depending on the path configuration. See “Clocking and Sample Rates” for details of the system clocks.

The WM5102 performs automatic checks to confirm that the SYSCLK and ASYNCCLK frequencies are high enough to support the commanded signal paths and processing functions. If an attempt is made to enable an AIF signal path, and there are insufficient SYSCLK or ASYNCCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error conditions can be monitored using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

AIF BCLK AND LRCLK CONTROL

The AIFnBCLK frequency is selected by the AIFn_BCLK_FREQ register. For each value of this register, the actual frequency depends upon whether AIFn is configured for a 48kHz-related sample rate or a 44.1kHz-related sample rate, as described below.

If AIFn_RATE < 1000 (see Table 20), then AIFn is referenced to the SYSCLK clocking domain and the applicable frequency depends upon the SAMPLE_RATE_1, SAMPLE_RATE_2 or SAMPLE_RATE_3 registers.

If AIFn_RATE ≥ 1000, then AIFn is referenced to the ASYNCCLK clocking domain and the applicable frequency depends upon the ASYNC_SAMPLE_RATE_1 or ASYNC_SAMPLE_RATE_2 registers.

The selected AIFnBCLK rate must be less than or equal to SYSCLK/2, or ASYNCCLK/2, as applicable. See “Clocking and Sample Rates” for details of SYSCLK and ASYNCCLK domains, and the associated control registers.

The AIFnRXLRCLK frequency is controlled relative to AIFnBCLK by the AIFnRX_BCPF divider.

Under default conditions, the AIFn input (RX) and output (TX) paths both use the AIFnRXLRCLK signal as the frame synchronisation clock. The AIFn output (TX) interface can be configured to use a separate frame clock, AIFnTXLRCLK, using the AIFnTX_LRCLK_SRC bit, as described in Table 26, Table 27 and Table 28 for AIF1, AIF2 and AIF3 respectively.

When the GPIO pin is configured as AIFnTXLRCLK, then the AIFnTXLRCLK frequency is controlled relative to AIFnBCLK by the AIFnTX_BCPF divider. See “General Purpose Input / Output” for details of how to configure the GPIO1, GPIO2 or GPIO3 pins.

Note that the BCLK rate must be configured in Master or Slave modes, using the AIFn_BCLK_FREQ registers. The LRCLK rate(s) only require to be configured in Master mode.

Table 34 AIF3 BCLK and LRCLK Control

The WM5102 performs automatic checks to confirm that each AIF is configured with valid settings. Invalid settings include conditions where one or more audio channel timeslots are in conflict.

If an AIF1 configuration error, AIF2 configuration error or AIF3 configuration error is detected, this can be indicated using the GPIO and/or Interrupt functions. See "General Purpose Input / Output" and "Interrupts" for further details.

AIF DIGITAL AUDIO DATA CONTROL

The register bits controlling the audio data format, word lengths and slot configurations for AIF1, AIF2 and AIF3 are described in Table 35, Table 36 and Table 37 respectively.

Note that Left-Justified and DSP-B modes are valid in Master mode only (ie. BCLK and LRCLK are outputs from the WM5102).

The AIFn Slot Length is the number of BCLK cycles in one timeslot within the overall LRCLK frame. The Word Length is the number of valid data bits within each timeslot. (If the word length is less than the slot length, then there will be unused BCLK cycles at the end of each timeslot.) The AIFn word length and slot length is independently selectable for the input (RX) and output (TX) paths.

For each AIF input (RX) and AIF output (TX) channel, the position of the audio data sample within the LRCLK frame is configurable. The _SLOT registers define the timeslot position of the audio sample for the associated audio channel. Valid selections are Slot 0 upwards. The timeslots are numbered as illustrated in Figure 45 through to Figure 48.

Note that, in DSP modes, the timeslots are ordered consecutively from the start of the LRCLK frame. In I2S and Left-Justified modes, the even-numbered timeslots are arranged in the first half of the LRCLK frame, and the odd-numbered timeslots are arranged in the second half of the frame.

Table 37 AIF3 Digital Audio Data Control

The WM5102 performs automatic checks to confirm that each AIF is configured with valid settings. Invalid settings include conditions where one or more audio channel timeslots are in conflict.

If an AIF1 configuration error, AIF2 configuration error or AIF3 configuration error is detected, this can be indicated using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

AIF TDM AND TRI-STATE CONTROL

The AIFn output pins are tri-stated when the AIFn_TRI register is set. Note that, when a GPIO pin is configured as a GPIO, this pin is not affected by the respective AIFn_TRI register. See "General Purpose Input / Output" to configure the GPIO pins.

Under default conditions, the AIFnTXDAT output is held at logic 0 when the WM5102 is not transmitting data (ie. during timeslots that are not enabled for output by the WM5102). When the AIFnTX_DAT_TRI register is set, the WM5102 tri-states the respective AIFnTXDAT pin when not transmitting data, allowing other devices to drive the AIFnTXDAT connection.

AIF DIGITAL PULL-UP AND PULL-DOWN

The WM5102 provides integrated pull-up and pull-down resistors on each of the AIFnLRCLK, AIFnBCLK and AIFnRXDAT pins. This provides a flexible capability for interfacing with other devices.

Each of the pull-up and pull-down resistors can be configured independently using the register bits described in Table 41, Table 42 and Table 43. Note that if the Pull-up and Pull-down are both enabled for any pin, then the pull-up and pull-down will be disabled.

SLIMBUS INTERFACE

The WM5102 features a MIPI-compliant SLIMbus interface, providing 8 channels of audio input and 8 channels of audio output. Mixed audio sample rates are supported on the SLIMbus interface. The SLIMbus interface also supports read/write access to the WM5102 control registers.

The SLIMbus interface on WM5102 comprises an Interface Device, Framer Device, and Generic Device. A maximum of 16 Ports can be configured, providing up to 8 input (RX) channels and up to 8 output (TX) channels.

The audio paths associated with the SLIMbus interface are described in the “Digital Core” section.

The SLIMbus interface supports read/write access to the WM5102 control registers, as described later in this section.

The SLIMbus clocking rate and channel allocations are controlled by the Manager Device. The Message Channel and Data Channel bandwidth may be dynamically adjusted according to the application requirements. Note that the Manager Device functions are not implemented on the WM5102, and these bandwidth allocation requirements are outside the scope of this datasheet.

SLIMBUS DEVICE PARAMETERS

The Enumeration Address of each Device within the SLIMbus interface is derived from the parameters noted in Table 44.

DESCRIPTION	MANUFACTURER ID	PRODUCT CODE	DEVICE ID	INSTANCE VALUE	ENUMERATION ADDRESS
Interface	0x012F	0x5102	0x7F	0x00	012F_5102_7F00
Framer	0x012F	0x5102	0x55	0x00	012F_5102_5500
Generic	0x012F	0x5102	0x00	0x00	012F_5102_0000

Table 44 SLIMbus Device Parameters

The WM5102 SLIMbus interface supports up to 8 input (RX) channels and up to 8 output (TX) channels. The SLIMbus port numbers for these audio channels are detailed in Table 45.

WM5102 CHANNEL	SLIMBUS PORT NUMBER	WM5102 CHANNEL	SLIMBUS PORT NUMBER
RX Channel 1	0	TX Channel 1	8
RX Channel 2	1	TX Channel 2	9
RX Channel 3	2	TX Channel 3	10
RX Channel 4	3	TX Channel 4	11
RX Channel 5	4	TX Channel 5	12
RX Channel 6	5	TX Channel 6	13
RX Channel 7	6	TX Channel 7	14
RX Channel 8	7	TX Channel 8	15

Table 45 SLIMbus Port Numbers

SLIMBUS SAMPLE RATE CONTROL

The SLIMbus RX inputs may be selected as input to the digital mixers or signal processing functions within the WM5102 digital core. The SLIMbus TX outputs are derived from the respective output mixers.

The sample rate for each SLIMbus channel is configured using the SLIMRXn_RATE and SLIMTXn_RATE registers - see Table 20 within the “Digital Core” section.

Note that the SLIMbus interface provides simultaneous support for SYSCLK-referenced and ASYNCCLOCK-referenced sample rates on different channels. For example, 48kHz and 44.1kHz SLIMbus audio paths can be simultaneously supported.

Sample rate conversion is required when routing the SLIMbus paths to any signal chain that is asynchronous and/or configured for a different sample rate.

SLIMBUS SIGNAL PATH ENABLE

The SLIMbus interface supports up to 8 input (RX) channels and up to 8 output (TX) channels. Each of these channels can be enabled or disabled using the register bits defined in Table 46.

Note that the SLIMbus audio channels can only be supported when the corresponding ports have been enabled by the Manager Device. The status bits in Registers R1527 and R1528 indicate the status of each of the SLIMbus ports.

The system clock, SYSCLK, must be configured and enabled before any audio path is enabled. The ASYNCCLK may also be required, depending on the path configuration. See "Clocking and Sample Rates" for details of the system clocks.

The WM5102 performs automatic checks to confirm that the SYSCLK and ASYNCCLK frequencies are high enough to support the commanded signal paths and processing functions. If an attempt is made to enable a SLIMbus signal path, and there are insufficient SYSCLK or ASYNCCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error conditions can be monitored using the GPIO and/or Interrupt functions. See "General Purpose Input / Output" and "Interrupts" for further details.

SLIMBUS CONTROL REGISTER ACCESS

Control register access is supported via the SLIMbus interface. Full read/write access to all registers is possible, via the "User Value Elements" portion of the Value Map.

Register Write operations are implemented using the "CHANGE_VALUE" message. A maximum of two messages may be required, depending on circumstances: the first "CHANGE_VALUE" message selects the register page (bits [23:8] of the Control Register address); the second message contains the data and bits [7:0] of the register address. The first message may be omitted if the register page is unchanged from the previous Read or Write operation.

The associated parameters are described in Table 47 and Table 48, for the generic case of writing the value 0xVVVV to control register address 0xYYYYZZ.

Write Message 1 – CHANGE_VALUE		
PARAMETER	VALUE	DESCRIPTION
Source Address	0xFF	Identifies the Manager Device as the message source, using the 8-bit Logical Address. The value is always 0xFF.
Destination Address	0xLL	'LL' is the 8-bit Logical Address of the message destination (ie. the WM5102 SLIMbus Interface Device). The value is assigned by the SLIMbus Manager Device.
Access Mode	0b1	Selects Byte-based access mode.
Byte Address	0x800	Identifies the User Value element for selecting the Control Register page address.
Slice Size	0b001	Selects 2-byte slice size
Value Update	0xYYYY	'YYYY' is bits [23:8] of the applicable Control Register address.

Table 47 Register Write Message (1)

Write Message 2 – CHANGE_VALUE		
PARAMETER	VALUE	DESCRIPTION
Source Address	0xFF	Identifies the Manager Device as the message source, using the 8-bit Logical Address. The value is always 0xFF.
Destination Address	0xLL	'LL' is the 8-bit Logical Address of the message destination (ie. the WM5102 SLIMbus Interface Device). The value is assigned by the SLIMbus Manager Device.
Access Mode	0b1	Selects Byte-based access mode.
Byte Address	0xUUU	Specifies the Value Map address, calculated as $0xA00 + (2 \times 0xZZ)$, where 'ZZ' is bits [7:0] of the applicable Control Register address.
Slice Size	0b001	Selects 2-byte slice size
Value Update	0xVVVV	'VVVV' is the 16-bit data to be written.

Table 48 Register Write Message (2)

Note that the first message may be omitted if its contents are unchanged from the previous CHANGE_VALUE message sent to the WM5102.

Register Read operations are implemented using the “CHANGE_VALUE” and “REQUEST_VALUE” messages. A maximum of two messages may be required, depending on circumstances: the “CHANGE_VALUE” message selects the register page (bits [23:8] of the Control Register address); the “REQUEST_VALUE” message contains bits [7:0] of the register address. The first message may be omitted if the register page is unchanged from the previous Read or Write operation.

The associated parameters are described in Table 49 and Table 50, for the generic case of reading the contents of control register address 0xYYYYZZ.

Read Message 1 – CHANGE_VALUE		
PARAMETER	VALUE	DESCRIPTION
Source Address	0xFF	Identifies the Manager Device as the message source, using the 8-bit Logical Address. The value is always 0xFF.
Destination Address	0xLL	'LL' is the 8-bit Logical Address of the message destination (ie. the WM5102 SLIMbus Interface Device). The value is assigned by the SLIMbus Manager Device.
Access Mode	0b1	Selects Byte-based access mode.
Byte Address	0x800	Identifies the User Value element for selecting the Control Register page address.
Slice Size	0b001	Selects 2-byte slice size
Value Update	0xYYYY	'YYYY' is bits [23:8] of the applicable Control Register address.

Table 49 Register Read Message (1)

Read Message 2 – REQUEST_VALUE		
PARAMETER	VALUE	DESCRIPTION
Source Address	0xFF	Identifies the Manager Device as the message source, using the 8-bit Logical Address. The value is always 0xFF.
Destination Address	0xLL	'LL' is the 8-bit Logical Address of the message destination (ie. the WM5102 SLIMbus Interface Device). The value is assigned by the SLIMbus Manager Device.
Access Mode	0b1	Selects Byte-based access mode.
Byte Address	0xUUU	Specifies the Value Map address, calculated as 0xA00 + (2 x 0xZZ), where 'ZZ' is bits [7:0] of the applicable Control Register address.
Slice Size	0b001	Selects 2-byte slice size
Transaction ID	0xTTTT	'TTTT' is the 16-bit Transaction ID for the message. The value is assigned by the SLIMbus Manager Device.

Table 50 Register Read Message (2)

Note that the first message may be omitted if its contents are unchanged from the previous CHANGE_VALUE message sent to the WM5102.

The WM5102 will respond to the Register Read commands in accordance with the normal SLIMbus protocols.

Note that the WM5102 assumes that sufficient Control Space Slots are available in which to provide its response before the next REQUEST_VALUE message is received. The WM5102 response is made using a REPLY_VALUE message; the SLIMbus Manager should wait until the REPLY_VALUE message has been received before sending the next REQUEST_VALUE message. If additional REQUEST_VALUE message(s) are received before the WM5102 response has been made, then the earlier REQUEST_VALUE message(s) will be ignored (ie. only the last REQUEST_VALUE message will be serviced)

SLIMBUS CLOCKING CONTROL

The clock frequency of the SLIMbus interface is not fixed, and may be set according to the application requirements. The clock frequency can be reconfigured dynamically as required.

The WM5102 SLIMbus interface includes a Framer Device. When configured as the active Framer, the SLIMbus clock (SLIMCLK) is an output from the WM5102. At other times, SLIMCLK is an input. The Framer function can be transferred from one device to another; this is known as Framer Handover, and is controlled by the Manager Device.

The supported Root Frequencies in Active Framer mode are 24.576MHz or 22.5792MHz only. At other times, the supported Root Frequencies are as defined in the MIPI Alliance specification for SLIMbus.

Under normal operating conditions, the SLIMbus interface operates with a fixed Root Frequency (RF); dynamic updates to the bus rate are applied using a selectable Clock Gear (CG) function. The Root Frequency and the Clock Gear setting are controlled by the Manager Device; these parameters are transmitted in every SLIMbus superframe to all devices on the bus.

In Gear 10 (the highest Clock Gear setting), the SLIMCLK input (or output) frequency is equal to the Root Frequency. In lower gears, the SLIMCLK frequency is reduced by increasing powers of 2.

The Clock Gear definition is shown in Table 51. Note that 24.576MHz Root Frequency is an example only; other frequencies are also supported.

CLOCK GEAR	DESCRIPTION	SLIMCLK FREQUENCY (assuming 24.576MHz Root Frequency)
10	Divide by 1	24.576MHz
9	Divide by 2	12.288MHz
8	Divide by 4	6.144MHz
7	Divide by 8	3.072MHz
6	Divide by 16	1.536MHz
5	Divide by 32	768kHz
4	Divide by 64	384kHz
3	Divide by 128	192kHz
2	Divide by 256	96kHz
1	Divide by 512	48kHz

Table 51 SLIMbus Clock Gear Selection

When the WM5102 is the active Framer, the SLIMCLK output is synchronised to the SYSCLK or ASYNCCLK system clock, as selected by the SLIMCLK_SRC register bit.

The applicable system clock must be enabled, and configured at the SLIMbus Root Frequency, whenever the WM5102 is the active Framer. See “Clocking and Sample Rates” for details of the SYSCLK and ASYNCCLK system clocks.

When the WM5102 is not configured as the active Framer device, then the SLIMCLK input can be used to provide a reference source for the Frequency Locked Loops (FLLs). The frequency of this reference is controlled using the SLIMCLK_REF_GEAR register, as described in Table 52.

The SLIMbus clock reference is generated using an adaptive divider on the SLIMCLK input. The divider automatically adapts to the SLIMbus Clock Gear (CG).

Note that, if the Clock Gear (CG) on the bus is lower than the SLIMCLK_REF_GEAR, then the selected reference frequency cannot be supported, and the SLIMbus clock reference is disabled.

The SLIMbus clock reference is selected as input to the FLLs using the FLLn_REFCLK_SRC registers. See “Clocking and Sample Rates” for details of system clocking and the FLLs.

Table 52 SLIMbus Clock Reference Control

OUTPUT SIGNAL PATH

The WM5102 provides four stereo and one mono analogue output signal paths. These outputs comprise ground-referenced headphone drivers, a differential earpiece driver, differential speaker drivers and a digital output interface suitable for external speaker drivers. The output signal paths are summarised in Table 53.

SIGNAL PATH	DESCRIPTIONS	OUTPUT PINS
OUT1L, OUT1R	Ground-referenced headphone output	HPOUT1L, HPOUT1R
OUT2L, OUT2R	Ground-referenced headphone output	HPOUT2L, HPOUT2R
OUT3	Differential (BTL) earpiece output	EPOUTP, EPOUTN
OUT4L, OUT4R	Differential speaker output	SPKOUTLN, SPKOUTLP, SPKOUTRP, SPKOUTRN
OUT5L, OUT5R	Digital speaker (PDM) output	SPKDAT1, SPKCLK1

Table 53 Output Signal Path Summary

The analogue output paths incorporate high performance 24-bit sigma-delta DACs.

Under default conditions, the headphone drivers provide a stereo, single-ended output. A mono mode is also available on each headphone output pair, providing a differential (BTL) configuration. The ground-referenced headphone output paths incorporate a common mode feedback path for rejection of system-related noise. These outputs support direct connection to headphone loads, with no requirement for AC coupling capacitors.

The earpiece path provides a differential (BTL) output, suitable for a typical earpiece load. The differential configuration offers built-in common mode noise rejection.

The speaker output paths are configured to drive a stereo pair of differential (BTL) outputs. The Class D design offers high efficiency at large signal levels. With a suitable choice of external speaker, the Class D output can drive loudspeakers directly, without any additional filter components.

The digital output path provides a stereo Pulse Density Modulation (PDM) output interface, for connection to external audio devices.

Digital volume control is available on all outputs (analogue and digital), with programmable ramp control for smooth, glitch-free operation. Any of the output signal paths may be selected as input to the Acoustic Echo Cancellation (AEC) loopback path.

The WM5102 output signal paths are illustrated in Figure 52.

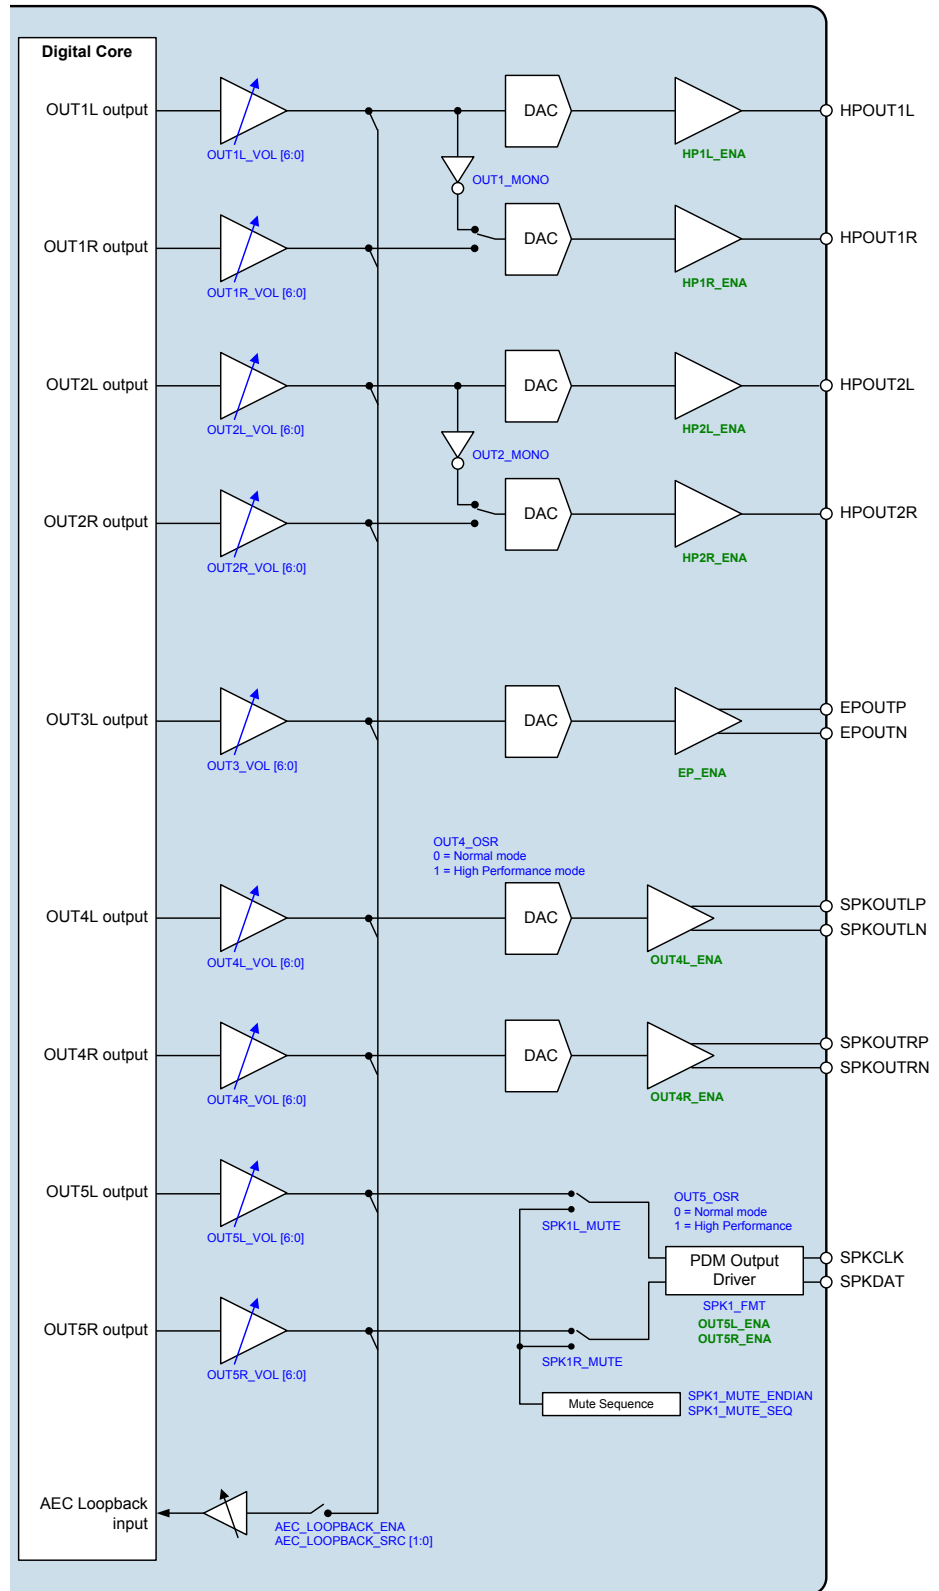

Figure 52 Output Signal Paths

OUTPUT SIGNAL PATH ENABLE

The output signal paths are enabled using the register bits described in Table 54. The respective bit(s) must be enabled for analogue or digital output on the respective output path(s).

The supply rails for outputs (OUT1, OUT2 and OUT3) are generated using an integrated dual-mode Charge Pump, CP1. The Charge Pump is enabled automatically by the WM5102 when required by the output drivers. See the “Charge Pumps, Regulators and Voltage Reference” section for further details.

The WM5102 schedules a pop-suppressed control sequence to enable or disable the OUT1, OUT2 and OUT3 signal paths. This is automatically managed in response to setting the respective HPnx_ENA or EP_ENA register bits. See “Control Write Sequencer” for further details.

The system clock, SYSCLK, must be configured and enabled before any audio path is enabled. The ASYNCLK may also be required, depending on the path configuration. See “Clocking and Sample Rates” for details of the system clocks.

The WM5102 performs automatic checks to confirm that the SYSCLK frequency is high enough to support the output signal paths and associated DACs. If an attempt is made to enable an output signal path, and there are insufficient SYSCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error condition can be monitored using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

The status bits in Register R1025 and R1030 indicate the status of each of the output signal paths. If an Underclocked Error condition occurs, then these bits provide readback of which signal path(s) have been successfully enabled.

Table 54 Output Signal Path Enable

OUTPUT SIGNAL PATH SAMPLE RATE CONTROL

The output signal paths are derived from the respective output mixers within the WM5102 digital core. The sample rate for the output signal paths is configured using the OUT_RATE register - see Table 20 within the "Digital Core" section.

Note that sample rate conversion is required when routing the output signal paths to any signal chain that is asynchronous and/or configured for a different sample rate.

OUTPUT SIGNAL PATH CONTROL

A high performance mode can be selected on the speaker output signal paths (OUT4 and OUT5) by setting the _OSR bits for the respective paths. When the _OSR bit is set, the audio performance is improved, but power consumption is also increased.

The SPKCLK frequency of the PDM output path (OUT5) is controlled by the OUT5_OSR register, as described in Table 55. When the OUT5_OSR bit is set, the audio performance is improved, but power consumption is also increased.

Note that the SPKCLK frequencies noted in Table 55 assume that the SYSCLK frequency is a multiple of 6.144MHz (SYSCLK_FRAC=0). If the SYSCLK frequency is a multiple of 5.6448MHz (SYSCLK_FRAC=1), then the SPKCLK frequencies will be scaled accordingly.

CONDITION	SPKCLK FREQUENCY
OUT5_OSR = 0	3.072MHz
OUT5_OSR = 1	6.144MHz

Table 56 Output Signal Path Control

OUTPUT SIGNAL PATH DIGITAL VOLUME CONTROL

A digital volume control is provided on each of the output signal paths, providing -64dB to +31.5dB gain control in 0.5dB steps. An independent mute control is also provided for each output signal path.

Whenever the gain or mute setting is changed, the signal path gain is ramped up or down to the new settings at a programmable rate. For increasing gain (or un-mute), the rate is controlled by the OUT_VI_RAMP register. For decreasing gain (or mute), the rate is controlled by the OUT_VD_RAMP register. Note that the OUT_VI_RAMP and OUT_VD_RAMP registers should not be changed while a volume ramp is in progress.

The OUT_VU bits control the loading of the output signal path digital volume and mute controls. When OUT_VU is set to 0, the digital volume and mute settings will be loaded into the respective control register, but will not actually change the signal path gain. The digital volume and mute settings on all of the output signal paths are updated when a 1 is written to OUT_VU. This makes it possible to update the gain of multiple signal paths simultaneously.

For correct gain ramp behaviour, the OUT_VU bits should not be written during the 0.28ms after any of the output path enable bits (see Table 54) have been asserted. It is recommended that the output path mute bit be set when the respective output driver is enabled; the signal path can then be un-muted after the 0.28ms has elapsed.

Note that, although the digital volume control registers provide 0.5dB steps, the internal circuits provide signal gain adjustment in 0.125dB steps. This allows a very high degree of gain control, and smooth volume ramping under all operating conditions.

The digital volume control register fields are described in Table 57 and Table 58.

Table 58 Output Signal Path Digital Volume Range

OUTPUT SIGNAL PATH DIGITAL VOLUME LIMIT

A digital limit control is provided on each of the output signal paths. Any signal which exceeds the applicable limit will be clipped at that level. The limit control is implemented in the digital domain, before the output path DACs.

For typical applications, a limit of 0dBFS is recommended for the analogue output paths (OUT1, OUT2, OUT3 and OUT4).

The digital speaker output (OUT5) can handle signal levels up to +3dBFS; a maximum setting of +3dBFS is recommended for this output path.

Caution is advised when selecting other limits, as the output signal may clip in the digital and/or analogue stages of the respective signal path(s).

The digital limit register fields are described in Table 59 and Table 60.

OUTPUT SIGNAL PATH NOISE GATE CONTROL

The WM5102 provides a digital noise gate function for each of the output signal paths. The noise gate ensures best noise performance when the signal path is idle. When the noise gate is enabled, and the applicable signal level is below the noise gate threshold, then the noise gate is activated, causing the signal path to be muted.

The noise gate function is enabled using the NGATE_ENA register, as described in Table 61.

For each output path, the noise gate may be associated with one or more of the signal path threshold detection functions using the _NGATE_SRC register fields. When more than one signal threshold is selected, then the output path noise gate is only activated (ie. muted) when all of the respective signal thresholds are satisfied.

For example, if the OUT1L noise gate is associated with the OUT1L and OUT1R signal paths, then the OUT1L signal path will only be muted if both the OUT1L and OUT1R signal levels are below the respective thresholds.

The noise gate threshold (the signal level below which the noise gate is activated) is set using NGATE_THR. Note that, for each output path, the noise gate threshold represents the signal level at the respective output pin(s) - the threshold is therefore independent of the digital volume and PGA gain settings.

Note that, although there is only one noise gate threshold level (NGATE_THR), each of the output path noise gates may be activated independently, according to the respective signal content and the associated threshold configuration(s).

To prevent erroneous triggering, a time delay is applied before the gate is activated; the noise gate is only activated (ie. muted) when the output levels are below the applicable signal level threshold(s) for longer than the noise gate 'hold time'. The 'hold time' is set using the NGATE_HOLD register.

When the noise gate is activated, the WM5102 gradually attenuates the respective signal path at the rate set by the OUT_VD_RAMP register (see Table 57). When the noise gate is de-activated, the output volume increases at the rate set by the OUT_VI_RAMP register.

OUTPUT SIGNAL PATH AEC LOOPBACK

The WM5102 incorporates loopback signal path, which is ideally suited as a reference for Acoustic Echo Cancellation (AEC) processing. Any of the output signal paths may be selected as the AEC loopback source.

When configured with suitable DSP firmware, the WM5102 can provide an integrated AEC capability. The AEC loopback feature also enables convenient hook-up to an external device for implementing the required signal processing algorithms.

The AEC Loopback source is connected after the respective digital volume controls, as illustrated in Figure 52. A digital gain control is incorporated in the AEC Loopback path, which is automatically set according to the PGA gain of the selected output path, where applicable. When OUT1n, OUT2n or OUT3 is selected as the AEC Loopback source, the loopback gain matches the corresponding PGA gain, ensuring that the loopback signal level will exactly match the selected output, regardless of the digital or analogue gain settings.

The AEC Loopback signal can be selected as input to any of the digital mixers within the WM5102 digital core. The sample rate for the AEC Loopback path is configured using the OUT_RATE register - see Table 20 within the "Digital Core" section.

The AEC loopback function is enabled using the AEC_LOOPBACK_ENA register. The source signal for the Transmit Path AEC function is selected using the AEC_LOOPBACK_SRC register.

The WM5102 performs automatic checks to confirm that the SYSCLK frequency is high enough to support the AEC Loopback function. If an attempt is made to enable this function, and there are insufficient SYSCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

The Underclocked Error condition can be monitored using the GPIO and/or Interrupt functions. See "General Purpose Input / Output" and "Interrupts" for further details.

The AEC_ENA_STS register indicates the status of the AEC Loopback function. If an Underclocked Error condition occurs, then this bit can provide indication of whether the AEC Loopback function has been successfully enabled.

Table 62 Output Signal Path AEC Loopback Control

HEADPHONE/EARPIECE OUTPUTS AND MONO MODE

The headphone drivers can provide a mono differential (BTL) output; this is ideal for driving an earpiece or hearing aid coil. The mono differential (BTL) configuration is selected using the OUTn_MONO register bits. When the OUTn_MONO bit is set, then the respective Right channel output is an inverted copy of the Left channel output signal; this creates a differential output between the respective OUTnL and OUTnR pins.

In mono configuration, the effective gain of the signal path is increased by 6dB.

The mono (BTL) signal paths are illustrated in Figure 52.

The OUT1L and OUT1R output signal paths are associated with the analogue outputs HPOUT1L and HPOUT1R respectively.

The OUT2L and OUT2R output signal paths are associated with the analogue outputs HPOUT2L and HPOUT2R respectively.

The OUT3 output signal path is associated with the analogue outputs EPOUTP and EPOUTN.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION

Table 63 Headphone Driver Mono Mode Control

The headphone driver outputs HPOUT1L, HPOUT1R, HPOUT2L and HPOUT2R are suitable for direct connection to external headphones and earpieces. The outputs are ground-referenced, eliminating any requirement for AC coupling capacitors.

The headphone outputs incorporate a common mode, or ground loop, feedback path which provides rejection of system-related ground noise. The feedback pins must be connected to ground for normal operation of the headphone outputs.

Note that the feedback pins should be connected to GND close to the respective headphone jack, as illustrated in Figure 53. In mono (differential) mode, the feedback pin(s) should be connected to the ground plane that is physically closest to the earpiece output PCB tracks.

The ground feedback path for HPOUT1L and HPOUT1R is provided via the HPOUT1FB1 or HPOUT1FB2 pins; the applicable connection must be selected using the ACCDET_SRC register, as described in Table 64.

The ground feedback path for HPOUT2L and HPOUT2R is provided via the HPOUT2FB pin. No register configuration is required for the HPOUT2FB connection.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R659 (0293h) Accessory Detect Mode 1	13	ACCDET_SRC	0	Accessory Detect / Headphone Feedback pin select 0 = Accessory detect on MICDET1, Headphone ground feedback on HPOUT1FB1 1 = Accessory detect on MICDET2, Headphone ground feedback on HPOUT1FB2

Table 64 Headphone Output (HPOUT1) Ground Feedback Control

The earpiece driver outputs EPOUTP and EPOUTN are suitable for direct connection to an earpiece. The output configuration is differential (BTL), driving both ends of the external load directly - note that there is no associated ground connection.

The headphone and earpiece connections are illustrated in Figure 53.

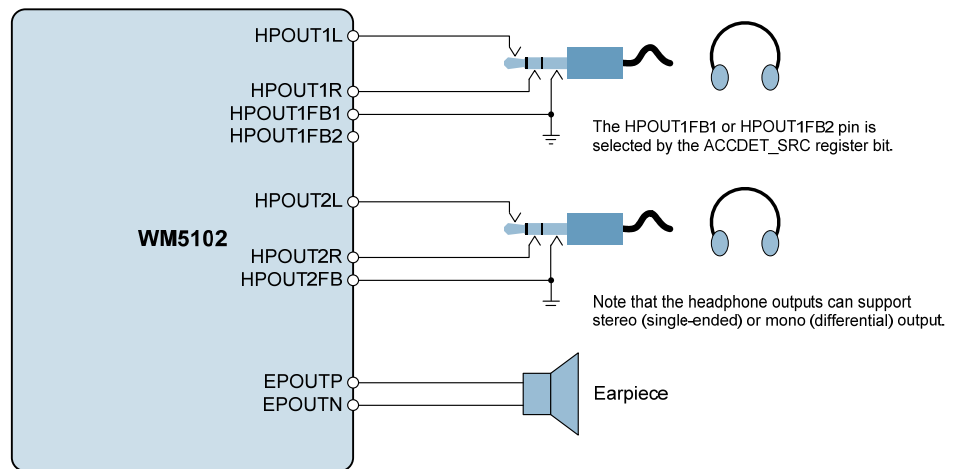

Figure 53 Headphone and Earpiece Connection

SPEAKER OUTPUTS (ANALOGUE)

The speaker driver outputs SPKOUTLP, SPKOUTLN, SPKOUTRP and SPKOUTRN provide two differential (BTL) outputs suitable for direct connection to external loudspeakers. The integrated Class D speaker driver provides high efficiency at large signal levels.

The speaker driver signal paths incorporate a boost function which shifts the signal levels between the AVDD and SPKVDD voltage domains. The boost is pre-configured (+12dB) for the recommended AVDD and SPKVDD operating voltages (see “Recommended Operating Conditions”).

Ultra-low leakage and high PSRR allow the speaker supply SPKVDD to be connected directly to a lithium battery. Note that SPKVDDL powers the Left Speaker driver, and SPKVDDR powers the Right Speaker driver; it is assumed that SPKVDDL = SPKVDDR = SPKVDD.

Note that SYSCLK must be present and enabled when using the Class D speaker output; see “Clocking and Sample Rates” for details of SYSCLK and the associated register control fields.

The OUT4L and OUT4R output signal paths are associated with the analogue outputs SPKOUTLP, SPKOUTLN, SPKOUTRP and SPKOUTRN.

The Class D speaker output is a pulse width modulated signal, and requires external filtering in order to recreate the audio signal. With a suitable choice of external speakers, the speakers themselves can provide the necessary filtering. See “Applications Information” for further information on Class D speaker connections.

The external speaker connection is illustrated in Figure 54, assuming suitable speakers are chosen to provide the PWM filtering.

Figure 54 Speaker Connection

SPEAKER OUTPUTS (DIGITAL PDM)

The WM5102 supports a two-channel Pulse Density Modulation (PDM) digital speaker interface; the PDM outputs are associated with the OUT5L and OUT5R output signal paths.

The PDM digital speaker interface is illustrated in Figure 55.

The OUT5L and OUT5R output signal paths are interleaved on the SPKDAT output pin, and clocked using SPKCLK.

Note that the PDM interface supports two different operating modes; these are selected using the SPK1_FMT register bit. See “Signal Timing Requirements” for detailed timing information in both modes.

When SPK1_FMT = 0 (Mode B), then the Left PDM channel is valid during the low phase of SPKCLK; the Right PDM channel is valid during the high phase of SPKCLK.

When SPK1_FMT = 1 (Mode A), then the Left PDM channel is valid at the rising edge of SPKCLK; the Right PDM channel is valid at the falling edge of SPKCLK.

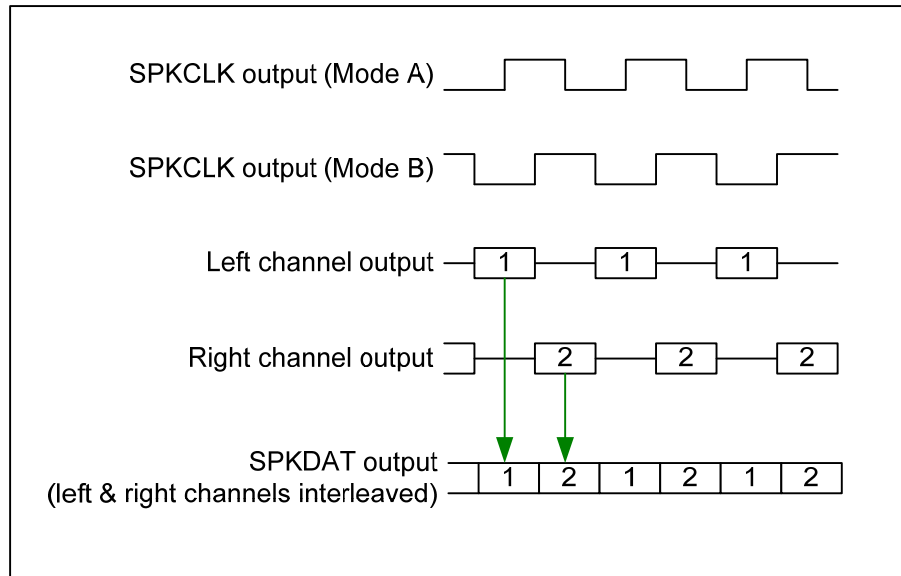

Figure 55 Digital Speaker (PDM) Interface Timing

Clocking for the PDM interface is derived from SYSCLK. Note that the SYSCLK_ENA register must also be set. See “Clocking and Sample Rates” for further details of the system clocks and control registers.

When the OUT5L or OUT5R output signal path is enabled, the PDM interface clock signal is output on the SPKCLK1 pin.

The output signal paths support normal and high performance operating modes, as described in the “Output Signal Path” section. The SPKCLK n frequency is set according to the operating mode of the relevant output path, as described in Table 65.

OUT5_OSR	DESCRIPTION	SPKCLK1 FREQUENCY
0	Normal mode	3.072MHz
1	High Performance mode	6.144MHz

Table 65 SPKCLK1 Frequency

The PDM output channels can be independently muted. When muted, the default output on each channel is a DSD-compliant silent stream (0110_1001b). The mute output code can be programmed to other values if required, using the SPK1_MUTE_SEQ register field. The mute output code can be transmitted MSB-first or LSB-first; this is selectable using the SPK1_MUTE_ENDIAN register.

Note that the PDM Mute function is not a soft-mute; the audio output is interrupted immediately when the PDM mute is asserted. It is recommended to use the Output Signal Path mute function before applying the PDM mute. See Table 57 for details of the OUT5L_MUTE and OUT5R_MUTE registers.

The PDM output interface registers are described in Table 66.

Table 66 Digital Speaker (PDM) Output Control

The digital speaker (PDM) outputs SPKDAT and SPKCLK are intended for direct connection to a compatible external speaker driver. A typical configuration is illustrated in Figure 56.

Figure 56 Digital Speaker (PDM) Connection

EXTERNAL ACCESSORY DETECTION

The WM5102 provides external accessory detection functions which can sense the presence and impedance of external components. This can be used to detect the insertion or removal of an external headphone or headset, and to provide an indication of key/button push events.

Jack insertion is detected using the JACKDET pin, which must be connected to a switch contact within the jack socket. An Interrupt event is generated whenever a jack insertion or jack removal event is detected. The jack detect function can also be used to trigger a Wake-Up transition (ie. exit from Sleep mode) or to trigger the Control Write Sequencer.

Suppression of pops and clicks caused by jack insertion or removal is provided using the MICDET clamp function. This function can also be used to trigger interrupt events, a Wake-Up transition (ie. exit from Sleep mode) or to trigger the Control Write Sequencer.

Microphones, push-buttons and other accessories can be detected via the MICDET1 or MICDET2 pins. The presence of a microphone, and the status of a hookswitch can be detected. This feature can also be used to detect push-button operation.

Headphone impedance can be detected via the HPDETL and HPDETR pins; this can be used to set different gain levels or other configuration settings according to the type of load connected. For example, different settings may be applicable to Headphone or Line output loads.

The MICVDD power domain must be enabled when using the accessory detection functions. This power domain is provided using an internal Charge Pump (CP2) and LDO Regulator (LDO2). See "Charge Pumps, Regulators and Voltage Reference" for details of these circuits.

The internal 32kHz clock must be present and enabled when using the jack insertion or accessory detection functions; see "Clocking and Sample Rates" for details of the internal 32kHz clock and associated register control fields.

JACK DETECT

The WM5102 provides support for jack insertion switch detection. The jack insertion status can be read using the relevant register status bit. A jack insertion or removal can also be used to trigger an interrupt (IRQ) event or to trigger the Control Write Sequencer.

When the WM5102 is in the low-power Sleep mode (see "Low Power Sleep Configuration"), the jack detect function can be used as a 'wake-up' input; a typical use case is where an application is idle in standby mode until a headphone or headset jack is inserted.

Jack insertion and removal is detected using the JACKDET pin. The recommended external connection circuit is illustrated in Figure 57.

The jack detect feature is enabled using JD1_ENA; the jack insertion status can be read using the JD1_STS register.

The JACKDET input de-bounce is selected using the JD1_DB register, as described in Table 67. Note that the de-bounce circuit uses the 32kHz clock, which must be enabled whenever input de-bounce functions are required.

Note that the Jack Detect signal, JD1, can be used as an input to the MICDET Clamp function. This provides additional functionality relating to jack insertion or jack removal events.

An Interrupt Request (IRQ) event is generated whenever a jack insertion or jack removal is detected (see "Interrupts"). Separate 'mask' bits are provided to enable IRQ events on the rising and/or falling edge of the JD1 status.

The Control Write Sequencer can be triggered by a jack insertion or jack removal detection. This is enabled using register bits described in the "Low Power Sleep Configuration" section.

The control registers associated with the Jack Detect function are described in Table 67.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION

R3414 (0D56h) Jack detect debounce	0	JD1_DB	0	JACKDET input de-bounce 0 = Disabled 1 = Enabled

Table 67 Jack Detect Control

A recommended connection circuit, including headphone output on HPOUT1 and microphone connections, is shown in Figure 57. See “Applications Information” for details of recommended external components.

Figure 57 Jack Detect and External Accessory Connections

The internal comparator circuit used to detect the JACKDET status is illustrated in Figure 58.

The threshold voltages for the jack detect circuit are noted in the “Electrical Characteristics”. Note that separate thresholds are defined for jack insertion and jack removal.

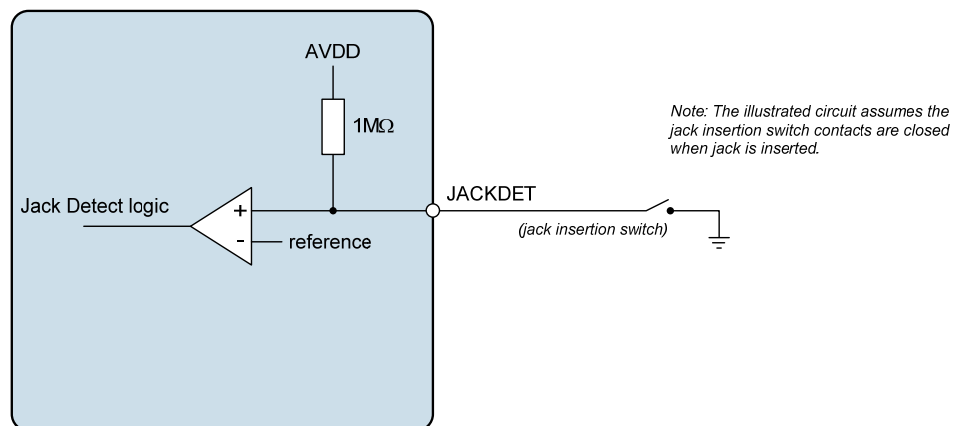

Figure 58 Jack Detect Comparator

JACK POP SUPPRESSION (MICDET CLAMP)

Under typical configuration of a 3.5mm headphone/accessory jack connection, there is a risk of pops and clicks arising from jack insertion or removal. This can occur when the headphone load makes momentary contact with the MICBIAS output when the jack is not fully inserted, as illustrated in Figure 59.

The WM5102 provides a MICDET Clamp function to suppress pops and clicks caused by jack insertion or removal. The clamp is activated by a configurable logic function derived from external logic inputs. The clamp status can be read using the relevant register status bit. The clamp status can also be used to trigger an interrupt (IRQ) event or to trigger the Control Write Sequencer.

When the WM5102 is in the low-power Sleep mode (see “Low Power Sleep Configuration”), the MICDET Clamp function can be used as a ‘wake-up’ input; a typical use case is where an application is idle in standby mode until a headphone or headset jack is inserted.

The MICDET Clamp function is controlled by a selectable logic condition, derived from the JD1 and/or GP5 signals. The function is enabled and configured using the MICD_CLAMP_MODE register.

The JD1 signal is derived from the Jack Detect function (see Table 67). The GP5 signal is derived from the GPIO5 input pin (see “General Purpose Input / Output”).

When the MICDET Clamp is active, the MICDET1/HPOUT1FB2 and HPOUT1FB1/MICDET2 pins are short-circuited to GND. Note that both pins are shorted, regardless of the ACCDET_SRC register.

The configurable logic provides flexibility in selecting the appropriate conditions for activating the MICDET Clamp. The clamp status can be read using the MICD_CLAMP_STS register.

The MICDET Clamp de-bounce is selected using the MICD_CLAMP_DB register, as described in Table 68. Note that the de-bounce circuit uses the 32kHz clock, which must be enabled whenever input de-bounce functions are required.

An Interrupt Request (IRQ) event is generated whenever the MICDET Clamp is asserted or de-asserted (see “Interrupts”). Separate ‘mask’ bits are provided to enable IRQ events on the rising and/or falling edge of the MICDET Clamp status.

The Control Write Sequencer can be triggered by the MICDET Clamp status. This is enabled using register bits described in the “Low Power Sleep Configuration” section.

The MICDET Clamp function is illustrated in Figure 59. Note that the jack plug is shown partially removed, with the MICDET1 pin in contact with the headphone load.

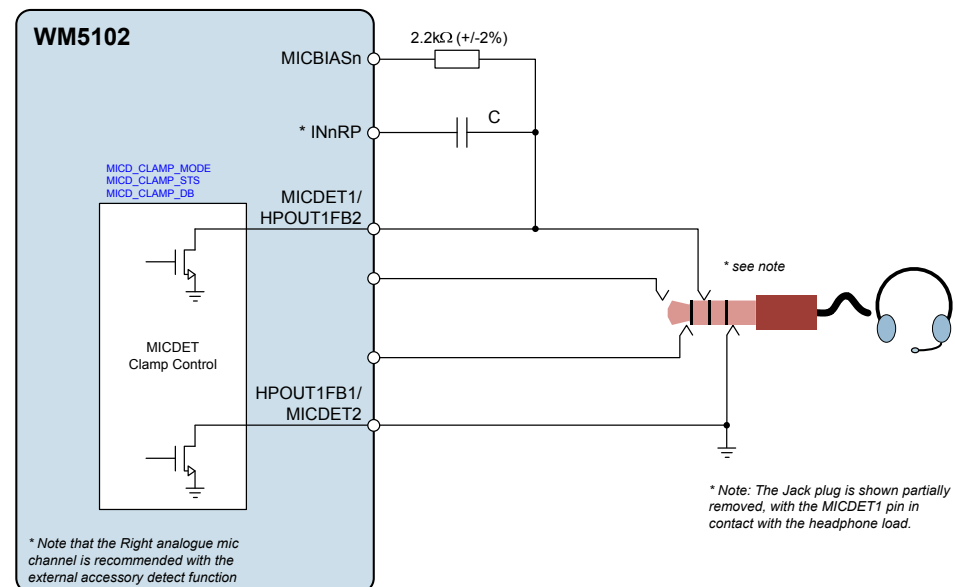

Figure 59 MICDET Clamp circuit

The control registers associated with the MICDET Clamp function are described in Table 68.

Table 68 MICDET Clamp Control

MICROPHONE DETECT

The WM5102 microphone detection circuit measures the impedance of an external load connected to one of the MICDET pins. This feature can be used to detect the presence of a microphone, and the status of the associated hookswitch. It can also be used to detect push-button status or the connection of other external accessories.

The microphone detection circuit measures the impedance connected to MICDET1 or MICDET2, and reports whether the measured impedance lies within one of 8 pre-defined levels (including the 'no accessory detected' level). This means it can detect the presence of a typical microphone and up to 6 push-buttons. One of the impedance levels is specifically designed to detect a video accessory (typical 75Ω) load if required.

The microphone detection circuit typically uses one of the MICBIAS outputs as a reference. The WM5102 will automatically enable the appropriate MICBIAS when required in order to perform the detection function; this allows the detection function to be supported in low-power standby operating conditions.

Note that the MICVDD power domain must be enabled when using the microphone detection function. This power domain is provided using an internal Charge Pump (CP2) and LDO Regulator (LDO2). See "Charge Pumps, Regulators and Voltage Reference" for details of these circuits.

To select microphone detection on one of the MICDET pins, the ACCDET_MODE register must be set to 00. The ACCDET_MODE register is defined in Table 69.

The WM5102 can only support one headphone or microphone detection function at any time. When the detection function is not in use, it is recommended to set ACCDET_MODE=00.

The microphone detection circuit can be enabled on the MICDET1 pin or the MICDET2 pin, selected by the ACCDET_SRC register. An internal pull-down resistor can be enabled on the selected MICDEtn pin; this is configured using the MICD_PD register bit. Note that the pull-down is only effective on one of the MICDEtn pins, as selected by ACCDET_SRC.

The microphone detection circuit uses MICVDD, MICBIAS1, MICBIAS2 or MICBIAS3 as a reference. The applicable source is configured using the MICD_BIAS_SRC register.

When ACCDET_MODE is set to 00, then Microphone detection is enabled by setting MICD_ENA.

When microphone detection is enabled, the WM5102 performs a number of measurements in order to determine the MICDET impedance. The measurement process is repeated at a cyclic rate controlled by MICD_RATE. (The MICD_RATE register selects the delay between completion of one measurement and the start of the next.)

For best accuracy, the measured impedance is only deemed valid after more than one successive measurement has produced the same result. The MICD_DBTIME register provides control of the de-bounce period; this can be either 2 measurements or 4 measurements.

When the microphone detection result has settled (ie. after the applicable de-bounce period), the WM5102 indicates valid data by setting the MICD_VALID bit. The measured impedance is indicated using the MICD_LVL and MICD_STS register bits, as described in Table 69.

The MICD_VALID bit, when set, remains asserted for as long as the microphone detection function is enabled (ie. while MICD_ENA = 1). If the detected impedance changes, then the MICD_LVL and MICD_STS fields will change, but the MICD_VALID bit will remain set, indicating valid data at all times.

The microphone detection reports a measurement result in one of the pre-defined impedance levels. Each measurement level can be enabled or disabled independently; this provides flexibility according to the required thresholds, and offers a faster measurement time in some applications. The MICD_LVL_SEL register is described in detail later in this section.

Note that the impedance levels quoted in the MICD_LVL description assume that a microphone (475Ω to 30kΩ impedance) is also present on the MICDET pin. The limits quoted in the “Electrical Characteristics” refer to the combined effective impedance on the MICDET pin. Typical external components are described in the “Applications Information” section.

The microphone detection function is an input to the Interrupt control circuit and can be used to trigger an Interrupt event every time an accessory insertion, removal or impedance change is detected. See “Interrupts” for further details.

The microphone detection function can also generate a GPIO output, providing an external indication of the microphone detection. This GPIO output is pulsed every time an accessory insertion, removal or impedance change is detected. See “General Purpose Input / Output” to configure a GPIO pin for this function.

The register fields associated with Microphone Detection (or other accessories) are described in Table 69. The external circuit configuration is illustrated in Figure 60.

Table 69 Microphone Detect Control

The external connections for the Microphone Detect circuit are illustrated in Figure 60. In typical applications, it can be used to detect a microphone or button press.

Note that, when using the Microphone Detect circuit, it is recommended to use one of the Right channel analogue microphone input paths, to ensure best immunity to electrical transients arising from the external accessory.

The voltage reference for the microphone detection is configured using the MICD_BIAS_SRC register, as described in Table 69. The microphone detection function will automatically enable the applicable reference when required for MICDET impedance measurement.

If the selected reference (MICBIAS1, MICBIAS2 or MICBIAS3) is not already enabled (ie. if $MICBn_ENA = 0$, where n is 1, 2 or 3 as appropriate), then the applicable MICBIAS source will be enabled for short periods of time only, every time the impedance measurement is scheduled. To allow time for the MICBIAS source to start-up, a time delay is applied before the measurement is performed; this is configured using the MICD_BIAS_STARTTIME register, as described in Table 69.

The MICD_BIAS_STARTTIME register should be set to 16ms or more if $MICBn_RATE = 1$ (pop-free start-up / shut-down). The MICD_BIAS_STARTTIME register should be set to 0.25ms or more if $MICBn_RATE = 0$ (fast start-up / shut-down).

If the selected reference is not enabled continuously (ie. if $MICBn_ENA = 0$), then the applicable MICBIAS discharge bit ($MICBn_DISCH$) should be set to 0.

The MICBIAS sources are configured using the registers described in the “Charge Pumps, Regulators and Voltage Reference” section.

Figure 60 Microphone and Accessory Detect Interface

The MICD_LVL_SEL [7:0] register bits allow each of the impedance measurement levels to be enabled or disabled independently. This allows the function to be tailored to the particular application requirements.

If one or more bits within the MICD_LVL_SEL register is set to 0, then the corresponding impedance level will be disabled. Any measured impedance which lies in a disabled level will be reported as the next lowest, enabled level.

For example, the MICD_LVL_SEL [2] bit enables the detection of impedances around 73Ω. If $MICD_LVL_SEL [2] = 0$, then an external impedance of 73Ω will not be indicated as 73Ω but will be indicated as 40Ω; this would be reported in the MICD_LVL register as $MICD_LVL [2] = 1$.

With all measurement levels enabled, the WM5102 can detect the presence of a typical microphone and up to 6 push-buttons. The microphone detect function is specifically designed to detect a video accessory (typical 75Ω) load if required.

See “Applications Information” for typical recommended external components for microphone, video or push-button accessory detection.

The microphone detection circuit assumes that a 2.2kΩ (2%) resistor is connected to the selected MICBIAS reference, as illustrated. Different resistor values will lead to inaccuracy in the impedance measurement.

The measurement accuracy of the microphone detect function is assured whenever the connected load is within the applicable limits specified in the “Electrical Characteristics”. Note that a 2.2kΩ (2%)

resistor must also be connected between MICDET and the selected MICBIAS reference.

Note that the connection of a microphone will change the measured impedance on the MICDET pin; see “Applications Information” for recommended components for typical applications.

The measurement time varies between 100 μ s and 500 μ s according to the impedance of the external load. A high impedance will be measured faster than a low impedance.

The timing of the microphone detect function is illustrated in Figure 61. Two different cases are shown, according to whether MICBIAS $_n$ is enabled periodically by the impedance measurement function (MICB $_n$ _ENA=0), or is enabled at all times (MICB $_n$ _ENA=1).

Figure 61 Microphone and Accessory Detect Timing

HEADPHONE DETECT

The WM5102 headphone detection circuit measures the impedance of an external headphone load. This feature can be used to set different gain levels or to apply other configuration settings according to the type of load connected. Separate monitor pins are provided for headphone detection on the left and right channels of HPOUT1.

Headphone detection may only be selected on one channel at a time. The available channels are the HPDETL pin or the HPDETR pin. The selected channel is determined by the ACCDET_MODE register as described in Table 70.

The WM5102 can only support one headphone or microphone detection function at any time. When the detection function is not in use, it is recommended to set ACCDET_MODE=00.

The impedance measurement range is configured using the HP_IMPEDANCE_RANGE register. This register should be set in accordance with the expected load impedance.

Headphone detection on the selected channel is commanded by writing a '1' to the HP_POLL register bit.

When headphone detection is commanded, the WM5102 uses an adjustable current source to determine the connected impedance. A sweep of measurement currents is applied. The rate of this sweep can be adjusted using the HP_RATE register. To avoid audible clicks, the default step size should always be used (HP_RATE = 0).

The timing of the current source ramp is also controlled by the HP_HOLDTIME register. It is recommended that the default setting (001b) be used for this parameter.

Completion of the headphone detection is indicated by the HP_DONE register bit. When this bit is set, the measured load impedance can be read from the HP_LVL register. Note that, after the HP_DONE bit has been asserted, it will remain asserted until a subsequent headphone detection measurement is commanded.

The headphone detection result (HP_LVL) is restricted to values that are close to the range defined by the HP_IMPEDANCE_RANGE register. If the HP_LVL register reports an impedance that is outside the selected range, then it is recommended to adjust the HP_IMPEDANCE_RANGE value and repeat the measurement. For minimum measurement time, the lowest impedance range (HP_IMPEDANCE_RANGE=00) should be selected in the first instance.

The headphone detection function is an input to the Interrupt control circuit and can be used to trigger an Interrupt event on completion of the headphone detection - see "Interrupts".

The headphone detection function can also generate a GPIO output, providing an external indication of the headphone detection. See "General Purpose Input / Output" to configure a GPIO pin for this function.

The register fields associated with Headphone Detection are described in Table 70. The external circuit configuration is illustrated in Figure 62.

If HP_LVL reports an impedance outside the selected range, then the range should be adjusted and the measurement repeated. A result of 0 ohms may be reported if the measurement is less than the minimum value for the selected range.

Table 70 Headphone Detect Control

Figure 62 Headphone Detect Interface

The external connections for the Headphone Detect circuit are illustrated in Figure 62. Note that only the HPOUT1L or HPOUT1R headphone outputs should be connected to HPDETL or HPDETR pins - impedance measurement is not supported on HPOUT2L, HPOUT2R, EPOUTP or EPOUTN.

Note that, where external resistors are connected in series with the headphone load, as illustrated, it is recommended that the HPDET n connection is to the headphone side of the resistors. If the HPDET n connection is made to the WM5102 'end' of these resistors, this will lead to a corresponding offset in the measured impedance.

Note that the measurement accuracy of the headphone detect function may be up to +/-30%.

Under default conditions, the measurement time varies between 17ms and 61ms according to the impedance of the external load. A high impedance will be measured faster than a low impedance.

LOW POWER SLEEP CONFIGURATION

The WM5102 supports a low-power 'Sleep' mode, where most functions are disabled, and power consumption is minimised. A selectable 'Wake-Up' event can be configured to return the device to full operation and/or execute a specific response to the particular Wake-Up condition.

A Wake-Up event is triggered via hardware input pin(s); in typical applications, these inputs are associated with jack insert (via the JACKDET digital input) or external push-button detection (via the GPIO5 digital input).

The WM5102 enters Sleep mode when LDO1 is disabled (by setting LDO1_ENA=0), causing the DCVDD supply to be removed. The AVDD, DBVDD1 and LDOVDD supplies must be present, and the LDOENA pin held low, allowing the WM5102 registers to control LDO1.

Note that it is assumed that DCVDD is supplied by LDO1; see "Charge Pumps, Regulators and Voltage Reference" for specific control requirements where DCVDD is not powered from LDO1.

SLEEP MODE

The WM5102 enters Sleep mode when LDO1 is disabled (by setting LDO1_ENA=0). In this case, the DCVDD supply is disabled, and most of the Digital Core (and control registers) are held in reset.

Selected functions and control registers are maintained via an 'Always-On' internal supply domain in Sleep mode. The 'Always-On' control registers are listed in Table 71. These registers are maintained (ie. not reset) in Sleep mode.

Note that the Control Interface is not supported in Sleep mode. Read/Write access to the 'Always-On' registers is not possible in Sleep mode.

Table 71 Sleep Mode 'Always-On' Control Registers

The 'Always-On' digital input / output pins are listed in Table 72. All other digital input pins will have no effect in Sleep mode. The $\overline{\text{IRQ}}$ output is normally de-asserted in Sleep mode.

Note that, in Sleep mode, the $\overline{\text{IRQ}}$ output can only be asserted in response to the JD1 or GP5 control signals (these described in the following section). If the $\overline{\text{IRQ}}$ output is asserted in Sleep mode, it can only be de-asserted after a Wake-Up transition.

PIN NAME	DESCRIPTION	REFERENCE
LDOENA	Enable pin for LDO1	See "Charge Pumps, Regulators and Voltage Reference"
RESET	Digital Reset input (active low)	See "Hardware Reset, Software Reset, Wake-Up, and Device ID"
MCLK2	Master clock 2	See "Clocking and Sample Rates"
GPIO5	General Purpose pin GPIO5	See "General Purpose Input / Output"
$\overline{\text{IRQ}}$	Interrupt Request (IRQ) output	See "Interrupts"

Table 72 Sleep Mode 'Always-On' Digital Input Pins

A Wake-Up transition is triggered using the JD1 or GP5 control signals (defined below).

It is assumed that DCVDD is supplied by LDO1. The AVDD, DBVDD1 and LDOVDD supplies must be present, and the LDOENA pin held low, allowing the WM5102 registers to control LDO1. See "Charge Pumps, Regulators and Voltage Reference" for specific control requirements where DCVDD is not powered from LDO1.

Note that a logic '1' applied to the LDOENA pin will also cause a Wake-Up transition. In this event, however, the configurable Wake-Up events (described below) are not applicable.

SLEEP CONTROL SIGNALS - JD1, GP5, MICDET CLAMP

The internal control signals JD1 and GP5 are provided to support the low-power Sleep mode. The MICDET Clamp status is controlled by a selectable logic function, derived from JD1 and/or GP5. A rising or falling edge of these signals can be used to trigger a Wake-Up transition (ie. exit from Sleep mode).

The JD1, GP5 and MICDET Clamp status signals can also be used to trigger the Control Write Sequencer and/or the Interrupt Controller.

Note that it is possible to enable more than one response from these control signals. For example, a particular edge transition could trigger a Wake-Up transition, and also a Control Write Sequence.

The JD1, GP5 and MICDET Clamp status signals are described in this section. The Wake-Up, Write Sequencer, and Interrupt actions are described in the sections that follow.

The JD1 signal is derived from the Jack Detect function (see "External Accessory Detection"). This input can be used to trigger Wake-Up or other actions in response to a jack insertion or jack removal detection.

When the JD1 signal is enabled, it indicates the status of the JACKDET input pin. See Table 67 for details of the associated control registers.

The GP5 signal is derived from the GPIO5 input pin (see “General Purpose Input / Output”). This input can be used to trigger Wake-Up or other actions in response to a logic level input detected on the GPIO5 pin.

When using the GP5 signal, the GPIO5 pin must be configured as a GPIO input (GP5_DIR=1, GP5_FN=01h). An internal pull-up or pull-down resistor may be enabled on the GPIO5 pin if required.

The GPIO pin control registers are defined in Table 76.

The MICDET Clamp status is controlled by the JD1 and/or GP5 signals (see “External Accessory Detection”). The configurable logic provides flexibility in selecting the appropriate conditions for activating the MICDET Clamp. The clamp status can be used to trigger Wake-Up or other actions in response to a jack insertion or jack removal detection.

The MICDET Clamp function is configured using the MICD_CLAMP_MODE register, as described in Table 68.

Whenever a rising or falling edge is detected on JD1, GP5 or MICDET Clamp status, the WM5102 will assert the respective trigger status (_TRIG_STS) bit. The trigger status bits are latching fields and, once they are set, they are not reset until a ‘1’ is written to the respective register bit(s).

The JD1, GP5 and MICDET Clamp trigger status bits are described in Table 73.

The trigger status bits can be used to control Wake-Up and Write Sequencer actions. The JD1, GP5 and MICDET Clamp signals are inputs to the Interrupt Controller. Each of these functions is described in the following sections.

	3	JD1_FALL_TRIG_STS	0	JD1 Trigger Status (Falling edge triggered) Note: Cleared when a ‘1’ is written
	2	JD1_RISE_TRIG_STS	0	JD1 Trigger Status (Rising edge triggered) Note: Cleared when a ‘1’ is written

Table 73 JD1, GP5 and MICDET Clamp Trigger Status Registers

Note that the de-bounce function on all inputs (including JD1, GP5 and MICDET Clamp status) use the 32kHz clock (see “Clocking and Sample Rates”). The 32kHz clock must be enabled whenever input de-bounce functions are required.

Note that the MCLK2 input pin is on the ‘Always-On’ domain, and is supported in Sleep mode. (MCLK1 input is not supported in Sleep mode.)

If input de-bounce is enabled in Sleep mode, the 32kHz clock must use MCLK2 (direct) input as its source (CLK_32K_SRC = 01).

WAKE-UP TRANSITION

A Wake-Up transition (exit from Sleep) can be associated with any of the JD1, GP5 or MICDET Clamp trigger status bits. This is selected using the register bits described in Table 74.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R64 (0040h) Wake Control	7	WKUP_MICD_CLAMP_FALL	0	MICDET Clamp (Falling) Wake-Up Select 0 = Disabled 1 = Enabled
	6	WKUP_MICD_CLAMP_RISE	0	MICDET Clamp (Rising) Wake-Up Select 0 = Disabled 1 = Enabled
	5	WKUP_GP5_FALL	0	GP5 (Falling) Wake-Up Select 0 = Disabled 1 = Enabled
	4	WKUP_GP5_RISE	0	GP5 (Rising) Wake-Up Select 0 = Disabled 1 = Enabled
	3	WKUP_JD1_FALL	0	JD1 (Falling) Wake-Up Select 0 = Disabled 1 = Enabled
	2	WKUP_JD1_RISE	0	JD1 (Rising) Wake-Up Select 0 = Disabled 1 = Enabled

Table 74 JD1, GP5 and MICDET Clamp Wake-Up Control Registers

When a valid 'Wake-Up' event is detected, the WM5102 will enable LDO1 (and DCVDD), and a user-configurable Boot Sequence is executed (see "Hardware Reset, Software Reset, Wake-Up, and Device ID").

Note that the trigger status (_TRIG_STS) bits are latching fields. Care is required when resetting these bits, to ensure the intended device behaviour - resetting the _TRIG_STS register(s) may cause LDO1 (and DCVDD) to be disabled.

For normal device operation following a 'Wake-Up' transition, the LDO1_ENA register must be set before the _TRIG_STS bit(s) are reset. (Note that further options are described in the next section.)

WRITE SEQUENCE CONTROL

A Control Write Sequence can be associated with any of the JD1, GP5 or MICDET Clamp trigger status bits. This is selected using the register bits described in Table 75.

Note that the JD1 and GP5 trigger status bits can be used to trigger the Control Write Sequencer at any time. This feature may be used during normal operation, or immediately following a Wake-Up transition.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R65 (0041h) Sequence Control	7	WSEQ_ENA_MICD_CLAMP_FALL	0	MICDET Clamp (Falling) Write Sequencer Select 0 = Disabled 1 = Enabled
	6	WSEQ_ENA_MICD_CLAMP_RISE	0	MICDET Clamp (Rising) Write Sequencer Select 0 = Disabled 1 = Enabled
	5	WSEQ_ENA_GP5_FALL	0	GP5 (Falling) Write Sequencer Select 0 = Disabled 1 = Enabled
	4	WSEQ_ENA_GP5_RISE	0	GP5 (Rising) Write Sequencer Select 0 = Disabled 1 = Enabled
	3	WSEQ_ENA_JD1_FALL	0	JD1 (Falling) Write Sequencer Select 0 = Disabled 1 = Enabled
	2	WSEQ_ENA_JD1_RISE	0	JD1 (Rising) Write Sequencer Select 0 = Disabled 1 = Enabled

Table 75 JD1, GP5 and MICDET Clamp Write Sequencer Control Registers

When a valid 'Write Sequencer' control event is detected, the respective control sequence will be scheduled. See "Control Write Sequencer" for further details.

Note that the trigger status (_TRIG_STS) bits are latching fields. Care is required when resetting these bits, to ensure the intended device behaviour - resetting the _TRIG_STS register(s) may cause LDO1 (and DCVDD) to be disabled.

A valid clock (SYSCLK) must be enabled whenever a Control Write Sequence is scheduled.

If the JD1, GP5 or MICDET Clamp trigger status bits are associated with the Control Write Sequencer (using the register bits in Table 75) and also configured as Wake-Up events (using the register bits in Table 74), then the Boot Sequence must be programmed to configure and enable SYSCLK. (Note that the default SYSCLK frequency must be used in this case.)

The Boot Sequence (see "Hardware Reset, Software Reset, Wake-Up, and Device ID") is scheduled as part of the Wake-Up transition, and provides the capability to configure SYSCLK (and other register settings) prior to the Control Write Sequencer being triggered.

Note that, if the Control Write Sequencer is triggered during normal operation, then SYSCLK will typically be already available, and no additional requirements will apply.

To return to Sleep mode following a Wake-Up / Write Sequence, the last step of the control sequence must be to write '1' to the applicable trigger status bit(s). The `_TRIG_STS` bit(s) will be reset, LDO1 will be disabled, and the WM5102 will be in Sleep mode. (The `LDO1_ENA` bit must be set to 0, and the LDOENA pin must not be asserted.)

To remain 'On' at the end of a Wake-up / Write Sequence, the control sequence must write '1' to the `LDO1_ENA` bit before resetting the trigger status bit(s).

When the Control Write Sequencer is triggered during normal operation, it can be programmed to select the Sleep mode by writing '0' to the `LDO1_ENA` bit. (The LDOENA pin must not be asserted.)

See "Charge Pumps, Regulators and Voltage Reference" for details of the `LDO1_ENA` control bit.

INTERRUPT CONTROL

An Interrupt Request (IRQ) event can be associated with the JD1, GP5 or MICDET Clamp signals. Separate 'mask' bits are provided to enable IRQ events on the rising and/or falling edges of each signal.

See "Interrupts" for further details.

GENERAL PURPOSE INPUT / OUTPUT

The WM5102 provides a number of GPIO functions to enable interfacing and detection of external hardware and to provide logic outputs to other devices. The GPIO input functions can be used to generate an Interrupt (IRQ) event. The GPIO and Interrupt circuits support the following functions:

- Digital audio interface function (AIFnTXLRCLK)
- Logic input / Button detect (GPIO input)
- Logic '1' and logic '0' output (GPIO output)
- Interrupt (IRQ) status output
- DSP Status Flag (DSP IRQn) and RAM status output
- Clock output
- Frequency Locked Loop (FLL) status output
- Frequency Locked Loop (FLL) Clock output
- Pulse Width Modulation (PWM) Signal output
- Headphone Detection status output
- Microphone / Accessory Detection status output
- Asynchronous Sample Rate Converter (ASRC) Lock status and Configuration Error output
- Control Write Sequencer status output
- Boot Sequence status output
- Over-Temperature status output
- Dynamic Range Control (DRC) status output
- Control Interface Error status output
- Clocking Error status output
- Digital audio interface Configuration Error status output

Note that the GPIO pins are referenced to different power domains (DBVDD1, DBVDD2 or DBVDD3), as noted in the "Pin Description" section.

In addition to the functions described in this section, the GPIO5 pin can be configured as an input to the Control Write Sequencer (see "Control Write Sequencer"). See also Table 75 for details of the associated register control fields.

The GPIO5 pin is one of the 'Always On' digital input / output pins and can be used as a 'Wake-Up' input in the low-power 'Sleep' mode. The GPIO5 pin can also be used as an input to the MICDET Clamp function, supporting additional functionality relating to jack insertion or jack removal events. See "Low Power Sleep Configuration" for further details.

GPIO CONTROL

For each GPIO, the selected function is determined by the GPn_FN field, where n identifies the GPIO pin (1, 2, 3, 4 or 5). The pin direction, set by GPn_DIR , must be set according to function selected by GPn_FN .

When a pin is configured as a GPIO input ($GPn_DIR = 1$, $GPn_FN = 01h$), the logic level at the pin can be read from the respective GPn_LVL bit. Note that GPn_LVL is not affected by the GPn_POL bit.

A de-bounce circuit can be enabled on any GPIO input, to avoid false event triggers. This is enabled on each pin by setting the respective GPn_DB bit. The de-bounce circuit uses the 32kHz clock, which must be enabled whenever input de-bounce functions are required. The de-bounce time is configurable using the GP_DBTIME register. See "Clocking and Sample Rates" for further details of the WM5102 clocking configuration.

Each of the GPIO pins is an input to the Interrupt control circuit and can be used to trigger an Interrupt event. An interrupt event is triggered on the rising and falling edges of the GPIO input. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

When a pin is configured as a GPIO input, internal pull-up and pull-down resistors may be enabled using the GPn_PU and GPn_PD fields; this allows greater flexibility to interface with different signals from other devices. (Note that, if the pin is configured as an output, or if GPn_PU and GPn_PD are both set for any GPIO pin, then the pull-up and pull-down will be disabled.)

When a pin is configured as a GPIO output ($GPn_DIR = 0$, $GPn_FN = 01h$), its level can be set to logic 0 or logic 1 using the GPn_LVL field. Note that the GPn_LVL registers are 'write only' when the respective GPIO pin is configured as an output.

When a pin is configured as an output ($GPn_DIR = 0$), the polarity can be inverted using the GPn_POL bit. When $GPn_POL = 1$, then the selected output function is inverted. In the case of Logic Level output ($GPn_FN = 01h$), the external output will be the opposite logic level to GPn_LVL when $GPn_POL = 1$.

A GPIO output can be either CMOS driven or Open Drain. This is selected on each pin using the respective GPn_OP_CFG bit.

The register fields that control the GPIO pins are described in Table 76.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R3072 (0C00h) GPIO1 CTRL to R3076 (0C04h) GPIO5 CTRL	15	GPn_DIR	1	GPIO Pin Direction 0 = Output 1 = Input

Note: <i>n</i> is a number (1, 2, 3, 4 or 5) that identifies the individual GPIO.				

Table 76 GPIO Control

GPIO FUNCTION SELECT

The available GPIO functions are described in Table 77. The function of each GPIO is set using the GPn_FN register, where n identifies the GPIO pin (1, 2, 3, 4 or 5). Note that the respective GPn_DIR must also be set according to whether the function is an input or output.

GPn_FN	DESCRIPTION	COMMENTS

Table 77 GPIO Function Select

DIGITAL AUDIO INTERFACE FUNCTION (AIFnTXLRCLK)

GPn_FN = 00h.

The WM5102 provides three digital audio interfaces (AIF1, AIF2 and AIF3).

Under default conditions, the input (RX) and output (TX) paths of each interface use the respective AIFnRXLRCLK signal as the frame synchronisation clock. If desired, the output (TX) interface can be configured to use a separate frame clock, AIFnTXLRCLK, using the AIFnTX_LRCLK_SRC registers as described in "Digital Audio Interface Control".

The AIFnTXLRCLK function is selected on the respective GPIO pin by setting the GPIO registers as described in "GPIO Control".

BUTTON DETECT (GPIO INPUT)

GPn_FN = 01h.

Button detect functionality can be selected on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control". The same functionality can be used to support a Jack Detect input function.

It is recommended to enable the GPIO input de-bounce feature when using GPIOs as button input or Jack Detect input.

The GPn_LVL fields may be read to determine the logic levels on a GPIO input, after the selectable de-bounce controls. Note that GPn_LVL is not affected by the GPn_POL bit.

The de-bounced GPIO signals are also inputs to the Interrupt control circuit. An interrupt event is triggered on the rising and falling edges of the GPIO input. The associated interrupt bits are latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

LOGIC '1' AND LOGIC '0' OUTPUT (GPIO OUTPUT)

GP_n_FN = 01h.

The WM5102 can be programmed to drive a logic high or logic low level on any GPIO pin by selecting the "GPIO Output" function as described in "GPIO Control".

The output logic level is selected using the respective GP_n_LVL bit. Note that the GP_n_LVL registers are 'write only' when the respective GPIO pin is configured as an output.

The polarity of the GPIO output can be inverted using the GP_n_POL registers. If GP_n_POL=1, then the external output will be the opposite logic level to GP_n_LVL.

INTERRUPT (IRQ) STATUS OUTPUT

GP_n_FN = 02h, 03h.

The WM5102 has an Interrupt Controller which can be used to indicate when any selected Interrupt events occur. An interrupt can be generated by any of the events described throughout the GPIO function definition above. Individual interrupts may be masked in order to configure the Interrupt as required. See "Interrupts" for further details.

The Interrupt Controller supports two separate Interrupt Request (IRQ) outputs. The IRQ1 or IRQ2 status may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

Note that the IRQ1 status is output on the $\overline{\text{IRQ}}$ pin at all times.

DSP STATUS FLAG (DSP IRQ_n) OUTPUT

GP_n_FN = 35h, 36h, 45h.

The WM5102 supports two DSP Status flags as outputs from the DSP block. These are configurable within the DSP to provide external indication of the required function(s). A status flag indicating the DSP1 RAM status is also supported. See "Digital Core" for more details of the DSP.

The DSP Status and DSP RAM Ready flags may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control". The DSP Status and DSP RAM Ready outputs are described in Table 78.

The DSP Status flags are inputs to the Interrupt Controller circuit. An interrupt event is triggered on the rising edge of the DSP Status (DSP_IRQ_n) flags or DSP RAM Ready flags. The associated interrupt bits are latched once set; they can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

GP _N _FN	DESCRIPTION	COMMENTS
35h	DSP Status (DSP_IRQ1)	External indication of DSP_IRQ1_STS
36h	DSP Status (DSP_IRQ2)	External indication of DSP_IRQ2_STS
45h	DSP1 RAM Ready	Indicates DSP1 RAM Ready status

Table 78 DSP Status and RAM Ready Indications

OPCLK AND OPCLK_ASYNC CLOCK OUTPUT

GP_n_FN = 04h, 3Dh.

A clock output (OPCLK) derived from SYSCLK can be output on any GPIO pin. The OPCLK frequency is controlled by OPCLK_DIV and OPCLK_SEL. The OPCLK output is enabled using the OPCLK_ENA register, as described in Table 79.

A clock output (OPCLK_ASYNC) derived from ASYNCCLK can be output on any GPIO pin. The OPCLK_ASYNC frequency is controlled by OPCLK_ASYNC_DIV and OPCLK_ASYNC_SEL. The OPCLK_ASYNC output is enabled using the OPCLK_ASYNC_ENA register

It is recommended to disable the clock output (OPCLK_ENA=0 or OPCLK_ASYNC_ENA=0) before making any change to the respective OPCLK_DIV or OPCLK_ASYNC_DIV register.

The OPCLK or OPCLK_ASYNC Clock outputs can be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

Note that the OPCLK source frequency cannot be higher than the SYSCLK frequency. The OPCLK_ASYNC source frequency cannot be higher than the ASYNCCLK frequency. The maximum output frequency supported for GPIO output is noted in the "Electrical Characteristics".

See "Clocking and Sample Rates" for more details of the system clocks (SYSCLK and ASYNCCLK).

Table 79 OPCLK and OPCLK_ASYNC Control

FREQUENCY LOCKED LOOP (FLL) STATUS OUTPUT

GPn_FN = 0Ch, 0Dh, 0Fh, 10h.

The WM5102 supports FLL status flags, which may be used to control other events. See “Clocking and Sample Rates” for more details of the FLL.

The ‘FLL Clock OK’ signals indicate that the respective FLL has started up and is providing an output clock. The ‘FLL Lock’ signals indicate whether FLL Lock has been achieved.

The FLL Clock OK and FLL Lock signals may be output directly on any GPIO pin by setting the respective GPIO registers as described in “GPIO Control”.

The FLL Clock OK and FLL Lock signals are inputs to the Interrupt Controller circuit. An interrupt event is triggered on the rising and falling edges of these signals. The associated interrupt bits are latched once set; they can be polled at any time or used to control the IRQ signal. See “Interrupts” for more details of the Interrupt event handling.

FREQUENCY LOCKED LOOP (FLL) CLOCK OUTPUT

GPn_FN = 05h, 06h.

Clock outputs derived from the FLLs may be output on any GPIO pin. The GPIO output from each FLLn (where ‘n’ is 1 or 2) is controlled by the respective FLLn_GPCLK_DIV and FLLn_GPCLK_ENA registers, as described in Table 80.

It is recommended to disable the clock output (FLLn_GPCLK_ENA=0) before making any change to the respective FLLn_GPCLK_DIV register.

Note that the FLLn_GPCLK_DIV and FLLn_GPCLK_ENA registers affect the GPIO outputs only; they do not affect the FLL frequency. The maximum output frequency supported for GPIO output is noted in the “Electrical Characteristics”.

The Frequency Locked Loop (FLL) Clock outputs may be output directly on any GPIO pin by setting the respective GPIO registers as described in “GPIO Control”.

See “Clocking and Sample Rates” for more details of the WM5102 system clocking and for details of how to configure the FLLs.

Table 80 FLL Clock Output Control

PULSE WIDTH MODULATION (PWM) SIGNAL OUTPUT

GP_n_FN = 08h, 09h.

The WM5102 incorporates two Pulse Width Modulation (PWM) signal generators which can be enabled as GPIO outputs. The duty cycle of each PWM signal can be modulated by an audio source, or can be set to a fixed value using a control register setting.

The Pulse Width Modulation (PWM) outputs may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

See "Digital Core" for details of how to configure the PWM signal generators.

HEADPHONE DETECTION STATUS OUTPUT

GP_n_FN = 12h.

The WM5102 provides a headphone detection circuit on the HPDETL and HPDETR pins to measure the impedance of an external load connected to the headphone outputs. See "External Accessory Detection" for further details.

A logic signal from the headphone detection circuit may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control". This logic signal is set low when a Headphone Detect measurement is triggered, and is set high when the Headphone Detect function has completed. A rising edge indicates completion of a Headphone Detect measurement.

The headphone detection circuit is also an input to the Interrupt control circuit. An interrupt event is triggered whenever a headphone detection measurement has completed. Note that the HPDET_EINT flag is also asserted when the headphone detection is initiated. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

MICROPHONE / ACCESSORY DETECTION STATUS OUTPUT

GP_n_FN = 13h.

The WM5102 provides an impedance measurement circuit on the MICDET_n pins to detect the connection of a microphone or other external accessory. See "External Accessory Detection" for further details.

A logic signal from the microphone detect circuit may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control". This logic signal is set high for a pulse duration of 31μs whenever an accessory insertion, removal or impedance change is detected.

The microphone detection circuit is also an input to the Interrupt control circuit. An interrupt event is triggered whenever an accessory insertion, removal or impedance change is detected. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

BOOT DONE STATUS OUTPUT

GP_n_FN = 44h.

The WM5102 executes a user-configurable Boot Sequence following Power-On Reset (POR), Hardware Reset, Software Reset or Wake-Up (from Sleep mode). Control register writes should not be attempted while the Boot Sequence is running.

For details of the Boot Sequence, see "Control Write Sequencer".

The BOOT_DONE_STS register bit (see Table 113) indicates the status of the Boot Sequence. (When BOOT_DONE_STS=1, then the Boot Sequence is complete.)

The BOOT_DONE_STS signal may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

The BOOT_DONE_STS signal is also an input to the Interrupt Controller circuit. An interrupt event is triggered on the rising edge of this signal. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

ASYNCHRONOUS SAMPLE RATE CONVERTER (ASRC) LOCK STATUS OUTPUT

GP_n_FN = 1Ah, 1Bh.

The WM5102 maintains a flag indicating the lock status of the Asynchronous Sample Rate Converters (ASRCs), which may be used to control other events if required. See "Digital Core" for more details of the ASRCs.

The ASRC Lock signals may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

The ASRC Lock signals are inputs to the Interrupt control circuit. An interrupt event is triggered on the rising and falling edges of the ASRC Lock signals. The associated interrupt bits are latched once set; they can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

ASYNCHRONOUS SAMPLE RATE CONVERTER (ASRC) CONFIGURATION ERROR STATUS OUTPUT

GPn_FN = 1Ch.

The WM5102 performs automatic checks to confirm that the ASRCs are configured with valid settings. Invalid settings include conditions where one of the associated sample rates is higher than 48kHz. If an invalid ASRC configuration is detected, this can be indicated using the GPIO and/or Interrupt functions.

The ASRC Configuration Error signal may be output directly on any GPIO pin by setting the respective GPIO registers as described in “GPIO Control”.

The ASRC Configuration Error signal is an input to the Interrupt Controller circuit. An interrupt event is triggered on the rising and falling edges of the ASRC Configuration Error signal. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See “Interrupts” for more details of the Interrupt event handling.

OVER-TEMPERATURE STATUS OUTPUT

GPn_FN = 2Bh, 2Ch.

The WM5102 incorporates a temperature sensor which detects when the device temperature is within normal limits or if the device is approaching a hazardous temperature condition.

The temperature status may be output directly on any GPIO pin by setting the respective GPIO registers as described in “GPIO Control”. Any GPIO pin can be used to indicate either a Warning Temperature event or the Shutdown Temperature event.

The Warning Temperature and Shutdown Temperature status are inputs to the Interrupt control circuit. An interrupt event may be triggered on the rising and falling edges of these signals. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See “Interrupts” for more details of the Interrupt event handling.

It is strongly recommended that the speaker drivers be disabled if the Shutdown Temperature condition occurs.

DYNAMIC RANGE CONTROL (DRC) STATUS OUTPUT

GPn_FN = 1Dh, 1Eh, 1Fh, 20h, 21h.

The Dynamic Range Control (DRC) circuit provides status outputs, which may be used to control other events if required.

The DRC status flags may be output directly on any GPIO pin by setting the respective GPIO registers as described in “GPIO Control”. The DRC status outputs are described in Table 81.

See “Digital Core” for more details of the DRC.

GPn_FN	DESCRIPTION	COMMENTS
1Dh	DRC1 Signal Detect	Indicates a signal is present on the respective DRC path. The threshold level is configurable (see Table 14).
1Eh	DRC1 Anti-Clip Active	Indicates the DRC anti-clip function has been triggered; the DRC gain is decreasing in response to a rising signal level.
1Fh	DRC1 Decay Active	Indicates that the DRC gain is increasing in response to a low-level signal input.
20h	DRC1 Noise Gate Active	Indicates that the DRC noise gate has been triggered; an idle signal condition has been detected.
21h	DRC1 Quick Release Active	Indicates that the DRC quick-release function has been triggered; the DRC gain is increasing rapidly following detection of a short transient peak.

Table 81 Dynamic Range Control (DRC) Status Indications

CONTROL WRITE SEQUENCER STATUS DETECTION

GP_n_FN = 15h.

The WM5102 Control Write Sequencer (WSEQ) can be used to execute a sequence of register write operations in response to a simple trigger event. See “Control Write Sequencer” for details of the Control Write Sequencer.

The WSEQ_BUSY register bit (see Table 107) indicates the status of the Control Write Sequencer. When WSEQ_BUSY=1, this indicates that one or more Write Sequence operations are in progress or are queued for sequential execution.

The Write Sequencer status may be output directly on any GPIO pin by setting the respective GPIO registers as described in “GPIO Control”.

The Write Sequencer status is an input to the Interrupt control circuit. An interrupt event is triggered on completion of a Control Sequence. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See “Interrupts” for more details of the Interrupt event handling.

CONTROL INTERFACE ERROR STATUS OUTPUT

GP_n_FN = 16h.

The WM5102 is controlled by writing to registers through a 2-wire serial control interface, as described in the “Control Interface” section. The SLIMbus interface also supports read/write access to the control registers, as described in the “SLIMBus Interface” section.

The WM5102 performs automatic checks to confirm if a register access is successful. Register access will be unsuccessful if an invalid register address is selected. Read/write access to the DSP firmware memory will be unsuccessful if the associated clocking is not enabled. If an invalid or unsuccessful register operation is attempted, this can be indicated using the GPIO and/or Interrupt functions.

The Control Interface Error signal may be output directly on any GPIO pin by setting the respective GPIO registers as described in “GPIO Control”.

The Control Interface Error signal is an input to the Interrupt Controller circuit. An interrupt event is triggered on the rising edge of the Control Interface Error signal. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See “Interrupts” for more details of the Interrupt event handling.

SYSTEM CLOCKS ENABLE STATUS OUTPUT

GP_n_FN = 4Bh, 4Ch.

The WM5102 requires a system clock (SYSCLK) for its internal functions and to support the input/output signal paths. The WM5102 can support two independent clock domains, with selected functions referenced to the ASYNCCLK clock domain. See “Clocking and Sample Rates” for details of these clocks.

The SYSCLK_ENA and ASYNC_CLK_ENA registers (see Table 90) control the SYSCLK and ASYNCCLK signals respectively. When ‘0’ is written to these registers, the host processor must wait until the WM5102 has shut down the associated functions before issuing any other register write commands.

The SYSCLK Enable and ASYNCCLK Enable status may be output directly on any GPIO pin by setting the respective GPIO registers as described in “GPIO Control”.

The SYSCLK Enable and ASYNCCLK Enable signals are inputs to the Interrupt Controller circuit. An interrupt event is triggered when the respective clock functions have been shut down. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See “Interrupts” for more details of the Interrupt event handling.

CLOCKING ERROR STATUS OUTPUT

GPN_FN = 0Ah, 0Bh, 27h, 2Dh, 2Eh.

The WM5102 performs automatic checks to confirm that the system clocks are correctly configured according to the commanded functionality. An invalid configuration is one where there are insufficient clock cycles to support the digital processing required by the commanded signal paths.

An Underclocked Error condition is where there are insufficient clock cycles for the requested functionality, and increasing the SYSCLK or ASYNCCLK frequency (as applicable) should allow the selected configuration to be supported.

An Overclocked Error condition is where the requested functionality cannot be supported, as the clocking requirements of the requested configuration exceed the device limits.

The system clocks (SYSCLK and, where applicable, ASYNCCLK) must be enabled before any signal path is enabled. If an attempt is made to enable a signal path, and there are insufficient clock cycles to support that path, then the attempt will be unsuccessful. Note that any signal paths that are already active will not be affected under these circumstances.

The Clocking Error signals may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control". The Clocking Error conditions are described in Table 82.

The Clocking Error signals are inputs to the Interrupt Controller circuit. An interrupt event is triggered on the rising and falling edges of the Clocking Error signals. The associated interrupt bits are latched once set; they can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

GPN_FN	DESCRIPTION	COMMENTS
0Ah	SYSCLK Underclocked	Indicates insufficient SYSCLK cycles for the commanded functionality.
0Bh	ASYNCCLK Underclocked	Indicates insufficient ASYNCCLK cycles for the commanded functionality.
27h	Mixer Dropped Sample Error	Indicates a dropped sample in the digital core mixer function.
2Dh	Underclocked Error	<p>Indicates insufficient SYSCLK or ASYNCCLK cycles for one or more of the selected signal paths or signal processing functions. Increasing the SYSCLK or ASYNCCLK frequency (as applicable) should allow the selected configuration to be supported.</p> <p>Status bits associated with specific sub-systems provide further de-bug capability.</p> <p>The INnx_ENA_STS bits in register R769 indicate the status of each of the input (analogue or digital microphone) signal paths.</p> <p>The OUTnx_ENA_STS bits in registers R1025 and R1030 indicate the status of each of the output (Headphone, Speaker or PDM) signal paths.</p> <p>The ASRCnx_ENA_STS bits in register R3809 indicate the status of each of the ASRC signal paths.</p> <p>The FX_STS field in register R3585 indicates the status of each of the Effects (EQ, DRC or LHPF) signal paths.</p> <p>The *MIX_STS_n fields in registers R1600 to R2920 indicate the status of each of the Digital Core mixer signal paths.</p> <p>The ISRC_n and AIFn functions are also inputs to the Underclocked Error status indication, but there are specific _STS register bits associated with these.</p>
2Eh	Overclocked Error	Indicates that an unsupported device configuration has been attempted, as the clocking requirements of the requested configuration exceed the device limits.

Table 82 Clocking Error Status Indications

DIGITAL AUDIO INTERFACE CONFIGURATION ERROR STATUS OUTPUT

GPn_FN = 28h, 29h, 2Ah.

The WM5102 performs automatic checks to confirm that AIF1, AIF2 and AIF3 are configured with valid settings. Invalid settings include conditions where one or more audio channel timeslots are in conflict.

If an invalid AIF1, AIF2 or AIF3 configuration is detected, this can be indicated using the GPIO and/or Interrupt functions.

The AIF Configuration Error signals may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

The AIF Configuration Error signals are an input to the Interrupt Controller circuit. An interrupt event is triggered on the rising and falling edges of the AIF Configuration Error signal. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

INTERRUPTS

The Interrupt Controller has multiple inputs. These include the Jack Detect and GPIO input pins, DSP_IRQn flags, headphone / accessory detection, FLL / ASRC Lock detection, and Clocking configuration error indications. Any combination of these inputs can be used to trigger an Interrupt Request (IRQ) event.

The Interrupt Controller supports two sets of interrupt registers. This allows two separate Interrupt Request (IRQ) outputs to be generated, and for each IRQ to report a different set of input or status conditions.

For each Interrupt Request (IRQ1 and IRQ2) output, there is an Interrupt register field associated with each of the interrupt inputs. These fields are asserted whenever a logic edge is detected on the respective input. Some inputs are triggered on rising edges only; some are triggered on both edges. Separate rising and falling interrupt registers are provided for the JD1 and GP5 signals. The Interrupt register fields for IRQ1 are described in Table 84. The Interrupt register fields for IRQ2 are described in Table 85. The Interrupt flags can be polled at any time, or else in response to the Interrupt Request (IRQ) output being signalled via the $\overline{\text{IRQ}}$ pin or a GPIO pin.

All of the Interrupts are edge-triggered, as noted above. Many of these are triggered on both the rising and falling edges and, therefore, the Interrupt registers cannot indicate which edge has been detected. The "Raw Status" fields described in Table 86 provide readback of the current value of the corresponding inputs to the Interrupt Controller. Note that the status of any GPIO inputs can be read using the GPN_LVL registers, as described in Table 76.

The UNDERCLOCKED_STS and OVERCLOCKED_STS registers represent the logical 'OR' of status flags from multiple sub-systems. The status bits in registers R3364 to R3367 (see Table 86) provide readback of these lower-level signals. See "Clocking and Sample Rates" for a description of the Underclocked and Overclocked Error conditions.

Individual mask bits can enable or disable different functions from the Interrupt controller. The mask bits are described in Table 84 (for IRQ1) and Table 85 (for IRQ2). Note that a masked interrupt input will not assert the corresponding interrupt register field, and will not cause the associated Interrupt Request (IRQ) output to be asserted.

The Interrupt Request (IRQ) outputs represent the logical 'OR' of the associated interrupt registers. (IRQ1 is derived from the _EINT1 registers; IRQ2 is derived from the _EINT2 registers). The Interrupt register fields are latching fields and, once they are set, they are not reset until a '1' is written to the respective register bit(s). The Interrupt Request (IRQ) outputs are not reset until each of the associated interrupts has been reset.

A de-bounce circuit can be enabled on any GPIO input, to avoid false event triggers. This is enabled on each pin using the register bits described in Table 76.

The IRQ outputs can be globally masked using the IM_IRQ1 and IM_IRQ2 register bits. When not masked, the IRQ status can be read from IRQ1_STS and IRQ2_STS for the respective IRQ outputs.

The IRQ1 output is provided externally on the $\overline{\text{IRQ}}$ pin. Under default conditions, this output is 'Active Low'. The polarity can be inverted using the IRQ_POL register. The $\overline{\text{IRQ}}$ output can be either CMOS driven or Open Drain; this is selected using the IRQ_OP_CFG register.

The IRQ1 and IRQ2 signals may be output on a GPIO pin - see "General Purpose Input / Output".

The WM5102 Interrupt Controller circuit is illustrated in Figure 63. (Note that not all interrupt inputs are shown.) The associated control fields are described in Table 83 to Table 86.

Note that, under default register conditions, the 'Boot Done' status is the only un-masked interrupt source; a falling edge on the $\overline{\text{IRQ}}$ pin will indicate completion of the Boot Sequence.

Table 86 Interrupt Status

CLOCKING AND SAMPLE RATES

The WM5102 requires a clock reference for its internal functions and also for the input (ADC) paths, output (DAC) paths and digital audio interfaces. Under typical clocking configurations, all commonly-used audio sample rates can be derived directly from the external reference; for additional flexibility, the WM5102 incorporates two Frequency Locked Loop (FLL) circuits to perform frequency conversion and filtering.

External clock signals may be connected via MCLK1 and MCLK2. (Note that MCLK1 and MCLK2 are referenced to the DBVDD1 and DBVDD2 power domains respectively.) In AIF Slave modes, the BCLK signals may be used as a reference for the system clocks. The SLIMBus interface can provide the clock reference, when used as the input to one of the FLLs. To avoid audible glitches, all clock configurations must be set up before enabling playback.

SYSTEM CLOCKING

The WM5102 supports two independent clock domains, referenced to the SYSCLK and ASYNCCLK system clocks respectively.

Up to five different sample rates may be independently selected for specific audio interfaces and other input/output signal paths. Each selected sample rate must be synchronised either to SYSCLK or to ASYNCCLK, as described later.

The two system clocks are independent (ie. not synchronised). Stereo full-duplex sample rate conversion is supported, allowing asynchronous audio data to be mixed and to be routed between independent interfaces. See "Digital Core" for further details.

Each subsystem within the WM5102 digital core is clocked at a dynamically-controlled rate, limited by the SYSCLK (or ASYNCCLK) frequency, as applicable. For maximum signal mixing and processing capacity, it is recommended that the highest possible SYSCLK and ASYNCCLK frequencies are configured.

If the SUBSYS_MAX_FREQ bit is set to '0', then the digital core clocking rate is restricted to a maximum of 24.576MHz (or 22.5792MHz), even if a higher system clock frequency is configured.

The maximum digital core clocking rates of 49.152MHz (or 45.1584MHz) are only supported when SUBSYS_MAX_FREQ is set to '1', and the DCVDD voltage is 1.8V (nominal).

See "Recommended Operating Conditions" for details of the DCVDD operating conditions. Note that, if DCVDD is less than the minimum level for >24.576MHz clocking, then SUBSYS_MAX_FREQ must be set to '0'.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R353 (0161h) Dynamic Frequency Scaling 1	0	SUBSYS_MAX_F REQ	0	Digital Core Clocking Limit Sets the maximum digital core clocking rate. The higher rate should only be selected when the DCVDD voltage is 1.8V (nominal). 0 = 24.576MHz (22.5792MHz) 1 = 49.152MHz (45.1584MHz)

Table 87 System Clocking

SAMPLE RATE CONTROL

The WM5102 supports two independent clock domains, referenced to SYSCLK and ASYNCCLK respectively.

Different sample rates may be selected for each of the audio interfaces (AIF1, AIF2, AIF3, SLIMbus), and for the input (ADC) and output (DAC) paths. Each of these must be referenced either to SYSCLK or to ASYNCCLK. (Note that the SLIMbus interface supports multiple sample rates, selected independently for each input or output channel.)

The WM5102 can support a maximum of five different sample rates at any time. The supported

sample rates range from 4kHz to 192kHz.

Up to three different sample rates can be selected using the SAMPLE_RATE_1, SAMPLE_RATE_2 and SAMPLE_RATE_3 registers. These must each be numerically related to each other and to the SYSCLK frequency (further details of these requirements are provided in Table 88 and the accompanying text).

The remaining two sample rates can be selected using the ASYNC_SAMPLE_RATE_1 and ASYNC_SAMPLE_RATE_2 registers. These sample rates must be numerically related to each other and to the ASYNCLK frequency (further details of these requirements are provided in Table 89 and the accompanying text).

Each of the audio interfaces, input paths and output paths is associated with one of the sample rates selected by the SAMPLE_RATE_n or ASYNC_SAMPLE_RATE_n registers.

Note that if any two interfaces are operating at the same sample rate, but are not synchronised, then one of these must be referenced to the ASYNCLK domain, and the other to the SYSCLK domain.

Note that, when any of the SAMPLE_RATE_n or ASYNC_SAMPLE_RATE_n registers is written to, the activation of the new setting is automatically synchronised by the WM5102 to ensure continuity of all active signal paths. The SAMPLE_RATE_n_STS and ASYNC_SAMPLE_RATE_n_STS registers provide readback of the sample rate selections that have been implemented.

There are some restrictions to be observed regarding the sample rate control configuration, as noted below:

- The input (ADC / Digital Microphone) and output (DAC) signal paths must always be associated with the SYSCLK clocking domain.
- All external clock references (MCLK input or Slave mode AIF input) must be within 1% of the applicable register setting(s).
- The input (ADC / DMIC) sample rate is valid from 8kHz to 192kHz.
- The output (DAC) sample rate is valid from 8kHz to 96kHz.
- The Mic Mute mixer sample rate is valid from 8kHz to 192kHz.
- The Effects (EQ, DRC, LHPF) sample rate is valid from 8kHz to 192kHz.
- The Tone Generator sample rate is valid from 8kHz to 192kHz.
- The Haptic Signal Generator sample rate is valid from 8kHz to 192kHz.
- The Asynchronous Sample Rate Converter (ASRC) supports sample rates 8kHz to 48kHz. The associated SYSCLK and ASYNCLK sample rates must both be 8kHz to 48kHz.
- The Isochronous Sample Rate Converters (ISRCs) support sample rates 8kHz to 192kHz. For each ISRC, the higher sample rate must be an integer multiple of the lower rate. Integer ratios in the range 1 to 6 are supported.

AUTOMATIC SAMPLE RATE DETECTION

The WM5102 supports automatic sample rate detection on the digital audio interfaces (AIF1, AIF2 and AIF3). Note that this is only possible when the respective interface is operating in Slave mode (ie. when LRCLK and BCLK are inputs to the WM5102).

Automatic sample rate detection is enabled using the RATE_EST_ENA register bit. The LRCLK input pin selected for sample rate detection is set using the LRCLK_SRC register.

Up to four audio sample rates can be configured for automatic detection; these sample rates are selected using the SAMPLE_RATE_DETECT_n registers. Note that the function will only detect sample rates that match one of the SAMPLE_RATE_DETECT_n registers.

If one of the selected audio sample rates is detected on the selected LRCLK input, then a Control Write Sequence will be triggered. A unique sequence of actions may be programmed for each of the detected sample rates. Note that the applicable control sequences must be programmed by the user for each detection outcome. See "Control Write Sequencer" for further details.

The TRIG_ON_STARTUP register controls whether the sample rate detection circuit responds to the initial detection of the applicable interface (ie. when the AIFn interface starts up).

When TRIG_ON_STARTUP=0, then the detection circuit will only respond (ie. trigger the Control Write Sequencer) to a change in the detected sample rate - the initial sample rate detection will be ignored. (Note that the 'initial sample rate detection' is the first detection of a sample rate that matches one of the SAMPLE_RATE_DETECT_n registers.)

When TRIG_ON_STARTUP=1, then the detection circuit will trigger the Control Write Sequencer whenever a selected sample rate is detected, including when the AIF interface starts up, or when the sample rate detection is first enabled.

There are some restrictions to be observed regarding the sample rate control configuration, as noted below:

- The same sample rate must not be selected on more than one of the SAMPLE_RATE_DETECT_n registers.
- Sample rates 192kHz and 176.4kHz must not be selected concurrently.
- Sample rates 96kHz and 88.2kHz must not be selected concurrently.

The control registers associated with the automatic sample rate detection function are described in Table 90.

SYSCLK AND ASYNCCLK CONTROL

The SYSCLK and ASYNCCLK clocks may be provided directly from external inputs (MCLK, or slave mode BCLK inputs). Alternatively, the SYSCLK and ASYNCCLK clocks can be derived using the integrated FLL(s), with MCLK, BCLK, LRCLK or SLIMCLK as a reference.

The required SYSCLK frequency is dependent on the SAMPLE_RATE_n registers. Table 88 illustrates the valid SYSCLK frequencies for every supported sample rate.

The SYSCLK_FREQ and SYSCLK_FRAC registers are used to identify the applicable SYSCLK frequency. It is recommended that the highest possible SYSCLK frequency is selected.

The chosen SYSCLK frequency must be valid for all of the SAMPLE_RATE_n registers. It follows that all of the SAMPLE_RATE_n registers must select numerically-related values, ie. all from the same cell as represented in Table 88.

Sample Rate	SAMPLE_RATE_n	SYSCLK Frequency	SYSCLK_FREQ	SYSCLK_FRAC
12kHz	01h			
24kHz	02h			
48kHz	03h			
96kHz	04h	6.144MHz,	000,	
192kHz	05h	12.288MHz,	001,	0
		24.576MHz,	010,	
4kHz	10h	or	or	
8kHz	11h	49.152MHz	011	
16kHz	12h			
32kHz	13h			
11.025kHz	09h	5.6448MHz,	000,	
22.05kHz	0Ah	11.2896MHz,	001,	1
44.1kHz	0Bh	22.5792MHz,	010,	
88.2kHz	0Ch	or	or	
176.4kHz	0Dh	45.1584MHz	011	

Note that each of the SAMPLE_RATE_n registers must select a sample rate value from the same group in the two lists above.

Table 88 SYSCLK Frequency Selection

The required ASYNCCLK frequency is dependent on the ASYNC_SAMPLE_RATE_n registers. Table 89 illustrates the valid ASYNCCLK frequencies for every supported sample rate.

The ASYNC_CLK_FREQ register is used to identify the applicable ASYNCCLK frequency. It is recommended that the highest possible ASYNCCLK frequency is selected.

Note that, if all the sample rates in the system are synchronised to SYSCLK, then the ASYNCCLK may not be required at all. In this case, the ASYNCCLK should be disabled (see Table 90), and the associated register values are not important.

Sample Rate	ASYNC_SAMPLE_RATE_n	ASYNCCLK Frequency	ASYNC_CLK_FREQ
12kHz	01h	6.144MHz, 12.288MHz, 24.576MHz, or 49.152MHz	000, 001, 010, or 011
24kHz	02h		
48kHz	03h		
96kHz	04h		
192kHz	05h		
4kHz	10h		
8kHz	11h		
16kHz	12h		
32kHz	13h		
11.025kHz	09h	5.6448MHz, 11.2896MHz, 22.5792MHz or 45.1584MHz	000, 001, 010, or 011
22.05kHz	0Ah		
44.1kHz	0Bh		
88.2kHz	0Ch		
176.4kHz	0Dh		

Note that each of the ASYNC_SAMPLE_RATE_n registers must select a sample rate value from the same group in the two lists above.

Table 89 ASYNCCLK Frequency Selection

The WM5102 supports automatic clocking configuration. The programmable dividers associated with the ADCs, DACs and all DSP functions are configured automatically, with values determined from the SYSCLK_FREQ, SAMPLE_RATE_n, ASYNC_CLK_FREQ and ASYNC_SAMPLE_RATE_n fields.

Note that the digital audio interface (AIF) clocking rates must be configured separately.

The sample rates of each AIF, the input (ADC) paths, output (DAC) paths and DSP functions are selected as described in the respective sections. Stereo full-duplex sample rate conversion is supported in multiple configurations to allow digital audio to be routed between interfaces and for asynchronous audio data to be mixed. See “Digital Core” for further details.

The SYSCLK_SRC register is used to select the SYSCLK source, as described in Table 90. The source may be MCLn, AIFnBCLK or FLLn. If one of the Frequency Locked Loop (FLL) circuits is selected as the source, then the relevant FLL must be enabled and configured, as described later.

The SYSCLK_FREQ and SYSCLK_FRAC registers are set according to the frequency of the selected SYSCLK source.

The SYSCLK-referenced circuits within the digital core are clocked at a dynamically-controlled rate, limited by the SYSCLK frequency itself. For maximum signal mixing and processing capacity, it is recommended that the highest possible SYSCLK frequency is configured.

If the SUBSYS_MAX_FREQ bit is set to ‘0’, then the digital core clocking rate is restricted to a maximum of 24.576MHz (or 22.5792MHz), even if a higher SYSCLK frequency is configured. The SUBSYS_MAX_FREQ should only be set to ‘1’ when the applicable DCVDD condition is satisfied, as described in Table 87.

The SAMPLE_RATE_n registers are set according to the sample rate(s) that are required by one or more of the WM5102 audio interfaces. The WM5102 supports sample rates ranging from 4kHz to 192kHz.

The SYSCLK signal is enabled by the register bit SYSCLK_ENA. The applicable clock source (MCLKn, AIFnBCLK or FLLn) must be enabled before setting SYSCLK_ENA=1. This bit should be set to 0 when reconfiguring the clock sources (see below for additional requirements when setting SYSCLK_ENA=0).

When disabling SYSCLK, note that all of the input, output or digital core functions associated with the SYSCLK clock domain must be disabled before setting SYSCLK_ENA=0.

When '0' is written to SYSCLK_ENA, the host processor must wait until the WM5102 has shut down the associated functions before issuing any other register write commands. The SYSCLK Enable status can be polled via the SYSCLK_ENA_LOW_STS bit (see Table 86), or else monitored using the Interrupt or GPIO functions.

The SYSCLK Enable status is an input to the Interrupt control circuit and can be used to trigger an Interrupt event - see "Interrupts". The corresponding Interrupt event indicates that the WM5102 has shut down the SYSCLK functions and is ready to accept register write commands.

The SYSCLK Enable status can be output directly on a GPIO pin as an external indication of the SYSCLK status. See "General Purpose Input / Output" to configure a GPIO pin for this function.

The required control sequence for disabling SYSCLK is summarised below:

- Disable all SYSCLK-associated functions (inputs, outputs, digital core)
- Set SYSCLK_ENA = 0
- Wait until SYSCLK_ENA_LOW = 1 (or wait for the corresponding IRQ/GPIO event)

The ASYNC_CLK_SRC register is used to select the ASYNCCLK source, as described in Table 90. The source may be MCLKn, AIFnBCLK or FLLn. If one of the Frequency Locked Loop (FLL) circuits is selected as the source, then the relevant FLL must be enabled and configured, as described later.

The ASYNC_CLK_FREQ register is set according to the frequency of the selected ASYNCCLK source.

The ASYNCCLK-referenced circuits within the digital core are clocked at a dynamically-controlled rate, limited by the ASYNCCLK frequency itself. For maximum signal mixing and processing capacity, it is recommended that the highest possible ASYNCCLK frequency is configured.

If the SUBSYS_MAX_FREQ bit is set to '0', then the digital core clocking rate is restricted to a maximum of 24.576MHz (or 22.5792MHz), even if a higher ASYNCCLK frequency is configured. The SUBSYS_MAX_FREQ should only be set to '1' when the applicable DCVDD condition is satisfied, as described in Table 87.

The ASYNC_SAMPLE_RATE_n registers are set according to the sample rate(s) of any audio interface that is not synchronised to the SYSCLK clock domain.

The ASYNCCLK signal is enabled by the register bit ASYNC_CLK_ENA. The applicable clock source (MCLKn, AIFnBCLK or FLLn) must be enabled before setting ASYNC_CLK_ENA=1. This bit should be set to 0 when reconfiguring the clock sources (see below for additional requirements when setting ASYNC_CLK_ENA=0).

When disabling ASYNCCLK, note that all of the input, output or digital core functions associated with the ASYNCCLK clock domain must be disabled before setting ASYNC_CLK_ENA=0.

When '0' is written to ASYNC_CLK_ENA, the host processor must wait until the WM5102 has shut down the associated functions before issuing any other register write commands. The ASYNCCLK Enable status can be polled via the ASYNC_CLK_ENA_LOW_STS bit (see Table 86), or else monitored using the Interrupt or GPIO functions.

The ASNYCCLK Enable status is an input to the Interrupt control circuit and can be used to trigger an Interrupt event - see "Interrupts". The corresponding Interrupt event indicates that the WM5102 has shut down the ASNYCCLK functions and is ready to accept register write commands.

The ASNYCCLK Enable status can be output directly on a GPIO pin as an external indication of the ASNYCCLK status. See "General Purpose Input / Output" to configure a GPIO pin for this function.

The required control sequence for disabling ASYNCCLK is summarised below:

- Disable all ASYNCCLK-associated functions (inputs, outputs, digital core)
- Set ASYNCCLK_ENA = 0
- Wait until ASYNCCLK_ENA_LOW = 1 (or wait for the corresponding IRQ/GPIO event)

The SYSCLK (and ASYNCCLK, when applicable) clocks must be configured and enabled before any audio path is enabled.

The WM5102 performs automatic checks to confirm that the SYSCLK and ASYNCCLK frequencies are high enough to support the commanded signal paths and processing functions. If an attempt is made to enable a signal path or processing function, and there are insufficient SYSCLK or ASYNCCLK cycles to support it, then the attempt will be unsuccessful. (Note that any signal paths that are already active will not be affected under these circumstances.)

An Underclocked Error condition is where there are insufficient clock cycles for the requested functionality, and increasing the SYSCLK or ASYNCCLK frequency (as applicable) should allow the selected configuration to be supported.

An Overclocked Error condition is where the requested functionality cannot be supported, as the clocking requirements of the requested configuration exceed the device limits.

The SYSCLK Underclocked condition, ASYNCCLK Underclocked condition, and other Clocking Error conditions can be monitored using the GPIO and/or Interrupt functions. See “General Purpose Input / Output” and “Interrupts” for further details.

MISCELLANEOUS CLOCK CONTROLS

The WM5102 requires a 32kHz clock for miscellaneous de-bounce functions. This can be generated automatically from SYSCLK, or may be input directly as MCLK1 or MCLK2. The 32kHz clock source is selected using the CLK_32K_SRC register. The 32kHz clock is enabled using the CLK_32K_ENA register.

A clock output (OPCLK) derived from SYSCLK can be output on a GPIO pin. See “General Purpose Input / Output” to configure a GPIO pin for this function.

A clock output (OPCLK_ASYNC) derived from ASYNCCLK can be output on a GPIO pin. See “General Purpose Input / Output” to configure a GPIO pin for this function.

The WM5102 provides integrated pull-down resistors on the MCLK1 and MCLK2 pins. This provides a flexible capability for interfacing with other devices.

The clocking scheme for the WM5102 is illustrated in Figure 64.

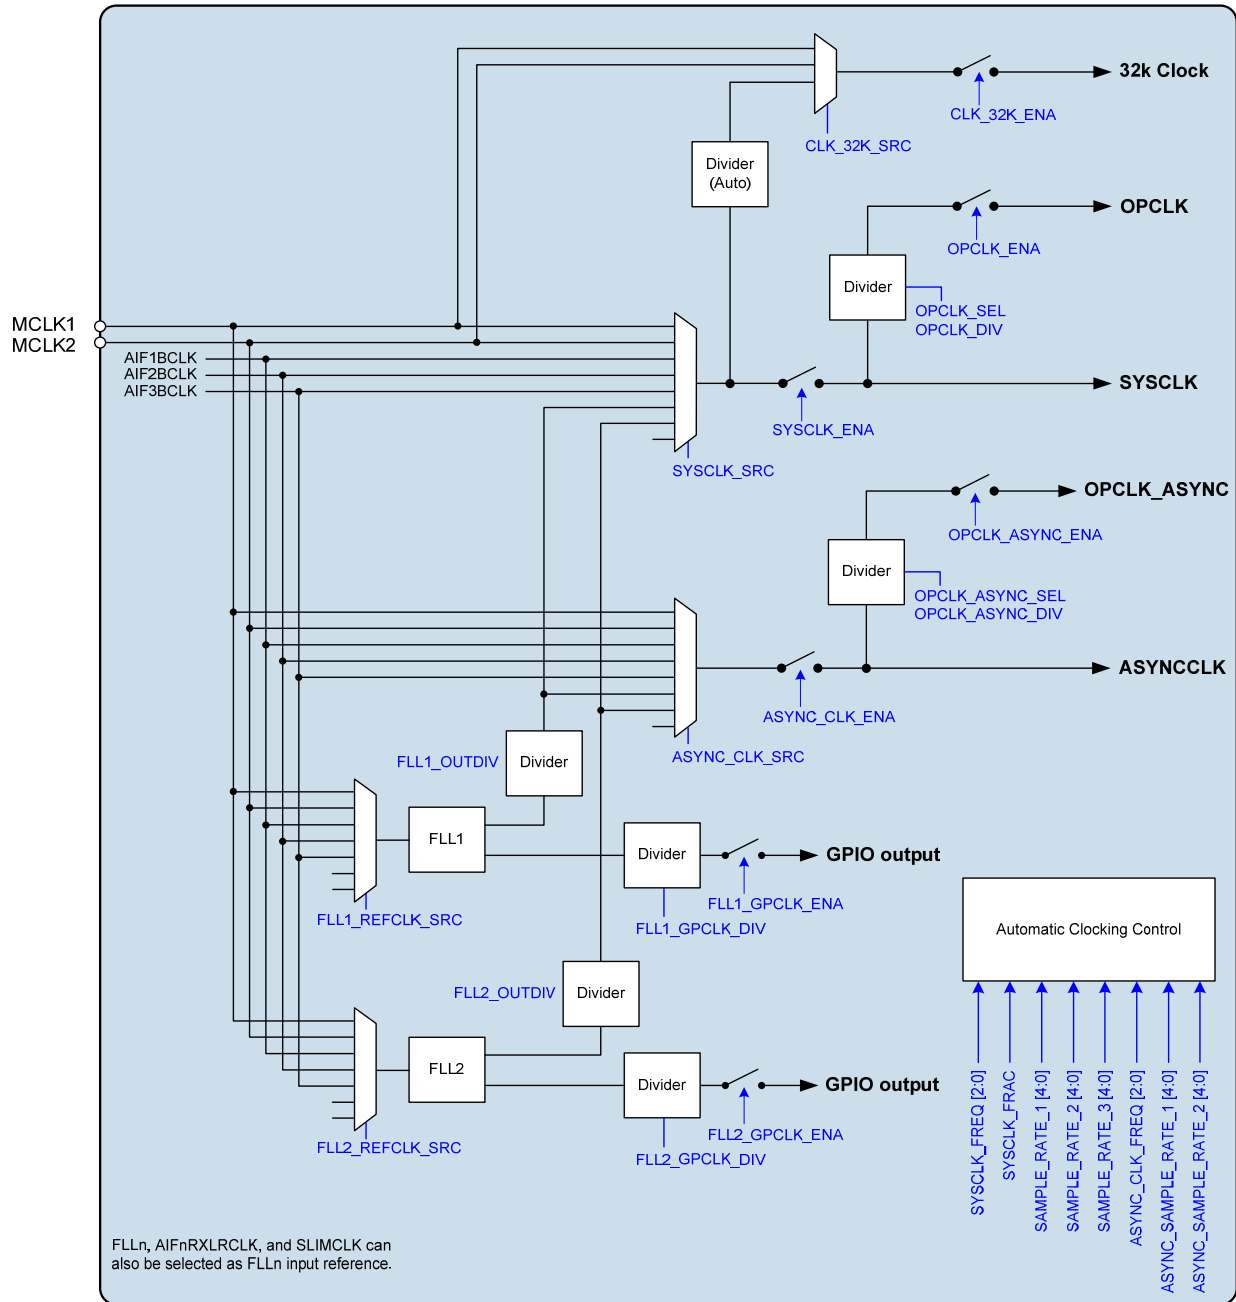

Figure 64 System Clocking

The WM5102 clocking control registers are described in Table 90.

Table 90 Clocking Control

In AIF Slave modes, it is important to ensure the applicable clock domain (SYSCLK or ASYNCCLK) is synchronised with the associated external LRCLK. This can be achieved by selecting an MCLK input that is derived from the same reference as the LRCLK, or can be achieved by selecting the external BCLK or LRCLK signal as a reference input to one of the FLLs, as a source for SYSCLK or ASYNCCLK.

If the AIF clock domain is not synchronised with the LRCLK, then clicks arising from dropped or repeated audio samples will occur, due to the inherent tolerances of multiple, asynchronous, system clocks. See "Applications Information" for further details on valid clocking configurations.

BCLK AND LRCLK CONTROL

The digital audio interfaces (AIF1, AIF2 and AIF3) use BCLK and LRCLK signals for synchronisation. In master mode, these are output signals, generated by the WM5102. In slave mode, these are input signals to the WM5102. It is also possible to support mixed master/slave operation.

The BCLK and LRCLK signals are controlled as illustrated in Figure 65. See the “Digital Audio Interface Control” section for further details of the relevant control registers.

Note that the BCLK and LRCLK signals are synchronised to SYSCLK or ASYNCLK, depending upon the applicable clocking domain for the respective interface. See “Digital Core” for further details.

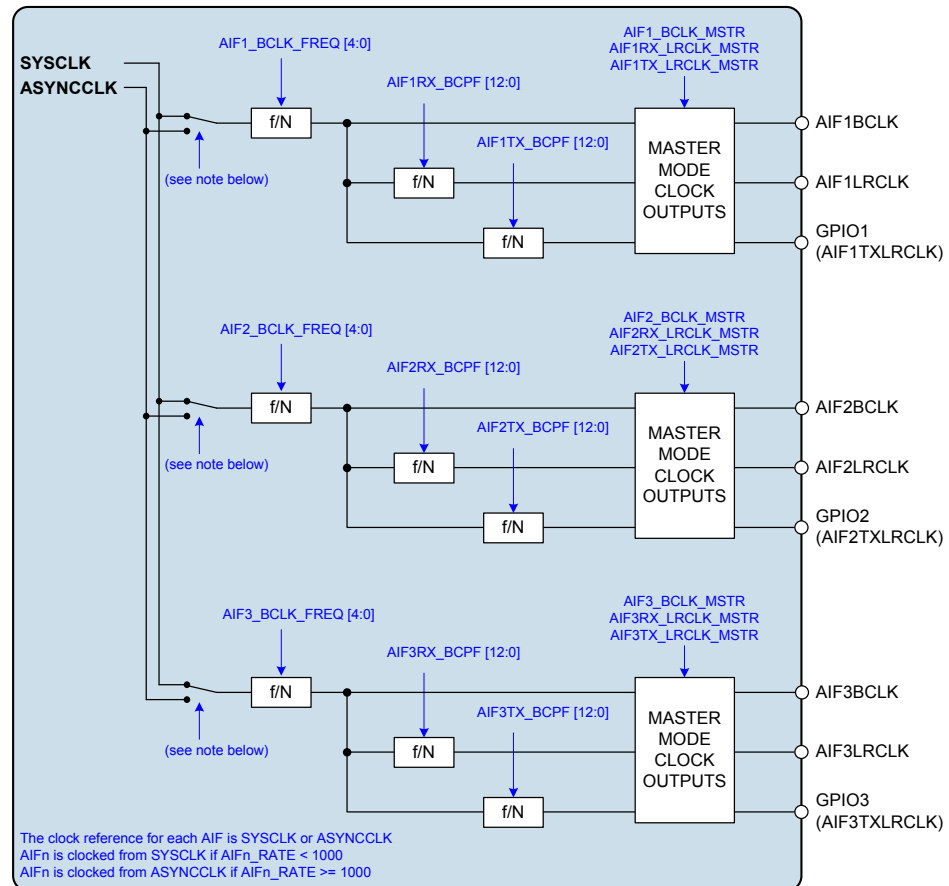

Figure 65 BCLK and LRCLK Control

CONTROL INTERFACE CLOCKING

Register map access is possible with or without a system clock. Clocking is provided from SYSCLK; the SYSCLK_SRC register selects the applicable SYSCLK source.

See “Control Interface” for further details of control register access.

FREQUENCY LOCKED LOOP (FLL)

Two integrated FLLs are provided to support the clocking requirements of the WM5102. These can be enabled and configured independently according to the available reference clocks and the application requirements. The reference clock may be a high frequency (eg. 12.288MHz) or low frequency (eg. 32.768kHz).

The FLL is tolerant of jitter and may be used to generate a stable output clock from a less stable input reference. The FLL characteristics are summarised in “Electrical Characteristics”. Note that the FLL can be used to generate a free-running clock in the absence of an external reference source. This is described in the “Free-Running FLL Mode” section below. Configurable spread-spectrum modulation

can be applied to the FLL outputs, to control EMI effects.

Each of the FLLs comprises two sub-systems - the 'main' loop and the 'synchroniser' loop; these can be used together to maintain best frequency accuracy and noise (jitter) performance across multiple use-cases. The two-loop design enables the FLL to synchronise effectively to an input clock that may be intermittent or noisy, whilst also achieving the performance benefits of a stable clock reference that may be asynchronous to the audio data.

The main loop takes a constant and stable clock reference as its input. For best performance, a high frequency (eg. 12.288MHz) reference is recommended.

The synchroniser loop takes a separate clock reference as its input. The synchroniser input may be intermittent (eg. during voice calls only). The FLL uses the synchroniser input, when available, as the frequency reference. To achieve the designed performance advantage, the synchroniser input must be synchronous with the audio data.

Note that, if only a single clock input reference is used, this must be configured as the main FLL input reference. The synchroniser can be disabled in this case.

The FLL is enabled using the FLL_n_ENA register bit (where *n* = 1 or 2 for the corresponding FLL). The FLL Synchroniser is enabled using the FLL_n_SYNC_ENA register bit.

Note that the other FLL registers should be configured before enabling the FLL; the FLL_n_ENA and FLL_n_SYNC_ENA register bits should be set as the final step of the FLL_n enable sequence.

When changing FLL settings, it is recommended that the digital circuit be disabled via FLL_n_ENA and then re-enabled after the other register settings have been updated. When changing the input reference frequency *F*_{REF}, it is recommended that the FLL be reset by setting FLL_n_ENA to 0.

Note that some of the FLL configuration registers can be updated while the FLL is enabled, as described below. As a general rule, however, it is recommended to configure the FLL (and FLL Synchroniser, if applicable), before setting the corresponding _ENA register bit(s).

The FLL configuration requirements are illustrated in Figure 66.

Figure 66 FLL Configuration

The procedure for configuring the FLL is described below. Note that the configuration of the main FLL path and the FLL Synchroniser path are very similar. One or both paths must be configured, depending on the application requirements:

- If a single clock input reference is used, then only the main FLL path is required.
- If two clock input references are used, then the constant or low-noise clock is configured on the main FLL path, and the high-accuracy clock is configured on the FLL synchroniser path. Note that the synchroniser input must be synchronous with the audio data.

The following description is applicable to FLL1 and FLL2. The associated register control fields are described in Table 94 and Table 95 respectively.

The main input reference is selected using FLL_n_REFCLK_SRC. The synchroniser input reference is selected using FLL_n_SYNCCLK_SRC. The available options in each case comprise MCLK1, MCLK2, SLIMCLK, AIFnBCLK, AIFnRXLRCLK, or the output from another FLL.

The SLIMCLK reference is controlled by an adaptive divider on the external SLIMCLK input. The divider automatically adapts to the SLIMbus Clock Gear, to provide a constant reference frequency for the FLL. See “SLIMBus Interface” for details.

The FLL_n_REFCLK_DIV field controls a programmable divider on the main input reference. The FLL_n_SYNCCLK_DIV field controls a programmable divider on the synchroniser input reference. Each input can be divided by 1, 2, 4 or 8. These registers should be set to bring each reference down to 13.5MHz or below. For best performance, it is recommended that the highest possible frequency - within the 13.5MHz limit - should be selected.

The FLL output frequency, relative to the main input reference F_{REF} , is directly determined from FLL_n_FRATIO, FLL_n_OUTDIV and the real number represented by N.K.

The integer value, N, is held in the FLL_n_N register field. The fractional portion, K, is determined by the ratio FLL_n_THETA / FLL_n_LAMBDA.

The FLL output frequency is generated according to the following equation:

$$F_{OUT} = (F_{VCO} / FLLn_OUTDIV)$$

The FLL operating frequency, F_{VCO} is set according to the following equation:

$$F_{VCO} = (F_{REF} \times N.K \times FLLn_FRATIO)$$

F_{REF} is the input frequency, as determined by FLL_n_REFCLK_DIV.

F_{VCO} must be in the range 90MHz to 104MHz. Frequencies outside this range cannot be supported.

Note that the output frequencies that do not lie within the ranges quoted above cannot be guaranteed across the full range of device operating conditions.

In order to follow the above requirements for F_{VCO} , the value of FLL_n_OUTDIV should be selected according to the desired output F_{OUT} . The divider, FLL_n_OUTDIV, must be set so that F_{VCO} is in the range 90MHz to 104MHz. Supported settings of FLL_n_OUTDIV are noted in Table 91.

OUTPUT FREQUENCY F_{OUT}	FLL _n _OUTDIV
22.5 MHz to 26 MHz	100 (divide by 4)
45 MHz to 50 MHz	010 (divide by 2)

Table 91 Selection of FLL_n_OUTDIV

The FLL_n_FRATIO field selects the frequency division ratio of the FLL input. The FLL_n_GAIN field is used to optimise the FLL, according to the input frequency. These fields should be set as described in Table 92.

REFERENCE FREQUENCY F _{REF}	FLL _n _FRATIO	FLL _n _GAIN
1MHz - 13.5MHz	0h (divide by 1)	4h (16x gain)
256kHz - 1MHz	1h (divide by 2)	2h (4x gain)
128kHz - 256kHz	2h (divide by 4)	0h (1x gain)
64kHz - 128kHz	3h (divide by 8)	0h (1x gain)
Less than 64kHz	4h (divide by 16)	0h (1x gain)

Table 92 Selection of FLL_n_FRATIO and FLL_n_GAIN

In order to determine the remaining FLL parameters, the FLL operating frequency, F_{VCO}, must be calculated, as given by the following equation:

$$F_{VCO} = (F_{OUT} \times FLLn_OUTDIV)$$

The value of N.K can then be determined as follows:

$$N.K = F_{VCO} / (FLLn_FRATIO \times F_{REF})$$

Note that, in the above equations:

FLL_n_OUTDIV is the F_{OUT} clock ratio.

F_{REF} is the input frequency, after division by FLL_n_REFCLK_DIV, where applicable.

FLL_n_FRATIO is the F_{VCO} clock ratio (1, 2, 4, 8 or 16).

The value of N is held in the FLL_n_N register field.

The value of K is determined by the ratio FLL_n_THETA / FLL_n_LAMBDA.

The FLL_n_N, FLL_n_THETA and FLL_n_LAMBDA fields are all coded as integers (LSB = 1).

The FLL_n_N and FLL_n_THETA values are applied to the FLL when a '1' is written to the FLL_n_CTRL_UPD bit. This makes it possible to update the two registers simultaneously, allowing the FLL to be reconfigured without disabling the FLL (provided that only these two registers require to be changed).

The values of FLL_n_THETA and FLL_n_LAMBDA can be calculated as described later.

A similar procedure applies for the derivation of the FLL Synchroniser parameters - assuming that this function is used.

The FLL_n_SYNC_FRATIO field selects the frequency division ratio of the FLL synchroniser input. The FLL_n_GAIN and FLL_n_SYNC_DFSAT fields are used to optimise the FLL, according to the input frequency. These fields should be set as described in Table 93.

SYNCHRONISER FREQUENCY F _{SYNC}	FLL _n _SYNC_FRATIO	FLL _n _SYNC_GAIN	FLL _n _SYNC_DFSAT
1MHz - 13.5MHz	0h (divide by 1)	4h (16x gain)	0 (wide bandwidth)
256kHz - 1MHz	1h (divide by 2)	2h (4x gain)	0 (wide bandwidth)
128kHz - 256kHz	2h (divide by 4)	0h (1x gain)	0 (wide bandwidth)
64kHz - 128kHz	3h (divide by 8)	0h (1x gain)	1 (narrow bandwidth)
Less than 64kHz	4h (divide by 16)	0h (1x gain)	1 (narrow bandwidth)

Table 93 Selection of FLL_n_SYNC_FRATIO, FLL_n_SYNC_GAIN, FLL_n_SYNC_DFSAT

The FLL operating frequency, F_{VCO} , is the same frequency calculated as described above.

The value of N.K (Sync) can then be determined as follows:

$$N.K \text{ (Sync)} = F_{VCO} / (FLLn_SYNC_FRATIO \times F_{SYNC})$$

Note that, in the above equations:

F_{SYNC} is the synchroniser input frequency, after division by $FLLn_SYNCCLK_DIV$, where applicable.

$FLLn_SYNC_FRATIO$ is the F_{VCO} clock ratio (1, 2, 4, 8 or 16).

The value of N (Sync) is held in the $FLLn_SYNC_N$ register field.

The value of K (Sync) is determined by the ratio $FLLn_SYNC_THETA / FLLn_SYNC_LAMBDA$.

The $FLLn_SYNC_N$, $FLLn_SYNC_THETA$ and $FLLn_SYNC_LAMBDA$ fields are all coded as integers (LSB = 1).

In Fractional Mode ($FLLn_THETA > 0$), the register fields $FLLn_THETA$ and $FLLn_LAMBDA$ can be calculated as described below.

Note that an equivalent procedure is also used to derive the $FLLn_SYNC_THETA$ and $FLLn_SYNC_LAMBDA$ register values from the corresponding synchroniser parameters.

Calculate GCD(FLL) using the 'Greatest Common Denominator' function:

$$GCD(FLL) = GCD(FLLn_FRATIO \times F_{REF}, F_{VCO})$$

where GCD(x, y) is the greatest common denominator of x and y

F_{REF} is the input frequency, after division by $FLLn_REFCLK_DIV$, where applicable.

Next, calculate $FLLn_THETA$ and $FLLn_LAMBDA$ using the following equations:

$$FLLn_THETA = (F_{VCO} - (FLL_N \times FLLn_FRATIO \times F_{REF})) / GCD(FLL)$$

$$FLLn_LAMBDA = (FLLn_FRATIO \times F_{REF}) / GCD(FLL)$$

Note that, in Fractional Mode, the values of $FLLn_THETA$ and $FLLn_LAMBDA$ must be co-prime (ie. not divisible by any common integer). The calculation above ensures that the values will be co-prime.

The value of K must be a fraction less than 1 (ie. $FLLn_THETA$ must be less than $FLLn_LAMBDA$).

The FLL control registers are described in Table 94 and Table 95. Example settings for a variety of reference frequencies and output frequencies are shown in Table 98.

Table 95 FLL2 Register Map

FREE-RUNNING FLL MODE

The FLL can generate a clock signal even when no external reference is available. This may be because the normal input reference has been interrupted, or may be during a standby or start-up period when no initial reference clock is available.

Free-running FLL mode is enabled using the FLLn_FREERUN register. (Note that FLLn_ENA must also be enabled in Free-running FLL mode.)

In Free-running FLL mode, the normal feedback mechanism of the FLL is halted, and the FLL oscillates independently of the external input reference(s).

If the FLL was previously operating normally, (with an input reference clock), then the FLL output frequency will remain unchanged when Free-running FLL mode is enabled.

If the FLL was not previously configured, then the FLL output frequency will be as specified in the "Electrical Characteristics" section.

Note that the FLL integrator setting does not ensure a specific output frequency for the FLL across all devices and operating conditions; a significant level of variation will apply, especially if the FLL is operating independently of any input reference.

Note that the free-running FLL clock may be selected as the SYSCLK source or ASYNCLK source as shown Figure 64.

The Free-running FLL mode is enabled using the register bits described in Table 96.

SPREAD SPECTRUM FLL CONTROL

The WM5102 can apply modulation to the FLL outputs, using spread spectrum techniques. This can be used to control the EMI characteristics of the circuits that are clocked via the FLLs.

Each of the FLLs can be individually configured for Triangle modulation, Zero Mean Frequency Modulation (ZMFM) or Dither. The amplitude and frequency parameters of the spread spectrum functions is also programmable, using the registers described in Table 97.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION

Table 97 FLL Spread Spectrum Control

GPIO OUTPUTS FROM FLL

For each FLL, the WM5102 supports an 'FLL Clock OK' signal which, when asserted, indicates that the FLL has started up and is providing an output clock. Each FLL also supports an 'FLL Lock' signal which indicates whether FLL Lock has been achieved.

The FLL Clock OK status and FLL Lock status are inputs to the Interrupt control circuit and can be used to trigger an Interrupt event - see "Interrupts".

The FLL Clock OK and FLL Lock signals can be output directly on a GPIO pin as an external indication of the FLL status. See "General Purpose Input / Output" to configure a GPIO pin for these functions.

Clock output signals derived from the FLL can be output on a GPIO pin. See "General Purpose Input / Output" to configure a GPIO pin for this function.

The FLL clocking configuration is illustrated in Figure 66.

EXAMPLE FLL CALCULATION

The following example illustrates how to derive the FLL1 registers to generate 49.152 MHz output (F_{OUT}) from a 12.000 MHz reference clock (F_{REF}):

- Set FLL1_REFCLK_DIV in order to generate $F_{REF} \leq 13.5\text{MHz}$:
FLL1_REFCLK_DIV = 00 (divide by 1)
- Set FLL1_OUTDIV for the required output frequency as shown in Table 91:-
 $F_{OUT} = 49.152\text{ MHz}$, therefore FLL1_OUTDIV = 2h (divide by 2)
- Set FLL1_FRATIO for the given reference frequency as shown in Table 92:
 $F_{REF} = 12\text{MHz}$, therefore FLL1_FRATIO = 0h (divide by 1)
- Calculate F_{VCO} as given by $F_{VCO} = F_{OUT} \times FLL1_OUTDIV$:-
 $F_{VCO} = 49.152 \times 2 = 98.304\text{MHz}$
- Calculate N.K as given by $N.K = F_{VCO} / (FLL1_FRATIO \times F_{REF})$:
 $N.K = 98.304 / (1 \times 12) = 8.192$
- Determine FLL1_N from the integer portion of N.K:-
FLL1_N = 8 (008h)
- Determine GCD(FLL), as given by $GCD(FLL) = GCD(FLL1_FRATIO \times F_{REF}, F_{VCO})$:
 $GCD(FLL) = GCD(1 \times 12000000, 98304000) = 96000$
- Determine FLL1_THETA, as given by
 $FLL1_THETA = (F_{VCO} - (FLL1_N \times FLL1_FRATIO \times F_{REF})) / GCD(FLL)$:
 $FLL1_THETA = (98304000 - (8 \times 1 \times 12000000)) / 96000$
FLL1_THETA = 24 (0018h)
- Determine FLL_LAMBDA, as given by
 $FLL1_LAMBDA = (FLL1_FRATIO \times F_{REF}) / GCD(FLL)$:
 $FLL1_LAMBDA = (1 \times 12000000) / 96000$
FLL1_LAMBDA = 125 (007Dh)

EXAMPLE FLL SETTINGS

Table 98 provides example FLL settings for generating 49.152MHz or 24.576MHz SYSCLK from a variety of low and high frequency reference inputs.

F _{SOURCE}	F _{OUT} (MHz)	F _{REF} Divider	N.K	FRATIO	F _{VCO} (MHz)	OUTDIV	FLLn_N	FLLn_THETA	FLLn_LAMBDA

26 MHz	24.576	2	7.5618	1	98.304	4	007h	0391h	0659h
27 MHz	49.152	2	7.2818	1	98.304	2	007h	013Dh	0465h
27 MHz	24.576	2	7.2818	1	98.304	4	007h	013Dh	0465h

$F_{OUT} = (F_{SOURCE} / F_{REF} \text{ Divider}) * N.K * FRATIO / OUTDIV$
 The values of N and K are contained in the FLLn_N, FLLn_THETA and FLLn_LAMBDA registers as shown above.
 See Table 94 and Table 95 for the coding of the FLLn_REFCLK_DIV, FLLn_FRATIO and FLLn_OUTDIV registers.

Table 98 Example FLL Settings

CONTROL INTERFACE

The WM5102 is controlled by writing to its control registers. Readback is available for all registers. Two independent Control Interfaces are provided, giving flexible capability as described below. Note that the SLIMbus interface also supports read/write access to the WM5102 control registers - see "SLIMBus Interface".

Note that the Control Interface function can be supported with or without system clocking. Where applicable, the register map access is synchronised with SYSCLK in order to ensure predictable operation of cross-domain functions. See "Clocking and Sample Rates" for further details of Control Interface clocking.

When SYSCLK is present and enabled, register access is possible on all of the Control Interfaces (including SLIMbus) simultaneously.

When SYSCLK is disabled, then register access will only be supported on whichever interface (I2C, SPI, or SLIMbus) is the first to attempt any register access after SYSCLK has stopped. Full access via all interfaces will be restored when SYSCLK is enabled.

The WM5102 executes a Boot Sequence following Power-On Reset (POR), Hardware Reset, Software Reset or Wake-Up (from Sleep mode). Note that Control Register writes should not be attempted until the Boot Sequence has completed. See "Power-On Reset (POR)" for further details.

The WM5102 performs automatic checks to confirm that the control interface does not attempt a Read or Write operation to an invalid register address. The Control Interface Address Error condition can be monitored using the GPIO and/or Interrupt functions. See "General Purpose Input / Output" and "Interrupts" for further details.

Control Interface 1 (CIF1) is a 2-wire (I2C) interface, comprising the following pins:

- CIF1SDA - serial interface data input/output
- CIF1SCLK - serial interface clock input
- CIF1ADDR - logic level controlling the I2C device ID

Control Interface 2 (CIF2) is a 4-wire (SPI) interface, comprising the following pins:

- CIF2MOSI - SPI data input
- CIF2MISO - SPI data output
- CIF2SCLK - SPI clock input
- $\overline{\text{CIF1SS}}$ - SPI Slave Select input (active low)

A detailed description of the 2-wire (I2C) interface and 4-wire (SPI) interfaces is provided in the following sections. The Control Interface configuration registers are described in Table 99.

Table 99 Control Interface Configuration

2-WIRE (I2C) CONTROL MODE

The 2-wire (I2C) Control Interface mode is supported on CIF1 only, and uses the corresponding SCLK, SDA pins. The ADDR pin is also used to select the I2C Device ID.

In 2-wire (I2C) mode, the WM5102 is a slave device on the control interface; SCLK is a clock input, while SDA is a bi-directional data pin. To allow arbitration of multiple slaves (and/or multiple masters) on the same interface, the WM5102 transmits logic 1 by tri-stating the SDA pin, rather than pulling it high. An external pull-up resistor is required to pull the SDA line high so that the logic 1 can be recognised by the master.

In order to allow many devices to share a single 2-wire control bus, every device on the bus has a unique 8-bit device ID (this is not the same as the address of each register in the WM5102).

The CIF1 device ID is selectable using the CIF1ADDR pin, as described in Table 100. The LSB of the Device ID is the Read/Write bit; this bit is set to logic 1 for "Read" and logic 0 for "Write".

The CIF1ADDR logic level is referenced to the DBVDD1 power domain. An internal pull-down resistor is enabled by default on the CIF1ADDR pin; this can be configured using the ADDR_PD register bit described in Table 99.

CIF1ADDR	DEVICE ID (CIF1)
Logic 0	0011 010x = 34h (write) / 35h (read)
Logic 1	0011 011x = 36h (write) / 37h (read)

Table 100 Control Interface Device ID Selection

The WM5102 operates as a slave device only. The controller indicates the start of data transfer with a high to low transition on SDA while SCLK remains high. This indicates that a device ID, register address and data will follow. The WM5102 responds to the start condition and shifts in the next eight bits on SDA (8-bit device ID, including Read/Write bit, MSB first). If the device ID received matches the device ID of the WM5102, then the WM5102 responds by pulling SDA low on the next clock pulse (ACK). If the device ID is not recognised or the R/W bit is set incorrectly, the WM5102 returns to the idle condition and waits for a new start condition and valid address.

If the device ID matches the device ID of the WM5102, the data transfer continues as described below. The controller indicates the end of data transfer with a low to high transition on SDA while SCLK remains high. After receiving a complete address and data sequence the WM5102 returns to the idle state and waits for another start condition. If a start or stop condition is detected out of sequence at any point during data transfer (i.e. SDA changes while SCLK is high), the device returns to the idle condition.

The WM5102 supports the following read and write operations:

- Single write
- Single read
- Multiple write using auto-increment
- Multiple read using auto-increment

The sequence of signals associated with a single register write operation is illustrated in Figure 67.

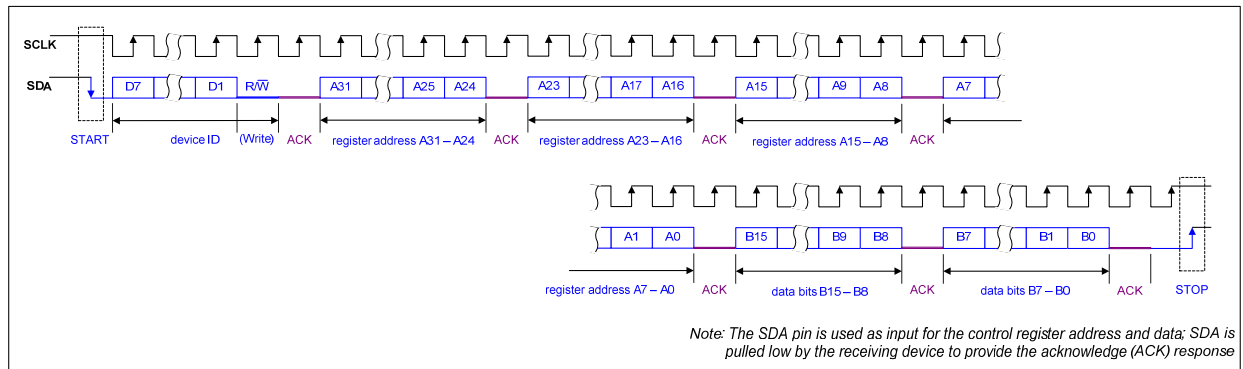

Figure 67 Control Interface 2-wire (I2C) Register Write

The sequence of signals associated with a single register read operation is illustrated in Figure 68.

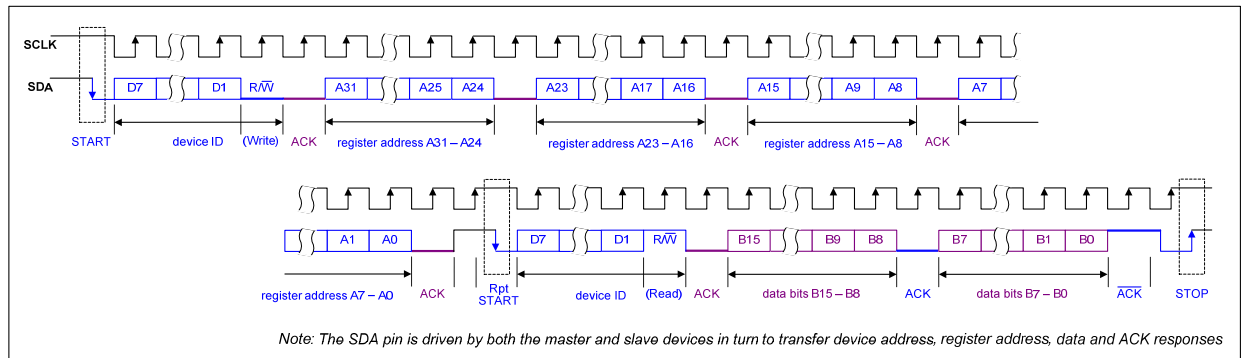

Figure 68 Control Interface 2-wire (I2C) Register Read

The Control Interface also supports other register operations, as listed above. The interface protocol for these operations is summarised below. The terminology used in the following figures is detailed in Table 101.

Note that, for multiple write and multiple read operations, the auto-increment option must be enabled. This feature is enabled by default, as noted in Table 99.

TERMINOLOGY		DESCRIPTION	
S		Start Condition	
Sr		Repeated start	
A		Acknowledge (SDA Low)	
\bar{A}		Not Acknowledge (SDA High)	
P		Stop Condition	
R/W	ReadNotWrite	0 = Write 1 = Read	
[White field]		Data flow from bus master to WM5102	
[Grey field]		Data flow from WM5102 to bus master	

Table 101 Control Interface (I2C) Terminology

Figure 69 Single Register Write to Specified Address

Figure 70 Single Register Read from Specified Address

Figure 71 Multiple Register Write to Specified Address using Auto-increment

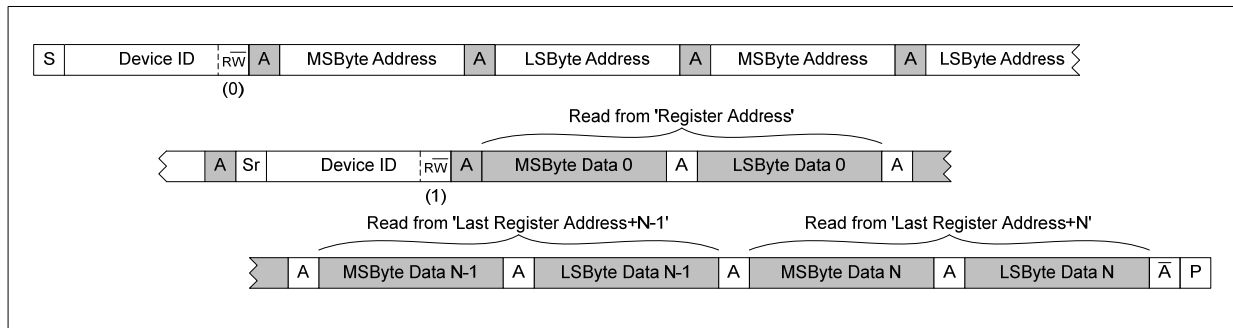

Figure 72 Multiple Register Read from Specified Address using Auto-increment

Figure 73 Multiple Register Read from Last Address using Auto-increment

Continuous read and write modes enable multiple register operations to be scheduled faster than is possible with single register operations. The auto-increment function supports selectable address increments for each successive register access. This function is controlled using the I2C1_AUTO_INC register. Auto-increment (by 1) is enabled by default, as described in Table 99.

4-WIRE (SPI) CONTROL MODE

The 4-wire (SPI) Control Interface mode is supported on CIF2 only, and uses the corresponding \overline{SS} , SCLK, MOSI and MISO pins.

The MISO output pin can be configured as CMOS or 'Wired OR', as described in Table 99. In CMOS mode, MISO is driven low when not outputting register data bits. In 'Wired OR' mode, MISO is undriven (high impedance) when not outputting register data bits.

In Write operations (R/W=0), all MOSI bits are driven by the controlling device.

In Read operations (R/W=1), the MOSI pin is ignored following receipt of the valid register address. MISO is driven by the WM5102.

Continuous read and write modes enable multiple register operations to be scheduled faster than is possible with single register operations. The auto-increment function supports selectable address increments for each successive register access. This function is controlled using the SPI_AUTO_INC register. Auto-increment (by 1) is enabled by default, as described in Table 99.

When auto-increment is enabled, the WM5102 will increment the register address at the end of the sequences illustrated below, and every 16 clock cycles thereafter, for as long as \overline{SS} is held low and SCLK is toggled. Successive data words can be input/output every 16 clock cycles.

The 4-wire (SPI) protocol is illustrated in Figure 74 and Figure 75.

Figure 74 Control Interface 4-wire (SPI) Register Write

Figure 75 Control Interface 4-wire (SPI) Register Read

CONTROL WRITE SEQUENCER

The Control Write Sequencer is a programmable unit that forms part of the WM5102 control interface logic. It provides the ability to perform a sequence of register write operations with the minimum of demands on the host processor - the sequence may be initiated by a single operation from the host processor and then left to execute independently.

Default sequences for pop-suppressed start-up and shut-down of each headphone/earpiece output driver are provided (these are scheduled automatically when the respective output paths are enabled or disabled). Other control sequences can be programmed, and may be associated with Jack Detect, Wake-Up or Sample Rate Detection functions - these sequences are automatically scheduled whenever a corresponding event is detected.

When a sequence is initiated, the sequencer performs a series of pre-defined register writes. The 'start index' of a control sequence within the sequencer's memory may be commanded directly by the host processor. In the case of a headphone or earpiece enable/disable event, or sequences associated with Jack Detect, Wake-Up or Sample Rate Detection, the applicable 'start index' is held in a user-programmed control register for each sequence.

The Control Write Sequencer may be triggered in a number of ways, as described above. Multiple sequences will be queued if necessary, and each is scheduled in turn. When all of the queued sequences have completed, the sequencer stops, and an Interrupt status flag is asserted.

A valid clock (SYSCLK) must be enabled whenever a Control Write Sequence is scheduled. See "Clocking and Sample Rates" for further details.

INITIATING A SEQUENCE

The Register fields associated with running the Control Write Sequencer are described in Table 102.

The Write Sequencer is enabled using the WSEQ_ENA bit. The index location of the first command in the selected sequence is held in the WSEQ_START_INDEX register.

Writing a '1' to the WSEQ_START bit commands the sequencer to execute a control sequence, starting at the given index. Note that, if the sequencer is already running, then the WSEQ_START command will be queued, and will be executed later when the sequencer becomes available.

The Write Sequencer can be interrupted by writing a '1' to the WSEQ_ABORT bit. Note that this command will only abort a sequence that is currently running; if other sequence commands are pending and not yet started, these sequences will not be aborted by writing to the WSEQ_ABORT bit.

The Write Sequencer stores up to 256 register write commands. These are defined in Registers R12288 (3000h) to R12799 (31FFh). Each of the 256 possible commands is defined in 2 control registers - see Table 108 for a description of these registers.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R22 (0016h) Write Sequencer Ctrl 0	11	WSEQ_ABORT	0	Writing a 1 to this bit aborts the current sequence.
	10	WSEQ_START	0	Writing a 1 to this bit starts the write sequencer at the index location selected by WSEQ_START_INDEX. At the end of the sequence, this bit will be reset by the Write Sequencer.
	9	WSEQ_ENA	0	Write Sequencer Enable 0 = Disabled 1 = Enabled Only applies to sequences triggered using the WSEQ_START bit.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
	8:0	WSEQ_START_INDEX [8:0]	000h	Sequence Start Index This field contains the index location in the sequencer memory of the first command in the selected sequence. Only applies to sequences triggered using the WSEQ_START bit. Valid from 0 to 255 (0FFh).

Table 102 Write Sequencer Control - Initiating a Sequence

AUTOMATIC SAMPLE RATE DETECTION SEQUENCES

The WM5102 supports automatic sample rate detection on the digital audio interfaces (AIF1, AIF2 and AIF3), when operating in AIF Slave mode. Automatic sample rate detection is enabled using the RATE_EST_ENA register bit (see Table 90).

Up to four audio sample rates can be configured for automatic detection; these sample rates are selected using the SAMPLE_RATE_DETECT_n registers. If one of the selected audio sample rates is detected, then the Control Write Sequencer will be triggered. The applicable start index location within the sequencer memory is separately configurable for each detected sample rate.

The WSEQ_SAMPLE_RATE_DETECT_A_INDEX register defines the sequencer start index corresponding to the SAMPLE_RATE_DETECT_A sample rate. Equivalent start index values are defined for the other sample rates, as described in Table 103.

Note that a sequencer start index of 1FFh will cause the respective sequence to be aborted.

The automatic sample rate detection control sequences are undefined following Power-On Reset (POR), but can be user-programmed after power-up. Note that all control sequences are maintained in the sequencer memory through Hardware Reset, Software Reset and in Sleep mode.

See "Clocking and Sample Rates" for further details of the automatic sample rate detection function.

Table 103 Write Sequencer Control - Automatic Sample Rate Detection

JACK DETECT, GPIO, MICDET CLAMP, AND WAKE-UP SEQUENCES

The WM5102 supports external accessory detection and GPIO functions. The JD1 signal (associated with external accessory detection) and the GP5 signal (associated with the GPIO5 pin) can be used to trigger the Control Write Sequencer.

The JD1 signal is configured using the register bits described in Table 67. The GP5 signal is derived from the GPIO5 pin, which is configured using the register bits described in Table 76.

The MICDET Clamp is controlled by the JD1 and/or GP5 signals, as described in Table 68. The MICDET Clamp status can also be used to trigger the Control Write Sequencer.

A Control Write Sequence can be associated with a rising edge and/or a falling edge of the JD1, GP5 or MICDET Clamp. This is configured using the register bits described in Table 75.

If one of the selected logic conditions is detected, then the Control Write Sequencer will be triggered. The applicable start index location within the sequencer memory is separately configurable for each logic condition.

The WSEQ_GP5_RISE_INDEX register defines the sequencer start index corresponding to a GP5 Rising Edge event. Equivalent start index values are defined for the other logic conditions, as described in Table 104.

Note that a sequencer start index of 1FFh will cause the respective sequence to be aborted.

The JD1, GP5 and MICDET Clamp control sequences are undefined following Power-On Reset (POR), but can be user-programmed after power-up. Note that all control sequences are maintained in the sequencer memory through Hardware Reset, Software Reset and in Sleep mode.

See “Low Power Sleep Configuration” for further details of the JD1, GP5 and MICDET Clamp status signals. See also “General Purpose Input / Output” for details of the GPIO5 pin.

Table 104 Write Sequencer Control - JD1, GP5 and MICDET Clamp

A valid clock (SYSCLK) must be enabled whenever a Control Write Sequence is scheduled.

If the JD1, GP5 or MICDET Clamp trigger status bits are associated with the Control Write Sequencer (using the register bits in Table 75) and also configured as Wake-Up events (using the register bits in Table 74), then the Boot Sequence must be programmed to configure and enable SYSCLK. (Note that the default SYSCLK frequency must be used in this case.)

The Boot Sequence (see below) is scheduled as part of the Wake-Up transition, and provides the capability to configure SYSCLK (and other register settings) prior to the Control Write Sequencer being triggered.

Note that, if the Control Write Sequencer is triggered during normal operation, then SYSCLK will typically be already available, and no additional requirements will apply.

DRC SIGNAL DETECT SEQUENCES

The Dynamic Range Control (DRC) function within the WM5102 Digital Core provides a configurable signal detect function. This allows the signal level at the DRC input to be monitored and used to trigger other events.

The DRC Signal Detect function is enabled and configured using the register fields described in Table 14.

A Control Write Sequence can be associated with a rising edge and/or a falling edge of the DRC Signal Detect output. This is enabled using the DRC1_WSEQ_SIG_DET_ENA register bit.

When the DRC Signal Detect sequence is enabled, the Control Write Sequencer will be triggered whenever the Signal Detect output transitions (high or low). The applicable start index location within the sequencer memory is separately configurable for each logic condition.

The WSEQ_SIG_DET_RISE_SEQ_INDEX register defines the sequencer start index corresponding to a DRC Signal Detect Rising Edge event, as described in Table 105. The WSEQ_SIG_DET_FALL_SEQ_INDEX register defines the sequencer start index corresponding to a DRC Signal Detect Falling Edge event.

Note that a sequencer start index of 1FFh will cause the respective sequence to be aborted.

The DRC Signal Detect sequences cannot be independently enabled for rising and falling edges. Instead, a start index of 1FFh can be used to disable the sequence for either edge, if required.

The DRC Signal Detect control sequences are undefined following Power-On Reset (POR), but can be user-programmed after power-up. Note that all control sequences are maintained in the sequencer memory through Hardware Reset, Software Reset and in Sleep mode.

See “Digital Core” for further details of the Dynamic Range Control (DRC) function.

Table 105 Write Sequencer Control - DRC Signal Detect

BOOT SEQUENCE

The WM5102 executes a Boot Sequence following Power-On Reset (POR), Hardware Reset, Software Reset or Wake-Up (from Sleep mode).

See “Power-On Reset (POR)” and “Hardware Reset, Software Reset, Wake-Up, and Device ID” for further details.

The Boot Sequence is undefined following Power-On Reset (POR), but can be user-programmed after power-up. Note that all control sequences are maintained in the sequencer memory through Hardware Reset, Software Reset and in Sleep mode.

If the Boot Sequence is programmed to enable SYSCLK, note that the default SYSCLK frequency must be used. If a different SYSCLK frequency is required, this must be configured after the Boot Sequence has completed.

The start index location of the the Boot Sequence is 192 (0C0h).

The Boot Sequence can be commanded at any time by writing ‘1’ to the WSEQ_BOOT_START bit.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R24 (0018h) Write Sequencer Ctrl 2	1	WSEQ_BOOT_START	0	Writing a 1 to this bit starts the write sequencer at the index location configured for the Boot Sequence. The Boot Sequence start index is 192 (0C0h).

Table 106 Write Sequencer Control - Boot Sequence

SEQUENCER OUTPUTS AND READBACK

The status of the Write Sequencer can be read using the WSEQ_BUSY and WSEQ_CURRENT_INDEX registers, as described in Table 107.

When the WSEQ_BUSY bit is asserted, this indicates that the Write Sequencer is busy.

The index address of the most recent Write Sequencer command can be read from the WSEQ_CURRENT_INDEX field. This can be used to provide a precise indication of the Write Sequencer progress.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R23 (0017h) Write Sequencer Ctrl 1	9	WSEQ_BUSY (read only)	0	Sequencer Busy flag (Read Only). 0 = Sequencer idle 1 = Sequencer busy
	8:0	WSEQ_CURREN T_INDEX [8:0] (read only)	000h	Sequence Current Index. This indicates the memory location of the most recently accessed command in the write sequencer memory. Coding is the same as WSEQ_START_INDEX.

Table 107 Write Sequencer Control - Status Readback

The Write Sequencer status is an input to the Interrupt control circuit and can be used to trigger an Interrupt event - see "Interrupts".

The Write Sequencer status can be output directly on a GPIO pin as an external indication of the Write Sequencer. See "General Purpose Input / Output" to configure a GPIO pin for this function.

PROGRAMMING A SEQUENCE

A Control Write Sequence comprises a series of write operations to data bits (or groups of bits) within the control register map. Each write operation is defined by a block of 2 registers, each containing 5 fields, as described below.

The block of 2 registers is replicated 256 times, defining each of the sequencer's 256 possible index addresses. Many sequences can be stored in the sequencer memory at the same time, with each assigned a unique range of index addresses.

The WSEQ_DELAY_n register is used to identify the 'end of sequence' position, as described below.

Note that, in the following descriptions, the term 'n' denotes the sequencer index address (valid from 0 to 255).

WSEQ_DATA_WIDTH_n is a 3-bit field which identifies the width of the data block to be written. Note that the maximum value of this field selects a width of 8-bits; writing to register fields greater than 8 bits wide must be performed using two separate operations of the Write Sequencer.

WSEQ_ADDR_n is a 13-bit field containing the register address in which the data should be written.

WSEQ_DELAY_n is a 4-bit field which controls the waiting time between the current step and the next step in the sequence (ie. the delay occurs after the write in which it was called). The total delay time per step (including execution) is defined below, giving a useful range of execution/delay times from 3.3µs up to 1s per step. Setting this field to 0xF identifies the step as the last in the sequence.

If WSEQ_DELAY_n = 0h or Fh, the step execution time is 3.3µs

For all other values, the step execution time is $61.44\mu\text{s} \times ((2^{\text{WSEQ_DELAY}}) - 1)$

WSEQ_DATA_START_n is a 4-bit field which identifies the LSB position within the selected control register to which the data should be written. For example, setting WSEQ_DATA_START_n = 0100 will

select bit 4 as the LSB position of the data to be written.

WSEQ_DATA n is an 8-bit field which contains the data to be written to the selected control register. The WSEQ_DATA_WIDTH n field determines how many of these bits are written to the selected control register; the most significant bits (above the number indicated by WSEQ_DATA_WIDTH n) are ignored.

The register definitions for Step 0 are described in Table 108. The equivalent definitions also apply to Step 1 through to Step 255, in the subsequent register address locations.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R12288 (3000h) WSEQ Sequence 1	15:13	WSEQ_DATA_WIDTH0 [2:0]	000	Width of the data block written in this sequence step. 000 = 1 bit 001 = 2 bits 010 = 3 bits 011 = 4 bits 100 = 5 bits 101 = 6 bits 110 = 7 bits 111 = 8 bits
	12:0	WSEQ_ADDR0 [12:0]	0000h	Control Register Address to be written to in this sequence step.
R12289 (3001h) WSEQ Sequence 2	15:12	WSEQ_DELAY0 [3:0]	0000	Time delay after executing this step. 00h = 3.3us 01h to 0Eh = 61.44us x ((2 ^{WSEQ_DELAY})-1) 0Fh = End of sequence marker
	11:8	WSEQ_DATA_S TART0 [3:0]	0000	Bit position of the LSB of the data block written in this sequence step. 0000 = Bit 0 ... 1111 = Bit 15
	7:0	WSEQ_DATA0 [7:0]	00h	Data to be written in this sequence step. When the data width is less than 8 bits, then one or more of the MSBs of WSEQ_DATA n are ignored. It is recommended that unused bits be set to 0.

Table 108 Write Sequencer Control - Programming a Sequence

SEQUENCER MEMORY DEFINITION

The Write Sequencer memory defines up to 256 write operations; these are indexed as 0 to 255 in the sequencer memory map.

Following Power-On Reset (POR), the sequence memory will contain only the Headphone/Earpiece Enable and Headphone/Earpiece Disable sequence definitions. The remainder of the sequence memory will be undefined on power-up.

User-defined sequences can be programmed after power-up. Note that all control sequences are maintained in the sequencer memory through Hardware Reset, Software Reset and in Sleep mode.

The default control sequences can be overwritten in the sequencer memory, if required. Note that the headphone and earpiece output path enable registers (HP n _ENA, EP n _ENA) will always trigger the Write Sequencer (at the pre-determined start index addresses).

Writing '1' to the WSEQ_LOAD_MEM bit will clear the sequencer memory to the POR state.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R24 (0018h) Write Sequencer Ctrl 2	0	WSEQ_LOAD_MEM	0	Writing a 1 to this bit resets the sequencer memory to the POR state.

Table 109 Write Sequencer Control - Load Memory Control

User-defined sequences must be assigned space within the Write Sequencer memory. The start index for the user-defined sequences is configured using the registers described in Table 103 and Table 104. The Boot Sequence has a fixed start address, as referenced in Table 106.

The sequencer memory is illustrated in Figure 76. The pre-programmed sequencer index locations are highlighted. User-defined sequences should be programmed in other areas of the sequencer memory.

Figure 76 Write Sequencer Memory

Further details of the pre-programmed sequencer index locations are provided in Table 110.

SEQUENCE NAME	START INDEX	DEFAULT SEQUENCE INDEX RANGES
HPOUT1L Enable	0 (000h)	0 to 11
HPOUT1L Disable	24 (018h)	24 to 27
HPOUT1R Enable	32 (020h)	32 to 43

EPOUT Disable	144 (090h)	144 to 147
Boot Sequence	192 (0C0h)	

Table 110 Default Sequencer Memory Allocation

CHARGE PUMPS, REGULATORS AND VOLTAGE REFERENCE

The WM5102 incorporates two Charge Pump circuits and two LDO Regulator circuits to generate supply rails for internal functions and to support external microphone requirements. The WM5102 also provides three MICBIAS generators which provide low noise reference voltages suitable for biasing electret condenser (ECM) type microphones or powering digital microphones.

Refer to the “Applications Information” section for recommended external components.

CHARGE PUMPS AND LDO2 REGULATOR

Charge Pump 1 (CP1) is used to generate the positive and negative supply rails for the analogue output drivers. CP1 is enabled automatically by the WM5102 when required by the output drivers.

Charge Pump 2 (CP2) powers LDO2, which provides the supply rail for analogue input circuits and for the MICBIAS generators. CP2 and LDO2 are enabled using the CP2_ENA register bit.

The 32kHz clock must be configured and enabled when using CP2. See “Clocking and Sample Rates” for details of the system clocks.

When CP2 and LDO2 are enabled, the MICVDD voltage can be selected using the LDO2_VSEL control field. Note that, when one or more of the MICBIAS generators is operating in normal (regulator) mode, then the MICVDD voltage must be at least 200mV greater than the highest selected MICBIAS_n output voltage(s).

When CP2 and LDO2 are enabled, an internal bypass path may be selected, connecting the MICVDD pin directly to the CPVDD supply. This path is controlled using the CP2_BYPASS register. Note that the bypass path is only supported when CP2 is enabled.

When CP2 is disabled, the CP2VOUT pin can be configured to be floating or to be actively discharged. This is selected using the CP2_DISCH register bit.

When LDO2 is disabled, the MICVDD pin can be configured to be floating or to be actively discharged. This is selected using the LDO2_DISCH register bit.

The MICVDD pin is connected to the output of LDO2. Note that the MICVDD does not support direct connection to an external supply; MICVDD is always powered internally to the WM5102.

The Charge Pumps and LDO2 Regulator circuits are illustrated in Figure 77. The associated register control bits are described in Table 111.

Note that decoupling capacitors and flyback capacitors are required for these circuits. Refer to the “Applications Information” section for recommended external components.

MICBIAS BIAS (MICBIAS) CONTROL

There are three MICBIAS generators which provide low noise reference voltages suitable for biasing electret condenser (ECM) type microphones or powering digital microphones. Refer to the “Applications Information” section for recommended external components.

The MICBIAS generators are powered from MICVDD, which is generated by an internal Charge Pump and LDO, as illustrated in Figure 77.

The MICBIAS outputs can be independently enabled using the MICB_n_ENA register bits (where $n = 1, 2$ or 3 for MICBIAS_{1, 2} or 3 respectively).

When a MICBIAS output is disabled, the output pin can be configured to be floating or to be actively discharged. This is selected using the MICB_n_DISCH register bits.

The MICBIAS generators can each operate as a voltage regulator or in bypass mode. The applicable mode is selected using the MICB_n_BYPASS registers.

In Regulator mode, the output voltage is selected using the MICB_n_LVL register bits. In this mode, MICVDD must be at least 200mV greater than the required MICBIAS output voltages. The MICBIAS

outputs are powered from the MICVDD pin, and use the internal bandgap circuit as a reference.

In Regulator mode, the MICBIAS regulators are designed to operate without external decoupling capacitors. The regulators can be configured to support a capacitive load if required, using the MICBn_EXT_CAP register bits. (This may be appropriate for a digital microphone supply.) It is important that the external capacitance is compatible with the applicable MICBn_EXT_CAP setting. The compatible load conditions are detailed in the “Electrical Characteristics” section.

In Bypass mode, the output pin (MICBIAS1, MICBIAS2 or MICBIAS3) is connected directly to MICVDD. This enables a low power operating state. Note that the MICBn_EXT_CAP register settings are not applicable in Bypass mode.

The MICBIAS generators incorporate a pop-free control circuit to ensure smooth transitions when the MICBIAS outputs are enabled or disabled in Bypass mode; this feature is enabled using the MICBn_RATE registers.

The MICBIAS generators are illustrated in Figure 77. The MICBIAS control register bits are described in Table 111.

The maximum output current for each MICBIASn pin is noted in the “Electrical Characteristics”. This limit must be observed on each MICBIAS output, especially if more than one microphone is connected to a single MICBIAS pin. Note that the maximum output current differs between Regulator mode and Bypass mode.

VOLTAGE REFERENCE CIRCUIT

The WM5102 incorporates a voltage reference circuit, powered by AVDD. This circuit ensures the accuracy of the LDO Regulator and MICBIAS voltage settings.

LDO1 REGULATOR AND DCVDD SUPPLY

The LDO1 voltage regulator is intended for generating the DCVDD domain, which powers the digital core functions on the WM5102. LDO1 is powered by LDOVDD and can be controlled using hardware or software controls.

Under hardware control, LDO1 is enabled when a logic ‘1’ is applied to the LDOENA pin. The logic level is determined with respect to the DBVDD1 voltage domain. LDO1 is also enabled when the LDO1_ENA software control register is set to 1. Note that, to disable LDO1, the hardware and software controls must both be de-asserted.

When LDO1 is enabled, an internal bypass path may be selected, connecting the LDOVOUT pin directly to the LDOVDD supply. This path is controlled using the LDO1_BYPASS register. Note that the bypass path is only supported when LDO1 is enabled.

When LDO1 is disabled, the LDOVOUT pin can be configured to be floating or to be actively discharged. This is selected using the LDO1_DISCH register bit.

When LDO1 is enabled, the LDOVOUT voltage can be controlled using the LDO1_VSEL register. Setting LDO1_HI_PWR=1 will override the LDO1_VSEL register and select 1.8V LDO output voltage. Note that, under default conditions, LDO1_HI_PWR is set to ‘1’.

It is possible to supply DCVDD from an external supply; separate LDOVOUT and DCVDD pins are provided for flexibility.

For recommended use of the Sleep / Wake-Up functions (see “Low Power Sleep Configuration”), it is assumed that DCVDD is powered from the output of LDO1. In this case, Sleep mode is selected by setting LDO1_ENA=0. The AVDD, DBVDD1 and LDOVDD supplies must be present, and the LDOENA pin held low, allowing the WM5102 registers to control LDO1.

If DCVDD is powered externally (not from LDO1), then the ISOLATE_DCVDD1 register bit must be controlled as described in Table 111 when selecting WM5102 Sleep mode. In this case, only the AVDD and DBVDD1 supplies are required in Sleep mode.

An internal pull-down resistor is enabled by default on the LDOENA pin. This is configurable using the LDO1ENA_PD register bit.

The LDO1 Regulator circuit is illustrated in Figure 77. The associated register control bits are described in Table 111.

Note that a decoupling capacitor is recommended. Refer to the "Applications Information" section for recommended external components.

BLOCK DIAGRAM AND CONTROL REGISTERS

The Charge Pump and Regulator circuits are illustrated in Figure 77. Note that decoupling capacitors and flyback capacitors are required for these circuits. Refer to the "Applications Information" section for recommended external components.

Table 112 LDO2 Voltage Control

JTAG INTERFACE

The JTAG interface provides test and debug access to the WM5102 DSP core. The interface comprises 5 pins, as detailed below.

- TCK: Clock input
- TDI: Data input
- TDO: Data output
- TMS: Mode select input
- TRST: Test Access Port reset input (active low, internal pull-down)

For normal operation (test and debug access disabled), the JTAG interface should be held in reset (ie. TRST should be at logic 0). An internal pull-down resistor holds the TRST pin low when not actively driven.

The other JTAG input pins (TCK, TDI, TMSDSP) should also be held at logic 0 for normal operation.

THERMAL SHUTDOWN

The WM5102 incorporates a temperature sensor which detects when the device temperature is within normal limits or if the device is approaching a hazardous temperature condition.

The temperature sensor is an input to the Interrupt control circuit and can be used to trigger an Interrupt event - see "Interrupts".

The Warning Temperature and Shutdown Temperature status flags can be output directly on a GPIO pin as an external indication of the temperature sensor. See "General Purpose Input / Output" to configure a GPIO pin for this function.

It is strongly recommended that the speaker drivers be disabled if the Shutdown Temperature condition occurs.

POWER-ON RESET (POR)

The WM5102 will remain in the reset state until AVDD, DBVDD1 and DCVDD are all above their respective reset thresholds. Note that specified device performance is not assured outside the voltage ranges defined in the "Recommended Operating Conditions" section.

Refer to "Recommended Operating Conditions" for the WM5102 power-up sequencing requirements.

Following Power-On Reset (POR), a Boot Sequence is executed. The BOOT_DONE_STS register is asserted on completion of the Boot Sequence, as described in Table 113. Control register writes should not be attempted until the BOOT_DONE_STS register has been asserted.

The BOOT_DONE_STS signal is an input to the Interrupt control circuit and can be used to trigger an Interrupt event - see "Interrupts". Under default register conditions, a falling edge on the $\overline{\text{IRQ}}$ pin will indicate completion of the Boot Sequence.

The BOOT_DONE_STS signal can be output directly on a GPIO pin as an external indication of the Boot Sequence. See "General Purpose Input / Output" to configure a GPIO pin for this function.

For details of the Boot Sequence, see "Control Write Sequencer".

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R3363 (0D23h) Interrupt Raw Status 5	8	BOOT_DONE_S TS	0	Boot Status 0 = Busy (boot sequence in progress) 1 = Idle (boot sequence completed) Control register writes should not be attempted until Boot Sequence has completed.

Table 113 Device Boot-Up Status

The WM5102 is in Sleep mode when AVDD and DBVDD1 are present, and DCVDD is below its reset threshold. (Note that specific control requirements are also applicable for entering Sleep mode, as described in “Low Power Sleep Configuration”.)

In Sleep mode, most of the Digital Core (and control registers) are held in reset; selected functions and control registers are maintained via an ‘Always-On’ internal supply domain. See “Low Power Sleep Configuration” for details of the ‘Always-On’ functions.

See “Hardware Reset, Software Reset, Wake-Up, and Device ID” for details of the Wake-Up transition (exit from Sleep mode).

Table 114 describes the default status of the WM5102 digital I/O pins on completion of Power-On Reset, prior to any register writes. The same default conditions are also applicable on completion of a Hardware Reset or Software Reset (see “Hardware Reset, Software Reset, Wake-Up, and Device ID”).

The same default conditions are applicable following a Wake-Up transition, except for the GPIO5, IRQ, LDOENA, MCLK2 and RESET pins. These are ‘Always-On’ pins whose configuration is unchanged in Sleep mode and during a Wake-Up transition.

Note that the default conditions described in Table 114 will not be valid if modified by the Boot Sequence or by a ‘Wake-Up’ control sequence. See “Control Write Sequencer” for details of these functions.

Table 114 WM5102 Digital I/O Status in Reset

Note that the dual function INnLN/DMICCLKn and INnRN/DMICDATn pins default to their respective analogue input functions after Power-On Reset is completed. The analogue input functions are referenced to the MICVDD power domain.

HARDWARE RESET, SOFTWARE RESET, WAKE-UP, AND DEVICE ID

The WM5102 provides a Hardware Reset function, which is executed whenever the $\overline{\text{RESET}}$ input is asserted (logic 0). The RESET input is active low and is referenced to the DBVDD1 power domain.

A Hardware Reset causes most of the WM5102 control registers to be reset to their default states. Note that the Control Write Sequencer memory and DSP firmware is not affected by Hardware Reset.

An internal pull-up resistor is enabled by default on the $\overline{\text{RESET}}$ pin; this can be configured using the RESET_PU register bit described in Table 115.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R3104 (0C20h) Misc Pad Ctrl 1	1	RESET_PU	1	RESET Pull-up enable 0 = Disabled 1 = Enabled

Table 115 Reset Pull-Up Configuration

A Software Reset is executed by writing any value to register R0. A Software Reset causes most of the WM5102 control registers to be reset to their default states. Note that the Control Write Sequencer memory and DSP firmware memory is not affected by Software Reset.

A Wake-Up transition (from Sleep mode) is similar to a Software Reset, but selected functions and control registers are maintained via an 'Always-On' internal supply domain. The 'Always-On' registers are not reset during Wake-Up. See "Low Power Sleep Configuration" for details of the 'Always-On' functions.

The Control Write Sequencer memory is not affected by Hardware Reset, Software Reset or Sleep mode; these registers are only reset following a Power-On Reset (POR).

Following Hardware Reset, Software Reset or Wake-Up (from Sleep mode), a Boot Sequence is executed. The BOOT_DONE_STS register (see Table 113) is de-asserted during Hardware Reset, Software Reset and in Sleep mode. The BOOT_DONE_STS register is asserted on completion of the boot-up sequence. Control register writes should not be attempted until the BOOT_DONE_STS register has been asserted.

The BOOT_DONE_STS signal is an input to the Interrupt control circuit and can be used to trigger an Interrupt event - see "Interrupts".

The BOOT_DONE_STS signal can be output directly on a GPIO pin as an external indication of the Boot Sequence. See "General Purpose Input / Output" to configure a GPIO pin for this function.

For details of the Boot Sequence, see "Control Write Sequencer".

The status of the WM5102 digital I/O pins following Hardware Reset, Software Reset or Wake-Up is described in the "Power-On Reset (POR)" section.

The Device ID can be read back from Register R0. The Revision can be read back from Register R1.

REGISTER ADDRESS	BIT	LABEL	DEFAULT	DESCRIPTION
R0 (0000h) Software Reset	15:0	SW_RST_DEV_ID [15:0]	5102h	Writing to this register resets all registers to their default state. Reading from this register will indicate Device ID 5102h.

APPLICATIONS INFORMATION

RECOMMENDED EXTERNAL COMPONENTS

ANALOGUE INPUT PATHS

The WM5102 provides up to 6 analogue audio input paths. Each of these inputs is referenced to the internal DC reference, VMID. A DC blocking capacitor is required for each analogue input pin used in the target application. The choice of capacitor is determined by the filter that is formed between that capacitor and the impedance of the input pin. The circuit is illustrated in Figure 78.

Figure 78 Audio Input Path DC Blocking Capacitor

In accordance with the WM5102 input pin resistance (see “Electrical Characteristics”), it is recommended that a 1µF capacitance for all input connections will give good results in most cases, with a 3dB cut-off frequency around 13Hz.

Ceramic capacitors are suitable, but care must be taken to ensure the desired capacitance is maintained at the AVDD operating voltage. Also, ceramic capacitors may show microphonic effects, where vibrations and mechanical conditions give rise to electrical signals. This is particularly problematic for microphone input paths where a large signal gain is required.

A single capacitor is required for a single-ended line or microphone input connection. For a differential input connection, a DC blocking capacitor is required on both input pins.

The external connections for single-ended and differential microphones, incorporating the WM5102 microphone bias circuit, are shown later in the “Microphone Bias Circuit” section - see Figure 79.

DIGITAL MICROPHONE INPUT PATHS

The WM5102 provides up to 6 digital microphone input paths; two channels of audio data can be multiplexed on each of the DMICDATn pins. Each of these stereo pairs is clocked using the respective DMICCLKn pin.

The external connections for digital microphones, incorporating the WM5102 microphone bias circuit, are shown later in the “Microphone Bias Circuit” section - see Figure 80.

Ceramic decoupling capacitors for the digital microphones may be required - refer to the specific recommendations for the application microphone(s).

When two microphones are connected to a single DMICDAT pin, the microphones must be configured to ensure that the Left mic transmits a data bit when DMICCLK is high, and the Right mic transmits a data bit when DMICCLK is low. The WM5102 samples the digital microphone data at the end of each DMICCLK phase. Each microphone must tri-state its data output when the other microphone is transmitting. Integrated pull-down resistors can be enabled on the DMICDAT pins if required.

The voltage reference for each digital microphone interface is selectable. It is important that the selected reference for the WM5102 interface is compatible with the applicable configuration of the external microphone.

MICROPHONE BIAS CIRCUIT

The WM5102 is designed to interface easily with up to 6 analogue or digital microphones.

Each microphone requires a bias current (electret condenser microphones) or voltage supply (silicon microphones); these can be provided by the MICBIAS1, MICBIAS2 or MICBIAS3 regulators on the WM5102.

Analogue microphones may be connected in single-ended or differential configurations, as illustrated in Figure 79. The differential configuration provides better performance due to its rejection of common-mode noise; the single-ended method provides a reduction in external component count.

A current-limiting resistor is required when using an electret condenser microphone (ECM). The resistance should be chosen according to the minimum operating impedance of the microphone and MICBIAS voltage so that the maximum bias current of the WM5102 is not exceeded.

A 2.2kΩ current-limiting resistor is recommended; this provides compatibility with a wide range of microphone components.

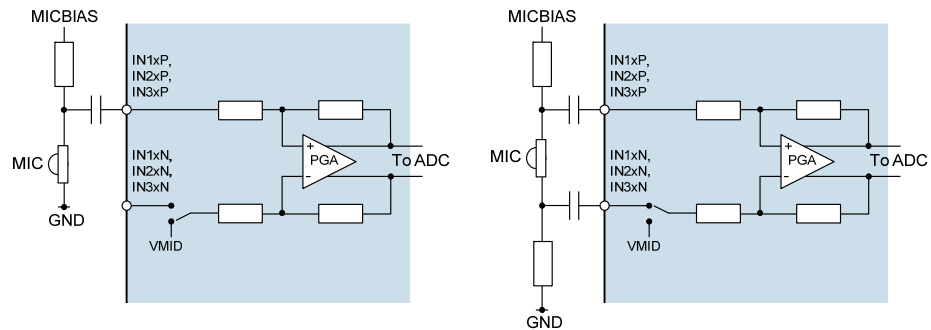

Figure 79 Single-Ended and Differential Analogue Microphone Connections

Digital microphone connection to the WM5102 is illustrated in Figure 80.

Ceramic decoupling capacitors for the digital microphones may be required - refer to the specific recommendations for the application microphone(s).

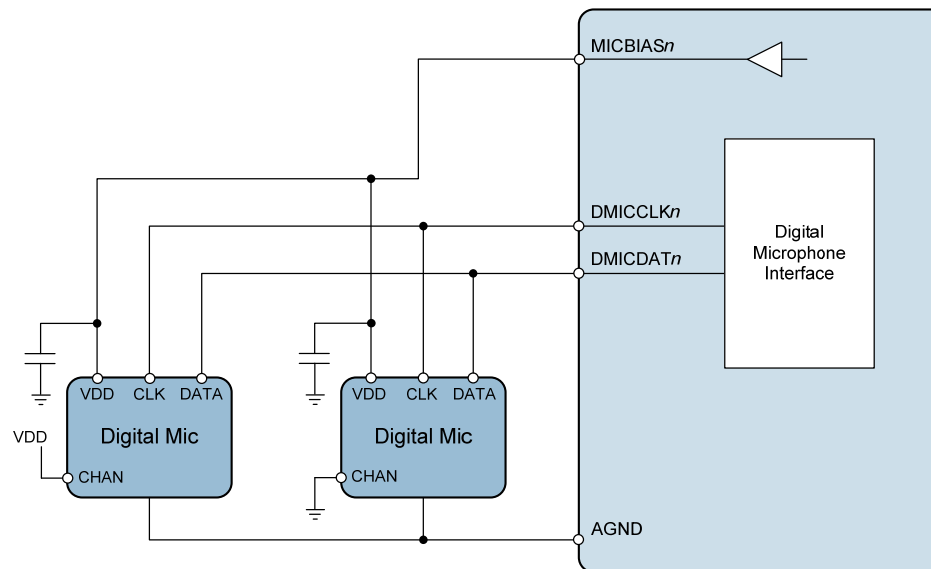

Figure 80 Digital Microphone Connection

The MICBIAS generators can each operate as a voltage regulator or in bypass mode. See “Charge Pumps, Regulators and Voltage Reference” for details of the MICBIAS generators.

In Regulator mode, the MICBIAS regulators are designed to operate without external decoupling capacitors. The regulators can be configured to support a capacitive load if required (eg. for digital microphone supply decoupling). The compatible load conditions are detailed in the “Electrical Characteristics” section.

If the capacitive load on MICBIAS1, MICBIAS2 or MICBIAS3 exceeds the specified conditions for Regulator mode (eg. due to a decoupling capacitor or long PCB trace), then the respective generator must be configured in Bypass mode.

The maximum output current for each MICBIAS n pin is noted in the “Electrical Characteristics”. This limit must be observed on each MICBIAS output, especially if more than one microphone is connected to a single MICBIAS pin. Note that the maximum output current differs between Regulator mode and Bypass mode. The MICBIAS output voltage can be adjusted using register control in Regulator mode.

HEADPHONE/EARPIECE DRIVER OUTPUT PATH

The WM5102 provides 2 stereo headphone and 1 mono earpiece output drivers. These outputs are all ground-referenced, allowing direct connection to the external load(s). There is no requirement for DC blocking capacitors.

In single-ended (default) configuration, the headphone outputs comprise 4 independently controlled output channels, for up to 2 stereo headphone or line outputs. In mono (BTL) mode, the headphone drivers support up to 2 differential outputs, suitable for a mono earpiece or hearing coil load.

The headphone outputs incorporate a common mode, or ground loop, feedback path which provides rejection of system-related ground noise. The feedback pins must be connected to ground for normal operation of the headphone outputs. Two alternate feedback pins are configurable for the HPOUT1L and HPOUT1R drivers.

The feedback pins should be connected to GND close to the respective headphone jack, as illustrated in Figure 81. In mono (differential) mode, the feedback pin(s) should be connected to the ground plane that is physically closest to the earpiece output PCB tracks.

The mono earpiece output is supported on the EPOUTP and EPOUTN pins. The output configuration is differential (BTL), suitable for direct connection to an external earpiece or hearing coil load.

Typical headphone and earpiece connections are illustrated in Figure 81.

It is recommended to ensure that the electrical characteristics of the PCB traces for each output pair are closely matched. This is particularly important to matching the two traces of a differential (BTL) output.

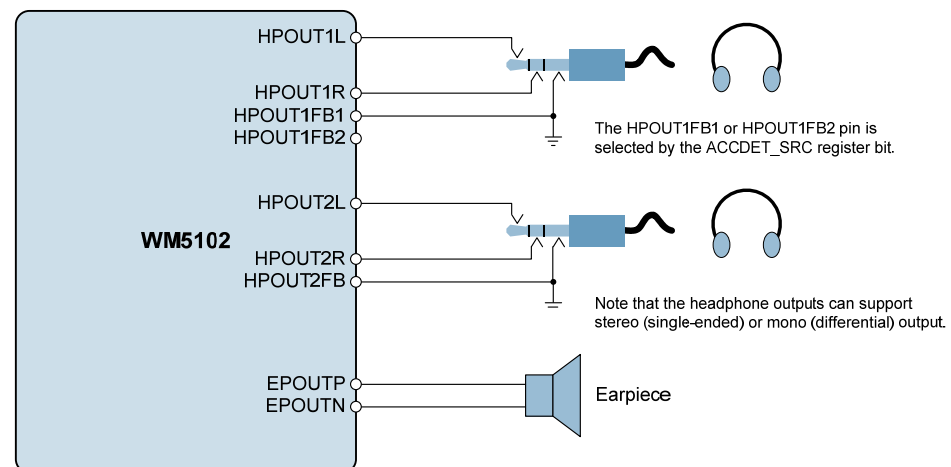

Figure 81 Headphone and Earpiece Connection

It is common for ESD diodes to be wired to pins that link to external connectors. This provides protection from potentially harmful ESD effects. In a typical application, ESD diodes would be recommended for both headphone paths (HPOUT1 and HPOUT2), when used as external headphone or line output.

The HPOUT1 and HPOUT2 outputs are ground-referenced, and the respective voltages may swing between +1.8V and -1.8V. The ESD diode configuration must be carefully chosen.

The recommended ESD diode configuration for these ground-referenced outputs is illustrated in Figure 82. The 'back-to-back' arrangement is necessary in order to prevent clipping and distortion of the output signal.

Note that similar care is required when connecting the WM5102 outputs to external circuits that provide input path ESD protection - the configuration on those input circuits must be correctly designed to accommodate ground-referenced signals.

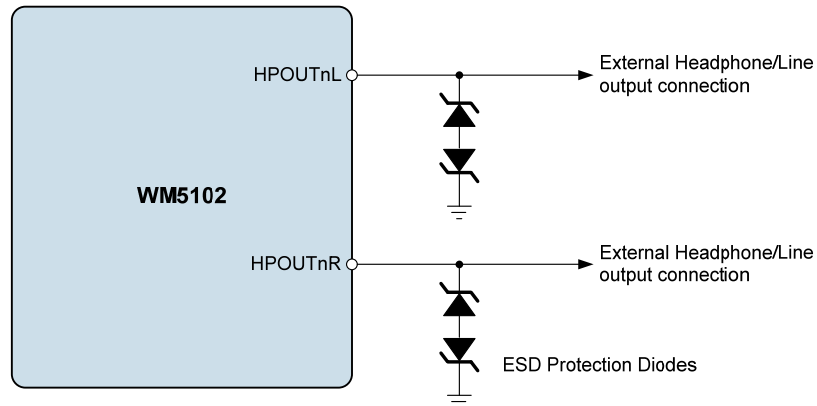

Figure 82 ESD Diode Configuration for External Output Connections

SPEAKER DRIVER OUTPUT PATH

The WM5102 incorporates two Class D speaker drivers, offering high amplifier efficiency at large signal levels. As the Class D output is a pulse width modulated signal, the choice of speakers and tracking of signals is critical for ensuring good performance and reducing EMI in this mode.

The efficiency of the speaker drivers is affected by the series resistance between the WM5102 and the speaker (e.g. PCB track loss and inductor ESR) as shown in Figure 83. This resistance should be as low as possible to maximise efficiency.

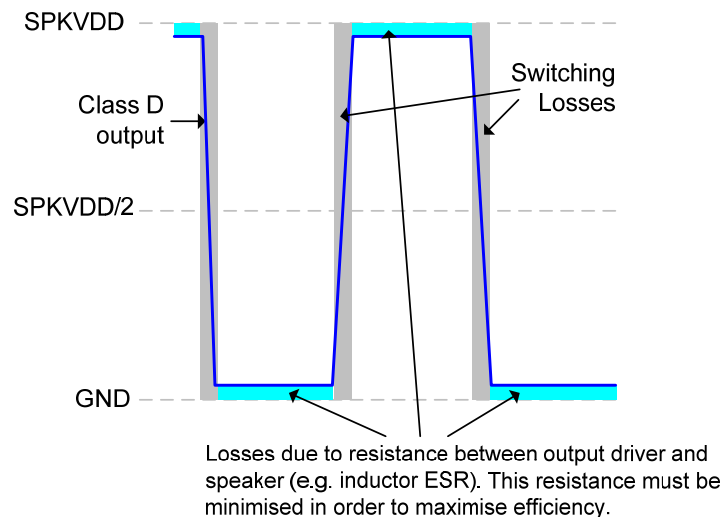

Figure 83 Speaker Connection Losses

The Class D output requires external filtering in order to recreate the audio signal. This may be implemented using a 2nd order LC or 1st order RC filter, or else may be achieved by using a loudspeaker whose internal inductance provides the required filter response. An LC or RC filter should be used if the loudspeaker characteristics are unknown or unsuitable, or if the length of the

loudspeaker connection is likely to lead to EMI problems.

In applications where it is necessary to provide Class D filter components, a 2nd order LC filter is the recommended solution as it provides more attenuation at higher frequencies and minimises power dissipated in the filter when compared to a first order RC filter (lower ESR). This maximises both rejection of unwanted switching frequencies and overall speaker efficiency. A suitable implementation is illustrated in Figure 84.

Figure 84 Class D Output Filter Components

A simple equivalent circuit of a loudspeaker consists of a serially connected resistor and inductor, as shown in Figure 85. This circuit provides a low pass filter for the speaker output. If the loudspeaker characteristics are suitable, then the loudspeaker itself can be used in place of the filter components described earlier. This is known as 'filterless' operation.

Figure 85 Speaker Equivalent Circuit for Filterless Operation

For filterless Class D operation, it is important to ensure that a speaker with suitable inductance is chosen. For example, if we know the speaker impedance is 8Ω and the desired cut-off frequency is 20kHz, then the optimum speaker inductance may be calculated as:

$$L = \frac{R}{2 \pi F_c} = \frac{8 \Omega}{2 \pi * 20 \text{kHz}} = 64 \mu\text{H}$$

8Ω loudspeakers typically have an inductance in the range 20µH to 100µH, however, it should be noted that a loudspeaker inductance will not be constant across the relevant frequencies for Class D operation (up to and beyond the Class D switching frequency). Care should be taken to ensure that the cut-off frequency of the loudspeaker's filtering is low enough to suppress the high frequency energy of the Class D switching and, in so doing, to prevent speaker damage. The Class D outputs of the WM5102 operate at much higher frequencies than is recommended for most speakers and it must be ensured that the cut-off frequency is low enough to protect the speaker.

POWER SUPPLY / REFERENCE DECOUPLING

Electrical coupling exists particularly in digital logic systems where switching in one sub-system causes fluctuations on the power supply. This effect occurs because the inductance of the power supply acts in opposition to the changes in current flow that are caused by the logic switching. The resultant variations ('spikes') in the power supply voltage can cause malfunctions and unintentional behavior in other components. A decoupling ('bypass') capacitor can be used as an energy storage component which will provide power to the decoupled circuit for the duration of these power supply variations, protecting it from malfunctions that could otherwise arise.

Coupling also occurs in a lower frequency form when ripple is present on the power supply rail caused by changes in the load current or by limitations of the power supply regulation method. In audio components such as the WM5102, these variations can alter the performance of the signal path, leading to degradation in signal quality. A decoupling capacitor can be used to filter these effects, by presenting the ripple voltage with a low impedance path that does not affect the circuit to be decoupled.

These coupling effects are addressed by placing a capacitor between the supply rail and the corresponding ground reference. In the case of systems comprising multiple power supply rails, decoupling should be provided on each rail.

The recommended power supply and voltage reference decoupling capacitors for WM5102 are detailed below in Table 117.

POWER SUPPLY	DECOUPLING CAPACITOR
LDOVDD, DBVDD1, DBVDD2, DBVDD3, AVDD	0.1 μ F ceramic (see Note)
CPVDD	4.7 μ F ceramic
MICVDD	4.7 μ F ceramic
DCVDD	4.7 μ F ceramic
SPKVDDL, SPKVDDR	4.7 μ F ceramic
VREFC	1.0 μ F ceramic

Table 117 Power Supply Decoupling Capacitors

Note: 0.1 μ F is required with 4.7 μ F a guide to the total required power rail capacitance.

All decoupling capacitors should be placed as close as possible to the WM5102 device. The connection between AGND, the AVDD decoupling capacitor and the main system ground should be made at a single point as close as possible to the AGND balls of the WM5102.

Due to the wide tolerance of many types of ceramic capacitors, care must be taken to ensure that the selected components provide the required capacitance across the required temperature and voltage ranges in the intended application. For most application the use of ceramic capacitors with capacitor dielectric X5R is recommended.

CHARGE PUMP COMPONENTS

The WM5102 incorporates two Charge Pump circuits, identified as CP1 and CP2.

CP1 generates the CP1VOUTP and CP1VOUTN supply rails for the ground-referenced headphone drivers; CP2 generates the CP2VOUT supply rail for the microphone bias (MICBIAS) regulators.

Decoupling capacitors are required on each of the Charge Pump outputs. A fly-back capacitor is also required for each Charge Pump.

The recommended Charge Pump capacitors for WM5102 are detailed below in Table 118.

DESCRIPTION	CAPACITOR
CP1VOUTP decoupling	Required capacitance is 2.0 μ F at 2V. Suitable component typically 4.7 μ F.
CP1VOUTN decoupling	Required capacitance is 2.0 μ F at 2V. Suitable component typically 4.7 μ F.
CP1 fly-back (connect between CP1CA and CP1CB)	Required capacitance is 1.0 μ F at 2V. Suitable component typically 2.2 μ F.
CP2VOUT decoupling	Required capacitance is 1.0 μ F at 3.6V. Suitable component typically 4.7 μ F.
CP2 fly-back (connect between CP2CA and CP2CB)	Required capacitance is 220nF at 2V. Suitable component typically 470nF.

Table 118 Charge Pump External Capacitors

Ceramic capacitors are recommended for these Charge Pump requirements. Note that, due to the wide tolerance of many types of ceramic capacitors, care must be taken to ensure that the selected components provide the required capacitance across the required temperature and voltage ranges in the intended application. Ceramic capacitors with X5R dielectric are recommended.

The positioning of the Charge Pump capacitors is important, particularly the fly-back capacitors. These capacitors should be placed as close as possible to the WM5102. The component choice and positioning of the CP1 components are more critical than those of CP2, due to the higher output power requirements of CP1.

EXTERNAL ACCESSORY DETECTION COMPONENTS

The external accessory detection circuit measures jack insertion using the JACKDET pin. The insertion switch status is detected using an internal pull-up resistor circuit on the JACKDET pin.

Microphone detection and key-button press detection is supported using the MICDETn pins. The applicable pin should be connected to one of the MICBIASn outputs, via a 2.2k Ω current-limiting resistor, as described in the "Microphone Bias Circuit" section. Note that, when using the External Accessory Detection function, the MICBIASn resistor must be 2.2k Ω +/-2%.

A recommended circuit configuration, including headphone output on HPOUT1 and microphone connections, is shown in Figure 86. See "Analogue Input Paths" for details of the DC-blocking microphone input capacitor selection.

The recommended external components and connections for microphone / push-button detection are illustrated in Figure 87.

Note that, when using the Microphone Detect circuit, it is recommended to use one of the Right channel analogue microphone input paths, to ensure best immunity to electrical transients arising from the external accessory.

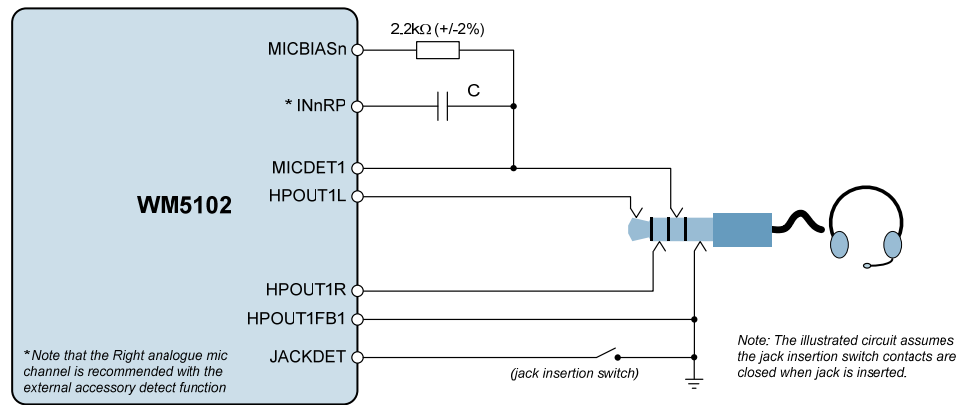

Figure 86 External Accessory Detection

The accessory detection circuit measures the impedance of an external load connected to one of the MICDET pins.

The microphone detection circuit uses MICVDD, MICBIAS1, MICBIAS2 or MICBIAS3 as a reference. The applicable source is configured using the MICD_BIAS_SRC register.

The WM5102 can detect the presence of a typical microphone and up to 6 push-buttons, using the components shown in Figure 87. When the microphone detection circuit is enabled, then each of the push-buttons shown will cause a different bit within the MICD_LVL register to be set.

The microphone detect function is specifically designed to detect a video accessory (typical 75Ω) load if required. A measured external impedance of 75Ω will cause the MICD_LVL [3] bit to be set.

The measured impedance is reported using the MICD_STS and MICD_LVL bits. When no accessory or push-button is detected, the MICD_STS bit is set to 0. When MICD_STS = 1, then one of the MICD_LVL bits is set to indicate the measured impedance. The applicable MICD_LVL bit for each push-button is noted below. Detection of the microphone alone (no push-buttons closed) is indicated in MICD_LVL[8].

RECOMMENDED EXTERNAL COMPONENTS DIAGRAM

DIGITAL AUDIO INTERFACE CLOCKING CONFIGURATIONS

The digital audio interfaces (AIF1, AIF2, AIF3) can be configured in Master or Slave modes. In all applications, it is important that the system clocking configuration is correctly designed. Incorrect clock configurations will lead to audible clicks arising from dropped or repeated audio samples; this is caused by the inherent tolerances of multiple asynchronous system clocks.

To ensure reliable clocking of the audio interface functions, it is a requirement that the external interface clocks (eg. BCLK, LRCLK) are derived from the same clock source as SYSCLK (or ASYNCCLK, where applicable).

In AIF Master mode, the external BCLK and LRCLK signals are generated by the WM5102 and synchronisation of these signals with SYSCLK (or ASYNCCLK) is guaranteed. In this case, clocking of the AIF is typically derived from the MCLK1 or MCLK2 inputs, either directly or via one of the Frequency Locked Loop (FLL) circuits. It is also possible to use a different interface (AIFn or SLIMbus) to provide the reference clock to which the AIF Master can be synchronised.

In AIF Slave mode, the external BCLK and LRCLK signals are generated by another device, as inputs to the WM5102. In this case, it must be ensured that the applicable system clock (SYSCLK or ASYNCCLK) is generated from a source that is synchronised to the external BCLK and LRCLK inputs.

In a typical Slave mode application, the BCLK input is selected as the clock reference, using the FLL to perform frequency shifting. It is also possible to use the MCLK1 or MCLK2 inputs, but only if the selected clock is synchronised externally to the BCLK and LRCLK inputs. The SLIMbus interface can also provide the clock reference, via one of the FLLs, provided that the BCLK and LRCLK signals are externally synchronised with the SLIMCLK input.

The valid AIF clocking configurations are listed in Table 119 for AIF Master and AIF Slave modes.

The applicable system clock (SYSCLK or ASYNCCLK) depends on the AIFn_RATE setting for the relevant digital audio interface; if AIFn_RATE < 1000, then SYSCLK is applicable; if AIFn_RATE ≥ 1000, then ASYNCCLK is applicable.

AIF MODE	CLOCKING CONFIGURATION
AIF Master Mode	SYSCLK_SRC (ASYNCCLK_SRC) selects MCLK1 or MCLK2 as SYSCLK (ASYNCCLK) source.
	SYSCLK_SRC (ASYNCCLK_SRC) selects FLLn as SYSCLK (ASYNCCLK) source; FLLn_REFCLK_SRC selects MCLK1 or MCLK2 as FLLn source.
	SYSCLK_SRC (ASYNCCLK_SRC) selects FLLn as SYSCLK (ASYNCCLK) source; FLLn_REFCLK_SRC selects a different interface (BCLK, LRCLK, SLIMCLK) as FLLn source.
AIF Slave Mode	SYSCLK_SRC (ASYNCCLK_SRC) selects FLLn as SYSCLK (ASYNCCLK) source; FLLn_REFCLK_SRC selects BCLK as FLLn source.
	SYSCLK_SRC (ASYNCCLK_SRC) selects MCLK1 or MCLK2 as SYSCLK (ASYNCCLK) source, provided MCLK is externally synchronised to the BCLK input.
	SYSCLK_SRC (ASYNCCLK_SRC) selects FLLn as SYSCLK (ASYNCCLK) source; FLLn_REFCLK_SRC selects MCLK1 or MCLK2 as FLLn source, provided MCLK is externally synchronised to the BCLK input.
	SYSCLK_SRC (ASYNCCLK_SRC) selects FLLn as SYSCLK (ASYNCCLK) source; FLLn_REFCLK_SRC selects a different interface (eg. SLIMCLK) as FLLn source, provided the other interface is externally synchronised to the BCLK input.

Table 119 Audio Interface (AIF) Clocking Configurations

In each case, the SYSCLK (ASYNCCLK) frequency must be a valid ratio to the LRCLK frequency; the supported clocking rates are defined by the SYSCLK_FREQ (ASYNC_CLK_FREQ) and SAMPLE_RATE_n (ASYNC_SAMPLE_RATE_n) registers.

The valid AIF clocking configurations are illustrated in Figure 88 to Figure 94 below. Note that, where MCLK1 is illustrated as the clock source, it is equally possible to select MCLK2 as the clock source. Similarly, in cases where FLL1 is illustrated, it is equally possible to select FLL2.

PCB LAYOUT CONSIDERATIONS

Poor PCB layout will degrade the performance and be a contributory factor in EMI, ground bounce and resistive voltage losses. All external components should be placed as close to the WM5102 device as possible, with current loop areas kept as small as possible.

PACKAGE DIMENSIONS

Symbols	Dimensions (mm)			NOTE
	MIN	NOM	MAX	
A	0.540	0.574	0.608	
A1	0.172	0.202	0.232	
A2	0.356	0.372	0.388	
D	5.378	5.403	5.428	
D1		4.80 BSC		
E	5.403	5.428	5.453	
E1		4.40 BSC		
e		0.400 BSC		5
f1		0.300 BSC		
f2		0.427 BSC		
f3		0.303 BSC		
f4		0.601 BSC		
g		0.022		
h	0.222	0.262	0.302	

- NOTES:
1. PRIMARY DATUM -Z- AND SEATING PLANE ARE DEFINED BY THE SPHERICAL CROWNS OF THE SOLDER BALLS.
 2. THIS DIMENSION INCLUDES STAND-OFF HEIGHT 'A1'.
 3. A1 CORNER IS IDENTIFIED BY INK/LASER MARK ON TOP PACKAGE.
 4. BILATERAL TOLERANCE ZONE IS APPLIED TO EACH SIDE OF THE PACKAGE BODY.
 5. 'e' REPRESENTS THE BASIC SOLDER BALL GRID PITCH.
 6. THIS DRAWING IS SUBJECT TO CHANGE WITHOUT NOTICE.
 7. FOLLOWS JEDEC DESIGN GUIDE MO-211-C.

IMPORTANT NOTICE

Wolfson Microelectronics plc ("Wolfson") products and services are sold subject to Wolfson's terms and conditions of sale, delivery and payment supplied at the time of order acknowledgement.

Wolfson warrants performance of its products to the specifications in effect at the date of shipment. Wolfson reserves the right to make changes to its products and specifications or to discontinue any product or service without notice. Customers should therefore obtain the latest version of relevant information from Wolfson to verify that the information is current.

Testing and other quality control techniques are utilised to the extent Wolfson deems necessary to support its warranty. Specific testing of all parameters of each device is not necessarily performed unless required by law or regulation.

In order to minimise risks associated with customer applications, the customer must use adequate design and operating safeguards to minimise inherent or procedural hazards. Wolfson is not liable for applications assistance or customer product design. The customer is solely responsible for its selection and use of Wolfson products. Wolfson is not liable for such selection or use nor for use of any circuitry other than circuitry entirely embodied in a Wolfson product.

Wolfson's products are not intended for use in life support systems, appliances, nuclear systems or systems where malfunction can reasonably be expected to result in personal injury, death or severe property or environmental damage. Any use of products by the customer for such purposes is at the customer's own risk.

Wolfson does not grant any licence (express or implied) under any patent right, copyright, mask work right or other intellectual property right of Wolfson covering or relating to any combination, machine, or process in which its products or services might be or are used. Any provision or publication of any third party's products or services does not constitute Wolfson's approval, licence, warranty or endorsement thereof. Any third party trade marks contained in this document belong to the respective third party owner.

Reproduction of information from Wolfson datasheets is permissible only if reproduction is without alteration and is accompanied by all associated copyright, proprietary and other notices (including this notice) and conditions. Wolfson is not liable for any unauthorised alteration of such information or for any reliance placed thereon.

Any representations made, warranties given, and/or liabilities accepted by any person which differ from those contained in this datasheet or in Wolfson's standard terms and conditions of sale, delivery and payment are made, given and/or accepted at that person's own risk. Wolfson is not liable for any such representations, warranties or liabilities or for any reliance placed thereon by any person.

REVISION HISTORY

DATE	REV	DESCRIPTION OF CHANGES	PAGE	CHANGED BY
05/04/12	1.0	Initial version		PH
18/04/12	2.0	HPDET_STS, MICDET_STS deleted PWM_CLK_SEL description updated (50MHz option deleted).		PH
08/06/12	2.0	Sample rates greater than 192kHz deleted. Power Domain information added. DCVDD & Configuration requirements for 50MHz clocking added. Electrical Characteristics updated (min/max limits deleted). FLL Synchroniser timing requirements added. DMICCLK, SPKCLK, BCLK timing requirements updated. LRA_FREQ register description updated (Haptics). Added details of the supported Sample Rates for different blocks. Additional details of SLIMbus clocking & Framer functions. Output Path noise gate function added. ECI_JD_SRC register deleted. ECI_BIAS_SRC register updated, noting permitted configurations of ECI digital/analogue bias sources. LDO2_ENA and LDO2_BYPASS register deleted – these are slaved to the CP2 controls. Clocking Configuration Applications Info updated to incorporate SLIMbus interface options. Analogue connections updated on External Components figure.		PH
03/07/12	2.0	Update to GPIO FLL clock output: FLLn_GPCLK_DIV controls the frequency relative to Fvco, ie. independent of FLLn_OUTDIV. Volume Ramp register descriptions updated. Maximum LDO2 output voltage amended to 3.25V.		PH
30/07/12	2.0	DRC2 deleted HP_CLK_DIV register deleted GP_DBTIME register updated DSP Firmware memory definitions updated MICBIAS description moved to Charge Pump & Regulator section.		PH
05/10/12	2.0	Package Drawing updated. Input Pin descriptions corrected. SUBSYS_MAX_FREQ bit, and associated LDO requirements added, enabling 49.152MHz DSP clocking.. Noted Left-Justified and DSP-B modes valid in Master mode only. Maximum LDO2 output voltage reverted to 3.3V. Electrical Characteristics updated. Noted MICVDD required for analogue inputs. Changed descriptions of Input PGA & Output PGA ramp control registers. Typical AIF system connections updated. Noted AIF format is 2's complement. Noted LRCLK rate registers only applicable in Slave mode. Noted MICVDD required for accessory detection. Deleted 64kHz & 128kHz audio sample rates. Noted 32kHz clock required for CP2.		PH
15/10/12	2.0	Rev B silicon updates added: Support for second ASYNCCLK sample rate. Write Sequencer trigger function from DRC Signal Detect added. Enhancement to Headphone Impedance measurement. Added MICDET clamp and associated WKUP/WSEQ controls. Input pin maximum ratings updated; recommended to use Right channel analogue mic paths when using accessory detect.		PH

DATE	REV	DESCRIPTION OF CHANGES	PAGE	CHANGED BY
18/10/12	2.0	Package Drawing updated. I2C timing diagram updated, with additional "SDA Valid" parameter.		PH
13/11/12	2.0	Electrical Characteristics updated. OUT[1-4]_OSR register bits deleted. OUTnx_PGA_VOL registers deleted. Correction to Pin Numbering (SPKOUTLP, SPKOUTLN, SPKOUTRP, SPKOUTRN)		PH
14/12/12	3.0	Updates describing automatic gain in AEC Loopback path. Package drawing updated. Generic description added for digital core mixer control registers. Typical power consumption data added		PH
19/02/13	3.0	Electrical Characteristics updated. ESD diode configuration details added for external outputs. OUT4_OSR register bit reinstated.		PH
20/03/13	4.0	FLL Gain and Bandwidth control registers added. DSP Firmware memory reset conditions amended (including DSP1_MEM_ENA description). DMA register control requirements added for disabling DSP.		PH
08/05/13	4.0	Deleted statements about automatic thermal shutdown - speaker drivers must be disabled via software control. IM_BOOT_DONE_EINT2 updated (default is 0 - unmasked)		PH
