Technical Data — Rev 4.0

Motorola reserves the right to make changes without further notice to any products herein. Motorola makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Motorola assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters which may be provided in Motorola data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. Motorola does not convey any license under its patent rights nor the rights of others. Motorola products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Motorola product could create a situation where personal injury or death may occur. Should Buyer purchase or use Motorola products for any such unintended or unauthorized application, Buyer shall indemnify and hold Motorola and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Motorola was negligent regarding the design or manufacture of the part. Motorola, Inc. is an Equal Opportunity/Affirmative Action Employer.

Section 1. General Description	29
Section 2. Memory Map	37
Section 3. Random-Access Memory (RAM)	53
Section 4. FLASH Memory	55
Section 5. Configuration Register (CONFIG)	67
Section 6. Central Processor Unit (CPU)	71
Section 7. System Integration Module (SIM)	89
Section 8. Clock Generator Module (CGM).....	111
Section 9. Pulse-Width Modulator for Motor Control (PWMMC)	139
Section 10. Monitor ROM (MON)	187
Section 11. Timer Interface A (TIMA).....	199
Section 12. Timer Interface B (TIMB).....	223
Section 13. Serial Communications Interface (SCI)...	247
Section 14. Input/Output (I/O) Ports	279
Section 15. Computer Operating Properly (COP)	291
Section 16. External Interrupt (IRQ)	297
Section 17. Low-Voltage Inhibit (LVI)	305
Section 18. Analog-to-Digital Converter (ADC).....	311
Section 19. Power-On Reset (POR)	327

List of Paragraphs

Section 20. Break (BRK)	329
Section 21. Electrical Specifications	339
Section 22. Mechanical Specifications	351
Section 23. Ordering Information	355
Technical Data — Revision History	357

Table of Contents

Section 1. General Description

1.1	Contents	29
1.2	Introduction	29
1.3	Features	30
1.4	MCU Block Diagram	31
1.5	Pin Assignments	33
1.5.1	Power Supply Pins (V_{DD} and V_{SS})	34
1.5.2	Oscillator Pins (OSC1 and OSC2)	34
1.5.3	External Reset Pin (\overline{RST})	34
1.5.4	External Interrupt Pin (\overline{IRQ})	35
1.5.5	CGM Power Supply Pins (V_{DDA} and V_{SSA})	35
1.5.6	ADC Reference Voltage Input Pin (V_{REFH})	35
1.5.7	External Filter Capacitor Pin (CGMXFC)	35
1.5.8	Port A Input/Output (I/O) Pins (PTA6/ATD6–PTA0/ATD0)	35
1.5.9	Port B I/O Pins (PTB6/TCHB1–PTB0/RxD)	36
1.5.10	Port C I/O Pins (PTC1/FAULT1–PTC0/FAULT4)	36
1.5.11	PWM Pins (PWM6–PWM1)	36

Section 2. Memory Map

2.1	Contents	37
2.2	Introduction	37
2.3	Unimplemented Memory Locations	38
2.4	Reserved Memory Locations	38
2.5	I/O Section	39
2.6	Monitor ROM	52

Section 3. Random-Access Memory (RAM)

3.1	Contents	53
3.2	Introduction	53
3.3	Functional Description	53

Section 4. FLASH Memory

4.1	Contents	55
4.2	Introduction	55
4.2.1	Functional Description	56
4.2.2	FLASH Control Register	57
4.2.3	FLASH Page Erase Operation	58
4.2.4	FLASH Mass Erase Operation	59
4.2.5	FLASH Program/Read Operation	59
4.3	FLASH Programming Algorithm	60
4.3.1	FLASH Block Protection	62
4.3.2	FLASH Block Protect Register	63
4.3.3	Low-Power Modes	64
4.3.3.1	Wait Mode	64
4.3.3.2	Stop Mode	65

Section 5. Configuration Register (CONFIG)

5.1	Contents	67
5.2	Introduction	67
5.3	CONFIG	68
5.4	CONFIG Bits	68

Section 6. Central Processor Unit (CPU)

6.1	Contents	71
6.2	Introduction	71
6.3	Features	72
6.4	CPU Registers	72
6.4.1	Accumulator	73
6.4.2	Index Register	73
6.4.3	Stack Pointer	74

6.4.4	Program Counter	75
6.4.5	Condition Code Register	76
6.5	Arithmetic/Logic Unit (ALU)	78
6.6	Low-Power Modes	78
6.6.1	Wait Mode	78
6.6.2	Stop Mode	78
6.7	Instruction Set Summary	79
6.8	Opcode Map	86

Section 7. System Integration Module (SIM)

7.1	Contents	89
7.2	Introduction	90
7.3	SIM Bus Clock Control and Generation	93
7.3.1	Bus Timing	93
7.3.2	Clock Startup from POR or LVI Reset	93
7.3.3	Clocks in Wait Mode	94
7.4	Reset and System Initialization	94
7.4.1	External Pin Reset	94
7.4.2	Active Resets from Internal Sources	95
7.4.2.1	Power-On Reset (POR)	96
7.4.2.2	Computer Operating Properly (COP) Reset	97
7.4.2.3	Illegal Opcode Reset	98
7.4.2.4	Illegal Address Reset	98
7.4.2.5	Low-Voltage Inhibit (LVI) Reset	98
7.5	SIM Counter	99
7.5.1	SIM Counter During Power-On Reset	99
7.5.2	SIM Counter and Reset States	99
7.6	Exception Control	99
7.6.1	Interrupts	100
7.6.1.1	Hardware Interrupts	102
7.6.1.2	SWI Instruction	103
7.6.2	Reset	103
7.6.3	Status Flag Protection in Break Mode	103
7.7	Low-Power Mode	104
7.7.1	Wait Mode	104

7.7.2	Stop Mode	106
7.7.3	SIM Break Status Register	106
7.7.4	SIM Reset Status Register	108
7.7.5	SIM Break Flag Control Register	109

Section 8. Clock Generator Module (CGM)

8.1	Contents	111
8.2	Introduction	112
8.3	Features	112
8.4	Functional Description	113
8.4.1	Crystal Oscillator Circuit	113
8.4.2	Phase-Locked Loop Circuit (PLL)	115
8.4.2.1	PLL Circuits	115
8.4.2.2	Acquisition and Tracking Modes	118
8.4.2.3	Manual and Automatic PLL Bandwidth Modes	118
8.4.2.4	Programming the PLL	120
8.4.2.5	Special Programming Exceptions	121
8.4.3	Base Clock Selector Circuit	121
8.4.4	CGM External Connections	122
8.5	I/O Signals	123
8.5.1	Crystal Amplifier Input Pin (OSC1)	123
8.5.2	Crystal Amplifier Output Pin (OSC2)	123
8.5.3	External Filter Capacitor Pin (CGMXFC)	123
8.5.4	PLL Analog Power Pin (V_{DDA})	124
8.5.5	Oscillator Enable Signal (SIMOSCEN)	124
8.5.6	Crystal Output Frequency Signal (CGMXCLK)	124
8.5.7	CGM Base Clock Output (CGMOUT)	124
8.5.8	CGM CPU Interrupt (CGMINT)	124
8.6	CGM Registers	125
8.6.1	PLL Control Register	126
8.6.2	PLL Bandwidth Control Register	129
8.6.3	PLL Programming Register	131
8.7	Interrupts	132
8.8	Wait Mode	133
8.9	Stop Mode	133

8.10	CGM During Break Mode	133
8.11	Acquisition/Lock Time Specifications	134
8.11.1	Acquisition/Lock Time Definitions	134
8.11.2	Parametric Influences on Reaction Time	135
8.11.3	Choosing a Filter Capacitor	136
8.11.4	Reaction Time Calculation	137

Section 9. Pulse-Width Modulator for Motor Control (PWMMC)

9.1	Contents	139
9.2	Introduction	140
9.3	Features	141
9.4	Timebase	146
9.4.1	Resolution	146
9.4.2	Prescaler	148
9.5	PWM Generators	148
9.5.1	Load Operation	148
9.5.2	PWM Data Overflow and Underflow Conditions	152
9.6	Output Control	152
9.6.1	Selecting Six Independent PWMs or Three Complementary PWM Pairs	152
9.6.2	Dead-Time Insertion	154
9.6.3	Output Polarity	157
9.6.4	Output Port Control Register	159
9.7	Fault Protection	161
9.7.1	Fault Condition Input Pins	164
9.7.1.1	Fault Pin Filter	165
9.7.1.2	Automatic Mode	165
9.7.1.3	Manual Mode	167
9.7.2	Software Output Disable	168
9.7.3	Output Port Control	168
9.8	Initialization and the PWMCN Bit	169
9.9	PWM Operation in Wait Mode	170
9.10	PWM Operation in Stop Mode	170
9.11	PWM Operation in Break Mode	171

9.12	Control Logic Block	172
9.12.1	PWM Counter Registers	172
9.12.2	PWM Counter Modulo Registers	173
9.12.3	PWMx Value Registers	174
9.12.4	PWM Control Register 1	175
9.12.5	PWM Control Register 2	177
9.12.6	Dead-Time Write-Once Register	179
9.12.7	PWM Disable Mapping Write-Once Register	179
9.12.8	Fault Control Register	180
9.12.9	Fault Status Register	181
9.12.10	Fault Acknowledge Register	182
9.12.11	PWM Output Control Register	184
9.13	PWM Glossary	185

Section 10. Monitor ROM (MON)

10.1	Contents	187
10.2	Introduction	187
10.3	Features	187
10.4	Functional Description	188
10.4.1	Entering Monitor Mode	188
10.4.2	Forced Monitor Mode	190
10.4.3	Baud Rate	191
10.4.4	Data Format	191
10.4.5	Echoing	192
10.4.6	Break Signal	192
10.4.7	Commands	193
10.5	Security	196

Section 11. Timer Interface A (TIMA)

11.1	Contents	199
11.2	Introduction	200
11.3	Features	200
11.4	Functional Description	204
11.4.1	TIMA Counter Prescaler	204
11.4.2	Input Capture	204

11.4.3	Output Compare	205
11.4.3.1	Unbuffered Output Compare	206
11.4.3.2	Buffered Output Compare	206
11.4.4	Pulse-Width Modulation (PWM)	207
11.4.4.1	Unbuffered PWM Signal Generation	208
11.4.4.2	Buffered PWM Signal Generation	209
11.4.4.3	PWM Initialization	210
11.5	Interrupts	211
11.6	Wait Mode	211
11.7	Stop Mode	212
11.8	TIMA During Break Interrupts	212
11.9	I/O Signals	212
11.9.1	TIMA Clock Pin (PTB2/TCLKA)	213
11.9.2	TIMA Channel I/O Pins (PTB3/TCH0A–PTB4/TCH1A)	213
11.10	I/O Registers	213
11.10.1	TIMA Status and Control Register	214
11.10.2	TIMA Counter Registers	216
11.10.3	TIMA Counter Modulo Registers	217
11.10.4	TIMA Channel Status and Control Registers	218
11.10.5	TIMA Channel Registers	222

Section 12. Timer Interface B (TIMB)

12.1	Contents	223
12.2	Introduction	224
12.3	Features	224
12.4	Functional Description	227
12.4.1	TIMB Counter Prescaler	228
12.4.2	Input Capture	228
12.4.3	Output Compare	230
12.4.3.1	Unbuffered Output Compare	230
12.4.3.2	Buffered Output Compare	231
12.4.4	Pulse-Width Modulation (PWM)	231
12.4.4.1	Unbuffered PWM Signal Generation	232
12.4.4.2	Buffered PWM Signal Generation	233
12.4.4.3	PWM Initialization	234

12.5	Interrupts	235
12.6	Wait Mode	235
12.7	Stop Mode	236
12.8	TIMB During Break Interrupts	236
12.9	TIMB Channel I/O Pins (PTB5/TCH0B–PTB6/TCH1B)	237
12.10	I/O Registers	237
12.10.1	TIMB Status and Control Register	237
12.10.2	TIMB Counter Registers	240
12.10.3	TIMB Counter Modulo Registers	241
12.10.4	TIMB Channel Status and Control Registers	242
12.10.5	TIMB Channel Registers	245

Section 13. Serial Communications Interface (SCI)

13.1	Contents	247
13.2	Introduction	248
13.3	Features	248
13.4	Functional Description	249
13.4.1	Data Format	251
13.4.2	Transmitter	252
13.4.2.1	Character Length	252
13.4.2.2	Character Transmission	252
13.4.2.3	Break Characters	253
13.4.2.4	Idle Characters	255
13.4.2.5	Inversion of Transmitted Output	255
13.4.2.6	Transmitter Interrupts	255
13.4.3	Receiver	256
13.4.3.1	Character Length	257
13.4.3.2	Character Reception	257
13.4.3.3	Data Sampling	257
13.4.3.4	Framing Errors	260
13.4.3.5	Receiver Wakeup	260
13.4.3.6	Receiver Interrupts	261
13.4.3.7	Error Interrupts	261
13.5	Wait Mode	262
13.6	Stop Mode	262

13.7	SCI During Break Module Interrupts	262
13.8	I/O Signals	263
13.8.1	PTE2/TxD (Transmit Data)	263
13.8.2	PTB0/RxD (Receive Data)	263
13.9	I/O Registers	263
13.9.1	SCI Control Register 1	264
13.9.2	SCI Control Register 2	267
13.9.3	SCI Control Register 3	269
13.9.4	SCI Status Register 1	271
13.9.5	SCI Status Register 2	275
13.9.6	SCI Data Register	276
13.9.7	SCI Baud Rate Register	276

Section 14. Input/Output (I/O) Ports

14.1	Contents	279
14.2	Introduction	279
14.3	Port A	281
14.3.1	Port A Data Register	281
14.3.2	Data Direction Register A	282
14.4	Port B	284
14.4.1	Port B Data Register	284
14.4.2	Data Direction Register B	285
14.5	Port C	286
14.5.1	Port C Data Register	287
14.5.2	Data Direction Register C	288

Section 15. Computer Operating Properly (COP)

15.1	Contents	291
15.2	Introduction	291
15.3	Functional Description	292
15.4	I/O Signals	293
15.4.1	CGMXCLK	293
15.4.2	COPCTL Write	293
15.4.3	Power-On Reset	293
15.4.4	Internal Reset	294

15.4.5	Reset Vector Fetch.	294
15.4.6	COP Disable.	294
15.5	COP Control Register.	294
15.6	Interrupts.	294
15.7	Monitor Mode	295
15.8	Wait Mode.	295
15.9	Stop Mode	295
15.10	COP Module During Break Mode	295

Section 16. External Interrupt (IRQ)

16.1	Contents	297
16.2	Introduction.	297
16.3	Features	297
16.4	Functional Description	298
16.5	$\overline{\text{IRQ}}$ Pin.	301
16.6	IRQ Module During Wait Mode.	302
16.7	IRQ Module During Stop Mode.	302
16.8	IRQ Module During Break Mode.	302
16.9	IRQ Status and Control Register	303

Section 17. Low-Voltage Inhibit (LVI)

17.1	Contents	305
17.2	Introduction.	305
17.3	Features	305
17.4	Functional Description	306
17.4.1	Polled LVI Operation	307
17.4.2	Forced Reset Operation.	307
17.4.3	False Reset Protection.	307
17.4.4	LVI Trip Selection.	308
17.5	LVI Status and Control Register	308
17.6	LVI Interrupts	309
17.7	Wait Mode.	309

17.8	Stop Mode	309
------	-----------------	-----

Section 18. Analog-to-Digital Converter (ADC)

18.1	Contents	311
18.2	Introduction	312
18.3	Features	312
18.4	Functional Description	312
18.4.1	ADC Port I/O Pins	313
18.4.2	Voltage Conversion	314
18.4.3	Conversion Time	314
18.4.4	Continuous Conversion	315
18.4.5	Result Justification	315
18.4.6	Monotonicity	316
18.5	Interrupts	316
18.6	Wait Mode	317
18.7	Stop Mode	317
18.8	I/O Signals	317
18.8.1	ADC Voltage Reference Pin (V_{REFH})	317
18.8.2	ADC Voltage In (ADV _{IN})	318
18.8.3	ADC External Connection	318
18.8.3.1	V_{REFH}	318
18.8.3.2	AN _x	318
18.8.3.3	Grounding	318
18.9	I/O Registers	319
18.9.1	ADC Status and Control Register	319
18.9.2	ADC Data Register High	322
18.9.3	ADC Data Register Low	323
18.9.4	ADC Clock Register	324

Section 19. Power-On Reset (POR)

19.1	Contents	327
19.2	Introduction	327
19.3	Functional Description	327

Section 20. Break (BRK)

20.1	Contents	329
20.2	Introduction	329
20.3	Features	330
20.4	Functional Description	330
20.4.1	Flag Protection During Break Interrupts	330
20.4.2	CPU During Break Interrupts	332
20.4.3	TIM During Break Interrupts	332
20.4.4	COP During Break Interrupts	332
20.5	Low-Power Modes	333
20.5.1	Wait Mode	333
20.5.2	Stop Mode	333
20.6	Break Module Registers	333
20.6.1	Break Status and Control Register	333
20.6.2	Break Address Registers	334
20.6.3	SIM Break Status Register	336
20.6.4	SIM Break Flag Control Register	337

Section 21. Electrical Specifications

21.1	Contents	339
21.2	Introduction	339
21.3	Absolute Maximum Ratings	340
21.4	Functional Operating Range	341
21.5	Thermal Characteristics	342
21.6	DC Electrical Characteristics	343
21.7	Memory Characteristics	345
21.8	Control Timing	346
21.9	Timer Interface Module Characteristics	346
21.10	Clock Generation Module Component Specifications	347
21.11	CGM Operating Conditions	347
21.12	CGM Acquisition/Lock Time Specifications	348
21.13	Analog-to-Digital Converter (ADC) Characteristics	349

Section 22. Mechanical Specifications

22.1	Contents	351
22.2	Introduction	351
22.3	32-Pin LQFP (Case #873A)	352
22.4	28-Pin PDIP (Case #710)	353
22.5	28-Pin SOIC (Case #751F)	353

Section 23. Ordering Information

23.1	Contents	355
23.2	Introduction	355
23.3	MC Order Numbers	355

Technical Data — Revision History

	Contents	357
	Introduction	357
	Changes from Rev 3.0 published in April 2002 to Rev 4.0 published in July 2002	357

List of Figures

Figure	Title	Page
1-1	MCU Block Diagram	32
1-2	QFP and DIP/SOIC Pin Assignments	33
1-3	Power Supply Bypassing	34
2-1	Memory Map	40
2-2	Control, Status, and Data Registers	41
4-1	FLASH Control Register (FLCR)	57
4-2	FLASH Programming Algorithm	61
4-3	FLASH Block Protect Register (FLBPR)	63
4-4	FLASH Block Protect Address	64
5-1	CONFIG Register	68
6-1	CPU Registers	72
6-2	Accumulator (A)	73
6-3	Index Register (H:X)	73
6-4	Stack Pointer (SP)	74
6-5	Program Counter (PC)	75
6-6	Condition Code Register (CCR)	76
7-1	SIM Block Diagram	91
7-2	SIM I/O Register Summary	92
7-3	CGM Clock Signals	93
7-4	External Reset Timing	95
7-5	Internal Reset Timing	95
7-6	Sources of Internal Reset	96
7-7	POR Recovery	97
7-8	Interrupt Entry	100
7-9	Interrupt Processing	101
7-10	Interrupt Recovery	102
7-11	Interrupt Recognition Example	103

List of Figures

7-12	Wait Mode Entry Timing	104
7-13	Wait Recovery from Interrupt or Break	105
7-14	Wait Recovery from Internal Reset	105
7-15	SIM Break Status Register (SBSR)	106
7-16	SIM Reset Status Register (SRSR)	108
7-17	SIM Break Flag Control Register (SBFCR)	109
8-1	CGM Block Diagram	114
8-2	CGM I/O Register Summary	115
8-3	CGM External Connections	123
8-4	CGM I/O Register Summary	125
8-5	PLL Control Register (PCTL)	126
8-6	PLL Bandwidth Control Register (PBWC)	129
8-7	PLL Programming Register (PPG)	131
9-1	PWM Module Block Diagram	141
9-2	Register Summary	142
9-3	Center-Aligned PWM (Positive Polarity)	147
9-4	Edge-Aligned PWM (Positive Polarity)	147
9-5	Reload Frequency Change	149
9-6	PWM Interrupt Requests	150
9-7	Center-Aligned PWM Value Loading	150
9-8	Center-Aligned Loading of Modulus	151
9-9	Edge-Aligned PWM Value Loading	151
9-10	Edge-Aligned Modulus Loading	151

1.2 Introduction

The MC68HC908MR8 is a member of the low-cost, high-performance M68HC08 Family of 8-bit microcontroller units (MCU). The M68HC08 Family is based on the customer-specified integrated circuit (CSIC) design strategy. All MCUs in the family use the enhanced M68HC08 central processor unit (CPU08) and are available with a variety of modules, memory sizes and types, and package types.

1.3 Features

Features of the MC68HC908MR8 include:

- High-performance M68HC08 architecture
- Fully upward-compatible object code with M6805, M146805, and M68HC05 Families
- 8-MHz internal bus frequency
- 8 Kbytes of on-chip FLASH
- On-chip programming firmware for use with host personal computer
- 256 bytes of on-chip random-access memory (RAM):
- 12-bit, 6-channel center-aligned or edge-aligned pulse-width modulator (PWMMC)
- Serial communications interface module (SCI)
- Two 16-bit, 2-channel timer interface modules (TIMA and TIMB)
- Eight high current sink and source pins (PTA1/ATD1, PTA0/ATD0, PTB6/TCH1B, PTB5/TCH0B, PTB4/TCH1A, PTB3/TCH0A, PTB2/TCLKA, and PTB1/TxD)
- Clock generator module (CGM)
- Digitally filtered low-voltage inhibit (LVI), software selectable for ± 5 percent or ± 10 percent tolerance
- 10-bit, 4 to 7-channel analog-to-digital converter (ADC)
- System protection features:
 - Optional computer operating properly (COP) reset
 - Low-voltage detection with optional reset
 - Illegal opcode detection with optional reset
 - Illegal address detection with optional reset
 - Fault detection with optional PWM disabling

- Available packages:
 - 32-pin low-profile quad flat pack (LQFP)
 - 28-pin dual in-line package (PDIP)
 - 28-pin small outline package (SOIC)
- Low-power design, fully static with stop and wait modes
- Break (BRK) module allows single breakpoint setting during in-circuit debugging
- Master reset pin and power-on reset (POR)

Features of the CPU08 include:

- Enhanced HC05 programming model
- Extensive loop control functions
- 16 addressing modes (eight more than the M68HC05)
- 16-bit index register and stack pointer
- Memory-to-memory data transfers
- Fast 8×8 multiply instruction
- Fast $16 \div 8$ divide instruction
- Binary-coded decimal (BCD) instructions
- Optimization for controller applications
- C language support

1.4 MCU Block Diagram

Figure 1-1 shows the structure of the MC68HC908MR8.

Figure 1-1. MCU Block Diagram

1.5 Pin Assignments

Figure 1-2 shows 32-pin QFP and 28-pin DIP/SOIC pin assignments.

* High current pins
** These pins are not bonded on the 28-pin package.

Figure 1-2. QFP and DIP/SOIC Pin Assignments

General Description

1.5.1 Power Supply Pins (V_{DD} and V_{SS})

V_{DD} and V_{SS} are the power supply and ground pins. The MCU operates from a single power supply.

Fast signal transitions on MCU pins place high, short-duration current demands on the power supply. To prevent noise problems, take special care to provide power supply bypassing at the MCU as [Figure 1-3](#) shows. Place the C1 bypass capacitor as close to the MCU as possible. Use a high-frequency-response ceramic capacitor for C1. C2 is an optional bulk current bypass capacitor for use in applications that require the port pins to source high current levels.

Note: Component values shown represent typical applications.

Figure 1-3. Power Supply Bypassing

1.5.2 Oscillator Pins (OSC1 and OSC2)

The OSC1 and OSC2 pins are the connections for the on-chip oscillator circuit. See [Section 8. Clock Generator Module \(CGM\)](#).

1.5.3 External Reset Pin (\overline{RST})

A logic 0 on the \overline{RST} pin forces the MCU to a known startup state. \overline{RST} is bidirectional, allowing a reset of the entire system. It is driven low when any internal reset source is asserted. See [Section 7. System Integration Module \(SIM\)](#).

1.5.4 External Interrupt Pin ($\overline{\text{IRQ}}$)

$\overline{\text{IRQ}}$ is an asynchronous external interrupt pin. See [Section 16. External Interrupt \(IRQ\)](#).

1.5.5 CGM Power Supply Pins (V_{DDA} and V_{SSA})

V_{DDA} and V_{SSA} are the power supply pins for the analog portion of the clock generator module (CGM) and the analog-to-digital converter (ADC). Decoupling of these pins should be per the digital supply. See [Section 8. Clock Generator Module \(CGM\)](#) and [Section 18. Analog-to-Digital Converter \(ADC\)](#).

1.5.6 ADC Reference Voltage Input Pin (V_{REFH})

V_{REFH} is the power supply input for setting the reference voltage. See [Section 18. Analog-to-Digital Converter \(ADC\)](#).

1.5.7 External Filter Capacitor Pin (CGMXFC)

CGMXFC is an external filter capacitor connection for the CGM. See [Section 8. Clock Generator Module \(CGM\)](#).

1.5.8 Port A Input/Output (I/O) Pins (PTA6/ATD6–PTA0/ATD0)

Port A is a 7-bit special function port, sharing all of its pins with the analog-to-digital converter (ADC). On the 32-pin QFP package, all seven bits (PTA6/ATD6–PTA0/ATD0) of the port are available. On the 28-pin package, four bits (PTA3/ATD3–PTA0/ATD0) are available.

PTA3–PTA0 have high current source and sink capability. See [Section 14. Input/Output \(I/O\) Ports](#).

1.5.9 Port B I/O Pins (PTB6/TCHB1–PTB0/RxD)

Port B is a 7-bit special function port, sharing five of its pins with the timer interface modules (TIMA and TIMB) and two of its pins with the serial communications interface (SCI). See [Section 11. Timer Interface A \(TIMA\)](#), [Section 12. Timer Interface B \(TIMB\)](#), [Section 14. Input/Output \(I/O\) Ports](#), and [Section 13. Serial Communications Interface \(SCI\)](#).

1.5.10 Port C I/O Pins (PTC1/FAULT1–PTC0/FAULT4)

Port C is a 2-bit special function port, sharing its pins with pulse-width modulator fault inputs. See [Section 9. Pulse-Width Modulator for Motor Control \(PWMMC\)](#) and [Section 14. Input/Output \(I/O\) Ports](#).

1.5.11 PWM Pins (PWM6–PWM1)

PWM6–PWM1 are dedicated pins used for the outputs of the pulse-width modulator module (PWMMC). See [Section 9. Pulse-Width Modulator for Motor Control \(PWMMC\)](#).

Section 2. Memory Map

2.1 Contents

2.2	Introduction	37
2.3	Unimplemented Memory Locations	38
2.4	Reserved Memory Locations	38
2.5	I/O Section	39
2.6	Monitor ROM	52

2.2 Introduction

The central processor unit (CPU08) can address 64 Kbytes of memory space.

The memory map, shown in **Figure 2-1**, includes these features:

- 8 Kbytes of FLASH
- 256 bytes of RAM
- 313 bytes of monitor ROM
- 46 bytes of user-defined vectors

2.3 Unimplemented Memory Locations

Some addresses are unimplemented. Accessing an unimplemented address will cause an illegal address reset. In the memory map and in the input/output (I/O) register summary, unimplemented addresses are shaded.

Some I/O bits are read-only; the write function is unimplemented. Writing to a read-only I/O bit has no effect on MCU operation. In register figures, the write function of read-only bits is shaded. Similarly, some I/O bits are write-only; the read function is unimplemented. Reading of write-only I/O bits has no effect on microcontroller unit (MCU) operation. In register figures, the read function of write-only bits is shaded.

2.4 Reserved Memory Locations

Some addresses are reserved. Writing to a reserved address can have unpredictable effects on MCU operation. In the memory map and in the I/O register summary, reserved addresses are marked with the word reserved.

Some I/O bits are reserved. Writing to a reserved bit can have unpredictable effects on MCU operation. In register figures, reserved bits are marked with the letter R.

2.5 I/O Section

Addresses \$0000–\$005F, shown in [Figure 2-2](#), contain most of the control, status, and data registers. Additional I/O registers have these addresses:

- \$FE00, system integration module (SIM) break status register (SBSR)
- \$FE01, SIM reset status register (SRSR)
- \$FE03, SIM break flag control register (SBFCR)
- \$FE08, FLASH control register (FLCR)
- \$FF57, FLASH test control register (FLTCR)
- \$FE0C, break address register high (BRKH)
- \$FE0D, break flag control register low (BRKL)
- \$FE0E, break status and control register (BRKSCR)
- \$FE0F, low-voltage inhibit (LVI) status and control register (LVISCR)
- \$FF7E, FLASH block protect register (FLBPR)
- \$FFFF, computer operating properly (COP) control register (COPCTL)

2.6 Monitor ROM

313 bytes at addresses \$FE10–\$FF48 are reserved ROM addresses that contain the instructions for the monitor functions.

See [Section 10. Monitor ROM \(MON\)](#).

Section 3. Random-Access Memory (RAM)

3.1 Contents

3.2	Introduction	53
3.3	Functional Description	53

3.2 Introduction

This section describes the 256 bytes of random-access memory (RAM) on the MC68HC908MR8.

3.3 Functional Description

Addresses \$0060–\$015F are RAM locations. The location of the stack RAM is programmable. The 16-bit stack pointer allows the stack to be anywhere in the 64-Kbyte memory space.

NOTE: *For correct operation, the stack pointer must point only to RAM locations.*

Within page zero are 160 bytes of RAM. Because the location of the stack RAM is programmable, all page zero RAM locations can be used for input/output (I/O) control and user data or code. When the stack pointer is moved from its reset location at \$00FF, direct addressing mode instructions can access efficiently all page zero RAM locations. Page zero RAM, therefore, provides ideal locations for frequently accessed global variables.

Before processing an interrupt, the CPU uses five bytes of the stack to save the contents of the central processor unit (CPU) registers.

NOTE: *For M6805 compatibility, the H register is not stacked.*

Random-Access Memory (RAM)

During a subroutine call, the CPU uses two bytes of the stack to store the return address. The stack pointer decrements during pushes and increments during pulls.

NOTE: *Be careful when using nested subroutines. The CPU may overwrite data in the RAM during a subroutine or during the interrupt stacking operation.*

4.3	FLASH Programming Algorithm	60
4.3.1	FLASH Block Protection	62
4.3.2	FLASH Block Protect Register	63
4.3.3	Low-Power Modes	64

4.2 Introduction

This section describes the operation of the MC68HC908MR8 embedded FLASH memory. This memory can be read, programmed, and erased from a single external supply. The program and erase operations are enabled through the use of an internal charge pump.

4.2.1 Functional Description

The FLASH memory physically consists of an array of 7680 bytes with an additional 46 bytes of user vectors and one byte of block protection. An erased bit reads as a logic 1 and a programmed bit reads as a logic 0. Program and erase operations are facilitated through control bits in a memory mapped register. Details for these operations appear later in this section.

Memory in the FLASH array is organized into two rows per page base. For the 8-K word by 8-bit embedded FLASH memory, the page size is 64 bytes per page. The minimum erase page size is 64 bytes. Program and erase operations are performed through control bits in the FLASH control register (FLCR).

The address ranges for the user memory, control register, and vectors are:

- \$E000–\$FDFF, user memory
- \$FF7E, block protect register (FLBPR)
- \$FE08, FLASH control register (FLCR)
- \$FFD2–\$FFFF, locations reserved for user-defined interrupt and reset vectors

Programming tools are available from Motorola. Contact a local Motorola representative for more information.

NOTE: *A security feature¹ prevents viewing of the FLASH contents.*

1. No security feature is absolutely secure. However, Motorola's strategy is to make reading or copying the FLASH difficult for unauthorized users.

4.2.2 FLASH Control Register

The FLASH control register (FLCR) controls the FLASH program, erase, and read operations.

Ad- \$FE08
dress:

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	HVEN	MASS	ERASE	PGM
Write:								
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

Figure 4-1. FLASH Control Register (FLCR)

HVEN — High-Voltage Enable Bit

This read/write bit enables the charge pump to drive high voltages for program and erase operations in the array. HVEN can be set only if either PGM = 1 or ERASE = 1 and the proper sequence for program/margin read or erase is followed.

- 1 = High voltage enabled to array and charge pump on
- 0 = High voltage disabled to array and charge pump off

MASS — Mass Erase Control Bit

This read/write bit configures the memory for mass erase operation.

- 1 = Mass erase operation selected
- 0 = Mass erase operation unselected

ERASE — Erase Control Bit

This read/write bit configures the memory for erase operation.

ERASE is interlocked with the PGM bit such that both bits cannot be set at the same time.

- 1 = Erase operation selected
- 0 = Erase operation unselected

PGM — Program Control Bit

This read/write bit configures the memory for program operation. PGM is interlocked with the ERASE bit such that both bits cannot be set at the same time.

- 1 = Program operation selected
- 0 = Program operation unselected

4.2.3 FLASH Page Erase Operation

Use this step-by-step procedure to erase a page (64 bytes) of FLASH memory to read as logic 1:

1. Set the ERASE bit and clear the MASS bit in the FLASH control register.
2. Read the FLASH block protect register.
3. Write to any FLASH address with any data within the page address range desired.
4. Wait for a time, t_{NVS} (minimum of 10 μ s).
5. Set the HVEN bit.
6. Wait for a time, t_{Erase} (minimum of 1 ms).
7. Clear the ERASE bit.
8. Wait for a time, t_{NVH} (minimum of 5 μ s).
9. Clear the HVEN bit.
10. After a time, t_{RCV} (typically 1 μ s), the memory can be accessed in read mode again.

NOTE: *While these operations must be performed in the order shown, other unrelated operations may occur between the steps. Do not exceed t_{NVH} maximum. See [21.7 Memory Characteristics](#).*

4.2.4 FLASH Mass Erase Operation

Use this step-by-step procedure to erase the entire FLASH memory to read as logic 1:

1. Set the ERASE bit and the MASS bit in the FLASH control register.
2. Read the block protect register.
3. Write to any FLASH address with any data within the page address range desired.
4. Wait for a time, t_{NVS} (minimum of 10 μ s).
5. Set the HVEN bit.
6. Wait for a time, t_{Erase} (minimum of 4 ms).
7. Clear the ERASE bit.
8. Wait for a time, t_{NVHL} (minimum of 100 μ s).
9. Clear the HVEN bit.
10. After a time, t_{RCV} (typically 1 μ s), the memory can be accessed in read mode again.

NOTE: *Programming and erasing of FLASH locations cannot be performed by code being executed from the FLASH memory. While these operations must be performed in the order shown, other unrelated operations may occur between the steps. Do not exceed t_{NVH} maximum. See [21.7 Memory Characteristics](#).*

4.2.5 FLASH Program/Read Operation

Programming of the FLASH memory is done on a row basis. A row consists of 32 consecutive bytes starting from address \$XX00, \$XX20, \$XX40, and \$XX80.

Use this step-by-step procedure to program a row of FLASH memory:

1. Set the PGM bit in the FLASH control register. This configures the memory for program operation and enables the latching of address and data programming.
2. Read the block protect register.
3. Write to any FLASH address with any data within the page

address range desired.

4. Wait for a time, t_{NVS} (minimum of 10 μs).
5. Set the HVEN bit.
6. Wait for a time, t_{PGS} (minimum of 5 μs).
7. Write data to the FLASH address to be programmed.
8. Wait for a time, t_{PROG} (minimum of 30 μs).
9. Repeat step 7 and step 8 until all the bytes within the row are programmed.
10. Clear the PGM bit.
11. Wait for a time, t_{NVH} (minimum of 5 μs).
12. Clear the HVEN bit.
13. After a time, t_{RCV} (typically 1 μs), the memory can be accessed in read mode again.

NOTE: *The time between each FLASH address change, or the time between the last FLASH address programmed to clear the PGM bit, must not exceed the maximum programming time, t_{PROG} .*

Programming and erasing of FLASH locations cannot be performed by code being executed from the FLASH memory. While these operations must be performed in the order shown, other unrelated operations may occur between the steps. Do not exceed t_{PROG} maximum. See [21.7 Memory Characteristics](#).

4.3 FLASH Programming Algorithm

Refer to [Figure 4-2](#) for an algorithm for programming a row (32 bytes) of FLASH memory.

Note:
This page program algorithm assumes the rows to be programmed are initially erased.

Note:
The time between each address change, or the time between the last FLASH address programmed to clear the PGM bit, must not exceed the maximum programming time, t_{PROG} .

Figure 4-2. FLASH Programming Algorithm

4.3.1 FLASH Block Protection

Due to the ability of the on-board charge pump to erase and program the FLASH memory in the target application, provision is made for protecting blocks of memory from unintentional erase or program operations due to system malfunction. This protection is done by using a FLASH protection register (FLBPR).

The FLBPR determines the range of the FLASH memory which is to be protected. The range of the protected area starts from a location defined by FLBPR and ends at the bottom of the FLASH memory (\$FFFF). When the memory is protected, the HVEN bit cannot be set in either erase or program operations.

NOTE: *In performing a program erase operation, the FLASH block protect register must be read after setting the PGM or ERASE bit and before asserting the HVEN bit.*

When the block protect register is erased (all 1s), the entire memory is accessible for program and erase. When bits within the register are programmed (set to 0), they lock blocks of memory address ranges as shown in [4.3.2 FLASH Block Protect Register](#). Once the block protect register is programmed with value other than \$FF, any erase or program of the block protect register or the protected pages will be prohibited. The block protect register itself can be erased or programmed only with an external voltage V_{HI} present on the \overline{IRQ} pin. The presence of V_{HI} on the \overline{IRQ} pin also allows entry into monitor mode out of reset. Therefore, the ability to change the block protect register is voltage dependent and can occur in either user or monitor modes.

4.3.2 FLASH Block Protect Register

The block protect register (FLBPR) is implemented as a byte within the FLASH memory, and therefore can only be written during a programming sequence of the FLASH memory. The value in this register determines the starting location of the protected range within the FLASH memory.

U= Unaffected by reset. Initial value from factory is 1.

Write to this register by a programming sequence to the FLASH memory.

Figure 4-3. FLASH Block Protect Register (FLBPR)

BPR[7:0] — Block Protect Register Bits

These eight bits represent bits [13:6] of a 16-bit memory address. Bits[15:14] are logical 1s and bits [5:0] are logic 0s.

The resultant 16-bit address is used for specifying the start address of the FLASH memory for block protection. The FLASH is protected from this start address to the end of FLASH memory at \$FFFF. With this mechanism, the protect start address can be \$XX00, \$XX40, \$XX80, and \$XXC0 (64-byte page boundaries) within the FLASH memory.

Figure 4-4. FLASH Block Protect Address

\$80 = The entire FLASH memory is protected.

\$81 = Protected range: \$E040–\$FFFF

\$82 = Protected range: \$E080–\$FFFF

↓ ↓ ↓

\$FE = Protected range: \$FF80–\$FFFF

\$FF = Entire FLASH memory is not protected.

If all bits are erased, then all of the memory is available for erase and program. The presence of a voltage V_{HI} on the \overline{IRQ} pin will bypass the block protection so that all of the memory, including the block protect register, is open for program and erase operations.

4.3.3 Low-Power Modes

The WAIT and STOP instructions will place the MCU in a low power-consumption standby mode.

4.3.3.1 Wait Mode

Putting the MCU into wait mode while the FLASH is in read mode does not affect the operation of the FLASH memory directly, but there will not be any memory activity since the CPU is inactive.

The WAIT instruction should never be executed while performing a program or erase operation on the FLASH. When the MCU is put into wait mode, the charge pump for the FLASH is disabled so that either a program or erase operation will not continue. If the memory is in either program mode (PGM = 1, HVEN = 1) or erase mode (ERASE = 1, HVEN = 1), then it will remain in that mode during wait.

NOTE: *Exiting from wait must now be done with a reset rather than an interrupt because if exiting wait with an interrupt, the memory will not be in read mode and the interrupt vector cannot be read from the memory.*

4.3.3.2 Stop Mode

If the FLASH is in read mode, when the MCU is put into stop mode, the FLASH will be put into low-power standby mode.

The STOP instruction should never be executed while performing a program or erase operation on the FLASH. Otherwise the operation will be discontinued and the FLASH will be in standby mode.

NOTE: *Standby mode is the power-saving mode of the FLASH module, in which all internal control signals to the FLASH are inactive and the current consumption of the FLASH is minimum.*

Section 5. Configuration Register (CONFIG)

5.1 Contents

5.2	Introduction	67
5.3	CONFIG	68
5.4	CONFIG Bits	68

5.2 Introduction

This section describes the configuration register (CONFIG).

The CONFIG registers contain bits that configure these options:

- Resets caused by the low-voltage inhibit (LVI) module
- Power to the LVI module
- Computer operating properly (COP) module
- Top-side pulse-width modulator (PWM) polarity
- Bottom-side PWM polarity
- Edge-aligned versus center-aligned PWMs
- Six independent PWMs versus three complementary PWM pairs
- STOP instruction enable

Configuration Register (CONFIG)

5.3 CONFIG

The configuration register (CONFIG) is a write-once register. Once the register is written, further writes will have no effect until a reset occurs.

5.4 CONFIG Bits

NOTE: *If the LVI module and the LVI reset signal are enabled, a reset occurs when V_{DD} falls to a voltage, LVI_{TRIPF} , and remains at or below that level for at least nine consecutive central processor unit (CPU) cycles. Once an LVI reset occurs, the microcontroller unit (MCU) remains in reset until V_{DD} rises to a voltage, LVI_{TRIPR} .*

Address: \$001F

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	EDGE	BOT-NEG	TOP-NEG	INDEP	LVIRST	LVIP-WR	STOPE	COPD
Write:								
Reset states:								
CONFIG	0	0	0	0	1	1	0	0

Figure 5-1. CONFIG Register

EDGE — Edge-Align Enable Bit

EDGE determines if the motor control PWM will operate in edge-aligned mode or center-aligned mode. See [Section 9. Pulse-Width Modulator for Motor Control \(PWMMC\)](#).

1 = Edge-aligned mode enabled

0 = Center-aligned mode enabled

BOTNEG — Bottom-Side PWM Polarity Bit

BOTNEG determines if the bottom-side PWMs will have positive or negative polarity. See [Section 9. Pulse-Width Modulator for Motor Control \(PWMMC\)](#).

1 = Negative polarity

0 = Positive polarity

TOPNEG — Top-Side PWM Polarity Bit

TOPNEG determines if the top-side PWMs will have positive or negative polarity. See [Section 9. Pulse-Width Modulator for Motor Control \(PWMMC\)](#).

- 1 = Negative polarity
- 0 = Positive polarity

INDEP — Independent Mode Enable Bit

INDEP determines if the motor control PWMs will be six independent PWMs or three complementary PWM pairs. See [Section 9. Pulse-Width Modulator for Motor Control \(PWMMC\)](#).

- 1 = Six independent PWMs
- 0 = Three complementary PWM pairs

LVIPWR — LVI Power Enable Bit

LVIPWR enables the LVI module. See [Section 17. Low-Voltage Inhibit \(LVI\)](#).

- 1 = LVI module power enabled
- 0 = LVI module power disabled

LVIRST — LVI Reset Enable Bit

LVIRST enables the reset signal from the LVI module. See [Section 17. Low-Voltage Inhibit \(LVI\)](#).

- 1 = LVI module resets enabled
- 0 = LVI module resets disabled

STOPE — STOP Enable Bit

STOPE enables the STOP instruction. See [Section 6. Central Processor Unit \(CPU\)](#).

- 1 = STOP instruction is enabled.
- 0 = STOP instruction is disabled and executes as an illegal instruction.

COPD — COP Disable Bit

COPD disables the COP module. See [Section 15. Computer Operating Properly \(COP\)](#).

- 1 = COP module disabled
- 0 = COP module enabled

6.2 Introduction

This section describes the central processor unit (CPU08, version A). The M68HC08 CPU is an enhanced and fully object-code-compatible version of the M68HC05 CPU. The *CPU08 Reference Manual*, Motorola document number CPU08RM/AD, contains a description of the CPU instruction set, addressing modes, and architecture.

6.3 Features

Features of the CPU include:

- Fully upward, object-code compatibility with M68HC05 family
- 16-bit stack pointer with stack manipulation instructions
- 16-bit index register with X-register manipulation instructions
- 8-MHz CPU internal bus frequency
- 64-Kbyte program/data memory space
- Sixteen addressing modes
- Memory-to-memory data moves without using the accumulator
- Fast 8-bit by 8-bit multiply and 16-bit by 8-bit divide instructions
- Enhanced binary-coded decimal (BCD) data handling
- Modular architecture with expandable internal bus definition for extension of addressing range beyond 64 Kbytes
- Low-power stop and wait modes

6.4 CPU Registers

Figure 6-1 shows the five CPU registers. CPU registers are not part of the memory map.

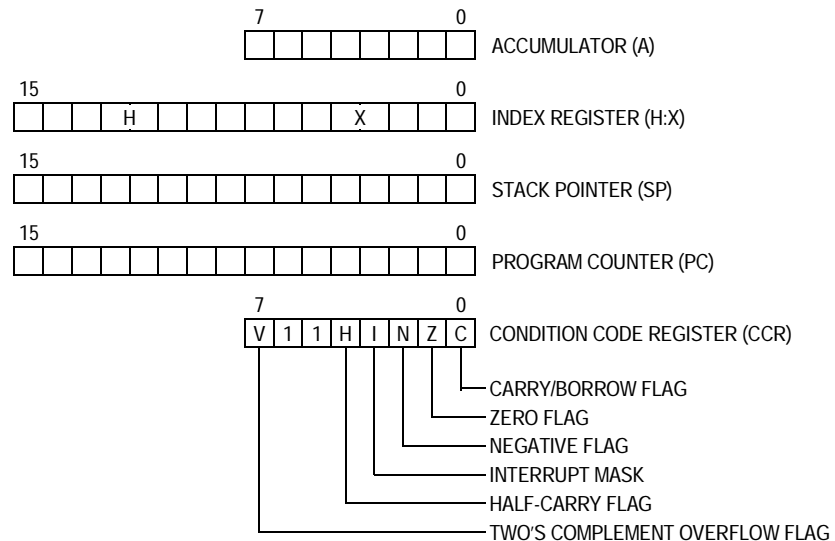

Figure 6-1. CPU Registers

6.4.1 Accumulator

The accumulator is a general-purpose 8-bit register. The CPU uses the accumulator to hold operands and the results of arithmetic/logic operations.

Figure 6-2. Accumulator (A)

6.4.2 Index Register

The 16-bit index register allows indexed addressing of a 64-Kbyte memory space. H is the upper byte of the index register, and X is the lower byte. H:X is the concatenated 16-bit index register.

In the indexed addressing modes, the CPU uses the contents of the index register to determine the conditional address of the operand.

Figure 6-3. Index Register (H:X)

The index register can serve also as a temporary data storage location.

6.4.3 Stack Pointer

The stack pointer (SP) is a 16-bit register that contains the address of the next location on the stack. During a reset, the stack pointer is preset to \$00FF. The reset stack pointer (RSP) instruction sets the least significant byte to \$FF and does not affect the most significant byte. The stack pointer decrements as data is pushed onto the stack and increments as data is pulled from the stack.

In the stack pointer 8-bit offset and 16-bit offset addressing modes, the stack pointer can function as an index register to access data on the stack. The CPU uses the contents of the stack pointer to determine the conditional address of the operand.

Figure 6-4. Stack Pointer (SP)

NOTE: *The location of the stack is arbitrary and may be relocated anywhere in RAM. Moving the SP out of page zero (\$0000 to \$00FF) frees direct address (page zero) space. For correct operation, the stack pointer must point only to RAM locations.*

6.4.4 Program Counter

The program counter (PC) is a 16-bit register that contains the address of the next instruction or operand to be fetched.

Normally, the program counter automatically increments to the next sequential memory location every time an instruction or operand is fetched. Jump, branch, and interrupt operations load the program counter with an address other than that of the next sequential location.

During reset, the program counter is loaded with the reset vector address located at \$FFFE and \$FFFF. The vector address is the address of the first instruction to be executed after exiting the reset state.

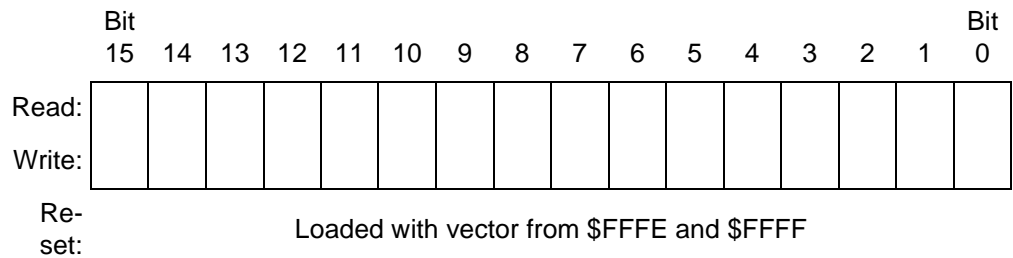

Figure 6-5. Program Counter (PC)

6.4.5 Condition Code Register

The 8-bit condition code register (CCR) contains the interrupt mask and five flags that indicate the results of the instruction just executed. Bit 6 and bit 5 are set permanently to logic 1. The functions of the condition code register are described here.

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	V	1	1	H	I	N	Z	C
Write:								
Re-set:	X	1	1	X	1	X	X	X

X = Indeterminate

Figure 6-6. Condition Code Register (CCR)

V — Overflow Flag

The CPU sets the overflow flag when a two's complement overflow occurs. The signed branch instructions BGT, BGE, BLE, and BLT use the overflow flag.

- 1 = Overflow
- 0 = No overflow

H — Half-Carry Flag

The CPU sets the half-carry flag when a carry occurs between accumulator bits 3 and 4 during an add without carry (ADD) or add with carry (ADC) operation. The half-carry flag is required for binary-coded decimal (BCD) arithmetic operations. The DAA instruction uses the states of the H and C flags to determine the appropriate correction factor.

- 1 = Carry between bits 3 and 4
- 0 = No carry between bits 3 and 4

I — Interrupt Mask

When the interrupt mask is set, all maskable CPU interrupts are disabled. CPU interrupts are enabled when the interrupt mask is cleared. When a CPU interrupt occurs, the interrupt mask is set automatically after the CPU registers are saved on the stack, but before the interrupt vector is fetched.

1 = Interrupts disabled
0 = Interrupts enabled

NOTE: *To maintain M6805 compatibility, the upper byte of the index register (H) is not stacked automatically. If the interrupt service routine modifies H, then the user must stack and unstack H using the PSHH and PULH instructions.*

After the I bit is cleared, the highest-priority interrupt request is serviced first.

A return-from-interrupt (RTI) instruction pulls the CPU registers from the stack and restores the interrupt mask from the stack. After any reset, the interrupt mask is set and can be cleared only by the clear interrupt mask software instruction (CLI).

N — Negative Flag

The CPU sets the negative flag when an arithmetic operation, logic operation, or data manipulation produces a negative result, setting bit 7 of the result.

1 = Negative result
0 = Non-negative result

Z — Zero Flag

The CPU sets the zero flag when an arithmetic operation, logic operation, or data manipulation produces a result of \$00.

1 = Zero result
0 = Non-zero result

C — Carry/Borrow Flag

The CPU sets the carry/borrow flag when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some instructions — such as bit test and branch, shift, and rotate — also clear or set the carry/borrow flag.

1 = Carry out of bit 7
0 = No carry out of bit 7

6.5 Arithmetic/Logic Unit (ALU)

The ALU performs the arithmetic and logic operations defined by the instruction set.

Refer to the *CPU08 Reference Manual*, Motorola document number CPU08RM/AD, for a description of the instructions and addressing modes and more detail about CPU architecture.

6.6 Low-Power Modes

The WAIT and STOP instructions put the MCU in low power-consumption standby modes.

6.6.1 Wait Mode

The WAIT instruction:

- Clears the interrupt mask (I bit) in the condition code register, enabling interrupts. After exit from wait mode by interrupt, the I bit remains clear. After exit by reset, the I bit is set.
- Disables the CPU clock

6.6.2 Stop Mode

The STOP instruction:

- Clears the interrupt mask (I bit) in the condition code register, enabling external interrupts. After exit from stop mode by external interrupt, the I bit remains clear. After exit by reset, the I bit is set.
- Disables the CPU clock

After exiting stop mode, the CPU clock begins running after the oscillator stabilization delay.

6.7 Instruction Set Summary

Table 6-1 provides a summary of the M68HC08 instruction set.

7.2 Introduction

This section describes the system integration module (SIM). Together with the central processor unit (CPU), the SIM controls all microcontroller unit (MCU) activities. A block diagram of the SIM is shown in [Figure 7-1](#). [Figure 7-2](#) is a summary of the SIM input/output (I/O) registers.

The SIM is a system state controller that coordinates CPU and exception timing. The SIM is responsible for:

- Bus clock generation and control for CPU and peripherals:
 - Stop, wait, reset, break entry, and recovery
 - Internal clock control
- Master reset control, including power-on reset (POR) and computer operating properly (COP) timeout
- Interrupt control:
 - Acknowledge timing
 - Arbitration control timing
 - Vector address generation
- CPU enable/disable timing
- Modular architecture expandable to 128 interrupt sources

Figure 7-2. SIM I/O Register Summary

Table 7-1 shows the internal signal names used in this section.

Table 7-1. Signal Name Conventions

Signal Name	Description
CGMXCLK	Buffered version of OSC1 from clock generator module (CGM)
CGMVCLK	PLL output
CGMOUT	PLL-based or OSC1-based clock output from CGM module (bus clock = CGMOUT divided by two)
IAB	Internal address bus
IDB	Internal data bus
PORRST	Signal from the power-on reset module to the SIM
IRST	Internal reset signal
R \overline{W}	Read/write signal

7.3 SIM Bus Clock Control and Generation

The bus clock generator provides system clock signals for the CPU and peripherals on the MCU. The system clocks are generated from an incoming clock, CGMOUT, as shown in [Figure 7-3](#). This clock can come from either an external oscillator or from the on-chip phase-locked loop (PLL). See [Section 8. Clock Generator Module \(CGM\)](#).

Figure 7-3. CGM Clock Signals

7.3.1 Bus Timing

In user mode, the internal bus frequency is either the crystal oscillator output (CGMXCLK) divided by four or the PLL output (CGMVCLK) divided by four. See [Section 8. Clock Generator Module \(CGM\)](#).

7.3.2 Clock Startup from POR or LVI Reset

When the power-on reset (POR) module or the low-voltage inhibit (LVI) module generates a reset, the clocks to the CPU and peripherals are inactive and held in an inactive phase until after the 4096 CGMXCLK cycle POR timeout has completed. The \overline{RST} pin is driven low by the SIM during this entire period. The IBUS clocks start upon completion of the timeout.

7.3.3 Clocks in Wait Mode

In wait mode, the CPU clocks are inactive. The SIM also produces two sets of clocks for other modules. Refer to the wait mode subsection of each module to see if the module is active or inactive in wait mode. Some modules can be programmed to be active in wait mode.

7.4 Reset and System Initialization

The MCU has these reset sources:

- Power-on reset module (POR)
- External reset pin ($\overline{\text{RST}}$)
- Computer operating properly module (COP)
- Low-voltage inhibit module (LVI)
- Illegal opcode
- Illegal address

All of these resets produce the vector \$FFFE–FFFF (\$FEFE–FEFF in monitor mode) and assert the internal reset signal (IRST). IRST causes all registers to be returned to their default values and all modules to be returned to their reset states.

An internal reset clears the SIM counter (see [7.5 SIM Counter](#)), but an external reset does not. Each of the resets sets a corresponding bit in the SIM reset status register (SRSR). See [7.7.4 SIM Reset Status Register](#).

7.4.1 External Pin Reset

Pulling the asynchronous $\overline{\text{RST}}$ pin low halts all processing. The PIN bit of the SIM reset status register (SRSR) is set as long as $\overline{\text{RST}}$ is held low for a minimum of 67 CGMXCLK cycles, assuming that neither the POR nor the LVI was the source of the reset. See [Table 7-2](#) for details. [Figure 7-4](#) shows the relative timing.

Table 7-2. PIN Bit Set Timing

Reset Type	Number of Cycles Required to set PIN
POR/LVI	4163 (4096 + 64 + 3)
All Others	67 (64 + 3)

Figure 7-4. External Reset Timing

7.4.2 Active Resets from Internal Sources

All internal reset sources actively pull the \overline{RST} pin low for 32 CGMXCLK cycles to allow resetting of external peripherals. The internal reset signal (IRST) continues to be asserted for an additional 32 cycles (see [Figure 7-5](#)). An internal reset can be caused by an illegal address, illegal opcode, COP timeout, LVI, or POR (see [Figure 7-6](#)).

NOTE: For LVI or POR resets, the SIM cycles through 4096 CGMXCLK cycles during which the SIM forces the \overline{RST} pin low. The internal reset signal then follows the sequence from the falling edge of \overline{RST} as shown in [Figure 7-5](#).

Figure 7-5. Internal Reset Timing

The COP reset is asynchronous to the bus clock.

Figure 7-6. Sources of Internal Reset

The active reset feature allows the part to issue a reset to peripherals and other chips within a system built around the MCU.

7.4.2.1 Power-On Reset (POR)

When power is first applied to the MCU, the power-on reset (POR) module generates a pulse to indicate that power-on has occurred. The external reset pin (\overline{RST}) is held low while the SIM counter counts out 4096 CGMXCLK cycles. Sixty-four CGMXCLK cycles later, the CPU and memories are released from reset to allow the reset vector sequence to occur.

At power-on, these events occur:

- A POR pulse is generated.
- The internal reset signal is asserted.
- The SIM enables CGMOUT.
- Internal clocks to the CPU and modules are held inactive for 4096 CGMXCLK cycles to allow stabilization of the oscillator.
- The \overline{RST} pin is driven low during the oscillator stabilization time.
- The POR bit of the SIM reset status register (SRSR) is set and all other bits in the register are cleared.

Figure 7-7. POR Recovery

7.4.2.2 Computer Operating Properly (COP) Reset

An input to the SIM is reserved for the COP reset signal. The overflow of the COP counter causes an internal reset and sets the COP bit in the SIM reset status register (SRSR). The SIM actively pulls down the $\overline{\text{RST}}$ pin for all internal reset sources.

To prevent a COP module timeout, write any value to location \$FFFF. Writing to location \$FFFF clears the COP counter and bits 12–4 of the SIM counter. The SIM counter output, which occurs at least every $2^{13}-2^4$ CGMXCLK cycles, drives the COP counter. The COP should be serviced as soon as possible out of reset to guarantee the maximum amount of time before the first timeout.

The COP module is disabled if the $\overline{\text{RST}}$ pin or the $\overline{\text{IRQ}}$ pin is held at $V_{\text{DD}} + V_{\text{HI}}$ while the MCU is in monitor mode. The COP module can be disabled only through combinational logic conditioned with the high voltage signal on the $\overline{\text{RST}}$ or the $\overline{\text{IRQ}}$ pin. This prevents the COP from becoming disabled as a result of external noise. During a break state, $V_{\text{DD}} + V_{\text{HI}}$ on the $\overline{\text{RST}}$ pin disables the COP module.

7.4.2.3 Illegal Opcode Reset

The SIM decodes signals from the CPU to detect illegal instructions. An illegal instruction sets the ILOP bit in the SIM reset status register (SRSR) and causes a reset.

Because the MC68HC08MR8 has stop mode disabled by bit 1 in the CONFIG register, execution of the STOP instruction will cause an illegal opcode reset if stop mode has not been enabled by setting CONFIG register bit 1.

7.4.2.4 Illegal Address Reset

An opcode fetch from addresses other than FLASH, I/O, or RAM addresses generates an illegal address reset (unimplemented locations within memory map). The SIM verifies that the CPU is fetching an opcode prior to asserting the ILAD bit in the SIM reset status register (SRSR) and resetting the MCU. A data fetch from an unmapped address does not generate a reset.

7.4.2.5 Low-Voltage Inhibit (LVI) Reset

The low-voltage inhibit module (LVI) asserts its output to the SIM when the V_{DD} voltage falls to the $LVI_{LV_{RX}}$ voltage and remains at or below that level for at least nine consecutive CPU cycles. The LVI bit in the SIM reset status register (SRSR) is set, and the external reset pin (\overline{RST}) is held low while the SIM counter counts out 4096 CGMXCLK cycles. Sixty-four CGMXCLK cycles later, the CPU is released from reset to allow the reset vector sequence to occur. The SIM actively pulls down the \overline{RST} pin for all internal reset sources.

7.5 SIM Counter

The SIM counter is used by the POR module to allow the oscillator time to stabilize before enabling the internal bus (IBUS) clocks. The SIM counter also serves as a prescaler for the COP module. The SIM counter overflow supplies the clock for the COP module. The SIM counter is 13 bits long and is clocked by the falling edge of CGMXCLK.

7.5.1 SIM Counter During Power-On Reset

The POR detects power applied to the MCU. At power-on, the POR circuit asserts the signal PORRST. Once the SIM is initialized, it enables the clock generation module (CGM) to drive the bus clock state machine.

7.5.2 SIM Counter and Reset States

External reset has no effect on the SIM counter. The SIM counter is free-running after all reset states. See [7.4.2 Active Resets from Internal Sources](#) for counter control and internal reset recovery sequences.

7.6 Exception Control

Normal, sequential program execution can be changed in three different ways:

1. Interrupts:
 - a. Maskable hardware CPU interrupts
 - b. Non-maskable software interrupt instruction (SWI)
2. Reset
3. Break interrupts

7.6.1 Interrupts

At the beginning of an interrupt, the CPU saves the CPU register contents on the stack and sets the interrupt mask (I bit) to prevent additional interrupts. At the end of an interrupt, the return from interrupt (RTI) instruction recovers the CPU register contents from the stack so that normal processing can resume. **Figure 7-8** shows interrupt entry timing. **Figure 7-10** shows interrupt recovery timing.

Interrupts are latched, and arbitration is performed in the SIM at the start of interrupt processing. The arbitration result is a constant that the CPU uses to determine which vector to fetch. Once an interrupt is latched by the SIM, no other interrupt can take precedence, regardless of priority, until the latched interrupt is serviced (or the I bit is cleared). See **Figure 7-9**.

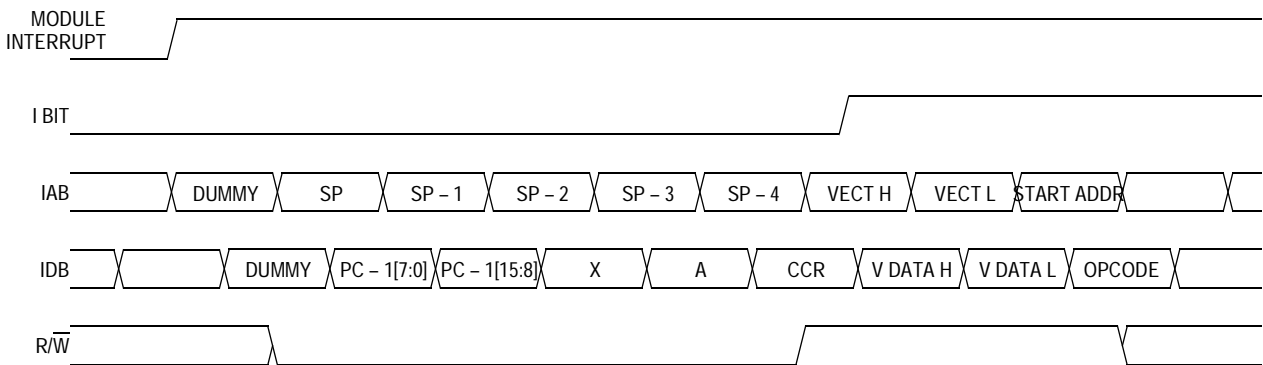

Figure 7-8. Interrupt Entry

Figure 7-9. Interrupt Processing

Figure 7-10. Interrupt Recovery

7.6.1.1 Hardware Interrupts

A hardware interrupt does not stop the current instruction. Processing of a hardware interrupt begins after completion of the current instruction. When the current instruction is complete, the SIM checks all pending hardware interrupts. If interrupts are not masked (I bit clear in the condition code register), and if the corresponding interrupt enable bit is set, the SIM proceeds with interrupt processing; otherwise, the next instruction is fetched and executed.

If more than one interrupt is pending at the end of an instruction execution, the highest priority interrupt is serviced first. [Figure 7-11](#) demonstrates what happens when two interrupts are pending. If an interrupt is pending upon exit from the original interrupt service routine, the pending interrupt is serviced before the LDA instruction is executed.

The LDA opcode is prefetched by both the INT1 and INT2 RTI instructions. However, in the case of the INT1 RTI prefetch, this is a redundant operation.

NOTE: *To maintain compatibility with the M6805 Family, the H register is not pushed on the stack during interrupt entry. If the interrupt service routine modifies the H register or uses the indexed addressing mode, software should save the H register and then restore it prior to exiting the routine.*

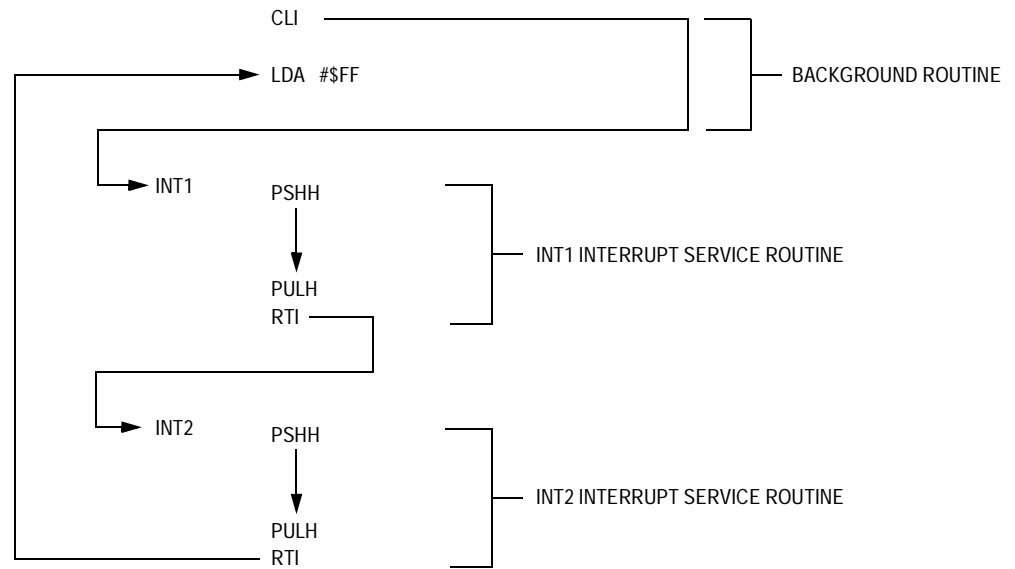

Figure 7-11. Interrupt Recognition Example

7.6.1.2 SWI Instruction

The SWI instruction is a non-maskable instruction that causes an interrupt regardless of the state of the interrupt mask (I bit) in the condition code register.

NOTE: *A software interrupt pushes PC onto the stack. A software interrupt does not push PC – 1, as a hardware interrupt does.*

7.6.2 Reset

All reset sources always have equal and highest priority and cannot be arbitrated.

7.6.3 Status Flag Protection in Break Mode

The SIM controls whether status flags contained in other modules can be cleared during break mode. The user can select whether flags are protected from being cleared by properly initializing the break clear flag enable bit (BCFE) in the SIM break flag control register (SBFCR).

Protecting flags in break mode ensures that set flags will not be cleared while in break mode. This protection allows registers to be freely read and written during break mode without losing status flag information.

Setting the BCFE bit enables the clearing mechanisms. Once cleared in break mode, a flag remains cleared even when break mode is exited. Status flags with a 2-step clearing mechanism — for example, a read of one register followed by the read or write of another — are protected, even when the first step is accomplished prior to entering break mode. Upon leaving break mode, execution of the second step will clear the flag as normal.

7.7 Low-Power Mode

Executing the WAIT or STOP instruction puts the MCU in a low power-consumption mode for standby situations. The SIM holds the CPU in a non-clocked state. Both STOP and WAIT clear the interrupt mask (I) in the condition code register, allowing interrupts to occur.

7.7.1 Wait Mode

In wait mode, the CPU clocks are inactive while the peripheral clocks continue to run. [Figure 7-12](#) shows the timing for wait mode entry.

Note: Previous data can be operand data or the WAIT opcode, depending on the last instruction.

Figure 7-12. Wait Mode Entry Timing

A module that is active during wait mode can wake up the CPU with an interrupt if the interrupt is enabled. Stacking for the interrupt begins one cycle after the WAIT instruction during which the interrupt occurred. Refer to the wait mode subsection of each module to see if the module

is active or inactive in wait mode. Some modules can be programmed to be active in wait mode.

Wait mode can also be exited by a reset or break. A break interrupt during wait mode sets the SIM break stop/wait bit, SBSW, in the SIM break status register (SBSR). If the COP disable bit, COPD, in the configuration register is logic 0, then the computer operating properly module (COP) is enabled and remains active in wait mode.

Figure 7-13 and **Figure 7-14** show the timing for wait recovery.

Note: EXITSTOPWAIT = $\overline{\text{RST}}$ pin or CPU interrupt or break interrupt

Figure 7-13. Wait Recovery from Interrupt or Break

Figure 7-14. Wait Recovery from Internal Reset

7.7.2 Stop Mode

In stop mode, the SIM counter is reset and the system clock is disabled. An external interrupt request will cause an exit from stop mode. Stacking for interrupts begins after the stop recovery delay time of 4096 CGMXCLK cycles has elapsed. Reset or break also cause an exit from stop mode.

The SIM disables the clock generator module outputs in stop mode, stopping the CPU and all peripherals.

NOTE: *It is important to note that when using the PWM generator its outputs will stop toggling when stop mode is entered. The PWM module must be disabled before entering stop mode to prevent external inverter failure.*

7.7.3 SIM Break Status Register

The SIM break status register (SBSR) contains a flag to indicate that a break caused an exit from wait mode.

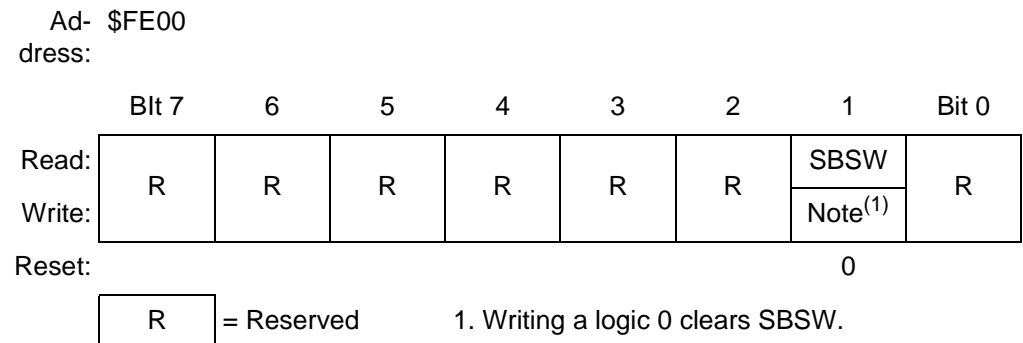

Figure 7-15. SIM Break Status Register (SBSR)

SBSW — SIM Break Stop/Wait Bit

This status bit is useful in applications requiring a return to wait mode after exiting from a break interrupt. Clear SBSW by writing a logic 0 to it. Reset clears SBSW.

1 = Wait mode was exited by break interrupt.

0 = Wait mode was not exited by break interrupt.

SBSW can be read within the break state SWI routine. The user can modify the return address on the stack by subtracting one from it. The following code is an example of this. Writing 0 to the SBSW bit clears it.

```

; This code works if the H register has been pushed onto the stack in the break
; service routine software. This code should be executed at the end of the break
; service routine software.

HIBYTE EQU 5
LOBYTE EQU 6
; If not SBSW, do RTI
BRCLR SBSW,SBSR, RETURN ; See if wait mode was exited by break.
;
TST LOBYTE,SP ; If RETURNLO is not zero,
BNE DOLO ; then just decrement low byte.
DEC HIBYTE,SP ; Else deal with high byte, too.
DOLO DEC LOBYTE,SP ; Point to WAIT opcode.
RETURN PULH ; Restore H register.
RTI

```

7.7.4 SIM Reset Status Register

The SIM reset status register (SRSR) contains six flags that show the source of the last reset. Clear the SRSR by reading it. A power-on reset sets the POR bit and clears all other bits in the register.

Ad- \$FE01
dress:

- 0 = POR or read of SRSR

LVI — Low-Voltage Inhibit Reset Bit

- 1 = Last reset was caused by the LVI circuit
- 0 = POR or read of SRSR

7.7.5 SIM Break Flag Control Register

The SIM break control register (SBFCR) contains a bit that enables software to clear status bits while the MCU is in a break state.

Figure 7-17. SIM Break Flag Control Register (SBFCR)

BCFE — Break Clear Flag Enable Bit

This read/write bit enables software to clear status bits by accessing status registers while the MCU is in a break state. To clear status bits during the break state, the BCFE bit must be set.

1 = Status bits clearable during break

0 = Status bits not clearable during break

8.2 Introduction

This section describes the clock generator module (CGM, version A). The CGM generates the crystal clock signal, CGMXCLK, which operates at the frequency of the crystal. The CGM also generates the base clock signal, CGMOUT, from which the system integration module (SIM) derives the system clocks.

CGMOUT is based on either the crystal clock divided by two or the phase-locked loop (PLL) clock, CGMVCLK, divided by two. The PLL is a frequency generator designed for use with crystals or ceramic resonators. The PLL can generate an 8-MHz bus frequency without using a 32-MHz crystal.

8.3 Features

Features of the CGM include:

- Phase-locked loop with output frequency in integer multiples of the crystal reference
- Programmable hardware voltage-controlled oscillator (VCO) for low-jitter operation
- Automatic bandwidth control mode for low-jitter operation
- Automatic frequency lock detector
- Central processor unit (CPU) interrupt on entry or exit from locked condition

8.4 Functional Description

The CGM consists of three major submodules:

1. Crystal oscillator circuit — The crystal oscillator circuit generates the constant crystal frequency clock, CGMXCLK.
2. Phase-locked loop (PLL) — The PLL generates the programmable VCO frequency clock, CGMVCLK.
3. Base clock selector circuit — This software-controlled circuit selects either CGMXCLK divided by two or the VCO clock, CGMVCLK, divided by two as the base clock, CGMOUT. The SIM derives the system clocks from CGMOUT.

Figure 8-1 shows the structure of the CGM.

8.4.1 Crystal Oscillator Circuit

The crystal oscillator circuit consists of an inverting amplifier and an external crystal. The OSC1 pin is the input to the amplifier and the OSC2 pin is the output. The SIMOSCEN signal from the system integration module (SIM) enables the crystal oscillator circuit.

The CGMXCLK signal is the output of the crystal oscillator circuit and runs at a rate equal to the crystal frequency. CGMXCLK is then buffered to produce CGMRCLK, the PLL reference clock.

CGMXCLK can be used by other modules which require precise timing for operation. The duty cycle of CGMXCLK is not guaranteed to be 50 percent and depends on external factors, including the crystal and related external components.

An externally generated clock also can feed the OSC1 pin of the crystal oscillator circuit. Connect the external clock to the OSC1 pin and let the OSC2 pin float.

Figure 8-2. CGM I/O Register Summary

8.4.2 Phase-Locked Loop Circuit (PLL)

The PLL is a frequency generator that can operate in either acquisition mode or tracking mode, depending on the accuracy of the output frequency. The PLL can change between acquisition and tracking modes either automatically or manually.

8.4.2.1 PLL Circuits

The PLL consists of these circuits:

- Voltage-controlled oscillator (VCO)
- Modulo VCO frequency divider

Clock Generator Module (CGM)

- Phase detector
- Loop filter
- Lock detector

The operating range of the VCO is programmable for a wide range of frequencies and for maximum immunity to external noise, including supply and CGMXFC noise. The VCO frequency is bound to a range from roughly one-half to twice the center-of-range frequency, f_{VRS} . Modulating the voltage on the CGMXFC pin changes the frequency within this range. By design, f_{VRS} is equal to the nominal center-of-range frequency, f_{NOM} , (4.9152 MHz) times a linear factor L, or $(L) f_{NOM}$.

CGMRCLK is the PLL reference clock, a buffered version of CGMXCLK. CGMRCLK runs at a frequency, f_{RCLK} , and is fed to the PLL through a buffer. The buffer output is the final reference clock, CGMRDV, running at a frequency, $f_{RDV} = f_{RCLK}$.

The VCO's output clock, CGMVCLK, running at a frequency f_{VCLK} , is fed back through a programmable modulo divider. The modulo divider reduces the VCO clock by a factor, N. The divider's output is the VCO feedback clock, CGMVDV, running at a frequency, $f_{VDV} = f_{VCLK}/N$. See [8.4.2.4 Programming the PLL](#) for more information.

The phase detector then compares the VCO feedback clock, CGMVDV, with the final reference clock, CGMRDV. A correction pulse is generated based on the phase difference between the two signals. The loop filter then slightly alters the dc voltage on the external capacitor connected to CGMXFC based on the width and direction of the correction pulse. The filter can make fast or slow corrections depending on its mode, described in [8.4.2.2 Acquisition and Tracking Modes](#). The value of the external capacitor and the reference frequency determines the speed of the corrections and the stability of the PLL.

The lock detector compares the frequencies of the VCO feedback clock, CGMVDV, and the final reference clock, CGMRDV. Therefore, the speed of the lock detector is directly proportional to the final reference frequency, f_{RDV} . The circuit determines the mode of the PLL and the lock condition based on this comparison.

8.4.2.2 Acquisition and Tracking Modes

The PLL filter is manually or automatically configurable into one of two operating modes:

- Acquisition mode — In acquisition mode, the filter can make large frequency corrections to the VCO. This mode is used at PLL startup or when the PLL has suffered a severe noise hit and the VCO frequency is far off the desired frequency. When in acquisition mode, the \overline{ACQ} bit is clear in the PLL bandwidth control register. See [8.6.2 PLL Bandwidth Control Register](#).
- Tracking mode — In tracking mode, the filter makes only small corrections to the frequency of the VCO. PLL jitter is much lower in tracking mode, but the response to noise is also slower. The PLL enters tracking mode when the VCO frequency is nearly correct, such as when the PLL is selected as the base clock source. The PLL is automatically in tracking mode when not in acquisition mode or when the \overline{ACQ} bit is set. See [8.4.3 Base Clock Selector Circuit](#).

8.4.2.3 Manual and Automatic PLL Bandwidth Modes

The PLL can change the bandwidth or operational mode of the loop filter manually or automatically.

In automatic bandwidth control mode ($AUTO = 1$), the lock detector automatically switches between acquisition and tracking modes. Automatic bandwidth control mode also is used to determine when the VCO clock, CGMVCLK, is safe to use as the source for the base clock, CGMOUT ([8.6.2 PLL Bandwidth Control Register](#)). If PLL interrupts are enabled, the software can wait for a PLL interrupt request and then check the LOCK bit. If interrupts are disabled, software can poll the LOCK bit continuously (during PLL startup, usually) or at periodic intervals. In either case, when the LOCK bit is set, the VCO clock is safe to use as the source for the base clock (see [8.4.3 Base Clock Selector Circuit](#)). If the VCO is selected as the source for the base clock and the LOCK bit is clear, the PLL has suffered a severe noise hit and the software must take appropriate action, depending on the application. See [8.7 Interrupts](#) for information and precautions on using interrupts.

These conditions apply when the PLL is in automatic bandwidth control mode:

- The $\overline{\text{ACQ}}$ bit (see [8.6.2 PLL Bandwidth Control Register](#)) is a read-only indicator of the mode of the filter. See [8.4.2.2 Acquisition and Tracking Modes](#).
- The $\overline{\text{ACQ}}$ bit is set when the VCO frequency is within a certain tolerance, Δ_{TRK} , and is cleared when the VCO frequency is out of a certain tolerance, Δ_{UNT} . See [8.11 Acquisition/Lock Time Specifications](#) for more information.
- The LOCK bit is a read-only indicator of the locked state of the PLL.
- The LOCK bit is set when the VCO frequency is within a certain tolerance, Δ_{Lock} , and is cleared when the VCO frequency is out of a certain tolerance, Δ_{UNL} . See [8.11 Acquisition/Lock Time Specifications](#) for more information.
- CPU interrupts can occur if enabled ($\text{PLLIE} = 1$) when the PLL's lock condition changes, toggling the LOCK bit. See [8.6.1 PLL Control Register](#).

The PLL also may operate in manual mode ($\text{AUTO} = 0$). Manual mode is used by systems that do not require an indicator of the lock condition for proper operation. Such systems typically operate well below f_{BUSMAX} and require fast startup.

These conditions apply when in manual mode:

- $\overline{\text{ACQ}}$ is a writable control bit that controls the mode of the filter. Before turning on the PLL in manual mode, the $\overline{\text{ACQ}}$ bit must be clear.
- Before entering tracking mode ($\overline{\text{ACQ}} = 1$), software must wait a given time, t_{ACQ} (see [8.11 Acquisition/Lock Time Specifications](#)), after turning on the PLL by setting PLLON in the PLL control register (PCTL).
- Software must wait a given time, t_{AL} , after entering tracking mode before selecting the PLL as the clock source to CGMOUT ($\text{BCS} = 1$).
- The LOCK bit is disabled.
- CPU interrupts from the CGM are disabled.

8.4.2.4 Programming the PLL

This procedure shows how to program the PLL.

NOTE: *The round function in the following equations means that the real number should be rounded to the nearest integer number.*

1. Choose the desired bus frequency, f_{BUSDES} .
2. Calculate the desired VCO frequency (four times the desired bus frequency).

$$f_{\text{VCLKDES}} = 4 \times f_{\text{BUSDES}}$$

3. Choose a practical PLL reference frequency, f_{RCLK} .
4. Select a VCO frequency multiplier, N .
5. Calculate and verify the adequacy of the VCO and bus frequencies f_{VCLK} and f_{BUS} .

$$f_{\text{VCLK}} = N \times f_{\text{RCLK}}$$

$$f_{\text{BUS}} = (f_{\text{VCLK}})^{1/4}$$

6. Select a VCO linear range multiplier, L ,
where $f_{\text{NOM}} = 4.9152$ MHz
7. Calculate and verify the adequacy of the VCO programmed center-of-range frequency, f_{VRS} .

$$f_{\text{VRS}} = (L) f_{\text{NOM}}$$

8. Verify the choice of N and L by comparing f_{VCLK} to f_{VRS} and f_{VCLKDES} . For proper operation, f_{VCLK} must be within the application's tolerance of f_{VCLKDES} , and f_{VRS} must be as close as possible to f_{VCLK} .

CAUTION: *Exceeding the recommended maximum bus frequency or VCO frequency can crash the MCU.*

9. Program the PLL registers accordingly:
 - a. In the upper four bits of the PLL programming register (PPG), program the binary equivalent of N .
 - b. In the lower four bits of the PLL programming register (PPG), program the binary equivalent of L .

8.4.2.5 Special Programming Exceptions

The programming method described in [8.4.2.4 Programming the PLL](#) does not account for possible exceptions. A value of 0 for N or L is meaningless when used in the equations given. To account for these exceptions:

- A 0 value for N is interpreted exactly the same as a value of 1.
- A 0 value for L disables the PLL and prevents its selection as the source for the base clock. See [8.4.3 Base Clock Selector Circuit](#).

8.4.3 Base Clock Selector Circuit

This circuit is used to select either the crystal clock, CGMXCLK, or the VCO clock, CGMVCLK, as the source of the base clock, CGMOUT. The two input clocks go through a transition control circuit that waits up to three CGMXCLK cycles and three CGMVCLK cycles to change from one clock source to the other. During this time, CGMOUT is held in state. The output of the transition control circuit is then divided by two to correct the duty cycle. Therefore, the bus clock frequency, which is one-half of the base clock frequency, is one-fourth the frequency of the selected clock (CGMXCLK or CGMVCLK).

The BCS bit in the PLL control register (PCTL) selects which clock drives CGMOUT. The VCO clock cannot be selected as the base clock source if the PLL is not turned on. The PLL cannot be turned off if the VCO clock is selected. The PLL cannot be turned on or off simultaneously with the selection or deselection of the VCO clock. The VCO clock also cannot be selected as the base clock source if the factor L is programmed to a 0. This value would set up a condition inconsistent with the operation of the PLL, so that the PLL would be disabled and the crystal clock would be forced as the source of the base clock.

8.4.4 CGM External Connections

In its typical configuration, the CGM requires seven external components. Five of these are for the crystal oscillator and two are for the PLL.

The crystal oscillator is normally connected in a Pierce oscillator configuration, as shown in [Figure 8-3](#). [Figure 8-3](#) shows only the logical representation of the internal components and may not represent actual circuitry.

The oscillator configuration uses five components:

1. Crystal, X_1
2. Fixed capacitor, C_1
3. Tuning capacitor, C_2 (can also be a fixed capacitor)
4. Feedback resistor, R_B
5. Series resistor, R_S (optional)

The series resistor (R_S) is included in the diagram to follow strict Pierce oscillator guidelines and may not be required for all ranges of operation, especially with high frequency crystals. Refer to the crystal manufacturer's data for more information.

[Figure 8-3](#) also shows the external components for the PLL:

- Bypass capacitor, C_{BYP}
- Filter capacitor, C_F

Routing should be done with great care to minimize signal cross talk and noise. See [8.11 Acquisition/Lock Time Specifications](#) for routing information and more information on the filter capacitor's value and its effects on PLL performance.

* R_S can be 0 (shorted) when used with higher-frequency crystals. Refer to manufacturer's data.

Figure 8-3. CGM External Connections

8.5 I/O Signals

The following paragraphs describe the CGM input/output (I/O) signals.

8.5.1 Crystal Amplifier Input Pin (OSC1)

The OSC1 pin is an input to the crystal oscillator amplifier.

8.5.2 Crystal Amplifier Output Pin (OSC2)

The OSC2 pin is the output of the crystal oscillator inverting amplifier.

8.5.3 External Filter Capacitor Pin (CGMXFC)

The CGMXFC pin is required by the loop filter to filter out phase corrections. A small external capacitor is connected to this pin.

NOTE: To prevent noise problems, C_F should be placed as close to the CGMXFC pin as possible, with minimum routing distances and no routing of other signals across the C_F connection.

8.5.4 PLL Analog Power Pin (V_{DDA})

V_{DDA} is a power pin used by the analog portions of the PLL. Connect the V_{DDA} pin to the same voltage potential as the V_{DD} pin.

NOTE: Route V_{DDA} carefully for maximum noise immunity and place bypass capacitors as close as possible to the package.

8.5.5 Oscillator Enable Signal (SIMOSCEN)

The SIMOSCEN signal comes from the system integration module (SIM) and enables the oscillator and PLL.

8.5.6 Crystal Output Frequency Signal (CGMXCLK)

CGMXCLK is the crystal oscillator output signal. It runs at the full speed of the crystal (f_{XCLK}) and comes directly from the crystal oscillator circuit. [Figure 8-3](#) shows only the logical relation of CGMXCLK to OSC1 and OSC2 and may not represent the actual circuitry. The duty cycle of CGMXCLK is unknown and may depend on the crystal and other external factors. Also, the frequency and amplitude of CGMXCLK can be unstable at startup.

8.5.7 CGM Base Clock Output (CGMOUT)

CGMOUT is the clock output of the CGM. This signal goes to the SIM, which generates the MCU clocks. CGMOUT is a 50 percent duty cycle clock running at twice the bus frequency. CGMOUT is software programmable to be either the oscillator output, CGMXCLK, divided by two or the VCO clock, CGMVCLK, divided by two.

8.5.8 CGM CPU Interrupt (CGMINT)

CGMINT is the interrupt signal generated by the PLL lock detector.

8.6 CGM Registers

These registers control and monitor operation of the CGM:

- PLL control register (PCTL), see [8.6.1 PLL Control Register](#)
- PLL bandwidth control register (PBWC), see [8.6.2 PLL Bandwidth Control Register](#)
- PLL programming register (PPG), see [8.6.3 PLL Programming Register](#)

Figure 8-4 is a summary of the CGM registers.

Addr.	Register Name	Bit 7	6	5	4	3	2	1	Bit 0

R

 = Reserved

Notes:

1. When AUTO = 0, PLLIE is forced to logic 0 and is read-only.
2. When AUTO = 0, PLLF and LOCK read as logic 0.
3. When AUTO = 1, ACQ is read-only.
4. When PLLON = 0 or VRS[7:4] = \$0, BCS is forced to logic 0 and is read-only.
5. When PLLON = 1, the PLL programming register is read-only.
6. When BCS = 1, PLLON is forced set and is read-only.

Figure 8-4. CGM I/O Register Summary

8.6.1 PLL Control Register

The PLL control register (PCTL) contains the interrupt enable and flag bits, the on/off switch, and the base clock selector bit.

Ad- \$005C
dress:

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	PLLIE	PLLF	PLLON	BCS	1	1	1	1
Write:		R			R	R	R	
Reset:	0	0	1	0	1	1	1	1

R

 = Reserved

Figure 8-5. PLL Control Register (PCTL)

PLLIE — PLL Interrupt Enable Bit

This read/write bit enables the PLL to generate an interrupt request when the LOCK bit toggles, setting the PLL flag, PLLF. When the AUTO bit in the PLL bandwidth control register (PBWC) is clear, PLLIE cannot be written and reads as logic 0. Reset clears the PLLIE bit.

- 1 = PLL interrupts enabled
- 0 = PLL interrupts disabled

PLLF — PLL Interrupt Flag Bit

This read-only bit is set whenever the LOCK bit toggles. PLLF generates an interrupt request if the PLLIE bit also is set. PLLF always reads as logic 0 when the AUTO bit in the PLL bandwidth control register (PBWC) is clear. Clear the PLLF bit by reading the PLL control register. Reset clears the PLLF bit.

- 1 = Change in lock condition
- 0 = No change in lock condition

NOTE: *Do not inadvertently clear the PLLF bit. Any read or read-modify-write operation on the PLL control register clears the PLLF bit.*

PLLON — PLL On Bit

This read/write bit activates the PLL and enables the VCO clock, CGMVCLK. PLLON cannot be cleared if the VCO clock is driving the base clock, CGMOUT (BCS = 1). Reset sets this bit so that the loop can stabilize as the MCU is powering up. See [8.4.3 Base Clock Selector Circuit](#).

- 1 = PLL on
- 0 = PLL off

BCS — Base Clock Select Bit

This read/write bit selects either the crystal oscillator output, CGMXCLK, or the VCO clock, CGMVCLK, as the source of the CGM output, CGMOUT. CGMOUT frequency is one-half the frequency of the selected clock. BCS cannot be set while the PLLON bit is clear. After toggling BCS, it may take up to three CGMXCLK and three CGMVCLK cycles to complete the transition from one source clock to the other. During the transition, CGMOUT is held in stasis. Reset clears the BCS bit. See [8.4.3 Base Clock Selector Circuit](#).

- 1 = CGMVCLK divided by two drives CGMOUT
- 0 = CGMXCLK divided by two drives CGMOUT

NOTE: *PLLON and BCS have built-in protection that prevents the base clock selector circuit from selecting the VCO clock as the source of the base clock if the PLL is off. Therefore, PLLON cannot be cleared when BCS is set, and BCS cannot be set when PLLON is clear. If the PLL is off (PLLON = 0), selecting CGMVCLK requires two writes to the PLL control register. See [8.4.3 Base Clock Selector Circuit](#).*

PCTL Bits 3–0 — Unimplemented Bits

These bits provide no function and always read as logic 1s.

8.6.2 PLL Bandwidth Control Register

The PLL bandwidth control register:

- Selects automatic or manual (software-controlled) bandwidth control mode
- Indicates when the PLL is locked
- In automatic bandwidth control mode, indicates when the PLL is in acquisition or tracking mode
- In manual operation, forces the PLL into acquisition or tracking mode

Ad- \$005D
dress:

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	AUTO	LOCK	$\overline{\text{ACQ}}$	XLD	0	0	0	0
Write:		R			R	R	R	R
Reset:	0	0	0	0	0	0	0	0

R = Reserved

Figure 8-6. PLL Bandwidth Control Register (PBWC)

AUTO — Automatic Bandwidth Control Bit

This read/write bit selects automatic or manual bandwidth control. When initializing the PLL for manual operation (AUTO = 0), clear the $\overline{\text{ACQ}}$ bit before turning on the PLL. Reset clears the AUTO bit.

- 1 = Automatic bandwidth control
- 0 = Manual bandwidth control

LOCK — Lock Indicator Bit

When the AUTO bit is set, LOCK is a read-only bit that becomes set when the VCO clock, CGMVCLK, is locked (running at the programmed frequency). When the AUTO bit is clear, LOCK reads as logic 0 and has no meaning. Reset clears the LOCK bit.

- 1 = VCO frequency correct or locked
- 0 = VCO frequency incorrect or unlocked

\overline{ACQ} — Acquisition Mode Bit

When the AUTO bit is set, \overline{ACQ} is a read-only bit that indicates whether the PLL is in acquisition mode or tracking mode. When the AUTO bit is clear, \overline{ACQ} is a read/write bit that controls whether the PLL is in acquisition or tracking mode.

In automatic bandwidth control mode (AUTO = 1), the last-written value from manual operation is stored in a temporary location and is recovered when manual operation resumes. Reset clears this bit, enabling acquisition mode.

1 = Tracking mode

0 = Acquisition mode

XLD — Crystal Loss Detect Bit

When the VCO output, CGMVCLK, is driving CGMOUT, this read/write bit can indicate whether the crystal reference frequency is active or not. To check the status of the crystal reference, follow these steps:

1. Write a logic 1 to XLD.
2. Wait $N \times 4$ cycles. (N is the VCO frequency multiplier.)
3. Read XLD.

1 = Crystal reference is not active.

0 = Crystal reference is active.

The crystal loss detect function works only when the BCS bit is set, selecting CGMVCLK to drive CGMOUT. When BCS is clear, XLD always reads as logic 0.

PBWC Bits 3–0 — Reserved for Test

These bits enable test functions not available in user mode. To ensure software portability from development systems to user applications, software should write 0s to PBWC[3:0] whenever writing to PBWC.

8.6.3 PLL Programming Register

The PLL programming register (PPG) contains the programming information for the modulo feedback divider and the programming information for the hardware configuration of the VCO.

Figure 8-7. PLL Programming Register (PPG)

MUL[7:4] — Multiplier Select Bits

These read/write bits control the modulo feedback divider that selects the VCO frequency multiplier, N. See [8.4.2.1 PLL Circuits](#) and [8.4.2.4 Programming the PLL](#). A value of \$0 in the multiplier select bits configures the modulo feedback divider the same as a value of \$1. Reset initializes these bits to \$6 to give a default multiply value of 6.

Table 8-1. VCO Frequency Multiplier (N) Selection

MUL7:MUL6:MUL5:MUL4	VCO Frequency Multiplier (N)
0000	1
0001	1
0010	2
0011	3
↓	↓
1101	13
1110	14
1111	15

NOTE: *The multiplier select bits have built-in protection that prevents them from being written when the PLL is on (PLLON = 1).*

VRS[7:4] — VCO Range Select Bits

These read/write bits control the hardware center-of-range linear multiplier L , which controls the hardware center-of-range frequency f_{VRS} . See [8.4.2.1 PLL Circuits](#), [8.4.2.4 Programming the PLL](#), and [8.6.1 PLL Control Register](#). VRS[7:4] cannot be written when the PLLON bit in the PLL control register (PCTL) is set. See [8.4.2.5 Special Programming Exceptions](#). A value of \$0 in the VCO range select bits disables the PLL and clears the BCS bit in the PCTL. See [8.4.3 Base Clock Selector Circuit](#) and [8.4.2.5 Special Programming Exceptions](#) for more information.

Reset initializes the bits to \$6 to give a default range multiply value of 6.

NOTE: *The VCO range select bits have built-in protection that prevents them from being written when the PLL is on (PLLON = 1) and prevents selection of the VCO clock as the source of the base clock (BCS = 1) if the VCO range select bits are all clear.*

The VCO range select bits must be programmed correctly. Incorrect programming may result in failure of the PLL to achieve lock.

8.7 Interrupts

When the AUTO bit is set in the PLL bandwidth control register (PBWC), the PLL can generate a CPU interrupt request every time the LOCK bit changes state. The PLLIE bit in the PLL control register (PCTL) enables CPU interrupts from the PLL. PLLF, the interrupt flag in the PCTL, becomes set whether interrupts are enabled or not. When the AUTO bit is clear, CPU interrupts from the PLL are disabled and PLLF reads as logic 0.

Software should read the LOCK bit after a PLL interrupt request to see if the request was due to an entry into lock or an exit from lock. When the PLL enters lock, the VCO clock, CGMVCLK, divided by two can be selected as the CGMOUT source by setting BCS in the PCTL. When the PLL exits lock, the VCO clock frequency is corrupt, and appropriate precautions should be taken. If the application is not

frequency-sensitive, interrupts should be disabled to prevent PLL interrupt service routines from impeding software performance or from exceeding stack limitations.

NOTE: *Software can select the CGMVCLK divided by two as the CGMOUT source even if the PLL is not locked (LOCK = 0). Therefore, software should make sure the PLL is locked before setting the BCS bit.*

8.8 Wait Mode

The WAIT instruction puts the MCU in low power-consumption standby mode.

The WAIT instruction does not affect the CGM. Before entering wait mode, software can disengage and turn off the PLL by clearing the BCS and PLLON bits in the PLL control register (PCTL). Less power-sensitive applications can disengage the PLL without turning it off. Applications that require the PLL to wake the MCU from wait mode also can deselect the PLL output without turning off the PLL.

8.9 Stop Mode

The STOP instruction puts the MCU in low power-consumption standby mode.

The STOP instruction disables the CGMC (oscillator and phase-lock loop) and holds the CGM outputs low.

8.10 CGM During Break Mode

The system integration module (SIM) controls whether status bits in other modules can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state. See [7.7.5 SIM Break Flag Control Register](#).

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect the PLLF bit during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), software can read and write the PLL control register during the break state without affecting the PLLF bit.

8.11 Acquisition/Lock Time Specifications

The acquisition and lock times of the PLL are, in many applications, the most critical PLL design parameters. Proper design and use of the PLL ensures the highest stability and lowest acquisition/lock times.

8.11.1 Acquisition/Lock Time Definitions

Typical control systems refer to the acquisition time or lock time as the reaction time, within specified tolerances, of the system to a step input. In a PLL, the step input occurs when the PLL is turned on or when it suffers a noise hit. The tolerance is usually specified as a percent of the step input or when the output settles to the desired value plus or minus a percent of the frequency change. Therefore, the reaction time is constant in this definition, regardless of the size of the step input. For example, consider a system with a 5 percent acquisition time tolerance. If a command instructs the system to change from 0 Hz to 1 MHz, the acquisition time is the time taken for the frequency to reach $1\text{ MHz} \pm 50\text{ kHz}$. Fifty kHz = 5 percent of the 1-MHz step input. If the system is operating at 1 MHz and suffers a –100-kHz noise hit, the acquisition time is the time taken to return from 900 kHz to $1\text{ MHz} \pm 5\text{ kHz}$. Five kHz = 5 percent of the 100-kHz step input.

Other systems refer to acquisition and lock times as the time the system takes to reduce the error between the actual output and the desired output to within specified tolerances. Therefore, the acquisition or lock time varies according to the original error in the output. Minor errors may not even be registered. Typical PLL applications prefer to use this definition because the system requires the output frequency to be within a certain tolerance of the desired frequency regardless of the size of the initial error.

The discrepancy in these definitions makes it difficult to specify an acquisition or lock time for a typical PLL. Therefore, the definitions for acquisition and lock times for this module are:

- Acquisition time, t_{ACQ} , is the time the PLL takes to reduce the error between the actual output frequency and the desired output frequency to less than the tracking mode entry tolerance, Δ_{TRK} . Acquisition time is based on an initial frequency error, $(f_{DES} - f_{ORIG})/f_{DES}$, of not more than ± 100 percent. In automatic bandwidth control mode (see [8.4.2.3 Manual and Automatic PLL Bandwidth Modes](#)), acquisition time expires when the \overline{ACQ} bit becomes set in the PLL bandwidth control register (PBWC).
- Lock time, t_{LOCK} , is the time the PLL takes to reduce the error between the actual output frequency and the desired output frequency to less than the lock mode entry tolerance, Δ_{LOCK} . Lock time is based on an initial frequency error, $(f_{DES} - f_{ORIG})/f_{DES}$, of not more than ± 100 percent. In automatic bandwidth control mode, lock time expires when the LOCK bit becomes set in the PLL bandwidth control register (PBWC). See [8.4.2.3 Manual and Automatic PLL Bandwidth Modes](#).

Obviously, the acquisition and lock times can vary according to how large the frequency error is and may be shorter or longer in many cases.

8.11.2 Parametric Influences on Reaction Time

Acquisition and lock times are designed to be as short as possible while still providing the highest possible stability. These reaction times are not constant, however. Many factors directly and indirectly affect the acquisition time.

The most critical parameter which affects the reaction times of the PLL is the reference frequency, f_{RDV} . This frequency is the input to the phase detector and controls how often the PLL makes corrections. For stability, the corrections must be small compared to the desired frequency, so several corrections are required to reduce the frequency error. Therefore, the slower the reference the longer it takes to make these corrections. This parameter is also under user control via the choice of crystal frequency, f_{XCLK} .

Another critical parameter is the external filter capacitor. The PLL modifies the voltage on the VCO by adding or subtracting charge from this capacitor. Therefore, the rate at which the voltage changes for a given frequency error (thus change in charge) is proportional to the capacitor size. The size of the capacitor also is related to the stability of the PLL. If the capacitor is too small, the PLL cannot make small enough adjustments to the voltage and the system cannot lock. If the capacitor is too large, the PLL may not be able to adjust the voltage in a reasonable time. See [8.11.3 Choosing a Filter Capacitor](#).

Also important is the operating voltage potential applied to V_{DDA} . The power supply potential alters the characteristics of the PLL. A fixed value is best. Variable supplies, such as batteries, are acceptable if they vary within a known range at very slow speeds. Noise on the power supply is not acceptable, because it causes small frequency errors which continually change the acquisition time of the PLL.

Temperature and processing also can affect acquisition time because the electrical characteristics of the PLL change. The part operates as specified as long as these influences stay within the specified limits. External factors, however, can cause drastic changes in the operation of the PLL. These factors include noise injected into the PLL through the filter capacitor, filter capacitor leakage, stray impedances on the circuit board, and even humidity or circuit board contamination.

8.11.3 Choosing a Filter Capacitor

As described in [8.11.2 Parametric Influences on Reaction Time](#), the external filter capacitor, C_F , is critical to the stability and reaction time of the PLL. The PLL is also dependent on reference frequency and supply voltage. The value of the capacitor must, therefore, be chosen with supply potential and reference frequency in mind. For proper operation, the external filter capacitor must be chosen according to this equation:

$$C_F = C_{FACT} \left(\frac{V_{DDA}}{f_{RDV}} \right)$$

For acceptable values of C_{FACT} , see [8.11 Acquisition/Lock Time Specifications](#). For the value of V_{DDA} , choose the voltage potential at which the MCU is operating. If the power supply is variable, choose a value near the middle of the range of possible supply values.

This equation does not always yield a commonly available capacitor size, so round to the nearest available size. If the value is between two different sizes, choose the higher value for better stability. Choosing the lower size may seem attractive for acquisition time improvement, but the PLL can become unstable. Also, always choose a capacitor with a tight tolerance (± 20 percent or better) and low dissipation.

8.11.4 Reaction Time Calculation

The actual acquisition and lock times can be calculated using the equations here. These equations yield nominal values under these conditions:

- Correct selection of filter capacitor, C_F ; see [8.11.3 Choosing a Filter Capacitor](#)
- Room temperature operation
- Negligible external leakage on CGMXFC
- Negligible noise

The K factor in the equations is derived from internal PLL parameters. K_{ACQ} is the K factor when the PLL is configured in acquisition mode, and K_{TRK} is the K factor when the PLL is configured in tracking mode. See [8.4.2.2 Acquisition and Tracking Modes](#).

$$t_{ACQ} = \left(\frac{V_{DDA}}{f_{RDV}} \right) \left(\frac{8}{K_{ACQ}} \right)$$

$$t_{AL} = \left(\frac{V_{DDA}}{f_{RDV}} \right) \left(\frac{4}{K_{TRK}} \right)$$

$$t_{Lock} = t_{ACQ} + t_{AL}$$

NOTE: *Inverse proportionality between the lock time and the reference frequency*

In automatic bandwidth control mode, the acquisition and lock times are quantized into units based on the reference frequency, see [8.4.2.3 Manual and Automatic PLL Bandwidth Modes](#). A certain number of clock cycles, n_{ACQ} , is required to ascertain that the PLL is within the tracking mode entry tolerance, Δ_{TRK} , before exiting acquisition mode. A

certain number of clock cycles, n_{TRK} , is required to ascertain that the PLL is within the lock mode entry tolerance, Δ_{Lock} . Therefore, the acquisition time, t_{ACQ} , is an integer multiple of n_{ACQ}/f_{RDV} , and the acquisition to lock time, t_{AL} , is an integer multiple of n_{TRK}/f_{RDV} . Also, since the average frequency over the entire measurement period must be within the specified tolerance, the total time usually is longer than t_{Lock} as calculated above.

In manual mode, it is usually necessary to wait considerably longer than t_{Lock} before selecting the PLL clock (see [8.4.3 Base Clock Selector Circuit](#)) because the factors described in [8.11.2 Parametric Influences on Reaction Time](#) may slow the lock time considerably.

9.2 Introduction

This section describes the pulse-width modulator for motor control (PWMMC, version A). The MC68HC908MR8 PWM module can generate three complementary PWM pairs or six independent PWM signals. These PWM signals can be center-aligned or edge-aligned. A block diagram of the PWM module is shown in [Figure 9-1](#).

A 12-bit timer PWM counter is common to all six channels. PWM resolution is one clock period for edge-aligned operation and two clock periods for center-aligned operation. The clock period is dependent on the internal operating frequency (f_{OP}) and a programmable prescaler. The highest resolution for edge-aligned operation is 125 ns ($f_{OP} = 8$ MHz). The highest resolution for center-aligned operation is 250 ns ($f_{OP} = 8$ MHz).

When generating complementary PWM signals, the module features automatic dead-time insertion to the PWM output pairs.

A summary of the PWM registers is shown in [Figure 9-2](#).

9.3 Features

Features of the PWMMC include:

- Three complimentary PWM pairs or six independent PWM signals
- Edge-aligned PWM signals or center-aligned PWM signals
- PWM signal polarity control
- Manual PWM output control through software
- Programmable fault protection
- Complimentary mode also features:
 - Dead-time insertion
 - Separate top/bottom pulse width correction via current sensing or programmable software bits

Figure 9-2. Register Summary (Sheet 4 of 4)

9.4 Timebase

This subsection provides for a discussion of the timebase.

9.4.1 Resolution

In center-aligned mode, a 12-bit up/down counter is used to create the PWM period. Therefore, the PWM resolution in center-aligned mode is two clocks (highest resolution is 250 ns @ $f_{OP} = 8$ MHz) as shown in [Figure 9-3](#). The up/down counter uses the value in the timer modulus register to determine its maximum count. The PWM period will equal:

$$(\text{timer modulus}) \times (\text{PWM clock period}) \times 2$$

For edge-aligned mode, a 12-bit up-only counter is used to create the PWM period. Therefore, the PWM resolution in edge-aligned mode is one clock (highest resolution is 125 ns @ $f_{OP} = 8$ MHz) as shown in [Figure 9-4](#). Again, the timer modulus register is used to determine the maximum count. The PWM period will equal:

$$(\text{timer modulus}) \times (\text{PWM clock period})$$

Center-aligned operation versus edge-aligned operation is determined by the option EDGE. See [5.4 CONFIG Bits](#).

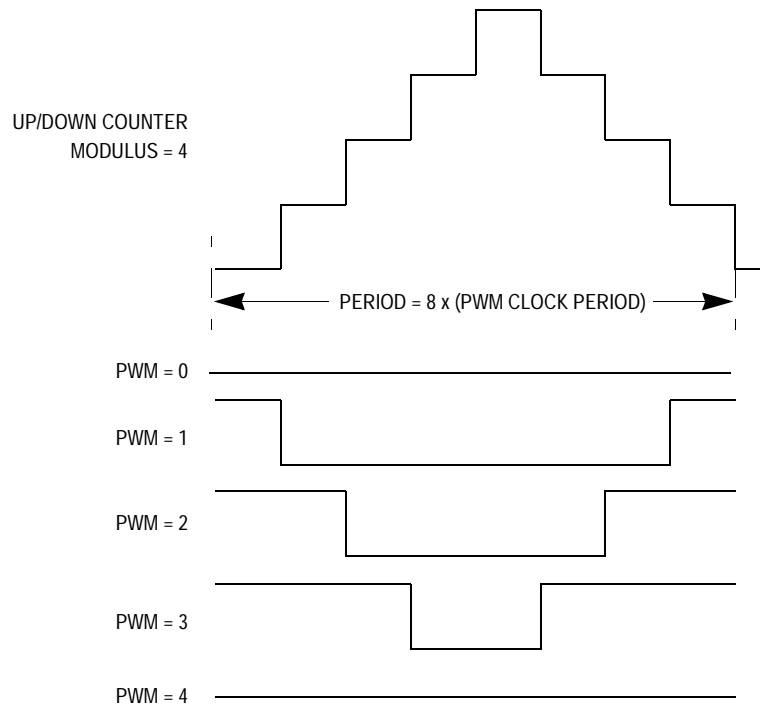

Figure 9-3. Center-Aligned PWM (Positive Polarity)

Figure 9-4. Edge-Aligned PWM (Positive Polarity)

9.4.2 Prescaler

To permit lower PWM frequencies, a prescaler is provided which will divide the PWM clock frequency by 1, 2, 4, or 8. [Table 9-1](#) shows how setting the prescaler bits in PWM control register 2 affects the PWM clock frequency. This prescaler is buffered and will not be used by the PWM generator until the LDOK bit is set and a new PWM reload-cycle begins.

Table 9-1. PWM Prescaler

Prescaler Bits PRSC1:PRSC0	PWM Clock Frequency
00	f_{OP}
01	$f_{OP}/2$
10	$f_{OP}/4$
11	$f_{OP}/8$

9.5 PWM Generators

This subsection describes the pulse-width modulator (PWM) generators.

9.5.1 Load Operation

To help avoid erroneous pulse widths and PWM periods, the modulus, prescaler, and PWM value registers are buffered. New PWM values, counter modulus values, and prescalers can be loaded from their buffers into the PWM module every one, two, four, or eight PWM cycles. LDFQ1:LDFQ0 in PWM control register 2 are used to control this reload frequency, as shown in [Table 9-2](#). When a reload cycle arrives, regardless of whether an actual reload occurs (as determined by the LDOK bit), the PWM reload flag bit in PWM control register 1 will be set. If the PWMINT bit in PWM control register 1 is set, a CPU interrupt request will be generated when PWMF is set. Software can use this interrupt to calculate new PWM parameters in real time for the PWM module.

Table 9-2. PWM Reload Frequency

Reload Frequency Bits LDFQ1:LDFQ0	PWM Reload Frequency
00	Every PWM cycle
01	Every 2 PWM cycles
10	Every 4 PWM cycles
11	Every 8 PWM cycles

For ease of software, the LDFQx bits are buffered. When the LDFQx bits are changed, the reload frequency will not change until the previous reload cycle is completed. See [Figure 9-5](#).

NOTE: When reading the LDFQx bits, the value is the buffered value (for example, not necessarily the value being acted upon).

Figure 9-5. Reload Frequency Change

PWMINT enables CPU interrupt requests as shown in [Figure 9-6](#). When this bit is set, CPU interrupt requests are generated when the PWMF bit is set. When the PWMINT bit is clear, PWM interrupt requests are inhibited. PWM reloads will still occur at the reload rate, but no interrupt requests will be generated.

Figure 9-8. Center-Aligned Loading of Modulus

Figure 9-9. Edge-Aligned PWM Value Loading

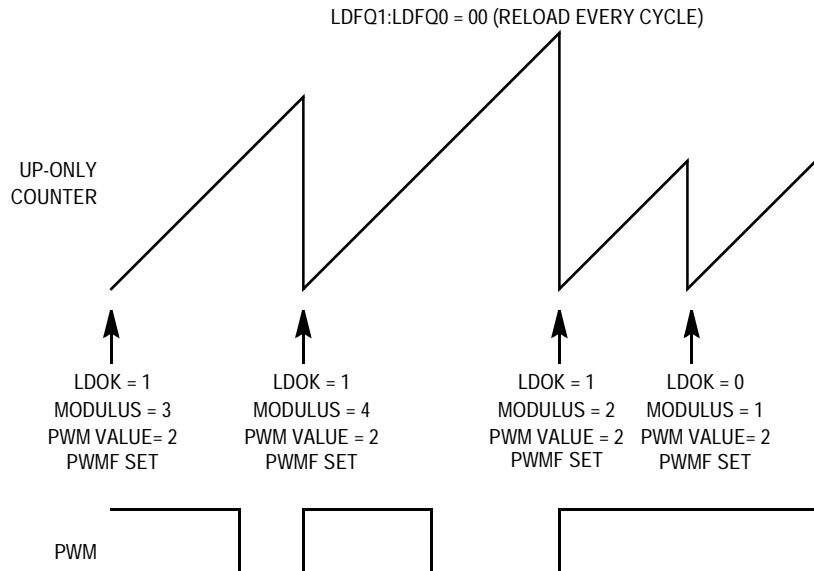

Figure 9-10. Edge-Aligned Modulus Loading

9.5.2 PWM Data Overflow and Underflow Conditions

The PWM value registers are 16-bit registers. Although the counter is only 12 bits, the user may write a 16-bit signed value to a PWM value register. As shown in [Figure 9-3](#) and [Figure 9-4](#), if the PWM value is less than or equal to 0, the PWM will be inactive for the entire period. Conversely, if the PWM value is greater than or equal to the timer modulus, the PWM will be active for the entire period. Refer to [Table 9-3](#).

NOTE: *The terms active and inactive refer to the asserted and negated states of the PWM signals and should not be confused with the high-impedance state of the PWM pins.*

Table 9-3. PWM Data Overflow and Underflow Conditions

PWMVALxH:PWMVALxL	Condition	PWM Value Used
\$0000–\$0FFF	Normal	Per registers contents
\$1000–\$7FFF	Overflow	\$FFF
\$8000–\$FFFF	Underflow	\$000

9.6 Output Control

This subsection discusses output control.

9.6.1 Selecting Six Independent PWMs or Three Complementary PWM Pairs

The PWM outputs can be configured as six independent PWM channels or three complementary channel pairs. The option INDEP determines which mode is used (see [5.4 CONFIG Bits](#)). If complementary operation is chosen, the PWM pins are paired as shown in [Figure 9-11](#). Operation of one pair is then determined by one PWM value register. This type of operation is meant for use in motor drive circuits such as the one in [Figure 9-12](#).

Figure 9-11. Complementary Pairing

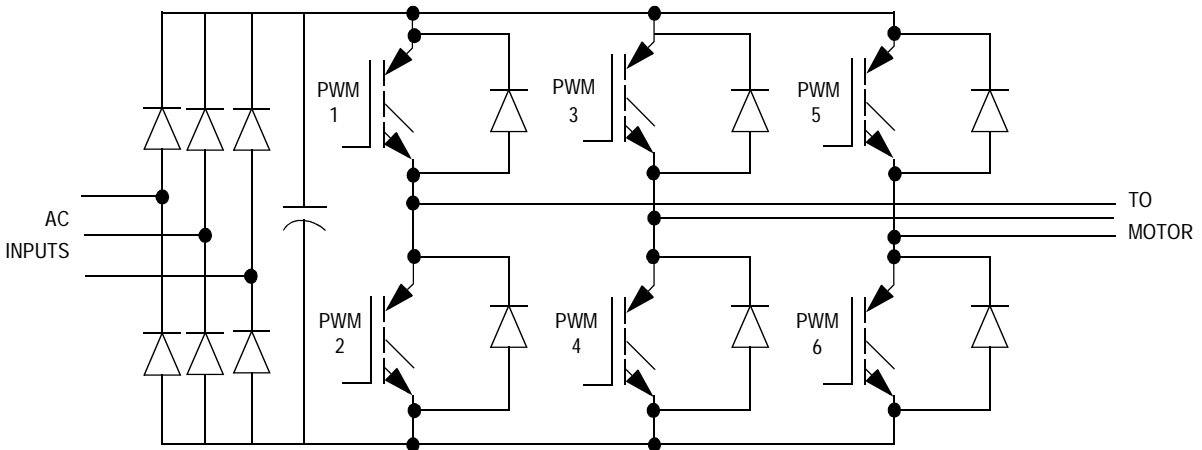

Figure 9-12. Typical AC Motor Drive

When complementary operation is used, two additional features are provided:

- Dead-time insertion
- Separate top/bottom pulse width correction to correct for distortions caused by the motor drive characteristics.

If independent operation is chosen, each PWM has its own PWM value register.

9.6.2 Dead-Time Insertion

As shown in [Figure 9-12](#), in complementary mode, each PWM pair can be used to drive top-side/bottom-side transistors.

NOTE: *When controlling DC-to-AC inverters such as this, the top and bottom PWMs in one pair should never be active at the same time.*

In [Figure 9-12](#), if PWM1 and PWM2 were on at the same time, large currents would flow through the two transistors as they discharge the bus capacitor. The IGBTs could be weakened or destroyed.

Simply forcing the two PWMs to be inversions of each other is not always sufficient. Since a time delay is associated with turning off the transistors in the motor drive, there must be a “dead-time” between the deactivation of one PWM and the activation of the other.

A dead-time can be specified in the dead-time write-once register. This 8-bit value specifies the number of CPU clock cycles to use for the dead-time. The dead-time is not affected by changes in the PWM period caused by the prescaler.

Dead-time insertion is achieved by feeding the top PWM outputs of the PWM generator into dead-time generators, as shown in [Figure 9-13](#). When output control is enabled, the odd OUT bits, rather than the PWM generator outputs, are fed into the dead-time generators. See [9.6.4 Output Port Control Register](#).

Figure 9-13. Dead-Time Generators

Whenever an input to a dead-time generator transitions, a dead-time is inserted (for example, both PWMs in the pair are forced to their inactive state). The BOTTOM PWM signal is generated from the TOP PWM and the dead-time. In the case of output control enabled, the odd **OUTx** bits control the top PWMs, the even **OUTx** bits control the bottom PWMs *with respect to the odd **OUTx** bits* (see [Table 9-4](#)). [Figure 9-14](#) shows the effects of the dead-time insertion.

Examples of dead-time insertion are shown in [Figure 9-14](#) through [Figure 9-16](#). [Figure 9-15](#) shows the effects of dead-time insertion at the duty cycle boundaries (near 0% and 100% duty cycles). [Figure 9-16](#) shows the effects of dead-time insertion on pulse widths smaller than the dead-time.

Pulse-Width Modulator for Motor Control

Figure 9-14. Effects of Dead-Time Insertion

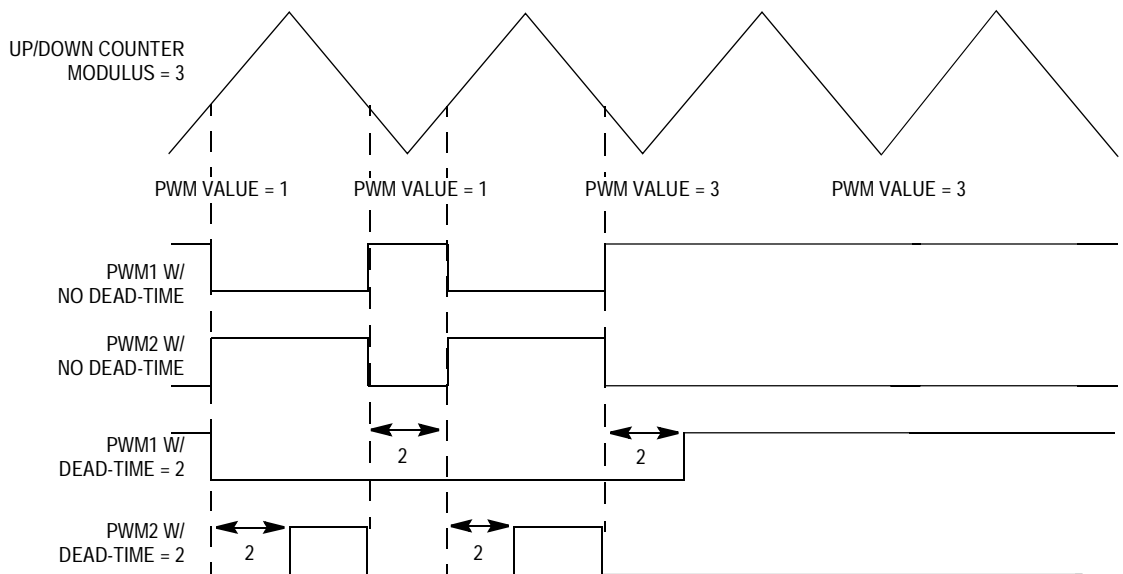

Figure 9-15. Dead-Time at Duty Cycle Boundaries

Figure 9-16. Dead-Time and Small Pulse Widths

9.6.3 Output Polarity

The output polarity of the PWMs is determined by two options: TOPNEG and BOTNEG. The top polarity option, TOPNEG, controls the polarity of PWMs 1, 3, and 5. The bottom polarity option, BOTNEG, controls the polarity of PWMs 2, 4, and 6. Positive polarity means that when the PWM is active, the PWM output is high. Conversely, negative polarity means that when the PWM is active, PWM output is low. See [Figure 9-17](#).

NOTE: Both bits are found in the CONFIG register, which is a write-once register. This reduces the chances of the software inadvertently changing the polarity of the PWM signals and possibly damaging the motor drive hardware.

Pulse-Width Modulator for Motor Control

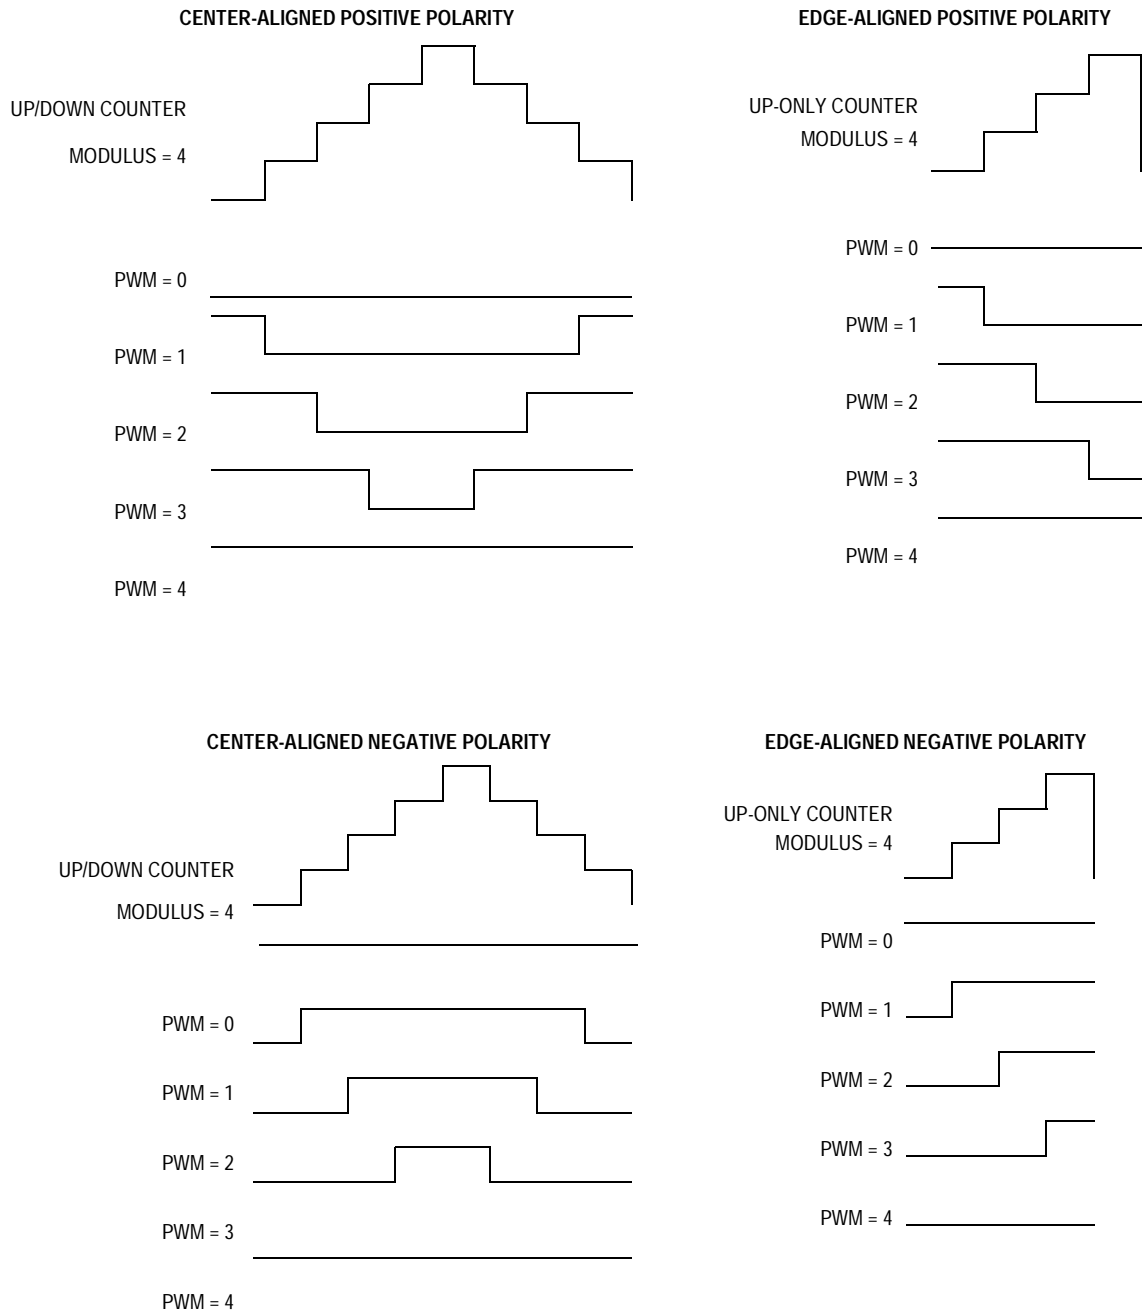

Figure 9-17. PWM Polarity

9.6.4 Output Port Control Register

Conditions may arise in which the PWM pins need to be individually controlled. This is made possible by the PWM output control register (PWMOUT) shown in [Figure 9-18](#).

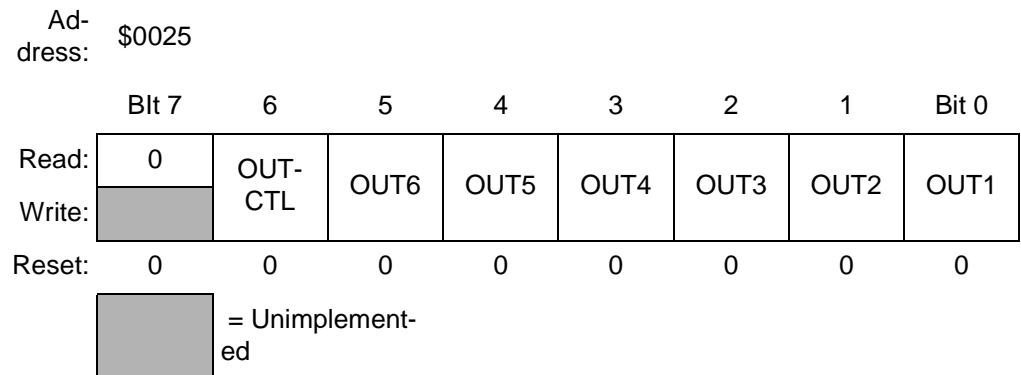

Figure 9-18. PWM Output Control Register (PWMOUT)

If the OUTCTL bit is set, the PWM pins can be controlled by the OUTx bits. These bits behave according to [Table 9-4](#).

Table 9-4. OUTx Bits

OUTx Bit	Complementary Mode	Independent Mode
OUT1	1 — PWM1 is active. 0 — PWM1 is inactive.	1 — PWM1 is active 0 — PWM1 is inactive
OUT2	1 — PWM2 is complement of PWM1. 0 — PWM2 is inactive.	1 — PWM2 is active 0 — PWM2 is inactive
OUT3	1 — PWM3 is active. 0 — PWM3 is inactive.	1 — PWM3 is active 0 — PWM3 is inactive
OUT4	1 — PWM4 is complement of PWM3. 0 — PWM4 is inactive.	1 — PWM4 is active 0 — PWM4 is inactive
OUT5	1 — PWM5 is active. 0 — PWM5 is inactive.	1 — PWM5 is active 0 — PWM5 is inactive
OUT6	1 — PWM6 is complement of PWM5. 0 — PWM6 is inactive.	1 — PWM6 is active 0 — PWM6 is inactive

When OUTCTL is set, the polarity options TOPPOL and BOTPOL will still affect the outputs. In addition, if complementary operation is in use, the PWM pairs will not be allowed to be active simultaneously, and dead-time will still not be violated. When OUTCTL is set and

Pulse-Width Modulator for Motor Control

complimentary operation is in use, the odd OUTx bits are inputs to the dead-time generators as shown in [Figure 9-14](#). Dead-time is inserted whenever the odd OUTx bit toggles as shown in [Figure 9-19](#). Although dead-time is not inserted when the even OUTx bits change, there will be no dead-time violation as shown in [Figure 9-20](#).

Setting the OUTCTL bit does not disable the PWM generator and current sensing circuitry. They continue to run, but are no longer controlling the output pins. In addition, OUTCTL will control the PWM pins even when PWMEN = 0. When OUTCTL is cleared, the outputs of the PWM generator become the inputs to the dead-time and output circuitry at the beginning of the next PWM cycle.

NOTE: To avoid an unexpected dead-time occurrence, it is recommended that the OUTx bits be cleared prior to entering and prior to exiting individual PWM output control mode.

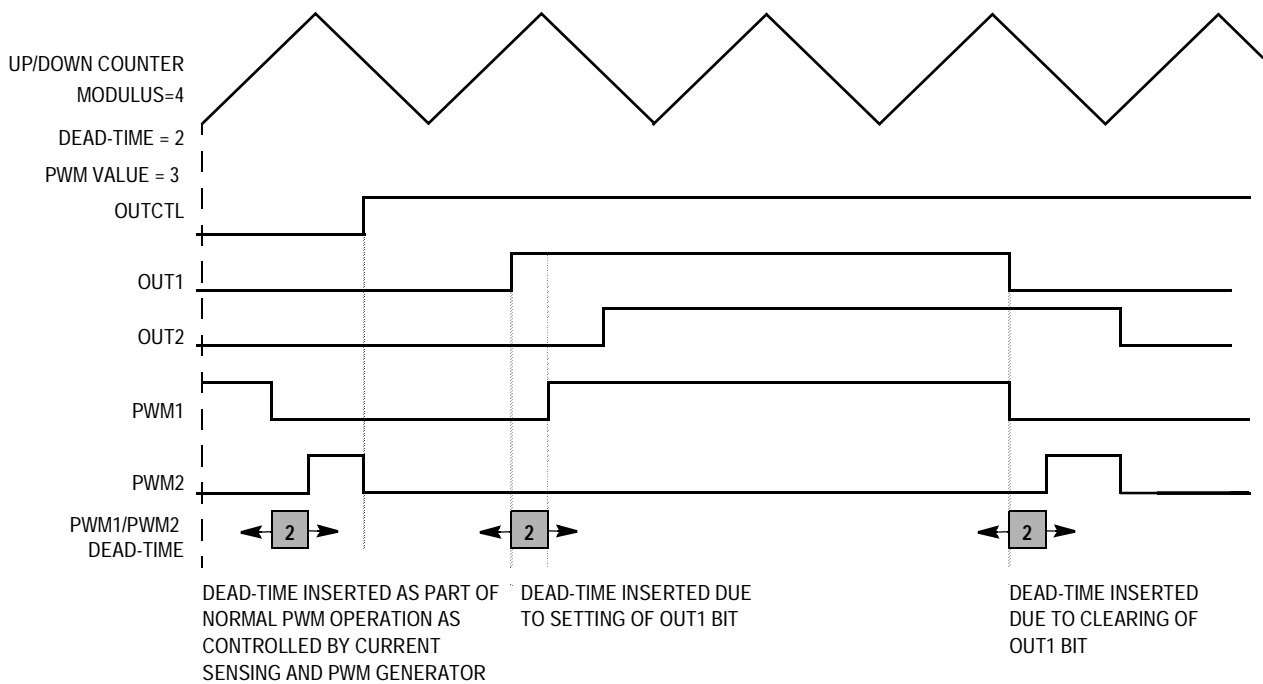

Figure 9-19. Dead-Time Insertion During OUTCTL = 1

Figure 9-20. Dead-Time Insertion During OUTCTL = 1

9.7 Fault Protection

Conditions may arise in the external drive circuitry which require that the PWM signals become inactive immediately, such as an overcurrent fault condition. Furthermore, it may be desirable to selectively disable PWM(s) solely with software.

One or more PWM pins can be disabled (forced to their inactive state) by applying a logic high to either of the two external fault pins or by writing a logic high to either of the disable bits (DISX and DISY in PWM control register 1). [Figure 9-21](#) shows the structure of the PWM disabling scheme. While the PWM pins are disabled, they are forced to their inactive state. The PWM generator continues to run — only the output pins are disabled

Pulse-Width Modulator for Motor Control

The example is of fault pin 4 with DISY.

Note: In manual mode (FMODE = 0), fault 4 may be cleared only if a logic level low at the input of the fault pin is present.

The example is of fault pin 1.

Note: In manual mode (FMODE = 0), fault 1 may be cleared regardless of the logic level at the input of the fault pin.

Figure 9-21. PWM Disabling Scheme

To allow for different motor configurations and the controlling of more than one motor, the PWM disabling function is organized as two banks, bank X and bank Y. Bank information combines with information from the disable mapping register to allow selective PWM disabling. Fault

pin 1 and PWM disable bit X constitute the disabling function of bank X. Fault pin 4 and PWM disable bit Y constitute the disabling function of bank Y. **Figure 9-22** and **Figure 9-23** show the disable mapping write-once register and the decoding scheme of the bank which selectively disables PWM(s). When all bits of the disable mapping register are set, any disable condition will disable all PWMs.

A fault can also generate a CPU interrupt. Each fault pin has its own interrupt vector.

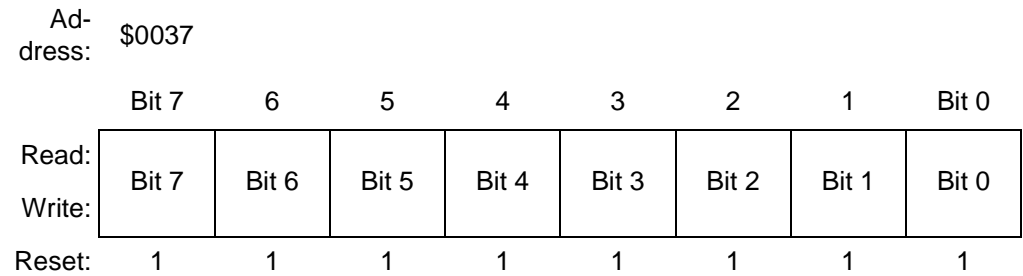

Figure 9-22. PWM Disable Mapping Write-Once Register (DISMAP)

Figure 9-23. PWM Disabling Decode Scheme

9.7.1 Fault Condition Input Pins

A logic high level on a fault pin disables the respective PWM(s) determined by the bank and the disable mapping register. Each fault pin incorporates a filter to assist in rejecting spurious faults. All of the external fault pins are software-configurable to re-enable the PWMs either with the fault pin (automatic mode) or with software (manual mode). Each fault pin has an associated FMODE bit to control the PWM re-enabling method. Automatic mode is selected by setting the FMODE_x bit in the fault control register. Manual mode is selected when FMODE_x is clear.

NOTE: *PORTC, when used as an input port, mirrors the state of the fault input pins, as PORTC has the capability of being used as an output port. When either pin of PORTC is set as an output, by setting its respective PORTC data direction register bit, the respective fault pin logic is disconnected from that pin and the fault input will be defaulted to normal*

non-fault condition to facilitate the use of PORTC as an output pin and not interfere with the PWM generator. To regain the fault capability for the respective fault input pin, clear the PORTC data direction register bit for that pin.

Additionally, when the device is reset, by default, PORTC is configured as an input. If either bit(s) of PORTC is intended to be used as an output, the logic state of the driven device's input is indeterminate. The state of the driven device, if at a logic one will drive the respective bit of PORTC input high, thus causing a fault to be input to the respective PORTC input and to the PWM module.

After setting the PORTC data direction register, clear the respective fault bits by writing a 1 to bit(s) 0 and or bit 6 in the FTACK Fault Acknowledge Register (FTACK) and Fault Status Registers (FSR), based on which PORTC bits that are used as output(s).

9.7.1.1 Fault Pin Filter

The two fault pins incorporate a filter to assist in determining a genuine fault condition. After a fault pin has been logic low for one CPU cycle, a rising edge (logic high) will be synchronously sampled once per CPU cycle for two cycles. If both samples are detected logic high, the corresponding FPIN bit and FFLAG bit will be set. The FPIN bit will remain set until the corresponding fault pin is logic low and synchronously sampled once in the following CPU cycle.

9.7.1.2 Automatic Mode

In automatic mode, the PWM(s) are disabled immediately once a filtered fault condition is detected (logic high). The PWM(s) remain disabled until the filtered fault condition is cleared (logic low) and a new PWM cycle begins as shown in [Figure 9-24](#). Clearing the corresponding FFLAGx event bit will not enable the PWMs in automatic mode.

Figure 9-24. PWM Disabling in Automatic Mode

The filtered fault pin's logic state is reflected in the respective FPINx bit. Any write to this bit is overwritten by the pin state. The FFLAGx event bit is set with each rising edge of the respective fault pin after filtering has been applied. To clear the FFLAGx bit, the user must write a 1 to the corresponding FTACKx bit.

If the FINTx bit is set, a fault condition resulting in setting the corresponding FFLAG bit will also latch a CPU interrupt request. The interrupt request latch is not cleared until one of these actions occurs:

- The FFLAGx bit is cleared by writing a 1 to the corresponding FTACKx bit.
- The FINTx bit is cleared. (This will not clear the FFLAGx bit.)
- Reset — A reset automatically clears all four interrupt latches.

If prior to a vector fetch the interrupt request latch is cleared by one of the above actions, a CPU interrupt will no longer be requested. A vector fetch does not alter the state of the PWMs, the FFLAGx event flag, or FINTx.

NOTE: *If the FFLAGx or FINTx bits are not cleared during the interrupt service routine, the interrupt request latch will not be cleared.*

9.7.1.3 Manual Mode

In manual mode, the PWM(s) are disabled immediately once a filtered fault condition is detected (logic high). The PWM(s) remain disabled until software clears the corresponding FFLAGx event bit and a new PWM cycle begins. In manual mode, the fault pins are grouped in pairs, each pair sharing common functionality. A fault condition on fault 1 may be cleared, allowing the PWM(s) to enable at the start of a PWM cycle regardless of the logic level at the fault pin. See [Figure 9-25](#). A fault condition on fault 4 can be cleared, allowing the PWM(s) to enable, only if a logic low level at the fault pin is present at the start of a PWM cycle. See [Figure 9-26](#).

Figure 9-25. PWM Disabling in Manual Mode (Example 1)

Figure 9-26. PWM Disabling in Manual Mode (Example 2)

The function of the fault control and event bits is the same as in automatic mode except that the PWMs are not re-enabled until the FFLAGx event bit is cleared by writing to the FTACKx bit and the filtered fault condition is cleared (logic low).

9.7.2 Software Output Disable

Setting PWM disable bit DISX or DISY in PWM control register 1 immediately disables the corresponding PWM pins as determined by the bank and disable mapping register. The PWM pin(s) remain disabled until the PWM disable bit is cleared and a new PWM cycle begins as shown in [Figure 9-27](#). Setting a PWM disable bit does not latch a CPU interrupt request, and there are no event flags associated with the PWM disable bits.

9.7.3 Output Port Control

When operating the PWMs using the OUTx bits (OUTCTL = 1), fault protection applies as described in this section. Due to the absence of periodic PWM cycles, fault conditions are cleared upon each CPU cycle and the PWM outputs are re-enabled, provided all fault clearing conditions are satisfied.

Figure 9-27. PWM Software Disable

9.8 Initialization and the PWMEN Bit

For proper operation, all registers should be initialized and the LDOK bit should be set before enabling the PWM via the PWMEN bit. When the PWMEN bit is first set, a reload will occur immediately, setting the PWMF flag and generating an interrupt if PWMINT is set. In addition, in complementary mode, PWM value registers 1, 3, and 5 will be used for the first PWM cycle if current sensing is selected.

NOTE: *If the LDOK bit is not set when PWMEN is set after a RESET, the prescaler and PWM values will be 0, but the modulus will be unknown. If the LDOK bit is not set after the PWMEN bit has been cleared then set (without a RESET), the modulus value that was last loaded will be used.*

If the dead-time register (DEADTM) is changed after PWMEN or OUTCTL is set, an improper dead-time insertion could occur. However, the dead-time can never be shorter than the specified value.

Because of the equals-comparator architecture of this PWM, the modulus = 0 case is considered illegal. Therefore, the modulus register is not reset, and a modulus value of 0 will result in waveforms inconsistent with the other modulus waveforms. See [9.12.2 PWM Counter Modulo Registers](#).

When PWMEN is set, the PWM pins change from high impedance to outputs. At this time, assuming no fault condition is present, the PWM pins will drive according to the PWM values, polarity, and dead-time. See the timing diagram in [Figure 9-28](#).

Figure 9-28. PWMEN and PWM Pins

When the PWMEN bit is cleared, the following will occur:

- PWM pins will be three-stated unless OUTCTL = 1.
- PWM counter is cleared and will not be clocked.
- Internally, the PWM generator will force its outputs to 0 to avoid glitches when the PWMEN is set again.

When PWMEN is cleared, these features remain active:

- All fault circuitry
- Manual PWM pin control via the PWMOUT register
- Dead-time insertion when PWM pins change via the PWMOUT register

NOTE: *The PWMF flag and pending CPU interrupts are NOT cleared when PWMEN = 0.*

9.9 PWM Operation in Wait Mode

When the microcontroller is put in low-power wait mode via the WAIT instruction, all clocks to the PWM module will continue to run. If an interrupt is issued from the PWM module (via a reload or a fault), the microcontroller will exit wait mode.

Clearing the PWMEN bit before entering wait mode will reduce power consumption in wait mode because the counter, prescaler divider, and LDFQ divider will no longer be clocked. In addition, power will be reduced because the PWMs will no longer toggle.

9.10 PWM Operation in Stop Mode

When the microcontroller is put in low-power wait mode via the STOP instruction, all clocks to the PWM module will stop.

NOTE: *It is imperative that the program to clear the PWMEN bit before entering stop mode. Leaving the PWM module enabled during stop mode can destroy power stages connected to the PWM outputs. The PWM generator will no longer be clocked during stop mode and the PWM outputs will no longer toggle.*

9.11 PWM Operation in Break Mode

If the microcontroller goes into break mode (or background mode), the clocks to the PWM generator and output control blocks will freeze. This allows the user to set a breakpoint on a development system and examine the register contents and PWM outputs at that point. It also allows the user to single-step through the code.

The clocks to the fault block will continue to run. Therefore, if a fault occurs while the microcontroller is in break mode, the PWM outputs will immediately be driven to their inactive state(s).

During break mode, the system integration module (SIM) controls whether status bits in other modules can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state. Refer to [7.7.5 SIM Break Flag Control Register](#).

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect the PWMF and FFLAGx bits during the break state, make sure BCFE is a logic 0. With BCFE at logic 0 (its default state), software can read and write the status and control registers during the break state without affecting the PWMF and FFLAGx bits.

9.12 Control Logic Block

This subsection provides a description of the control logic block.

9.12.1 PWM Counter Registers

The PWM counter registers (PCNTH and PCNTL) display the 12-bit up/down or up-only counter. When the high byte of the counter is read, the lower byte is latched. PCNTL will hold this latched value until it is read.

Figure 9-29. PWM Counter Register High (PCNTH)

Figure 9-30. PWM Counter Register Low (PCNTH)

9.12.2 PWM Counter Modulo Registers

The PWM counter modulus registers (PDMODH and PDMODL) hold a 12-bit unsigned number that determines the maximum count for the up/down or up-only counter. In center-aligned mode, the PWM period will be twice the modulus (assuming no prescaler). In edge-aligned mode, the PWM period will equal the modulus.

Figure 9-31. PWM Counter Modulo Register High (PDMODH)

Figure 9-32. PWM Counter Modulo Register Low (PDMODL)

To avoid erroneous PWM periods, this value is buffered and will not be used by the PWM generator until the LDOK bit has been set and the next PWM load cycle begins.

NOTE: *When reading this register, the value read is the buffer (not necessarily the value the PWM generator is currently using).*

Because of the equals-comparator architecture of this PWM, the modulus = 0 case is considered illegal. Therefore, the modulus register is not reset, and a modulus value of 0 will result in waveforms inconsistent with the other modulus waveforms. If a modulus of 0 is loaded, the counter will continually count down from \$FFF. This operation will not be tested or guaranteed. (The user should consider it

illegal.) However, the dead-time constraints and fault conditions will still be guaranteed.

9.12.3 PWMx Value Registers

Each of the six PWMs has a 16-bit PWM value register.

Figure 9-33. PWMx Value Registers High (PVALxH)

Figure 9-34. PWMx Value Registers Low (PVALxL)

The 16-bit signed value stored in this register determines the duty cycle of the PWM. The duty cycle is defined as: $(\text{PWM value}/\text{modulus}) \times 100$.

Writing a number less than or equal to 0 causes the PWM to be off for the entire PWM period. Writing a number greater than or equal to the 12-bit modulus causes the PWM to be on for the entire PWM period.

If the complementary mode is selected, the PWM pairs share PWM value registers.

To avoid erroneous PWM pulses, this value is buffered and will not be used by the PWM generator until the LDOK bit has been set and the next PWM load cycle begins.

NOTE: *When reading these registers, the value read is the buffer (not necessarily the value the PWM generator is currently using).*

9.12.4 PWM Control Register 1

PWM control register 1 controls PWM enabling/disabling, the loading of new modulus, prescaler, and PWM values, and the PWM correction method. In addition, this register contains the software disable bits to force the PWM outputs to their inactive states (according to the disable mapping register).

Figure 9-35. PWM Control Register 1 (PCTL1)

DISX — Software Disable for Bank X Bit

This read/write bit allows the user to disable one or more PWM pins in bank X. The pins that are disabled are determined by the disable mapping write-once register.

1 = Disable PWM pins in bank X

0 = Re-enable PWM pins at beginning of next PWM cycle

DISY — Software Disable for Bank Y Bit

This read/write bit allows the user to disable one or more PWM pins in bank Y. The pins that are disabled are determined by the disable mapping write-once register.

1 = Disable PWM pins in Bank Y Bit

0 = Re-enable PWM pins at beginning of next PWM cycle

PWMINT — PWM Interrupt Enable Bit

This read/write bit allows the user to enable and disable PWM CPU interrupts. If set, a CPU interrupt will be pending when the PWMF flag is set.

1 = Enable PWM CPU interrupts

0 = Disable PWM CPU interrupts

NOTE: When *PWMINT* is cleared, pending CPU interrupts are inhibited.

PWMF— PWM Reload Flag

This read/write bit is set at the beginning of every reload cycle regardless of the state of the LDOK bit. This bit is cleared by reading PWM control register 1 with the PWMF flag set, then writing a logic 0 to PWMF. If another reload occurs before the clearing sequence is complete, then writing logic 0 to PWMF has no effect.

1 = New reload cycle began.

0 = New reload cycle has not begun.

NOTE: When *PWMF* is cleared, pending PWM CPU interrupts are cleared (excluding fault interrupts).

CAUTION: *Bits 2 and/or 3 of PCTL1 are reserved and must never be set to a 1. Setting these bits to a 1 will affect the active PWM value registers. Undesirable results will occur.*

LDOK— Load OK Bit

This read/write bit allows the counter modulus, counter prescaler, and PWM values in the buffered registers to be used by the PWM generator. These values will not be used until the LDOK bit is set and a new PWM load cycle begins. LDOK may be cleared, if it is set, by writing a logic 0 to it prior to the beginning of a new PWM load cycle. Internally this bit is automatically cleared after the new values are loaded.

1 = Okay to load new modulus, prescaler, and PWM values at beginning of next PWM load cycle

0 = Not okay to load new modulus, prescaler, and PWM values

NOTE: *The user should initialize the PWM registers and set the LDOK bit before enabling the PWM.*

PWMEN — PWM Module Enable Bit

This read/write bit enables and disables the PWM generator and the PWM pins. When PWMEN is clear, the PWM generator is disabled and the PWM pins are in the high-impedance state (unless *OUTCTL* = 1). When the PWMEN bit is set, the PWM generator and PWM pins are activated. For more information, see [9.8 Initialization and the PWMEN Bit](#).

1 = PWM generator and PWM pins enabled

0 = PWM generator and PWM pins disabled

NOTE: A PWM CPU interrupt request can still be generated when LDOK is 0.

9.12.5 PWM Control Register 2

PWM control register 2 controls the PWM load frequency, the PWM correction method, and the PWM counter prescaler. For ease of software and to avoid erroneous PWM periods, some of these register bits are buffered. The PWM generator will not use the prescaler value until the LDOK bit has been set, and a new PWM cycle is starting. The correction bits are used at the beginning of each PWM cycle (if the ISENSx bits are configured for software correction). The load frequency bits are not used until the current load cycle is complete.

NOTE: The user should initialize this register before enabling the PWM.

Figure 9-36. PWM Control Register 2 (PCTL2)

LDFQ1 and LDFQ0 — PWM Load Frequency Bits

These buffered read/write bits select the PWM CPU load frequency according to [Table 9-5](#).

NOTE: When reading these bits, the value read is the buffer value (not necessarily the value the PWM generator is currently using).

Table 9-5. PWM Reload Frequency

Reload Frequency Bits LDFQ1:LDFQ0	PWM Reload Frequency
00	Every PWM cycle
01	Every 2 PWM cycles
10	Every 4 PWM cycles
11	Every 8 PWM cycles

SEL12 — Top/Bottom Correction Bit for PWM Pair 1 (PWMs 1 and 2)

This buffered read/write bit selects which PWM value register is used for PWM pins 1 and 2 in complementary mode.

1 = Use PWM value register 2.

0 = Use PWM value register 1.

NOTE: *When reading this bit, the value read is the buffer value (not necessarily the value the output control block is currently using).*

SEL34 — Top/Bottom Correction Bit for PWM Pair 2 (PWMs 3 and 4)

This buffered read/write bit selects which PWM value register is used for PWM pins 3 and 4 in complementary mode.

1 = Use PWM value register 4.

0 = Use PWM value register 3.

NOTE: *When reading this bit, the value read is the buffer value (not necessarily the value the output control block is currently using).*

SEL56 — Top/Bottom Correction Bit for PWM Pair 3 (PWMs 5 and 6)

This buffered read/write bit selects which PWM value register is used for PWM pins 5 and 6 in complementary mode.

1 = Use PWM value register 6.

0 = Use PWM value register 5.

NOTE: *When reading this bit, the value read is the buffer value (not necessarily the value the output control block is currently using).*

PRSC1:PRSC0 — PWM Prescaler Bits

These buffered read/write bits allow the PWM clock frequency to be modified as shown in [Table 9-6](#).

NOTE: *When reading these bits, the value read is the buffer value (not necessarily the value the PWM generator is currently using).*

Table 9-6. PWM Prescaler

Prescaler Bits PRSC1:PRSC0	PWM Clock Frequency
00	f_{OP}
01	$f_{OP}/2$
10	$f_{OP}/4$
11	$f_{OP}/8$

NOTE: *If PRSC1 and PRSC2 are set to any value other than 0, there is a one PWM cycle latency time before the PWM pins are driven after the PWMEN bit is set.*

9.12.6 Dead-Time Write-Once Register

The dead-time write-once register (DEADTM) holds an 8-bit value which specifies the number of CPU clock cycles to use for the dead-time when complementary PWM mode is selected. After this register is written for the first time, it cannot be rewritten unless a RESET occurs. The dead-time is not affected by changes to the prescaler value.

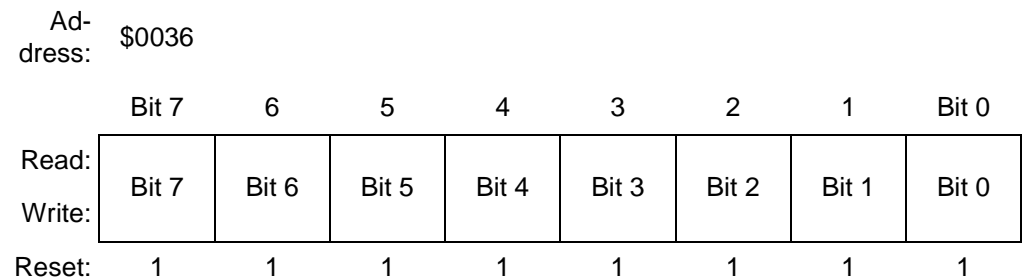

Figure 9-37. Dead-Time Write-Once Register (DEADTM)

9.12.7 PWM Disable Mapping Write-Once Register

The PWM disable mapping write-once register (DISMAP) holds an 8-bit value which determines which PWM pins will be disabled if an external fault or software disable occur. For a further description of the disable mapping, see [9.7 Fault Protection](#). After this register is written for the first time, it cannot be rewritten unless a reset occurs.

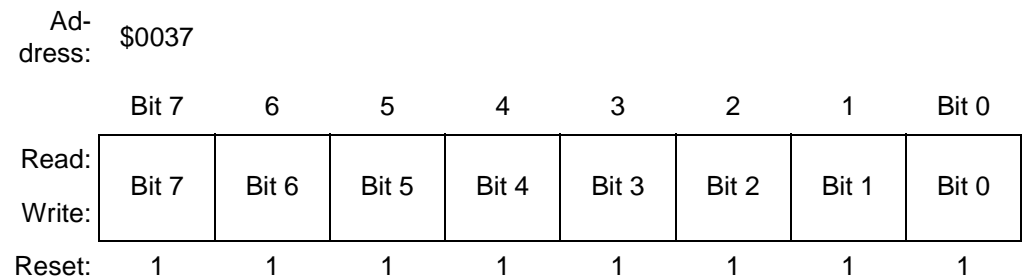

Figure 9-38. PWM Disable Mapping Write-Once Register (DISMAP)

9.12.8 Fault Control Register

This register controls the fault protection circuitry.

Figure 9-39. Fault Control Register (FCR)

FMODE1 — Fault Mode Selection for Fault Pin 1 Bit (Automatic versus Manual Mode)

This read/write bit allows the user to select between automatic and manual mode faults. For further description of each mode, see [9.7 Fault Protection](#).

9.7 Fault Protection.

1 = Automatic mode

0 = Manual mode

FINT1 — Fault 1 Interrupt Enable Bit

This read/write bit allows the CPU interrupt caused by faults on fault pin 1 to be enabled. The fault protection circuitry is independent of this bit and will always be active. If a fault is detected, the PWM pins will still be disabled according to the disable mapping register.

1 = Fault pin 1 will cause CPU interrupts.

0 = Fault pin 1 will not cause CPU interrupts.

FMODE4 — Fault Mode Selection for Fault Pin 4 Bit (Automatic versus Manual Mode)

This read/write bit allows the user to select between automatic and manual mode faults. For further description of each mode, see [9.7 Fault Protection](#).

9.7 Fault Protection.

1 = Automatic mode

0 = Manual mode

FINT4 — Fault 4 Interrupt Enable Bit

This read/write bit allows the CPU interrupt caused by faults on fault pin 4 to be enabled. The fault protection circuitry is independent of this bit and will always be active. If a fault is detected, the PWM pins will still be disabled according to the disable mapping register.

- 1 = Fault pin 4 will cause CPU interrupts.
- 0 = Fault pin 4 will not cause CPU interrupts.

9.12.9 Fault Status Register

This read-only register indicates the current fault status.

Ad- dress:	\$0023							
	Bit 7	6	5	4	3	2	1	Bit 0
Read:	FPIN4	FFLAG 4	0	0	0	0	FPIN1	FFLAG 1
Write:								
Reset:	U	0	U	0	U	0	U	0

= Unimplemented
 U = Unaffected

Figure 9-40. Fault Status Register (FSR)

FFLAG1 — Fault Event Flag 1

The FFLAG1 event bit is set within two CPU cycles after a rising edge on fault pin 1. To clear the FFLAG1 bit, the user must write a 1 to the FTACK1 bit in the fault acknowledge register.

- 1 = A fault has occurred on fault pin 1
- 0 = No new fault on fault pin 1

FPIN1 — State of Fault Pin 1

This read-only bit allows the user to read the current state of fault pin 1.

- 1 = Fault pin 1 is at logic 1
- 0 = Fault pin 1 is at logic 0

FFLAG4 — Fault Event Flag 4

The FFLAG4 event bit is set within two CPU cycles after a rising edge on fault pin 4. To clear the FFLAG4 bit, the user must write a 1 to the FTACK4 bit in the fault acknowledge register.

1 = A fault has occurred on fault pin 4

0 = No new fault on fault pin 4

FPIN4 — State of Fault Pin 4 Bit

This read-only bit allows the user to read the current state of fault pin 4.

1 = Fault pin 4 is at logic 1.

0 = Fault pin 4 is at logic 0.

9.12.10 Fault Acknowledge Register

The fault acknowledge register (FTACK) is used to acknowledge and clear the FFLAGS. In addition, it is used to monitor the current sensing bits to test proper operation.

Ad-
dress: \$0024

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	0	0	0	0
Write:		FTACK 4						FTACK 1
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

Figure 9-41. Fault Acknowledge Register (FTACK)

FTACK1 — Fault Acknowledge 1 Bit

The FTACK1 bit is used to acknowledge and clear FFLAG1. This bit will always read 0. Writing a 1 to this bit will clear FFLAG1. Writing a 0 will have no effect.

FTACK4 — Fault Acknowledge 4 Bit

The FTACK4 bit is used to acknowledge and clear FFLAG4. This bit will always read 0. Writing a 1 to this bit will clear FFLAG4. Writing a 0 will have no effect.

Pulse-Width Modulator for Motor Control

9.12.11 PWM Output Control Register

This register is used to manually control the PWM pins.

Address:	\$0025							
	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	OUT-CTL	OUT6	OUT5	OUT4	OUT3	OUT2	OUT1
Write:								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented
 U = Unaffected

Figure 9-42. PWM Output Control Register (PWMOUT)

OUTCTL— Output control enable

This read/write bit allows the user to manually control the PWM pins. When set, the PWM generator is no longer the input to the dead-time and output circuitry. The OUTx bits determine the state of the PWM pins. Setting the OUTCTL bit does not disable the PWM generator. The generator continues to run, but is no longer the input to the PWM dead-time and output circuitry. When OUTCTL is cleared, the outputs of the PWM generator immediately become the inputs to the dead-time and output circuitry.

1 = PWM outputs controlled manually

0 = PWM outputs determined by PWM generator

OUT6:OUT1— PWM Pin Output Control Bits

These read/write bits control the PWM pins according to [Table 9-7](#).

Table 9-7. OUTx Bits

OUTx Bit	Complementary Mode	Independent Mode
OUT1	1 — PWM1 is active 0 — PWM1 is inactive	1 — PWM1 is active 0 — PWM1 is inactive
OUT2	1 — PWM2 is complement of PWM 1 0 — PWM2 is inactive	1 — PWM2 is active 0 — PWM2 is inactive
OUT3	1 — PWM3 is active 0 — PWM3 is inactive	1 — PWM3 is active 0 — PWM3 is inactive
OUT4	1 — PWM4 is complement of PWM 3 0 — PWM4 is inactive	1 — PWM4 is active 0 — PWM4 is inactive
OUT5	1 — PWM5 is active 0 — PWM5 is inactive	1 — PWM5 is active 0 — PWM5 is inactive
OUT6	1 — PWM 6 is complement of PWM 5 0 — PWM6 is inactive	1 — PWM6 is active 0 — PWM6 is inactive

9.13 PWM Glossary

CPU Cycle — One internal bus cycle ($1/f_{OP}$)

PWM Clock Cycle (or Period) — One tick of the PWM counter ($1/f_{OP}$ with no prescaler). See [Figure 9-43](#).

PWM Cycle (or Period)

- Center-aligned mode: The time it takes the PWM counter to count up and count down (modulus * $2/f_{OP}$ assuming no prescaler). See [Figure 9-43](#).
- Edge-aligned mode: The time it takes the PWM counter to count up (modulus/ f_{OP}). See [Figure 9-43](#).

Pulse-Width Modulator for Motor Control

Figure 9-43. PWM Clock Cycle and PWM Cycle Definitions

PWM Load Frequency — The frequency at which new PWM parameters get loaded into the PWM. See [Figure 9-44](#).

Figure 9-44. PWM Load Cycle/Frequency Definition

10.2 Introduction

This section describes the monitor read-only memory (ROM). The monitor ROM (MON) allows complete testing of the microcontroller unit (MCU) through a 2-wire interface with a host computer.

10.3 Features

Features of the monitor ROM include:

- Normal user-mode pin functionality
- Standard mark/space non-return-to-zero (NRZ) communication with host computer
- 9600 baud communication with host computer
- Execution of code in random-access memory (RAM) or ROM

10.4 Functional Description

The monitor ROM receives and executes commands from a host computer. **Figure 10-1** shows a sample circuit used to enter monitor mode and communicate with a host computer via a standard RS-232 interface.

Simple monitor commands can access any memory address. In monitor mode, the MCU can execute host-computer code in RAM while all MCU pins retain normal operating mode functions. All communication between the host computer and the MCU is through the serial communications interface (SCI). A level-shifting RS-232 interface is required between the SCI and the host computer. PTB1 requires a pulldown resistor to ensure proper entry into monitor mode.

10.4.1 Entering Monitor Mode

Table 10-1 shows the pin conditions for entering monitor mode.

Table 10-1. Mode Selection

IRQ Pin	RESET	\$\$\$FFE/\$\$\$\$	PLL	PTB0	PTB1	External Clock	CGMOUT	f _{op}	COP	Baud Rate	Comment
X	V _{SS}	X	X	X	X	X	0	0	Disabled	0	No operation until reset = V _{DD}
V _{HI}	V _{DD} or V _{HI}	X	ON	V _{DD}	V _{SS}	4.0 MHz	16.0 MHz	8.0 MHz	Disabled	9600	PLL configured with BCS set by monitor code
V _{DD}	V _{DD}	Blank (FF)	ON	X	X	4.0 MHz	16.0 MHz	8.0 MHz	Disabled	9600	PLL configured with BCS set by monitor code
V _{SS}	V _{DD}	Blank (FF)	OFF	X	X	f _{osc}	f _{osc} /2	f _{osc} /4	Disabled	f _{osc} /1024	Enters monitor mode with any external clock rate within operating spec
V _{DD}	V _{DD}	Non-blank	X	X	X	X	X	X	Enabled	X	Enters user mode

X = Don't care

PTB0 = V_{DD} and PTB1 = V_{SS} to enter monitor mode

PTB0 (RXD) and PTB1 (TXD) used for serial communications (all monitor mode)

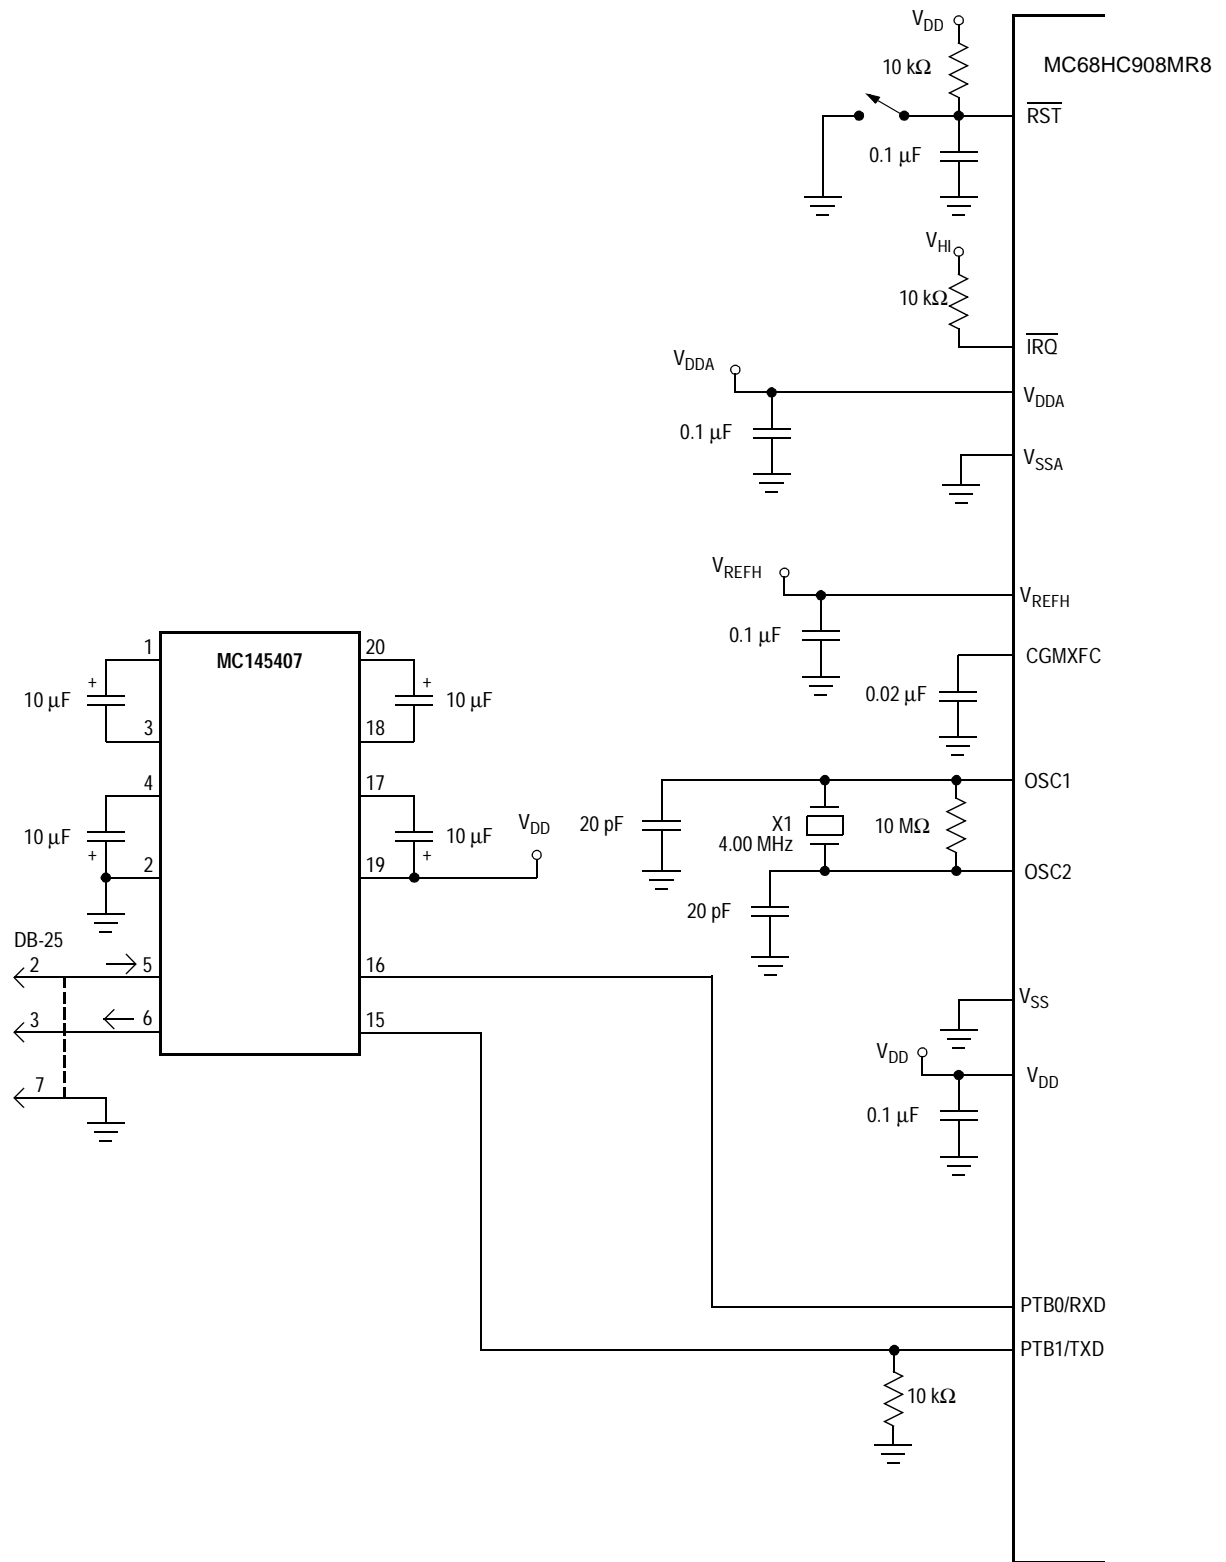

Figure 10-1. Monitor Mode Circuit

Monitor ROM (MON)

Enter monitor mode by applying a logic 0 and then a logic 1 to the $\overline{\text{RST}}$ pin (see [Table 10-1](#))

Once out of reset, the MCU waits for the host to send eight security bytes. After receiving the security bytes, the MCU sends a break signal (10 consecutive logic 0s) to the host computer, indicating that it is ready to receive a command.

Monitor mode uses alternate vectors for reset and SWI. The alternate vectors are in the \$FE page instead of the \$FF page and allow code execution from the internal monitor firmware instead of user code. The computer operating properly (COP) module is disabled in monitor mode as long as V_{HI} is applied to either the $\overline{\text{IRQ}}$ pin or the $\overline{\text{RST}}$ pin. Refer to [Section 7. System Integration Module \(SIM\)](#) for more information on modes of operation.

10.4.2 Forced Monitor Mode

On FLASH parts, if the voltage applied to the $\overline{\text{IRQ1}}$ is less than V_{HI} , the MCU will come out of reset in user mode. The memory reset module monitors the reset vector fetches and will assert an internal reset if it detects that the reset vectors are erased. When the MCU comes out of reset with its reset vector erased, it is forced into monitor mode without requiring high voltage on the $\overline{\text{IRQ1}}$ pin.

The computer operating properly (COP) module is disabled in forced monitor mode. Any reset other than a power-on reset (POR) will automatically force the MCU to come back to the forced monitor mode.

[Table 10-2](#) is a summary of the differences between user mode and monitor mode.

Table 10-2. Mode Differences

Modes	Functions				
	COP	Reset Vector High	Reset Vector Low	SWI Vector High	SWI Vector Low
User	Enabled	\$FFFE	\$FFFF	\$FFFC	\$FFFD
Monitor	Disabled ⁽¹⁾	\$FEFE	\$FEFF	\$FEFC	\$FEFD

1. If the high voltage (V_{HI}) is removed from the $\overline{\text{IRQ}}$ pin or the $\overline{\text{RST}}$ pin, the SIM asserts its COP enable output.

10.4.3 Baud Rate

With a 4.0-MHz reference clock source, data is transferred between the monitor and host at 9600 baud. The communication baud rate is achieved by stepping up the internal CPU frequency to 8 MHz, using the phase-locked loop (PLL). A 4.0-MHz reference frequency is necessary in this mode as the PLL will not lock with any other reference clock.

As described in [Table 10-1](#), on FLASH parts when V_{SS} is applied to IRQ with \$FFFE and \$FFFF = 0, the PLL setup is bypassed and the baud rate is equal to the reference frequency divided by 1024. This facilitates a faster communication rate in the interest of a first time programmed device. This allows selection of other reference frequencies and thus, facilitates a faster communication rate. The reference frequency, in this case while not utilizing the PLL, is limited to the range of f_{OP} . Refer to [21.8 Control Timing](#).

10.4.4 Data Format

Communication with the monitor ROM is in standard non-return-to-zero (NRZ) mark/space data format. See [Figure 10-2](#) and [Figure 10-3](#).

Figure 10-2. Monitor Data Format

Figure 10-3. Sample Monitor Waveforms

The data transmit and receive rate is 9600 baud. Transmit and receive baud rates will be identical.

10.4.5 Echoing

As shown in [Figure 10-4](#), the monitor ROM immediately echoes each received byte back to the PTB1/TXD pin for error checking.

Figure 10-4. Read Transaction

Any result of a command appears after the echo of the last byte of the command.

10.4.6 Break Signal

A start bit, followed by nine low bits, is a break signal. See [Figure 10-5](#). When the monitor receives a break signal, it delays two bit times before echoing the break signal.

Figure 10-5. Break Transaction

10.4.7 Commands

The monitor ROM uses these commands:

- READ, read memory
- WRITE, write memory
- IREAD, indexed read
- IWRITE, indexed write
- READSP, read stack pointer
- RUN, run user program

Refer to [Table 10-3](#) through [Table 10-8](#).

Table 10-3. READ (Read Memory) Command

Description	Read byte from memory
Operand	Specifies 2-byte address in high byte:low byte order
Data returned	Returns contents of specified address
Opcode	\$4A
Command sequence	

Table 10-4. WRITE (Write Memory) Command

Description	Write byte to memory
Operand	Specifies 2-byte address in high byte:low byte order; low byte followed by data byte
Data returned	None
Opcode	\$49
Command sequence	

Table 10-5. IREAD (Indexed Read) Command

Description	Read next 2 bytes in memory from last address accessed
Operand	Specifies 2-byte address in high byte:low byte order
Data returned	Returns contents of next two addresses
Opcode	\$1A
Command sequence	
<p>The diagram illustrates the IREAD command sequence. It consists of four blocks: IREAD, IREAD, DATA, and DATA. The first IREAD block is labeled 'SENT TO MONITOR' with an arrow pointing to it. The second IREAD block is labeled 'ECHO' with an arrow pointing to it. The first DATA block is labeled 'RESULT' with an arrow pointing to it. The second DATA block is also labeled 'RESULT' with an arrow pointing to it.</p>	

Table 10-6. IWRITE (Indexed Write) Command

Description	Write to last address accessed + 1
Operand	Specifies single data byte
Data returned	None
Opcode	\$19
Command sequence	
<p>The diagram illustrates the IWRITE command sequence. It consists of four blocks: IWRITE, IWRITE, DATA, and DATA. The first IWRITE block is labeled 'SENT TO MONITOR' with an arrow pointing to it. The second IWRITE block is labeled 'ECHO' with an arrow pointing to it. The first DATA block is also labeled 'SENT TO MONITOR' with an arrow pointing to it. The second DATA block is also labeled 'ECHO' with an arrow pointing to it.</p>	

NOTE: A sequence of IREAD or IWRITE commands can sequentially access a block of memory over the full 64-Kbyte memory map.

Table 10-7. READSP (Read Stack Pointer) Command

Description	Reads stack pointer
Operand	None
Data returned	Returns stack pointer in high byte:low byte order
Opcode	\$0C
Command sequence	

The diagram illustrates the command sequence for the READSP command. It consists of four data frames: READSP, READSP, SP HIGH, and SP LOW. The first READSP frame is labeled 'SENT TO MONITOR'. The second READSP frame is labeled 'ECHO'. The SP HIGH and SP LOW frames are collectively labeled 'RESULT'.

Table 10-8. RUN (Run User Program) Command

Description	Executes RTI instruction
Operand	None
Data returned	None
Opcode	\$28
Command sequence	

The diagram illustrates the command sequence for the RUN command. It consists of two data frames: RUN and RUN. The first RUN frame is labeled 'SENT TO MONITOR'. The second RUN frame is labeled 'ECHO'.

10.5 Security

A security feature discourages unauthorized reading of ROM locations while in monitor mode. The host can satisfy the security feature at monitor mode entry by sending eight security bytes that match the bytes at locations \$FFF6–\$FFFD. Locations \$FFF6–\$FFFD contain user-defined data.

NOTE: Do not leave locations \$FFF6–\$FFFD blank. For security reasons, program locations \$FFF6–\$FFFD even if they are not used for vectors.

During monitor mode entry, the MCU waits after the power-on reset for the host to send the eight security bytes on pin PTB0 (R_XD). If the received bytes match those at locations \$FFF6–\$FFFD, the host satisfies the security feature and can read all ROM locations and execute code from ROM. Security remains satisfied until a power-on reset occurs. If the reset was not a power-on reset, security remains satisfied and security code entry is not required. See [Figure 10-6](#).

Figure 10-6. Monitor Mode Entry Timing

Upon power-on reset, if the received bytes of the security code do not match the data at locations \$FFF6–\$FFFD, the host fails to satisfy the security feature. The MCU remains in monitor mode, but reading a ROM location returns an invalid value and trying to execute code from ROM causes an illegal address reset. After receiving the eight security bytes from the host, the MCU transmits a break character, signifying that it is ready to receive a command.

NOTE: *The MCU does not transmit a break character until after the host sends the eight security bytes.*

To determine whether the security code entered is correct, check to see if bit 6 of RAM address \$60 is set. If it is, then the correct security code has been entered and ROM can be accessed.

If the security sequence fails, the device can be reset (via power-pin reset only) and brought up in monitor mode to attempt another entry.

After failing the security sequence, the FLASH memory can also be bulk erased by executing an erase routine that was downloaded into internal RAM. The bulk erase operation clears the security code locations so that all eight security bytes become \$FF.

11.10.5	TIMA Channel Registers	222

11.2 Introduction

This section describes the timer interface module (TIMA). The TIMA is a 2-channel timer that provides:

- Timing reference with input capture
- Output compare
- Pulse-width modulation (PWM) functions

Refer to [Figure 11-1](#) for a block diagram of the TIMA and to [Figure 11-2](#) for a summary of the registers.

For further information regarding timers on M68HC08 family devices, please consult the HC08 Timer Reference Manual, TIM08RM/AD.

11.3 Features

Features of the TIMA include:

- Two input capture/output compare channels:
 - Rising-edge, falling-edge, or any-edge input capture trigger
 - Set, clear, or toggle output compare action
- Buffered and unbuffered pulse-width modulation (PWM) signal generation
- Programmable TIMA clock input:
 - 7-frequency internal bus clock prescaler selection
 - External TIMA clock input (4-MHz maximum frequency)
- Free-running or modulo up-count operation
- Toggle any channel pin on overflow
- TIMA counter stop and reset bits

Figure 11-2. TIMA I/O Register Summary (Continued)

11.4 Functional Description

Figure 11-1 shows the TIMA structure. The central component of the TIMA is the 16-bit TIMA counter that can operate as a free-running counter or a modulo up-counter. The TIMA counter provides the timing reference for the input capture and output compare functions. The TIMA counter modulo registers, TAMODH–TAMODL, control the modulo value of the TIMA counter. Software can read the TIMA counter value at any time without affecting the counting sequence.

The two TIMA channels are programmable independently as input capture or output compare channels.

11.4.1 TIMA Counter Prescaler

The TIMA clock source can be one of the seven prescaler outputs or the TIMA clock pin, PTB2/TCLKA. The prescaler generates seven clock rates from the internal bus clock. The prescaler select bits, PS[2:0], in the TIMA status and control register select the TIMA clock source.

11.4.2 Input Capture

An input capture function has three basic parts:

1. Edge select logic
2. Input capture latch
3. 16-bit counter

Two 8-bit registers, which make up the 16-bit input capture register, are used to latch the value of the free-running counter after the corresponding input capture edge detector senses a defined transition. The polarity of the active edge is programmable. The level transition which triggers the counter transfer is defined by the corresponding input edge bits (ELSxB and ELSxA in the TASC0 and TASC1 control registers with x referring to the active channel number).

When an active edge occurs on the pin of an input capture channel, the TIMA latches the contents of the TIMA counter into the TIMA channel registers, TCHxH–TCHxL. Input captures can generate TIMA CPU interrupt requests. Software can determine that an input capture event

has occurred by enabling input capture interrupts or by polling the status flag bit.

The free-running counter contents are transferred to the TIMA channel status and control registers TACHxH and TACHxL (see [11.10.5 TIMA Channel Registers](#)) on each proper signal transition regardless of whether the TIMA channel flag (CH0F–CH1F in the TASC0–TASC1 registers) is set or clear. When the status flag is set, a CPU interrupt is generated if enabled. The value of the count latched or captured is the time of the event. Because this value is stored in the input capture register two bus cycles after the actual event occurs, user software can respond to this event at a later time and determine the actual time of the event. However, this must be done prior to another input capture on the same pin; otherwise, the previous time value will be lost.

By recording the times for successive edges on an incoming signal, software can determine the period and/or pulse width of the signal. To measure a period, two successive edges of the same polarity are captured. To measure a pulse width, two alternate polarity edges are captured. Software should track the overflows at the 16-bit module counter to extend its range.

Another use for the input capture function is to establish a time reference. In this case, an input capture function is used in conjunction with an output compare function. For example, to activate an output signal a specified number of clock cycles after detecting an input event (edge), use the input capture function to record the time at which the edge occurred. A number corresponding to the desired delay is added to this captured value and stored to an output compare register (see [11.10.5 TIMA Channel Registers](#)). Because both input captures and output compares are referenced to the same 16-bit modulo counter, the delay can be controlled to the resolution of the counter independent of software latencies.

NOTE: *Reset does not affect the contents of the input capture channel register (TACHxH–TACHxL).*

11.4.3 Output Compare

With the output compare function, the TIMA can generate a periodic pulse with a programmable polarity, duration, and frequency. When the

counter reaches the value in the registers of an output compare channel, the TIMA can set, clear, or toggle the channel pin. Output compares can generate TIMA CPU interrupt requests.

11.4.3.1 Unbuffered Output Compare

Any output compare channel can generate unbuffered output compare pulses as described in [11.4.3 Output Compare](#). The pulses are unbuffered because changing the output compare value requires writing the new value over the old value currently in the TIMA channel registers.

An unsynchronized write to the TIMA channel registers to change an output compare value could cause incorrect operation for up to two counter overflow periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that counter overflow period. Also, using a TIMA overflow interrupt routine to write a new, smaller output compare value may cause the compare to be missed. The TIMA may pass the new value before it is written.

Use these methods to synchronize unbuffered changes in the output compare value on channel x:

- When changing to a smaller value, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current output compare pulse. The interrupt routine has until the end of the counter overflow period to write the new value.
- When changing to a larger output compare value, enable TIMA overflow interrupts and write the new value in the TIMA overflow interrupt routine. The TIMA overflow interrupt occurs at the end of the current counter overflow period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same counter overflow period.

11.4.3.2 Buffered Output Compare

Channels 0 and 1 can be linked to form a buffered output compare channel whose output appears on the PTB3/TCH0A pin. The TIMA channel registers of the linked pair alternately control the output.

Setting the MS0B bit in TIMA channel 0 status and control register (TASC0) links channel 0 and channel 1. The output compare value in the TIMA channel 0 registers initially controls the output on the PTB3/TCH0A pin. Writing to the TIMA channel 1 registers enables the TIMA channel 1 registers to synchronously control the output after the TIMA overflows. At each subsequent overflow, the TIMA channel registers (0 or 1) that control the output are the ones written to last. TSC0 controls and monitors the buffered output compare function, and TIMA channel 1 status and control register (TASC1) is unused. While the MS0B bit is set, the channel 1 pin, PTB4/TCH1A, is available as a general-purpose input/output (I/O) pin.

NOTE: *In buffered output compare operation, do not write new output compare values to the currently active channel registers. User software should track the currently active channel to prevent writing a new value to the active channel. Writing to the active channel registers is the same as generating unbuffered output compares.*

11.4.4 Pulse-Width Modulation (PWM)

By using the toggle-on-overflow feature with an output compare channel, the TIMA can generate a PWM signal. The value in the TIMA counter modulo registers determines the period of the PWM signal. The channel pin toggles when the counter reaches the value in the TIMA counter modulo registers. The time between overflows is the period of the PWM signal.

As [Figure 11-3](#) shows, the output compare value in the TIMA channel registers determines the pulse width of the PWM signal. The time between overflow and output compare is the pulse width. Program the TIMA to clear the channel pin on output compare if the state of the PWM pulse is logic 1. Program the TIMA to set the pin if the state of the PWM pulse is logic 0.

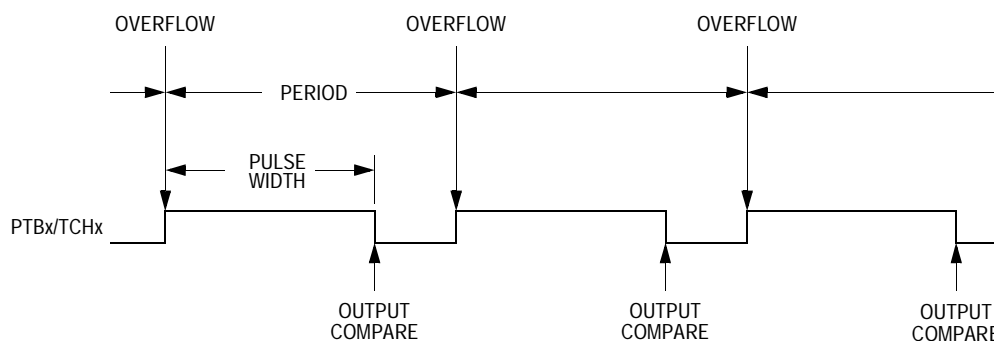

Figure 11-3. PWM Period and Pulse Width

The value in the TIMA counter modulo registers and the selected prescaler output determines the frequency of the PWM output. The frequency of an 8-bit PWM signal is variable in 256 increments. Writing \$00FF (255) to the TIMA counter modulo registers produces a PWM period of 256 times the internal bus clock period if the prescaler select value is \$000. See [11.10.1 TIMA Status and Control Register](#).

The value in the TIMA channel registers determines the pulse width of the PWM output. The pulse width of an 8-bit PWM signal is variable in 256 increments. Writing \$0080 (128) to the TIMA channel registers produces a duty cycle of 128/256 or 50 percent.

11.4.4.1 Unbuffered PWM Signal Generation

Any output compare channel can generate unbuffered PWM pulses as described in [11.4.4 Pulse-Width Modulation \(PWM\)](#). The pulses are unbuffered because changing the pulse width requires writing the new pulse width value over the value currently in the TIMA channel registers.

An unsynchronized write to the TIMA channel registers to change a pulse width value could cause incorrect operation for up to two PWM periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that PWM period. Also, using a TIMA overflow interrupt routine to write a new, smaller pulse width value may cause the compare to be missed. The TIMA may pass the new value before it is written to the TIMA channel registers.

Use these methods to synchronize unbuffered changes in the PWM pulse width on channel x:

- When changing to a shorter pulse width, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current pulse. The interrupt routine has until the end of the PWM period to write the new value.
- When changing to a longer pulse width, enable TIMA overflow interrupts and write the new value in the TIMA overflow interrupt routine. The TIMA overflow interrupt occurs at the end of the current PWM period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same PWM period.

NOTE: *In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0 percent duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output compare also can cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.*

11.4.4.2 Buffered PWM Signal Generation

Channels 0 and 1 can be linked to form a buffered PWM channel whose output appears on the PTB3/TCH0A pin. The TIMA channel registers of the linked pair alternately control the pulse width of the output.

Setting the MS0B bit in TIMA channel 0 status and control register (TASC0) links channel 0 and channel 1. The TIMA channel 0 registers initially control the pulse width on the PTB3/TCH0A pin. Writing to the TIMA channel 1 registers enables the TIMA channel 1 registers to synchronously control the pulse width at the beginning of the next PWM period. At each subsequent overflow, the TIMA channel registers (0 or 1) that control the pulse width are the ones written to last. TASC0 controls and monitors the buffered PWM function, and TIMA channel 1 status and control register (TASC1) is unused. While the MS0B bit is set, the channel 1 pin, PTB4/TCH1A, is available as a general-purpose I/O pin.

NOTE: *In buffered PWM signal generation, do not write new pulse width values to the currently active channel registers. User software should track the currently active channel to prevent writing a new value to the active channel. Writing to the active channel registers is the same as generating unbuffered PWM signals.*

11.4.4.3 PWM Initialization

To ensure correct operation when generating unbuffered or buffered PWM signals, use this initialization procedure:

1. In the TIMA status and control register (TASC):
 - a. Stop the TIMA counter by setting the TIMA stop bit, TSTOP.
 - b. Reset the TIMA counter and prescaler by setting the TIMA reset bit, TRST.
2. In the TIMA counter modulo registers (TAMODH–TAMODL), write the value for the required PWM period.
3. In the TIMA channel x registers (TACHxH–TACHxL), write the value for the required pulse width.
4. In TIMA channel x status and control register (TASCx):
 - a. Write 0:1 (for unbuffered output compare or PWM signals) or 1:0 (for buffered output compare or PWM signals) to the mode select bits, MSxB–MSxA. See [Table 11-2](#).
 - b. Write 1 to the toggle-on-overflow bit, TOVx.
 - c. Write 1:0 (to clear output on compare) or 1:1 (to set output on compare) to the edge/level select bits, ELSxB–ELSxA. The output action on compare must force the output to the complement of the pulse width level. See [Table 11-2](#).

NOTE: *In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0 percent duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output compare can also cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.*

5. In the TIMA status control register (TASC), clear the TIMA stop bit, TSTOP.

Setting MS0B links channels 0 and 1 and configures them for buffered PWM operation. The TIMA channel 0 registers (TACH0H–TACH0L) initially control the buffered PWM output. TIMA status control register 0 (TASC0) controls and monitors the PWM signal from the linked channels. MS0B takes priority over MS0A.

Clearing the toggle-on-overflow bit, TOVx, inhibits output toggles on TIMA overflows. Subsequent output compares try to force the output to a state it is already in and have no effect. The result is a 0 percent duty cycle output.

Setting the channel x maximum duty cycle bit (CHxMAX) and setting the TOVx bit generates a 100 percent duty cycle output. See [11.10.4 TIMA Channel Status and Control Registers](#).

11.5 Interrupts

These TIMA sources can generate interrupt requests:

- TIMA overflow flag (TOF) — The TOF bit is set when the TIMA counter reaches the modulo value programmed in the TIMA counter modulo registers. The TIMA overflow interrupt enable bit, TOIE, enables TIMA overflow CPU interrupt requests. TOF and TOIE are in the TIMA status and control register.
- TIMA channel flags (CH1F–CH0F) — The CHxF bit is set when an input capture or output compare occurs on channel x. Channel x TIMA CPU interrupt requests are controlled by the channel x interrupt enable bit, CHxIE.

11.6 Wait Mode

The WAIT instruction puts the MCU in low-power standby mode.

The TIMA remains active after the execution of a WAIT instruction. In wait mode, the TIMA registers are not accessible by the CPU. Any enabled CPU interrupt request from the TIMA can bring the MCU out of wait mode.

If TIMA functions are not required during wait mode, reduce power consumption by stopping the TIMA before executing the WAIT instruction.

11.7 Stop Mode

TIMA is inactive after execution of a STOP instruction. The STOP instruction does not affect register conditions or the state of the TIMA counter. TIMA operation resumes when the MCU exits stop mode after an external interrupt.

11.8 TIMA During Break Interrupts

A break interrupt stops the TIMA counter and inhibits input captures.

The system integration module (SIM) controls whether status bits in other modules can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state. See [7.7.5 SIM Break Flag Control Register](#).

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect status bits during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), software can read and write I/O registers during the break state without affecting status bits. Some status bits have a 2-step read/write clearing procedure. If software does the first step on such a bit before the break, the bit cannot change during the break state as long as BCFE is at logic 0. After the break, doing the second step clears the status bit.

11.9 I/O Signals

Port B shares three of its pins with the TIMA. PTB2/TCLKA is an external clock input to the TIMA prescaler. The two TIMA channel I/O pins are PTB3/TCH0A and PTB4/TCH1A.

11.9.1 TIMA Clock Pin (PTB2/TCLKA)

PTB2/TCLKA is an external clock input that can be the clock source for the TIMA counter instead of the prescaled internal bus clock. Select the PTB2/TCLKA input by writing logic 1s to the three prescaler select bits, PS[2:0] (see [11.10.1 TIMA Status and Control Register](#)). The minimum TCLK pulse width, TCLKLMIN or TCLKHMIN, is:

$$\frac{1}{\text{bus frequency}} + t_{su}$$

The maximum TCLK frequency is the least: 4 MHz or bus frequency \div 2.

PTB2/TCLKA is available as a general-purpose I/O pin or ADC channel when not used as the TIMA clock input. When the PTB2/TCLKA pin is the TIMA clock input, it is an input regardless of the state of the DDRB2 bit in data direction register B.

11.9.2 TIMA Channel I/O Pins (PTB3/TCH0A–PTB4/TCH1A)

Each channel I/O pin is programmable independently as an input capture pin or an output compare pin. PTB3/TCH0A and PTB3/TCH1A can be configured as buffered output compare or buffered PWM pins.

11.10 I/O Registers

These I/O registers control and monitor TIMA operation:

- TIMA status and control register (TASC)
- TIMA control registers (TACNTH–TACNTL)
- TIMA counter modulo registers (TAMODH–TAMODL)
- TIMA channel status and control registers (TASC0 and TASC1)
- TIMA channel registers (TACH0H–TACH0L and TACH1H–TACH1L)

11.10.1 TIMA Status and Control Register

The TIMA status and control register:

- Enables TIMA overflow interrupts
- Flags TIMA overflows
- Stops the TIMA counter
- Resets the TIMA counter
- Prescales the TIMA counter clock

Address \$000E

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	TOF	TOIE	TSTOP	0	0	PS2	PS1	PS0
Write:	0			TRST	R			
Reset:	0	0	1	0	0	0	0	0

R = Reserved

Figure 11-4. TIMA Status and Control Register (TASC)

TOF — TIMA Overflow Flag Bit

This read/write flag is set when the TIMA counter reaches the modulo value programmed in the TIMA counter modulo registers. Clear TOF by reading the TIMA status and control register when TOF is set and then writing a logic 0 to TOF. If another TIMA overflow occurs before the clearing sequence is complete, then writing logic 0 to TOF has no effect. Therefore, a TOF interrupt request cannot be lost due to inadvertent clearing of TOF. Reset clears the TOF bit. Writing a logic 1 to TOF has no effect.

1 = TIMA counter has reached modulo value.

0 = TIMA counter has not reached modulo value.

TOIE — TIMA Overflow Interrupt Enable Bit

This read/write bit enables TIMA overflow interrupts when the TOF bit becomes set. Reset clears the TOIE bit.

1 = TIMA overflow interrupts enabled

0 = TIMA overflow interrupts disabled

TSTOP — TIMA Stop Bit

This read/write bit stops the TIMA counter. Counting resumes when TSTOP is cleared. Reset sets the TSTOP bit, stopping the TIMA counter until software clears the TSTOP bit.

- 1 = TIMA counter stopped
- 0 = TIMA counter active

NOTE: *Do not set the TSTOP bit before entering wait mode if the TIMA is required to exit wait mode. Also, when the TSTOP bit is set and the timer is configured for input capture operation, input captures are inhibited until TSTOP is cleared.*

TRST — TIMA Reset Bit

Setting this write-only bit resets the TIMA counter and the TIMA prescaler. Setting TRST has no effect on any other registers. Counting resumes from \$0000. TRST is cleared automatically after the TIMA counter is reset and always reads as logic 0. Reset clears the TRST bit.

- 1 = Prescaler and TIMA counter cleared
- 0 = No effect

NOTE: *Setting the TSTOP and TRST bits simultaneously stops the TIMA counter at a value of \$0000.*

PS[2:0] — Prescaler Select Bits

These read/write bits select either the PTB2/TCLKA pin or one of the seven prescaler outputs as the input to the TIMA counter as [Table 11-1](#) shows. Reset clears the PS[2:0] bits.

Table 11-1. Prescaler Selection

PS[2:0]	TIMA Clock Source
000	Internal bus clock ÷ 1
001	Internal bus clock ÷ 2
010	Internal bus clock ÷ 4
011	Internal bus clock ÷ 8
100	Internal bus clock ÷ 16
101	Internal bus clock ÷ 32
110	Internal bus clock ÷ 64
111	PTB2/TCLKA

Timer Interface A (TIMA)

11.10.2 TIMA Counter Registers

The two read-only TIMA counter registers contain the high and low bytes of the value in the TIMA counter. Reading the high byte (TACNTH) latches the contents of the low byte (TACNTL) into a buffer. Subsequent reads of TACNTH do not affect the latched TACNTL value until TACNTL is read. Reset clears the TIMA counter registers. Setting the TIMA reset bit (TRST) also clears the TIMA counter registers.

NOTE: *If TACNTH is read during a break interrupt, be sure to unlatch TACNTL by reading TACNTL before exiting the break interrupt. Otherwise, TACNTL retains the value latched during the break.*

Figure 11-5. TIMA Counter Registers (TACNTH and TACNTL)

11.10.3 TIMA Counter Modulo Registers

The read/write TIMA modulo registers contain the modulo value for the TIMA counter. When the TIMA counter reaches the modulo value, the overflow flag (TOF) becomes set, and the TIMA counter resumes counting from \$0000 at the next timer clock. Writing to the high byte (TMODH) inhibits the TOF bit and overflow interrupts until the low byte (TMODL) is written. Reset sets the TIMA counter modulo registers.

NOTE: *Reset the TIMA counter before writing to the TIMA counter modulo registers.*

11.10.4 TIMA Channel Status and Control Registers

Each of the TIMA channel status and control registers:

- Flags input captures and output compares
- Enables input capture and output compare interrupts
- Selects input capture, output compare, or PWM operation
- Selects high, low, or toggling output on output compare
- Selects rising edge, falling edge, or any edge as the active input capture trigger
- Selects output toggling on TIMA overflow
- Selects 0% and 100% PWM duty cycle
- Selects buffered or unbuffered output compare/PWM operation

Figure 11-7. TIMA Channel Status and Control Registers (TASC0–TASC1)

CHxF — Channel x Flag Bit

When channel x is an input capture channel, this read/write bit is set when an active edge occurs on the channel x pin. When channel x is an output compare channel, CHxF is set when the value in the TIMA counter registers matches the value in the TIMA channel x registers.

When CHxIE = 1, clear CHxF by reading TIMA channel x status and control register with CHxF set, and then writing a logic 0 to CHxF. If another interrupt request occurs before the clearing sequence is complete, then writing logic 0 to CHxF has no effect. Therefore, an interrupt request cannot be lost due to inadvertent clearing of CHxF.

Reset clears the CHxF bit. Writing a logic 1 to CHxF has no effect.

- 1 = Input capture or output compare on channel x
- 0 = No input capture or output compare on channel x

CHxIE — Channel x Interrupt Enable Bit

This read/write bit enables TIMA CPU interrupts on channel x. Reset clears the CHxIE bit.

- 1 = Channel x CPU interrupt requests enabled
- 0 = Channel x CPU interrupt requests disabled

MSxB — Mode Select Bit B

This read/write bit selects buffered output compare/PWM operation. MSxB exists only in the TIMA channel 0. Setting MS0B disables the channel 1 status and control register and reverts TCH1A to general-purpose I/O. Reset clears the MSxB bit.

- 1 = Buffered output compare/PWM operation enabled
- 0 = Buffered output compare/PWM operation disabled

MSxA — Mode Select Bit A

When ELSxB:A ≠ 00, this read/write bit selects either input capture operation or unbuffered output compare/PWM operation. See [Table 11-2](#).

- 1 = Unbuffered output compare/PWM operation
- 0 = Input capture operation

When ELSxB:A = 00, this read/write bit selects the initial output level of the TCHx pin once PWM, input capture, or output compare operation is enabled. Reset clears the MSxA bit. See [Table 11-2](#).

- 1 = Initial output level low
- 0 = Initial output level high

NOTE: Before changing a channel function by writing to the MSxB or MSxA bit, set the TSTOP and TRST bits in the TIMA status and control register (TASC).

ELSxB and ELSxA — Edge/Level Select Bits

When channel x is an input capture channel, these read/write bits control the active edge-sensing logic on channel x.

When channel x is an output compare channel, ELSxB and ELSxA control the channel x output behavior when an output compare occurs.

When ELSxB and ELSxA are both clear, channel x is not connected to port B, and pin PTBx/TCHxA is available as a general-purpose I/O pin. However, channel x is at a state determined by these bits and becomes transparent to the respective pin when PWM, input capture, or output compare mode is enabled. [Table 11-2](#) shows how ELSxA and ELSxB work. Reset clears the ELSxB and ELSxA bits.

Table 11-2. Mode, Edge, and Level Selection

MSxB:MSxA	ELSxB:ELSxA	Mode	Configuration
X0	00	Output preset	Pin under port control: Initialize timer Output level high
X1	00		Pin under port control: Initialize timer Output level low
00	01	Input capture	Capture on rising edge only
00	10		Capture on falling edge only
00	11		Capture on rising or falling edge
01	01	Output compare or PWM	Toggle output on compare
01	10		Clear output on compare
01	11		Set output on compare
1X	01	Buffered output compare or buffered PWM	Toggle output on compare
1X	10		Clear output on compare
1X	11		Set output on compare

NOTE: Before enabling a TIMA channel register for input capture operation, make sure that the PTBx/TACHx pin is stable for at least two bus clocks.

TOVx — Toggle-On-Overflow Bit

When channel x is an output compare channel, this read/write bit controls the behavior of the channel x output when the TIMA counter overflows. When channel x is an input capture channel, TOVx has no effect. Reset clears the TOVx bit.

- 1 = Channel x pin toggles on TIMA counter overflow.
- 0 = Channel x pin does not toggle on TIMA counter overflow.

NOTE: When TOVx is set, a TIMA counter overflow takes precedence over a channel x output compare if both occur at the same time.

CHxMAX — Channel x Maximum Duty Cycle Bit

When the TOVx bit is at logic 1, setting the CHxMAX bit forces the duty cycle of buffered and unbuffered PWM signals to 100 percent. As **Figure 11-8** shows, the CHxMAX bit takes effect in the cycle after it is set or cleared. The output stays at the 100 percent duty cycle level until the cycle after CHxMAX is cleared.

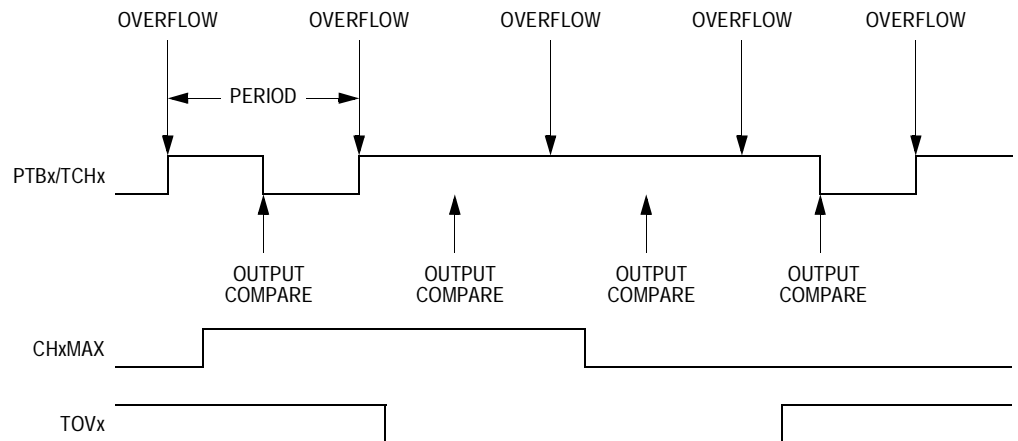

Figure 11-8. CHxMAX Latency

11.10.5 TIMA Channel Registers

These read/write registers contain the captured TIMA counter value of the input capture function or the output compare value of the output compare function. The state of the TIMA channel registers after reset is unknown.

In input capture mode ($MSxB-MSxA = 0:0$), reading the high byte of the TIMA channel x registers (TACHxH) inhibits input captures until the low byte (TACHxL) is read.

In output compare mode ($MSxB-MSxA \neq 0:0$), writing to the high byte of the TIMA channel x registers (TACHxH) inhibits output compares until the low byte (TACHxL) is written.

12.2 Introduction

This section describes the timer interface module (TIMB). The TIMB is a 2-channel timer that provides:

- A timing reference with input capture
- Output compare
- Pulse width modulation (PWM) functions

Refer to [Figure 12-1](#) for a block diagram of the TIMB and to [Figure 12-2](#) for a summary of the registers.

For further information regarding timers on M68HC08 family devices, please consult the HC08 Timer Reference Manual, TIM08RM/AD.

12.3 Features

Features of the TIMB include:

- Two input capture/output compare channels
 - Rising-edge, falling-edge, or any-edge input capture trigger
 - Set, clear, or toggle output compare action
- Buffered and unbuffered PWM signal generation
- Programmable TIMB clock with 7-frequency internal bus clock prescaler selection
- Free-running or modulo up-count operation
- Toggle any channel pin on overflow
- TIMB counter stop and reset bits

Figure 12-2. TIMB I/O Register Summary (Continued)

12.4 Functional Description

Figure 12-1 shows the TIMB structure. The central component of the TIMB is the 16-bit TIMB counter that can operate as a free-running counter or a modulo up-counter. The TIMB counter provides the timing reference for the input capture and output compare functions. The TIMB counter modulo registers, TBMODH–TBMODL, control the modulo value of the TIMB counter. Software can read the TIMB counter value at any time without affecting the counting sequence.

The two TIMB channels are programmable independently as input capture or output compare channels.

12.4.1 TIMB Counter Prescaler

The TIMB clock source can be one of the seven prescaler outputs. The prescaler generates seven clock rates from the internal bus clock. The prescaler select bits, PS[2:0], in the TIMB status and control register select the TIMB clock source.

12.4.2 Input Capture

An input capture function has three basic parts:

- Edge select logic
- Input capture latch
- 16-bit counter

Two 8-bit registers, which make up the 16-bit input capture register, are used to latch the value of the free-running counter after the corresponding input capture edge detector senses a defined transition. The polarity of the active edge is programmable. The level transition which triggers the counter transfer is defined by the corresponding input edge bits (ELSxB and ELSxA in TBSC0 through TBSC1 control registers with x referring to the active channel number). When an active edge occurs on the pin of an input capture channel, the TIMB latches the contents of the TIMB counter into the TIMB channel registers, TCHxH–TCHxL. Input captures can generate TIMB CPU interrupt requests. Software can determine that an input capture event has occurred by enabling input capture interrupts or by polling the status flag bit.

The free-running counter contents are transferred to the TIMB channel status and control register, TBCHxH–TBCHxL, (see [12.10.5 TIMB Channel Registers](#)) on each proper signal transition regardless of whether the TIMB channel flag (CH0F–CH1F in TBSC0–TBSC1 registers) is set or clear. When the status flag is set, a CPU interrupt is generated if enabled. The value of the count latched or “captured” is the time of the event. Because this value is stored in the input capture register two bus cycles after the actual event occurs, user software can

respond to this event at a later time and determine the actual time of the event. However, this must be done prior to another input capture on the same pin; otherwise, the previous time value will be lost.

By recording the times for successive edges on an incoming signal, software can determine the period and/or pulse width of the signal. To measure a period, two successive edges of the same polarity are captured. To measure a pulse width, two alternate polarity edges are captured. Software should track the overflows at the 16-bit module counter to extend its range.

Another use for the input capture function is to establish a time reference. In this case, an input capture function is used in conjunction with an output compare function. For example, to activate an output signal a specified number of clock cycles after detecting an input event (edge), use the input capture function to record the time at which the edge occurred. A number corresponding to the desired delay is added to this captured value and stored to an output compare register (see [12.10.5 TIMB Channel Registers](#)). Because both input captures and output compares are referenced to the same 16-bit modulo counter, the delay can be controlled to the resolution of the counter independent of software latencies.

NOTE: *Reset does not affect the contents of the input capture channel register (TBCHxH–TBCHxL).*

12.4.3 Output Compare

With the output compare function, the TIMB can generate a periodic pulse with a programmable polarity, duration, and frequency. When the counter reaches the value in the registers of an output compare channel, the TIMB can set, clear, or toggle the channel pin. Output compares can generate TIMB CPU interrupt requests.

12.4.3.1 Unbuffered Output Compare

Any output compare channel can generate unbuffered output compare pulses as described in [12.4.3 Output Compare](#). The pulses are unbuffered because changing the output compare value requires writing the new value over the old value currently in the TIMB channel registers.

An unsynchronized write to the TIMB channel registers to change an output compare value could cause incorrect operation for up to two counter overflow periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that counter overflow period. Also, using a TIMB overflow interrupt routine to write a new, smaller output compare value may cause the compare to be missed. The TIMB may pass the new value before it is written.

Use these methods to synchronize unbuffered changes in the output compare value on channel x:

- When changing to a smaller value, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current output compare pulse. The interrupt routine has until the end of the counter overflow period to write the new value.
- When changing to a larger output compare value, enable TIMB overflow interrupts and write the new value in the TIMB overflow interrupt routine. The TIMB overflow interrupt occurs at the end of the current counter overflow period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same counter overflow period.

12.4.3.2 Buffered Output Compare

Channels 0 and 1 can be linked to form a buffered output compare channel whose output appears on the PTB5/TCH0B pin. The TIMB channel registers of the linked pair alternately control the output.

Setting the MS0B bit in TIMB channel 0 status and control register (TBSC0) links channel 0 and channel 1. The output compare value in the TIMB channel 0 registers initially controls the output on the PTB5/TCH0B pin. Writing to the TIMB channel 1 registers enables the TIMB channel 1 registers to synchronously control the output after the TIMB overflows. At each subsequent overflow, the TIMB channel registers (0 or 1) that control the output are the ones written to last. TSC0 controls and monitors the buffered output compare function, and TIMB channel 1 status and control register (TBSC1) is unused. While the MS0B bit is set, the channel 1 pin, PTB6/TCH1B, is available as a general-purpose input/output (I/O) pin.

NOTE: *In buffered output compare operation, do not write new output compare values to the currently active channel registers. User software should track the currently active channel to prevent writing a new value to the active channel. Writing to the active channel registers is the same as generating unbuffered output compares.*

12.4.4 Pulse-Width Modulation (PWM)

By using the toggle-on-overflow feature with an output compare channel, the TIMB can generate a PWM signal. The value in the TIMB counter modulo registers determines the period of the PWM signal. The channel pin toggles when the counter reaches the value in the TIMB counter modulo registers. The time between overflows is the period of the PWM signal.

As [Figure 12-3](#) shows, the output compare value in the TIMB channel registers determines the pulse width of the PWM signal. The time between overflow and output compare is the pulse width. Program the TIMB to clear the channel pin on output compare if the state of the PWM pulse is logic 1. Program the TIMB to set the pin if the state of the PWM pulse is logic 0.

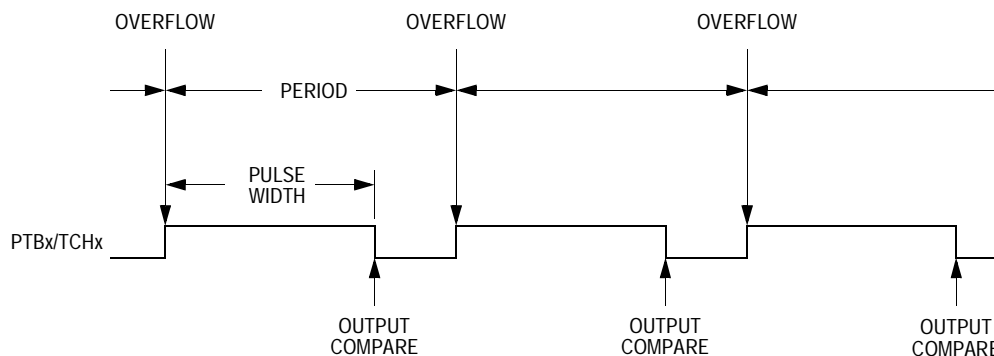

Figure 12-3. PWM Period and Pulse Width

The value in the TIMB counter modulo registers and the selected prescaler output determines the frequency of the PWM output. The frequency of an 8-bit PWM signal is variable in 256 increments. Writing \$00FF (255) to the TIMB counter modulo registers produces a PWM period of 256 times the internal bus clock period if the prescaler select value is \$000 (see [12.10.1 TIMB Status and Control Register](#)).

The value in the TIMB channel registers determines the pulse width of the PWM output. The pulse width of an 8-bit PWM signal is variable in 256 increments. Writing \$0080 (128) to the TIMB channel registers produces a duty cycle of 128/256 or 50 percent.

12.4.4.1 Unbuffered PWM Signal Generation

Any output compare channel can generate unbuffered PWM pulses as described in [12.4.4 Pulse-Width Modulation \(PWM\)](#). The pulses are unbuffered because changing the pulse width requires writing the new pulse width value over the value currently in the TIMB channel registers.

An unsynchronized write to the TIMB channel registers to change a pulse width value could cause incorrect operation for up to two PWM periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that PWM period. Also, using a TIMB overflow interrupt routine to write a new, smaller pulse width value may cause the compare to be missed. The TIMB may pass the new value before it is written to the TIMB channel registers.

Use these methods to synchronize unbuffered changes in the PWM pulse width on channel x:

- When changing to a shorter pulse width, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current pulse. The interrupt routine has until the end of the PWM period to write the new value.
- When changing to a longer pulse width, enable TIMB overflow interrupts and write the new value in the TIMB overflow interrupt routine. The TIMB overflow interrupt occurs at the end of the current PWM period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same PWM period.

NOTE: *In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0 percent duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output compare also can cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.*

12.4.4.2 Buffered PWM Signal Generation

Channels 0 and 1 can be linked to form a buffered PWM channel whose output appears on the PTB5/TCH0B pin. The TIMB channel registers of the linked pair alternately control the pulse width of the output.

Setting the MS0B bit in TIMB channel 0 status and control register (TBSC0) links channel 0 and channel 1. The TIMB channel 0 registers initially control the pulse width on the PTB5/TCH0B pin. Writing to the TIMB channel 1 registers enables the TIMB channel 1 registers to synchronously control the pulse width at the beginning of the next PWM period. At each subsequent overflow, the TIMB channel registers (0 or 1) that control the pulse width are the ones written to last. TBSC0 controls and monitors the buffered PWM function, and TIMB channel 1 status and control register (TBSC1) is unused. While the MS0B bit is set, the channel 1 pin, PTB6/TCH1B, is available as a general-purpose I/O pin.

NOTE: *In buffered PWM signal generation, do not write new pulse width values to the currently active channel registers. User software should track the currently active channel to prevent writing a new value to the active channel. Writing to the active channel registers is the same as generating unbuffered PWM signals.*

12.4.4.3 PWM Initialization

To ensure correct operation when generating unbuffered or buffered PWM signals, use this initialization procedure:

1. In the TIMB status and control register (TBSC):
 - a. Stop the TIMB counter by setting the TIMB stop bit, TSTOP.
 - b. Reset the TIMB counter and prescaler by setting the TIMB reset bit, TRST.
2. In the TIMB counter modulo registers (TBMODH–TBMODL), write the value for the required PWM period.
3. In the TIMB channel x registers (TBCHxH–TBCHxL), write the value for the required pulse width.
4. In TIMB channel x status and control register (TBSCx):
 - a. Write 0:1 (for unbuffered output compare or PWM signals) or 1:0 (for buffered output compare or PWM signals) to the mode select bits, MSxB–MSxA. See [Table 12-2](#).
 - b. Write 1 to the toggle-on-overflow bit, TOVx.
 - c. Write 1:0 (to clear output on compare) or 1:1 (to set output on compare) to the edge/level select bits, ELSxB–ELSxA. The output action on compare must force the output to the complement of the pulse width level. See [Table 12-2](#).

NOTE: *In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0 percent duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output compare can also cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.*

5. In the TIMB status control register (TBSC), clear the TIMB stop bit, TSTOP.

Setting MS0B links channels 0 and 1 and configures them for buffered PWM operation. The TIMB channel 0 registers (TBCH0H–TBCH0L) initially control the buffered PWM output. TIMB status control register 0 (TBSC0) controls and monitors the PWM signal from the linked channels. MS0B takes priority over MS0A.

Clearing the toggle-on-overflow bit, TOVx, inhibits output toggles on TIMB overflows. Subsequent output compares try to force the output to a state it is already in and have no effect. The result is a 0 percent duty cycle output.

Setting the channel x maximum duty cycle bit (CHxMAX) and setting the TOVx bit generates a 100 percent duty cycle output. See [12.10.4 TIMB Channel Status and Control Registers](#).

12.5 Interrupts

These TIMB sources can generate interrupt requests:

- TIMB overflow flag (TOF) — The TOF bit is set when the TIMB counter reaches the modulo value programmed in the TIMB counter modulo registers. The TIMB overflow interrupt enable bit, TOIE, enables TIMB overflow CPU interrupt requests. TOF and TOIE are in the TIMB status and control register.
- TIMB channel flags (CH1F–CH0F) — The CHxF bit is set when an input capture or output compare occurs on channel x. Channel x TIMB CPU interrupt requests are controlled by the channel x interrupt enable bit, CHxIE.

12.6 Wait Mode

The WAIT instruction puts the MCU in low-power standby mode.

The TIMB remains active after the execution of a WAIT instruction. In wait mode, the TIMB registers are not accessible by the CPU. Any enabled CPU interrupt request from the TIMB can bring the MCU out of wait mode.

If TIMB functions are not required during wait mode, reduce power consumption by stopping the TIMB before executing the WAIT instruction.

12.7 Stop Mode

TIMB is inactive after execution of a STOP instruction. The STOP instruction does not affect register conditions or the state of the TIMB counter.

TIMB operation resumes when the MCU exits stop mode after an external interrupt.

12.8 TIMB During Break Interrupts

A break interrupt stops the TIMB counter and inhibits input captures.

The system integration module (SIM) controls whether status bits in other modules can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state. See [7.7.5 SIM Break Flag Control Register](#).

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect status bits during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), software can read and write I/O registers during the break state without affecting status bits. Some status bits have a 2-step read/write clearing procedure. If software does the first step on such a bit before the break, the bit cannot change during the break state as long as BCFE is at logic 0. After the break, doing the second step clears the status bit.

12.9 TIMB Channel I/O Pins (PTB5/TCH0B–PTB6/TCH1B)

Port B shares two of its pins with the TIMB. The two TIMB channel I/O pins are PTB5/TCH0B and PTB6/TCH1B.

Each channel I/O pin is programmable independently as an input capture pin or an output compare pin. PTB5/TCH0B and PTB6/TCH1B can be configured as buffered output compare or buffered PWM pins.

12.10 I/O Registers

These I/O registers control and monitor TIMB operation:

- TIMB status and control register (TBSC)
- TIMB control registers (TBCNTH–TBCNTL)
- TIMB counter modulo registers (TBMODH–TBMODL)
- TIMB channel status and control registers (TBSC0 and TBSC1)
- TIMB channel registers (TBCH0H–TBCH0L and TBCH1H–TBCH1L)

12.10.1 TIMB Status and Control Register

The TIMB status and control register:

- Enables TIMB overflow interrupts
- Flags TIMB overflows
- Stops the TIMB counter
- Resets the TIMB counter
- Prescales the TIMB counter clock

Timer Interface B (TIMB)

Address \$0051

:

R = Reserved

Figure 12-4. TIMB Status and Control Register (TBSC)

TOF — TIMB Overflow Flag Bit

This read/write flag is set when the TIMB counter reaches the modulo value programmed in the TIMB counter modulo registers. Clear TOF by reading the TIMB status and control register when TOF is set and then writing a logic 0 to TOF. If another TIMB overflow occurs before the clearing sequence is complete, then writing logic 0 to TOF has no effect. Therefore, a TOF interrupt request cannot be lost due to inadvertent clearing of TOF. Reset clears the TOF bit. Writing a logic 1 to TOF has no effect.

1 = TIMB counter has reached modulo value.

0 = TIMB counter has not reached modulo value.

TOIE — TIMB Overflow Interrupt Enable Bit

This read/write bit enables TIMB overflow interrupts when the TOF bit becomes set. Reset clears the TOIE bit.

1 = TIMB overflow interrupts enabled

0 = TIMB overflow interrupts disabled

TSTOP — TIMB Stop Bit

This read/write bit stops the TIMB counter. Counting resumes when TSTOP is cleared. Reset sets the TSTOP bit, stopping the TIMB counter until software clears the TSTOP bit.

1 = TIMB counter stopped

0 = TIMB counter active

NOTE: Do not set the TSTOP bit before entering wait mode if the TIMB is required to exit wait mode. Also, when the TSTOP bit is set and the timer is configured for input capture operation, input captures are inhibited until TSTOP is cleared.

TRST — TIMB Reset Bit

Setting this write-only bit resets the TIMB counter and the TIMB prescaler. Setting TRST has no effect on any other registers. Counting resumes from \$0000. TRST is cleared automatically after the TIMB counter is reset and always reads as logic 0. Reset clears the TRST bit.

- 1 = Prescaler and TIMB counter cleared
- 0 = No effect

NOTE: *Setting the TSTOP and TRST bits simultaneously stops the TIMB counter at a value of \$0000.*

PS[2:0] — Prescaler Select Bits

These read/write bits select one of the seven prescaler outputs as the input to the TIMB counter as [Table 12-1](#) shows. Reset clears the PS[2:0] bits.

Table 12-1. Prescaler Selection

PS[2:0]	TIMB Clock Source
000	Internal Bus Clock ÷ 1
001	Internal Bus Clock ÷ 2
010	Internal Bus Clock ÷ 4
011	Internal Bus Clock ÷ 8
100	Internal Bus Clock ÷ 16
101	Internal Bus Clock ÷ 32
110	Internal Bus Clock ÷ 64
111	Invalid: do not use this value

Timer Interface B (TIMB)

12.10.2 TIMB Counter Registers

The two read-only TIMB counter registers contain the high and low bytes of the value in the TIMB counter. Reading the high byte (TBCNTH) latches the contents of the low byte (TBCNTL) into a buffer. Subsequent reads of TBCNTH do not affect the latched TBCNTL value until TBCNTL is read. Reset clears the TIMB counter registers. Setting the TIMB reset bit (TRST) also clears the TIMB counter registers.

NOTE: *If TBCNTH is read during a break interrupt, be sure to unlatch TBCNTL by reading TBCNTL before exiting the break interrupt. Otherwise, TBCNTL retains the value latched during the break.*

Register Name and Address: TBCNTH — \$0052

	Bit 7	6	5	4	3	2	1	Bit 0

Figure 12-5. TIMB Counter Registers (TBCNTH and TBCNTL)

12.10.3 TIMB Counter Modulo Registers

The read/write TIMB modulo registers contain the modulo value for the TIMB counter. When the TIMB counter reaches the modulo value, the overflow flag (TOF) becomes set, and the TIMB counter resumes counting from \$0000 at the next timer clock. Writing to the high byte (TMODH) inhibits the TOF bit and overflow interrupts until the low byte (TMODL) is written. Reset sets the TIMB counter modulo registers.

Figure 12-6. TIMB Counter Modulo Registers (TMODH and TMDL)

NOTE: Reset the TIMB counter before writing to the TIMB counter modulo registers.

12.10.4 TIMB Channel Status and Control Registers

Each of the TIMB channel status and control registers:

- Flags input captures and output compares
- Enables input capture and output compare interrupts
- Selects input capture, output compare, or PWM operation
- Selects high, low, or toggling output on output compare
- Selects rising edge, falling edge, or any edge as the active input capture trigger
- Selects output toggling on TIMB overflow
- Selects 0% and 100% PWM duty cycle
- Selects buffered or unbuffered output compare/PWM operation

Figure 12-7. TIMB Channel Status and Control Registers (TBSC0–TBSC1)

CHxF — Channel x Flag Bit

When channel x is an input capture channel, this read/write bit is set when an active edge occurs on the channel x pin. When channel x is an output compare channel, CHxF is set when the value in the TIMB counter registers matches the value in the TIMB channel x registers.

When CHxIE = 1, clear CHxF by reading TIMB channel x status and control register with CHxF set, and then writing a logic 0 to CHxF. If another interrupt request occurs before the clearing sequence is complete, then writing logic 0 to CHxF has no effect. Therefore, an interrupt request cannot be lost due to inadvertent clearing of CHxF.

Reset clears the CHxF bit. Writing a logic 1 to CHxF has no effect.

- 1 = Input capture or output compare on channel x
- 0 = No input capture or output compare on channel x

CHxIE — Channel x Interrupt Enable Bit

This read/write bit enables TIMB CPU interrupts on channel x. Reset clears the CHxIE bit.

- 1 = Channel x CPU interrupt requests enabled
- 0 = Channel x CPU interrupt requests disabled

MSxB — Mode Select Bit B

This read/write bit selects buffered output compare/PWM operation. MSxB exists only in the TIMB channel 0. Reset clears the MSxB bit.

- 1 = Buffered output compare/PWM operation enabled
- 0 = Buffered output compare/PWM operation disabled

MSxA — Mode Select Bit A

When ELSxB:A ≠ 00, this read/write bit selects either input capture operation or unbuffered output compare/PWM operation. See [Table 12-2](#).

- 1 = Unbuffered output compare/PWM operation
- 0 = Input capture operation

When ELSxB:A = 00, this read/write bit selects the initial output level of the TCHx pin once PWM, input capture, or output compare operation is enabled. Reset clears the MSxA bit. See [Table 12-2](#).

- 1 = Initial output level low
- 0 = Initial output level high

NOTE: Before changing a channel function by writing to the MSxB or MSxA bit, set the TSTOP and TRST bits in the TIMB status and control register (TBSC).

ELSxB and ELSxA — Edge/Level Select Bits

When channel x is an input capture channel, these read/write bits control the active edge-sensing logic on channel x.

When channel x is an output compare channel, ELSxB and ELSxA control the channel x output behavior when an output compare occurs.

When ELSxB and ELSxA are both clear, channel x is not connected to port B, and pin PTBx/TCHxB is available as a general-purpose I/O pin. However, channel x is at a state determined by these bits and becomes transparent to the respective pin when PWM, input capture, or output compare mode is enabled. [Table 12-2](#) shows how ELSxA and ELSxA work. Reset clears the ELSxB and ELSxA bits.

Table 12-2. Mode, Edge, and Level Selection

MSxB:MSxA	ELSxB:ELSxA	Mode	Configuration
X0	00	Output preset	Pin under port control; Initialize timer Output level high
X1	00		Pin under port control; Initialize timer Output level low
00	01	Input capture	Capture on rising edge only
00	10		Capture on falling edge only
00	11		Capture on rising or falling edge
01	01	Output compare or PWM	Toggle output on compare
01	10		Clear output on compare
01	11		Set output on compare
1X	01	Buffered output compare or buffered PWM	Toggle output on compare
1X	10		Clear output on compare
1X	11		Set output on compare

NOTE: Before enabling a TIMB channel register for input capture operation, make sure that the PTBx/TBCHx pin is stable for at least two bus clocks.

TOVx — Toggle-On-Overflow Bit

When channel x is an output compare channel, this read/write bit controls the behavior of the channel x output when the TIMB counter overflows. When channel x is an input capture channel, TOVx has no effect. Reset clears the TOVx bit.

- 1 = Channel x pin toggles on TIMB counter overflow.
- 0 = Channel x pin does not toggle on TIMB counter overflow.

NOTE: When TOVx is set, a TIMB counter overflow takes precedence over a channel x output compare if both occur at the same time.

CHxMAX — Channel x Maximum Duty Cycle Bit

When the TOVx bit is at logic 1, setting the CHxMAX bit forces the duty cycle of buffered and unbuffered PWM signals to 100 percent. As [Figure 12-8](#) shows, the CHxMAX bit takes effect in the cycle after it is set or cleared. The output stays at the 100 percent duty cycle level until the cycle after CHxMAX is cleared.

Figure 12-8. CHxMAX Latency

12.10.5 TIMB Channel Registers

These read/write registers contain the captured TIMB counter value of the input capture function or the output compare value of the output compare function. The state of the TIMB channel registers after reset is unknown.

Timer Interface B (TIMB)

In input capture mode ($MSxB-MSxA = 0:0$), reading the high byte of the TIMB channel x registers (TBCHxH) inhibits input captures until the low byte (TBCHxL) is read.

In output compare mode ($MSxB-MSxA \neq 0:0$), writing to the high byte of the TIMB channel x registers (TBCHxH) inhibits output compares until the low byte (TBCHxL) is written.

Figure 12-9. TIMB Channel Registers (TBCH0H/L–TBCH1H/L)

13.2 Introduction

This section describes the serial communications interface (SCI) module which allows high-speed asynchronous communications with peripheral devices and other microcontroller units (MCUs).

13.3 Features

Features of the SCI module include:

- Full duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- 32 programmable baud rates
- Programmable 8-bit or 9-bit character length
- Separately enabled transmitter and receiver
- Separate receiver and transmitter cpu interrupt requests
- Separate receiver and transmitter
- Programmable transmitter output polarity
- Two receiver wakeup methods:
 - Idle line wakeup
 - Address mark wakeup

- Interrupt-driven operation with eight interrupt flags:
 - Transmitter empty
 - Transmission complete
 - Receiver full
 - Idle receiver input
 - Receiver overrun
 - Noise error
 - Framing error
 - Parity error
- Receiver framing error detection
- Hardware parity checking
- 1/16 bit-time noise detection

13.4 Functional Description

The SCI allows full-duplex, asynchronous, NRZ serial communication among the MCU and remote devices, including other MCUs. The transmitter and receiver of the SCI operate independently, although they use the same baud rate generator. During normal operation, the CPU monitors the status of the SCI, writes the data to be transmitted, and processes received data.

Figure 13-1 shows the structure of the SCI module. **Figure 13-2** provides a summary of the input/output (I/O) registers.

Figure 13-2. SCI I/O Register Summary

13.4.1 Data Format

The SCI uses the standard non-return-to-zero mark/space data format illustrated in [Figure 13-3](#).

Serial Communications Interface (SCI)

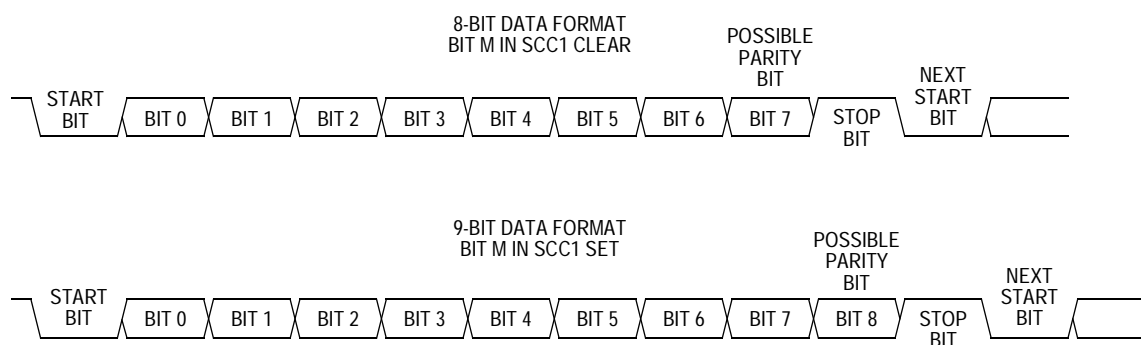

Figure 13-3. SCI Data Formats

13.4.2 Transmitter

Figure 13-4 shows the structure of the SCI transmitter.

13.4.2.1 Character Length

The transmitter can accommodate either 8-bit or 9-bit data. The state of the M bit in SCI control register 1 (SCC1) determines character length. When transmitting 9-bit data, bit T8 in SCI control register 3 (SCC3) is the ninth bit (bit 8).

13.4.2.2 Character Transmission

During an SCI transmission, the transmit shift register shifts a character out to the PTB1/TxD pin. The SCI data register (SCDR) is the write-only buffer between the internal data bus and the transmit shift register.

To initiate an SCI transmission:

1. Enable the SCI by writing a logic 1 to the enable SCI bit (ENSCI) in SCI control register 1 (SCC1).
2. Enable the transmitter by writing a logic 1 to the transmitter enable bit (TE) in SCI control register 2 (SCC2).
3. Clear the SCI transmitter empty bit by first reading SCI status register 1 (SCS1) and then writing to the SCDR.
4. Repeat step 3 for each subsequent transmission.

At the start of a transmission, transmitter control logic automatically loads the transmit shift register with a preamble of logic 1s. After the preamble shifts out, control logic transfers the SCDR data into the transmit shift register. A logic 0 start bit automatically goes into the least significant bit (LSB) position of the transmit shift register. A logic 1 stop bit goes into the most significant bit (MSB) position.

The SCI transmitter empty bit, SCTE, in SCS1 becomes set when the SCDR transfers a byte to the transmit shift register. The SCTE bit indicates that the SCDR can accept new data from the internal data bus. If the SCI transmit interrupt enable bit, SCTIE, in SCC2 is also set, the SCTE bit generates a transmitter CPU interrupt request.

When the transmit shift register is not transmitting a character, the PTB1/TxD pin goes to the idle condition, logic 1. If at any time software clears the ENSCI bit in SCI control register 1 (SCC1), the transmitter and receiver relinquish control of the port B pins.

13.4.2.3 Break Characters

Writing a logic 1 to the send break bit, SBK, in SCC2 loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on the M bit in SCC1. As long as SBK is at logic 1, transmitter logic continuously loads break characters into the transmit shift register. After software clears the SBK bit, the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next character.

The SCI recognizes a break character when a start bit is followed by eight or nine logic 0 data bits and a logic 0 where the stop bit should be.

Serial Communications Interface (SCI)

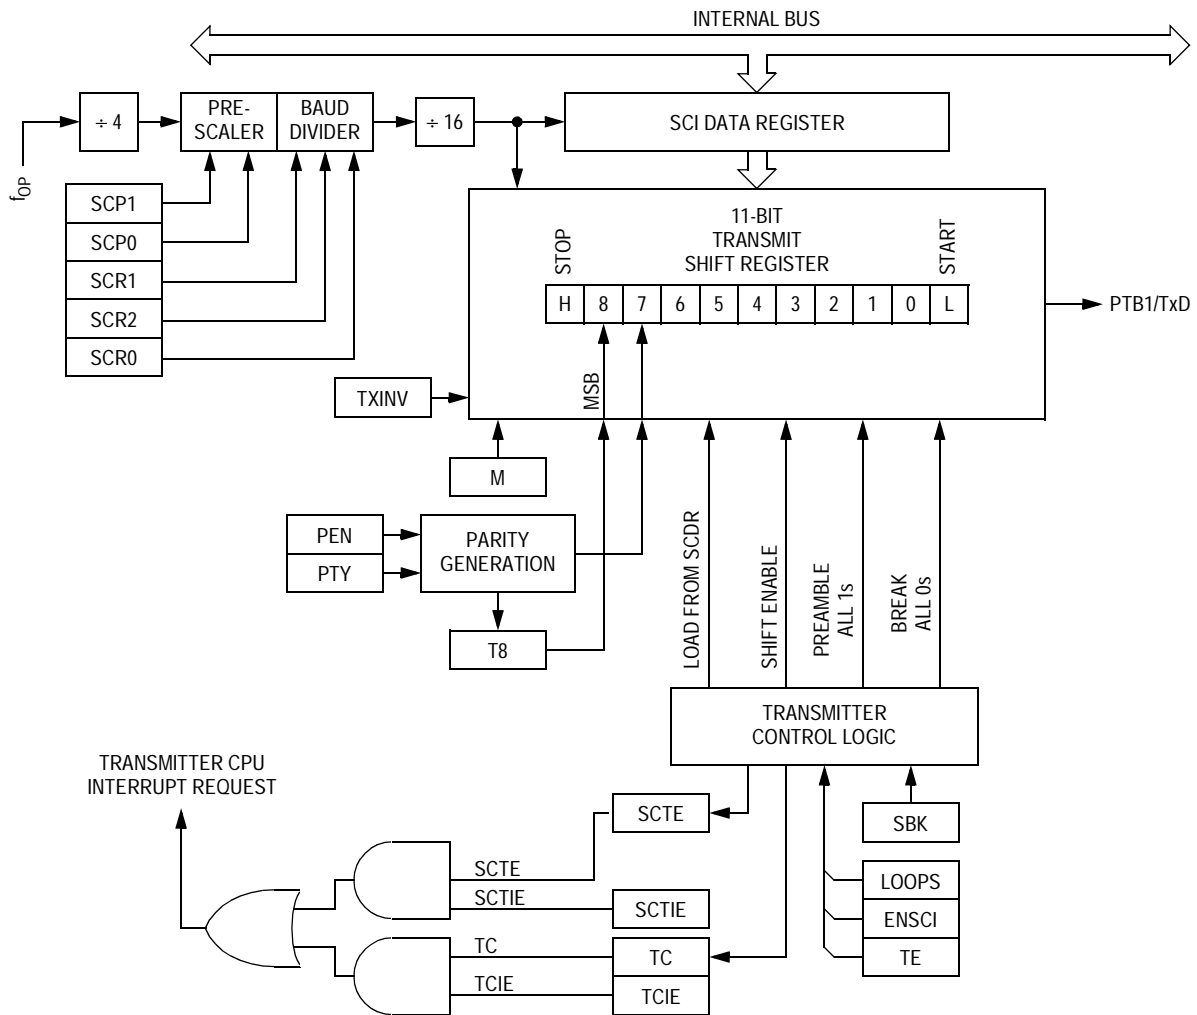

Figure 13-4. SCI Transmitter

Receiving a break character has these effects on SCI registers:

- Sets the framing error bit (FE) in SCS1
- Sets the SCI receiver full bit (SCRF) in SCS1
- Clears the SCI data register (SCDR)
- Clears the R8 bit in SCC3
- Sets the break flag bit (BKF) in SCS2
- May set the overrun (OR), noise flag (NF), parity error (PE), or reception-in-progress flag (RPF) bits

13.4.2.4 Idle Characters

An idle character contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on the M bit in SCC1. The preamble is a synchronizing idle character that begins every transmission.

If the TE bit is cleared during a transmission, the PTB1/TxD pin becomes idle after completion of the transmission in progress. Clearing and then setting the TE bit during a transmission queues an idle character to be sent after the character currently being transmitted.

NOTE: *When queueing an idle character, return the TE bit to logic 1 before the stop bit of the current character shifts out to the PTB1/TxD pin. Setting TE after the stop bit appears on PTB1/TxD causes data previously written to the SCDR to be lost.*

A good time to toggle the TE bit is when the SCTE bit becomes set and just before writing the next byte to the SCDR.

13.4.2.5 Inversion of Transmitted Output

The transmit inversion bit (TXINV) in SCI control register 1 (SCC1) reverses the polarity of transmitted data. All transmitted values, including idle, break, start, and stop bits, are inverted when TXINV is at logic 1. See [13.9.1 SCI Control Register 1](#).

13.4.2.6 Transmitter Interrupts

These conditions can generate CPU interrupt requests from the SCI transmitter:

- SCI transmitter empty (SCTE) — The SCTE bit in SCS1 indicates that the SCDR has transferred a character to the transmit shift register. SCTE can generate a transmitter CPU interrupt request. Setting the SCI transmit interrupt enable bit, SCTIE, in SCC2 enables the SCTE bit to generate transmitter CPU interrupt requests.
- Transmission complete (TC) — The TC bit in SCS1 indicates that the transmit shift register and the SCDR are empty and that no break or idle character has been generated. The transmission complete interrupt enable bit, TCIE, in SCC2 enables the TC bit to generate transmitter CPU interrupt requests.

13.4.3.1 Character Length

The receiver can accommodate either 8-bit or 9-bit data. The state of the M bit in SCI control register 1 (SCC1) determines character length. When receiving 9-bit data, bit R8 in SCI control register 2 (SCC2) is the ninth bit (bit 8). When receiving 8-bit data, bit R8 is a copy of the eighth bit (bit 7).

13.4.3.2 Character Reception

During an SCI reception, the receive shift register shifts characters in from the PTB0/RxD pin. The SCI data register (SCDR) is the read-only buffer between the internal data bus and the receive shift register.

After a complete character shifts into the receive shift register, the data portion of the character transfers to the SCDR. The SCI receiver full bit, SCRF, in SCI status register 1 (SCS1) becomes set, indicating that the received byte can be read. If the SCI receive interrupt enable bit, SCRIE, in SCC2 is also set, the SCRF bit generates a receiver CPU interrupt request.

13.4.3.3 Data Sampling

The receiver samples the PTB0/RxD pin at the RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock is resynchronized at these times (see [Figure 13-6](#)):

- After every start bit
- After the receiver detects a data bit change from logic 1 to logic 0 (after the majority of data bit samples at RT8, RT9, and RT10 return a valid logic 1 and the majority of the next RT8, RT9, and RT10 samples return a valid logic 0)

To locate the start bit, data recovery logic does an asynchronous search for a logic 0 preceded by three logic 1s. When the falling edge of a possible start bit occurs, the RT clock begins to count to 16.

Serial Communications Interface (SCI)

Figure 13-6. Receiver Data Sampling

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT5, and RT7. [Table 13-1](#) summarizes the results of the start bit verification samples.

Table 13-1. Start Bit Verification

RT3, RT5, and RT7 Samples	Start Bit Verification	Noise Flag
000	Yes	0
001	Yes	1
010	Yes	1
011	No	0
100	Yes	1
101	No	0
110	No	0
111	No	0

If start bit verification is not successful, the RT clock is reset and a new search for a start bit begins.

To determine the value of a data bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. [Table 13-2](#) summarizes the results of the data bit samples.

Table 13-2. Data Bit Recovery

RT8, RT9, and RT10 Samples	Data Bit Determination	Noise Flag
000	0	0
001	0	1
010	0	1
011	1	1
100	0	1
101	1	1
110	1	1
111	1	0

NOTE: *The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are logic 1s following a successful start bit verification, the noise flag (NF) is set and the receiver assumes that the bit is a start bit.*

To verify a stop bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. [Table 13-3](#) summarizes the results of the stop bit samples.

Table 13-3. Stop Bit Recovery

RT8, RT9, and RT10 Samples	Framing Error Flag	Noise Flag
000	1	0
001	1	1
010	1	1
011	0	1
100	1	1
101	0	1
110	0	1
111	0	0

13.4.3.4 Framing Errors

If the data recovery logic does not detect a logic 1 where the stop bit should be in an incoming character, it sets the framing error bit, FE, in SCC1. The FE flag is set at the same time that the SCRF bit is set. A break character that has no stop bit also sets the FE bit.

13.4.3.5 Receiver Wakeup

So that the MCU can ignore transmissions intended only for other receivers in multiple-receiver systems, the receiver can be put into a standby state. Setting the receiver wakeup bit, RWU, in SCC2 puts the receiver into a standby state during which receiver interrupts are disabled.

Depending on the state of the WAKE bit in SCC1, either of two conditions on the PTB0/RxD pin can bring the receiver out of the standby state:

- Address mark — An address mark is a logic 1 in the most significant bit position of a received character. When the WAKE bit is set, an address mark wakes the receiver from the standby state by clearing the RWU bit. The address mark also sets the SCI receiver full bit, SCRF. Software can then compare the character containing the address mark to the user-defined address of the receiver. If they are the same, the receiver remains awake and processes the characters that follow. If they are not the same, software can set the RWU bit and put the receiver back into the standby state.
- Idle input line condition — When the WAKE bit is clear, an idle character on the PTB0/RxD pin wakes the receiver from the standby state by clearing the RWU bit. The idle character that wakes the receiver does not set the receiver idle bit, IDLE, or the SCI receiver full bit, SCRF. The idle line type bit, ILTY, determines whether the receiver begins counting logic 1s as idle character bits after the start bit or after the stop bit.

NOTE: *Clearing the WAKE bit after the PTB0/RxD pin has been idle can cause the receiver to wake up immediately.*

13.4.3.6 Receiver Interrupts

These sources can generate CPU interrupt requests from the SCI receiver:

- SCI receiver full (SCRF) — The SCRF bit in SCS1 indicates that the receive shift register has transferred a character to the SCDR. SCRF can generate a receiver CPU interrupt request. Setting the SCI receive interrupt enable bit, SCRIE, in SCC2 enables the SCRF bit to generate receiver CPU interrupts.
- Idle input (IDLE) — The IDLE bit in SCS1 indicates that 10 or 11 consecutive logic 1s shifted in from the PTB0/RxD pin. The idle line interrupt enable bit, ILIE, in SCC2 enables the IDLE bit to generate CPU interrupt requests.

13.4.3.7 Error Interrupts

These receiver error flags in SCS1 can generate CPU interrupt requests:

- Receiver overrun (OR) — The OR bit indicates that the receive shift register shifted in a new character before the previous character was read from the SCDR. The previous character remains in the SCDR, and the new character is lost. The overrun interrupt enable bit, ORIE, in SCC3 enables OR to generate SCI error CPU interrupt requests.
- Noise flag (NF) — The NF bit is set when the SCI detects noise on incoming data or break characters, including start, data, and stop bits. The noise error interrupt enable bit, NEIE, in SCC3 enables NF to generate SCI error CPU interrupt requests.
- Framing error (FE) — The FE bit in SCS1 is set when a logic 0 occurs where the receiver expects a stop bit. The framing error interrupt enable bit, FEIE, in SCC3 enables FE to generate SCI error CPU interrupt requests.
- Parity error (PE) — The PE bit in SCS1 is set when the SCI detects a parity error in incoming data. The parity error interrupt enable bit, PEIE, in SCC3 enables PE to generate SCI error CPU interrupt requests.

13.5 Wait Mode

The WAIT and STOP instructions put the MCU in low power-consumption standby modes.

The SCI module remains active after the execution of a WAIT instruction. In wait mode the SCI module registers are not accessible by the CPU. Any enabled CPU interrupt request from the SCI module can bring the MCU out of wait mode.

If SCI module functions are not required during wait mode, reduce power consumption by disabling the module before executing the WAIT instruction.

13.6 Stop Mode

The SCI module is inactive after execution of a STOP instruction. The STOP instruction does not affect register conditions of the SCI. SCI operation resumes when the MCU exits stop mode after an external interrupt.

13.7 SCI During Break Module Interrupts

The system integration module (SIM) controls whether status bits in other modules can be cleared during interrupts generated by the break module. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state.

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect status bits during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), software can read and write I/O registers during the break state without affecting status bits. Some status bits have a 2-step read/write clearing procedure. If software does the first step on such a bit before the break, the bit cannot change during the break state as long as BCFE is at logic 0. After the break, doing the second step clears the status bit.

13.8 I/O Signals

Port B shares two of its pins with the SCI module. The two SCI I/O pins are:

- PTB1/TxD — Transmit data
- PTB0/RxD — Receive data

13.8.1 PTE2/TxD (Transmit Data)

The PTB1/TxD pin is the serial data output from the SCI transmitter. The SCI shares the PTB1/TxD pin with port B. When the SCI is enabled, the PTB1/TxD pin is an output regardless of the state of the DDRF1 bit in data direction register B (DDRB).

13.8.2 PTB0/RxD (Receive Data)

The PTB0/RxD pin is the serial data input to the SCI receiver. The SCI shares the PTB0/RxD pin with port B. When the SCI is enabled, the PTB0/RxD pin is an input regardless of the state of the DDRB0 bit in data direction register B (DDRB).

13.9 I/O Registers

These I/O registers control and monitor SCI operation:

- SCI control register 1 (SCC1)
- SCI control register 2 (SCC2)
- SCI control register 3 (SCC3)
- SCI status register 1 (SCS1)
- SCI status register 2 (SCS2)
- SCI data register (SCDR)
- SCI baud rate register (SCBR)

13.9.1 SCI Control Register 1

SCI control register 1 (SCC1):

- Enables loop mode operation
- Enables the SCI
- Controls output polarity
- Controls character length
- Controls SCI wake-up method
- Controls idle character detection
- Enables parity function
- Controls parity type

Figure 13-7. SCI Control Register 1 (SCC1)

LOOPS — Loop Mode Select Bit

This read/write bit enables loop mode operation. In loop mode the PTB0/RxD pin is disconnected from the SCI, and the transmitter output goes into the receiver input. Both the transmitter and the receiver must be enabled to use loop mode. Reset clears the LOOPS bit.

- 1 = Loop mode enabled
- 0 = Normal operation enabled

ENSCI — Enable SCI Bit

This read/write bit enables the SCI and the SCI baud rate generator. Clearing ENSCI sets the SCTE and TC bits in SCI status register 1 and disables transmitter interrupts. Reset clears the ENSCI bit.

- 1 = SCI enabled
- 0 = SCI disabled

TXINV — Transmit Inversion Bit

This read/write bit reverses the polarity of transmitted data. Reset clears the TXINV bit.

- 1 = Transmitter output inverted
- 0 = Transmitter output not inverted

NOTE: *Setting the TXINV bit inverts all transmitted values, including idle, break, start, and stop bits.*

M — Mode (Character Length) Bit

This read/write bit determines whether SCI characters are eight or nine bits long. (See [Table 13-4](#).) The ninth bit can serve as an extra stop bit, as a receiver wakeup signal, or as a parity bit. Reset clears the M bit.

- 1 = 9-bit SCI characters
- 0 = 8-bit SCI characters

WAKE — Wakeup Condition Bit

This read/write bit determines which condition wakes up the SCI: a logic 1 (address mark) in the most significant bit (MSB) position of a received character or an idle condition on the PTB0/RxD pin. Reset clears the WAKE bit.

- 1 = Address mark wakeup
- 0 = Idle line wakeup

ILTY — Idle Line Type Bit

This read/write bit determines when the SCI starts counting logic 1s as idle character bits. The counting begins either after the start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit may cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. Reset clears the ILTY bit.

- 1 = Idle character bit count begins after stop bit.
- 0 = Idle character bit count begins after start bit.

Serial Communications Interface (SCI)

PEN — Parity Enable Bit

This read/write bit enables the SCI parity function (see [Table 13-4](#)). When enabled, the parity function inserts a parity bit in the most significant bit position (see [Figure 13-3](#)). Reset clears the PEN bit.

1 = Parity function enabled

0 = Parity function disabled

PTY — Parity Bit

This read/write bit determines whether the SCI generates and checks for odd parity or even parity (see [Table 13-4](#)). Reset clears the PTY bit.

1 = Odd parity

0 = Even parity

NOTE: *Changing the PTY bit in the middle of a transmission or reception can generate a parity error.*

Table 13-4. Character Format Selection

Control Bits		Character Format				
M	PEN:PTY	Start Bits	Data Bits	Parity	Stop Bits	Character Length (Bits)
0	0X	1	8	None	1	10
1	0X	1	9	None	1	11
0	10	1	7	Even	1	10
0	11	1	7	Odd	1	10
1	10	1	8	Even	1	11
1	11	1	8	Odd	1	11

13.9.2 SCI Control Register 2

SCI control register 2 (SCC2):

- Enables these CPU interrupt requests:
 - Enables the SCTE bit to generate transmitter CPU interrupt requests
 - Enables the TC bit to generate transmitter CPU interrupt requests
 - Enables the SCRF bit to generate receiver CPU interrupt requests
 - Enables the IDLE bit to generate receiver CPU interrupt requests
- Enables the transmitter
- Enables the receiver
- Enables SCI wake up
- Transmits SCI break characters

Ad- dress:	\$0039							
	Bit 7	6	5	4	3	2	1	Bit 0
Read:	SCTIE	TCIE	SCRIE	ILIE	TE	RE	RWU	SBK
Write:								
Reset:	0	0	0	0	0	0	0	0

Figure 13-8. SCI Control Register 2 (SCC2)

SCTIE — SCI Transmit Interrupt Enable Bit

This read/write bit enables the SCTE bit to generate SCI transmitter CPU interrupt requests. Setting the SCTIE bit in SCC3 enables SCTE CPU interrupt requests. Reset clears the SCTIE bit.

- 1 = SCTE enabled to generate CPU interrupt
- 0 = SCTE not enabled to generate CPU interrupt

TCIE — Transmission Complete Interrupt Enable Bit

This read/write bit enables the TC bit to generate SCI transmitter CPU interrupt requests. Reset clears the TCIE bit.

1 = TC enabled to generate CPU interrupt requests

0 = TC not enabled to generate CPU interrupt requests

SCRIE — SCI Receive Interrupt Enable Bit

This read/write bit enables the SCRF bit to generate SCI receiver CPU interrupt requests. Setting the SCRIE bit in SCC3 enables the SCRF bit to generate CPU interrupt requests. Reset clears the SCRIE bit.

1 = SCRF enabled to generate CPU interrupt

0 = SCRF not enabled to generate CPU interrupt

ILIE — Idle Line Interrupt Enable Bit

This read/write bit enables the IDLE bit to generate SCI receiver CPU interrupt requests. Reset clears the ILIE bit.

1 = IDLE enabled to generate CPU interrupt requests

0 = IDLE not enabled to generate CPU interrupt requests

TE — Transmitter Enable Bit

Setting this read/write bit begins the transmission by sending a preamble of 10 or 11 logic 1s from the transmit shift register to the PTB1/TxD pin. If software clears the TE bit, the transmitter completes any transmission in progress before the PTB1/TxD returns to the idle condition (logic 1). Clearing and then setting TE during a transmission queues an idle character to be sent after the character currently being transmitted. Reset clears the TE bit.

1 = Transmitter enabled

0 = Transmitter disabled

NOTE: *Writing to the TE bit is not allowed when the enable SCI bit (ENSCI) is clear. ENSCI is in SCI control register 1.*

RE — Receiver Enable Bit

Setting this read/write bit enables the receiver. Clearing the RE bit disables the receiver but does not affect receiver interrupt flag bits. Reset clears the RE bit.

1 = Receiver enabled

0 = Receiver disabled

NOTE: *Writing to the RE bit is not allowed when the enable SCI bit (ENSCI) is clear. ENSCI is in SCI control register 1.*

RWU — Receiver Wakeup Bit

This read/write bit puts the receiver in a standby state during which receiver interrupts are disabled. The WAKE bit in SCC1 determines whether an idle input or an address mark brings the receiver out of the standby state and clears the RWU bit. Reset clears the RWU bit.

- 1 = Standby state
- 0 = Normal operation

SBK — Send Break Bit

Setting and then clearing this read/write bit transmits a break character followed by a logic 1. The logic 1 after the break character guarantees recognition of a valid start bit. If SBK remains set, the transmitter continuously transmits break characters with no logic 1s between them. Reset clears the SBK bit.

- 1 = Transmit break characters
- 0 = No break characters being transmitted

NOTE: *Do not toggle the SBK bit immediately after setting the SCTE bit. Toggling SBK too early causes the SCI to send a break character instead of a preamble.*

13.9.3 SCI Control Register 3

SCI control register 3 (SCC3):

- Stores the ninth SCI data bit received and the ninth SCI data bit to be transmitted
- Enables SCI receiver full (SCRF)
- Enables SCI transmitter empty (SCTE)
- Enables the following interrupts:
 - Receiver overrun interrupts
 - Noise error interrupts
 - Framing error interrupts
 - Parity error interrupts

Serial Communications Interface (SCI)

Figure 13-9. SCI Control Register 3 (SCC3)

R8 — Received Bit 8

When the SCI is receiving 9-bit characters, R8 is the read-only ninth bit (bit 8) of the received character. R8 is received at the same time that the SCDR receives the other 8 bits.

When the SCI is receiving 8-bit characters, R8 is a copy of the eighth bit (bit 7). Reset has no effect on the R8 bit.

T8 — Transmitted Bit 8

When the SCI is transmitting 9-bit characters, T8 is the read/write ninth bit (bit 8) of the transmitted character. T8 is loaded into the transmit shift register at the same time that the SCDR is loaded into the transmit shift register. Reset has no effect on the T8 bit.

ORIE — Receiver Overrun Interrupt Enable Bit

This read/write bit enables SCI error CPU interrupt requests generated by the receiver overrun bit, OR.

1 = SCI error CPU interrupt requests from OR bit enabled

0 = SCI error CPU interrupt requests from OR bit disabled

NEIE — Receiver Noise Error Interrupt Enable Bit

This read/write bit enables SCI error CPU interrupt requests generated by the noise error bit, NE. Reset clears NEIE.

1 = SCI error CPU interrupt requests from NE bit enabled

0 = SCI error CPU interrupt requests from NE bit disabled

FEIE — Receiver Framing Error Interrupt Enable Bit

This read/write bit enables SCI error CPU interrupt requests generated by the framing error bit, FE. Reset clears FEIE.

- 1 = SCI error CPU interrupt requests from FE bit enabled
- 0 = SCI error CPU interrupt requests from FE bit disabled

PEIE — Receiver Parity Error Interrupt Enable Bit

This read/write bit enables SCI receiver CPU interrupt requests generated by the parity error bit, PE. Reset clears PEIE. See [13.9.4 SCI Status Register 1](#)

- 1 = SCI error CPU interrupt requests from PE bit enabled
- 0 = SCI error CPU interrupt requests from PE bit disabled

13.9.4 SCI Status Register 1

SCI status register 1 (SCS1) contains flags to signal these conditions:

- Transfer of SCDR data to transmit shift register complete
- Transmission complete
- Transfer of receive shift register data to SCDR complete
- Receiver input idle
- Receiver overrun
- Noisy data
- Framing error
- Parity error

Reset:	1	1	0	0	0	0	0	0

R = Reserved

Figure 13-10. SCI Status Register 1 (SCS1)

SCTE — SCI Transmitter Empty Bit

This clearable, read-only bit is set when the SCDR transfers a character to the transmit shift register. SCTE can generate an SCI transmitter CPU interrupt request. When the SCTIE bit in SCC2 is set, SCTE generates an SCI transmitter CPU interrupt request. In normal operation, clear the SCTE bit by reading SCS1 with SCTE set and then writing to SCDR. Reset sets the SCTE bit.

- 1 = SCDR data transferred to transmit shift register
- 0 = SCDR data not transferred to transmit shift register

TC — Transmission Complete Bit

This read-only bit is set when the SCTE bit is set, and no data, preamble, or break character is being transmitted. TC generates an SCI transmitter CPU interrupt request if the TCIE bit in SCC2 is also set. TC is cleared automatically when data, preamble, or break is queued and ready to be sent. There may be up to 1.5 transmitter clocks of latency between queueing data, preamble, and break and the transmission actually starting. Reset sets the TC bit.

- 1 = No transmission in progress
- 0 = Transmission in progress

SCRF — SCI Receiver Full Bit

This clearable, read-only bit is set when the data in the receive shift register transfers to the SCI data register. SCRF can generate an SCI receiver CPU interrupt request. When the SCRIE bit in SCC2 is set, SCRF generates a CPU interrupt request. In normal operation, clear the SCRF bit by reading SCS1 with SCRF set and then reading the SCDR. Reset clears SCRF.

- 1 = Received data available in SCDR
- 0 = Data not available in SCDR

IDLE — Receiver Idle Bit

This clearable, read-only bit is set when 10 or 11 consecutive logic 1s appear on the receiver input. IDLE generates an SCI error CPU interrupt request if the ILIE bit in SCC2 is also set. Clear the IDLE bit by reading SCS1 with IDLE set and then reading the SCDR. After the receiver is enabled, it must receive a valid character that sets the SCRF bit before an idle condition can set the IDLE bit. Also, after the

IDLE bit has been cleared, a valid character must again set the SCRF bit before an idle condition can set the IDLE bit. Reset clears the IDLE bit.

1 = Receiver input idle

0 = Receiver input active or idle since the IDLE bit was cleared

OR — Receiver Overrun Bit

This clearable, read-only bit is set when software fails to read the SCDR before the receive shift register receives the next character. The OR bit generates an SCI error CPU interrupt request if the ORIE bit in SCC3 is also set. The data in the shift register is lost, but the data already in the SCDR is not affected. Clear the OR bit by reading SCS1 with OR set and then reading the SCDR. Reset clears the OR bit.

1 = Receive shift register full and SCRF = 1

0 = No receiver overrun

Software latency may allow an overrun to occur between reads of SCS1 and SCDR in the flag-clearing sequence. [Figure 13-11](#) shows the normal flag-clearing sequence and an example of an overrun caused by a delayed flag-clearing sequence. The delayed read of SCDR does not clear the OR bit because OR was not set when SCS1 was read. Byte 2 caused the overrun and is lost. The next flag-clearing sequence reads byte 3 in the SCDR instead of byte 2.

In applications that are subject to software latency or in which it is important to know which byte is lost due to an overrun, the flag-clearing routine can check the OR bit in a second read of SCS1 after reading the data register.

NF — Receiver Noise Flag Bit

This clearable, read-only bit is set when the SCI detects noise on the PTB0/RxD pin. NF generates an NF CPU interrupt request if the NEIE bit in SCC3 is also set. Clear the NF bit by reading SCS1 and then reading the SCDR. Reset clears the NF bit.

1 = Noise detected

0 = No noise detected

Serial Communications Interface (SCI)

FE — Receiver Framing Error Bit

This clearable, read-only bit is set when a logic 0 is accepted as the stop bit. FE generates an SCI error CPU interrupt request if the FEIE bit in SCC3 also is set. Clear the FE bit by reading SCS1 with FE set and then reading the SCDR. Reset clears the FE bit.

- 1 = Framing error detected
- 0 = No framing error detected

PE — Receiver Parity Error Bit

This clearable, read-only bit is set when the SCI detects a parity error in incoming data. PE generates a PE CPU interrupt request if the PEIE bit in SCC3 is also set. Clear the PE bit by reading SCS1 with PE set and then reading the SCDR. Reset clears the PE bit.

- 1 = Parity error detected
- 0 = No parity error detected

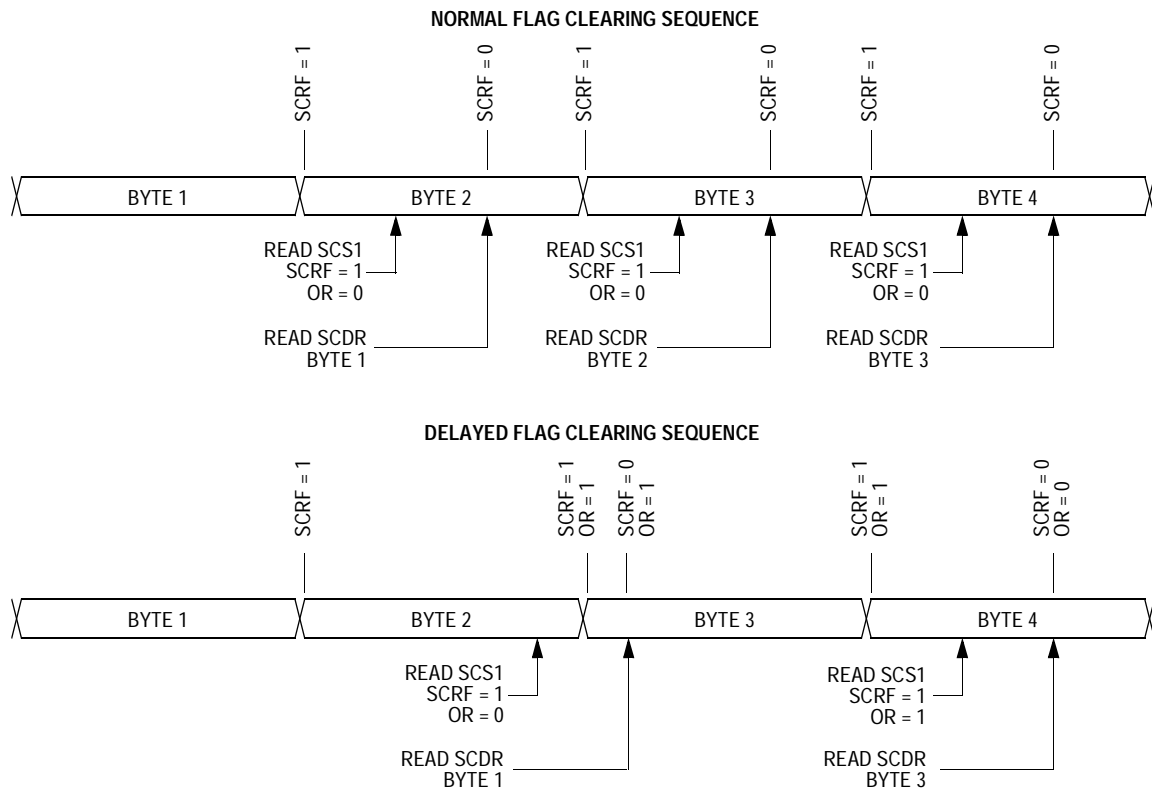

Figure 13-11. Flag Clearing Sequence

13.9.5 SCI Status Register 2

SCI status register 2 (SCS2) contains flags to signal these conditions:

Reset:	0	0	0	0	0	0	0	0

R = Reserved

Figure 13-12. SCI Status Register 2 (SCS2)

BKF — Break Flag Bit

This clearable, read-only bit is set when the SCI detects a break character on the PTB0/RxD pin. In SCS1, the FE and SCRF bits are also set. In 9-bit character transmissions, the R8 bit in SCC3 is cleared. BKF does not generate a CPU interrupt request. Clear BKF by reading SCS2 with BKF set and then reading the SCDR. Once cleared, BKF can become set again only after logic 1s again appear on the PTB0/RxD pin followed by another break character. Reset clears the BKF bit.

- 1 = Break character detected
- 0 = No break character detected

RPF — Reception-in-Progress Flag Bit

This read-only bit is set when the receiver detects a logic 0 during the RT1 time period of the start bit search. RPF does not generate an interrupt request. RPF is reset after the receiver detects false start bits (usually from noise or a baud rate mismatch, or when the receiver detects an idle character). Polling RPF before disabling the SCI module or entering stop mode can show whether a reception is in progress.

- 1 = Reception in progress
- 0 = No reception in progress

Serial Communications Interface (SCI)

13.9.6 SCI Data Register

The SCI data register (SCDR) is the buffer between the internal data bus and the receive and transmit shift registers. Reset has no effect on data in the SCI data register.

Ad-
dress: \$003D

Reset:	Unaffected by reset							

Figure 13-13. SCI Data Register (SCDR)

R7/T7:R0/T0 — Receive/Transmit Data Bits

Reading address \$003D accesses the read-only received data bits, R7:R0. Writing to address \$003D writes the data to be transmitted, T7:T0. Reset has no effect on the SCI data register.

13.9.7 SCI Baud Rate Register

The SCI baud rate register (SCBR) selects the baud rate for both the receiver and the transmitter.

Ad-
dress: \$003E

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	SCP1	SCP0	0	SCR2	SCR1	SCR0
Write:	R	R			R			
Reset:	0	0	0	0	0	0	0	0

R = Reserved

Figure 13-14. SCI Baud Rate Register (SCBR)

SCP1 and SCP0 — SCI Baud Rate Prescaler Bits

These read/write bits select the baud rate prescaler divisor as shown in [Table 13-5](#). Reset clears SCP1 and SCP0.

Table 13-5. SCI Baud Rate Prescaling

SCP1:SCP0	Prescaler Divisor (PD)
00	1
01	3
10	4
11	13

SCR2–SCR0 — SCI Baud Rate Select Bits

These read/write bits select the SCI baud rate divisor as shown in [Table 13-6](#). Reset clears SCR2–SCR0.

Table 13-6. SCI Baud Rate Selection

SCR2:SCR1:SCR0	Baud Rate Divisor (BD)
000	1
001	2
010	4
011	8
100	16
101	32
110	64
111	128

Use this formula to calculate the SCI baud rate:

$$\text{Baud rate} = f_{OP} / 64 \times \text{PD} \times \text{BD}$$

where:

f_{OP} = clock source (f_{BUS})

PD = prescaler divisor

BD = baud rate divisor

[Table 13-7](#) shows the SCI baud rates that can be generated with a 4.00-MHz crystal and the CGM set for an f_{OP} of 8.00 MHz and with a 4.9152-MHz crystal with the CGM set for an f_{OP} of 7.3728 MHz.

Serial Communications Interface (SCI)

Table 13-7. SCI Baud Rate Selection Examples

SCP1:SCP0	Prescaler Divisor (PD)	SCR2:SCR1:SCR0	Baud Rate Divisor (BD)	Baud Rate (f _{OP} = 7.3728 MHz)	Baud Rate (f _{OP} = 8.00 MHz)

14.2 Introduction

Fourteen bidirectional input-output (I/O) pins, two input pins, and six output pins form three parallel ports.

When using the 28-pin package versions of the MC68HC908MR8, set the data direction register bits in DDRA such that bits 6, 5, and 4 are written to a logic 1 (along with any other output bits on PORTA). Setting PORTA's data direction register bits 6, 5, and 4 will terminate the input buffers on that port.

NOTE: *Connect any unused I/O pins to an appropriate logic level, either V_{DD} or V_{SS} . (PWM6–PWM1 pins require no termination). Although the I/O ports do not require termination for proper operation, termination reduces excess current consumption and the possibility of electrostatic damage.*

Figure 14-1. I/O Port Register Summary

14.3 Port A

Port A is a 7-bit, general-purpose, bidirectional I/O port.

14.3.1 Port A Data Register

The port A data register (PTA) contains a data latch for each of the eight port A pins.

Figure 14-2. Port A Data Register (PTA)

PTA[6:0] — Port A Data Bits

These read/write bits are software programmable. Data direction of each port A pin is under the control of the corresponding bit in data direction register A. Reset has no effect on port A data.

14.3.2 Data Direction Register A

Data direction register A (DDRA) determines whether each port A pin is an input or an output. Writing a logic 1 to a DDRA bit enables the output buffer for the corresponding port A pin; a logic 0 disables the output buffer.

Figure 14-3. Data Direction Register A (DDRA)

DDRA[6:0] — Data Direction Register A Bits

These read/write bits control port A data direction. Reset clears DDRA[6:0], configuring all port A pins as inputs.

- 1 = Corresponding port A pin configured as output
- 0 = Corresponding port A pin configured as input

NOTE: *Avoid glitches on port A pins by writing to the port A data register before changing data direction register A bits from 0 to 1.*

Figure 14-4 shows the port A I/O logic.

Figure 14-4. Port A I/O Circuit

When bit DDRAx is a logic 1, reading address \$0000 reads the PTAx data latch. When bit DDRAx is a logic 0, reading address \$0000 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. [Table 14-1](#) summarizes the operation of the port A pins.

Table 14-1. Port A Pin Functions

DDRA Bit	PTA Bit	I/O Pin Mode	Accesses to DDRA	Accesses to PTA	
			Read/Write	Read	Write
0	X ⁽¹⁾	Input, Hi-Z ⁽²⁾	DDRA[6:0]	Pin	PTA[6:0] ⁽³⁾
1	X	Output	DDRA[6:0]	PTA[6:0]	PTA[6:0]

1. X = don't care
2. Hi-Z = high impedance
3. Writing affects data register, but does not affect input.

14.4 Port B

Port B is a 7-bit general-purpose bidirectional I/O port that shares its pins with the serial communications interface (SCI) module.

14.4.1 Port B Data Register

The port B data register (PTB) contains a data latch for each of the eight port B pins.

Figure 14-5. Port B Data Register (PTB)

PTB[6:0] — Port B Data Bits

These read/write bits are software-programmable. Data direction of each port B pin is under the control of the corresponding bit in data direction register B. Reset has no effect on port B data.

14.4.2 Data Direction Register B

Data direction register B (DDRB) determines whether each port B pin is an input or an output. Writing a logic 1 to a DDRB bit enables the output buffer for the corresponding port B pin; a logic 0 disables the output buffer.

Figure 14-6. Data Direction Register B (DDRB)

DDRB[6:0] — Data Direction Register B Bits

These read/write bits control port B data direction. Reset clears DDRB[6:0], configuring all port B pins as inputs.

- 1 = Corresponding port B pin configured as output
- 0 = Corresponding port B pin configured as input

NOTE: *Avoid glitches on port B pins by writing to the port B data register before changing data direction register B bits from 0 to 1.*

Figure 14-7 shows the port B I/O logic.

Figure 14-7. Port B I/O Circuit

When bit $DDRBx$ is a logic 1, reading address \$0001 reads the $PTBx$ data latch. When bit $DDRBx$ is a logic 0, reading address \$0001 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. [Table 14-2](#) summarizes the operation of the port B pins.

Table 14-2. Port B Pin Functions

DDRB Bit	PTB Bit	I/O Pin Mode	Accesses to DDRB	Accesses to PTB	
			Read/Write	Read	Write
0	X ⁽¹⁾	Input, Hi-Z ⁽²⁾	DDRB[6:0]	Pin	PTB[6:0] ⁽³⁾
1	X	Output	DDRB[6:0]	PTB[6:0]	PTB[6:0]

1. X = don't care
2. Hi-Z = high impedance
3. Writing affects data register, but does not affect input.

14.5 Port C

Port C is a 2-bit special-purpose I/O port sharing its pins with the pulse width modulator for motor control module (PMC) FAULT input pins. These two pins mirror the state of FAULT1 and FAULT4 pins. Level changes on these input pins will be interpreted as fault conditions.

The port C data register contains a data latch for each of the two port pins.

Port C bit 1 is not used on the 28-pin packages. For that reason, a pull-down resistor is connected to V_{SS} to prevent a false fault input on FAULT4.

NOTE: *PORTC has the capability of being used as an output port. When either pin of PORTC is set as an output, by setting its respective PORTC data direction register bit, the respective fault pin logic is disconnected from that pin and the fault input will be defaulted to normal non-fault condition to facilitate the use of PORTC as an output pin and not interfere with the PWM generator. To regain the fault capability for the respective fault input pin, clear the PORTC data direction register bit for that pin.*

14.5.1 Port C Data Register

The port C data register (PTC) contains a data latch for each of the two port C pins.

Figure 14-8. Port C Data Register (PTC)

PTC[1:0] — Port C Data Bits

These read/write bits are software programmable. Data direction of each port C pin is under the control of the corresponding bit in data direction register C. Reset has no effect on port C data.

14.5.2 Data Direction Register C

Data direction register C (DDRC) determines whether each port C pin is an input or an output. Writing a logic 1 to a DDRC bit enables the output buffer for the corresponding port C pin; a logic 0 disables the output buffer.

Figure 14-9. Data Direction Register C (DDRC)

DDRC[1:0] — Data Direction Register C Bits

These read/write bits control port C data direction. Reset clears DDRC[1:0], configuring all port C pins as inputs.

- 1 = Corresponding port C pin configured as output
- 0 = Corresponding port C pin configured as input

NOTE: *Avoid glitches on port C pins by writing to the port C data register before changing data direction register C bits from 0 to 1.*

Figure 14-10 shows the port C I/O logic.

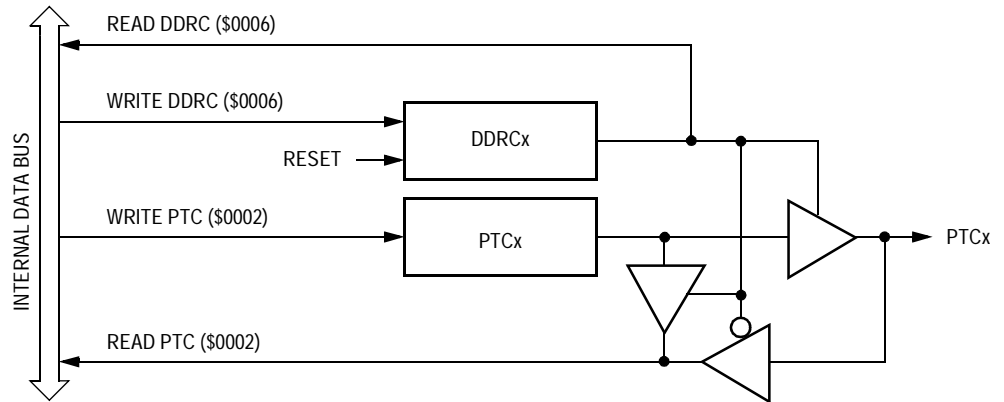

Figure 14-10. Port C I/O Circuit

When bit DDRCx is a logic 1, reading address \$0002 reads the PTCx data latch. When bit DDRCx is a logic 0, reading address \$0002 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. [Table 14-3](#) summarizes the operation of the port C pins.

Table 14-3. Port C Pin Functions

DDRC Bit	PTC Bit	I/O Pin Mode	Accesses to DDRC		Accesses to PTC	
			Read/Write	Read	Write	
0	X ⁽¹⁾	Input, Hi-Z ⁽²⁾	DDRC[1:0]	Pin	PTC[1:0] ⁽³⁾	
1	X	Output	DDRC[1:0]	PTC[1:0]	PTC[1:0]	

1. X = don't care

2. Hi-Z = high impedance on PTC0 and a pull-down R_{PD} on PTC1

3. Writing affects data register, but does not affect input.

15.10	COP Module During Break Mode	295

15.2 Introduction

This section describes the computer operating properly module (COP, version B), a free-running counter that generates a reset if allowed to overflow. The COP module helps software recover from runaway code. Prevent a COP reset by periodically clearing the COP counter.

15.3 Functional Description

Figure 15-1 shows the structure of the COP module.

Note: See 7.4.2 Active Resets from Internal Sources.

Figure 15-1. COP Block Diagram

Addr.	Register Name	Bit 7	6	5	4	3	2	1	Bit 0
\$FFFF	COP Control Register (COPCTL) See page 294.	Read: Low byte of reset vector							
		Write: Clear COP counter							
		Reset: Unaffected by reset							

Figure 15-2. COP I/O Register Summary

The COP counter is a free-running, 6-bit counter preceded by the 13-bit system integration module (SIM) counter. If not cleared by software, the COP counter overflows and generates an asynchronous reset after $2^{18}-2^4$ CGMXCLK cycles. With a 4.9152-MHz crystal, the COP timeout period is 53.3 ms. Writing any value to location \$FFFF before overflow occurs clears the COP counter and prevents reset.

A COP reset pulls the $\overline{\text{RST}}$ pin low for 32 CGMXCLK cycles and sets the COP bit in the SIM reset status register (SRSR) (see [7.7.4 SIM Reset Status Register](#)).

NOTE: *Place COP clearing instructions in the main program and not in an interrupt subroutine. Such an interrupt subroutine could keep the COP from generating a reset even while the main program is not working properly.*

15.4 I/O Signals

This subsection describes the signals shown in [Figure 15-1](#).

15.4.1 CGMXCLK

CGMXCLK is the crystal oscillator output signal. CGMXCLK frequency is equal to the crystal frequency.

15.4.2 COPCTL Write

Writing any value to the COP control register (COPCTL) (see [15.5 COP Control Register](#)) clears the COP counter and clears bits 12–4 of the SIM counter. Reading the COP control register returns the reset vector.

15.4.3 Power-On Reset

The power-on reset (POR) circuit in the SIM clears the SIM counter 4096 CGMXCLK cycles after power-up.

Computer Operating Properly (COP)

15.4.4 Internal Reset

An internal reset clears the SIM counter and the COP counter.

15.4.5 Reset Vector Fetch

A reset vector fetch occurs when the vector address appears on the data bus. A reset vector fetch clears the SIM counter.

15.4.6 COP Disable

The COP disable (COPD) signal reflects the state of the COP disable bit (COPD) in the configuration register (CONFIG). See [5.4 CONFIG Bits](#).

15.5 COP Control Register

The COP control register (COPCTL) is located at address \$FFFF and overlaps the reset vector. Writing any value to \$FFFF clears the COP counter and starts a new timeout period. Reading location \$FFFF returns the low byte of the reset vector.

Ad- dress:	\$FFFF
	Bit 7 6 5 4 3 2 1 Bit 0
Read:	Low byte of reset vector
Write:	Clear COP counter
Reset:	Unaffected by reset

Figure 15-3. COP Control Register (COPCTL)

15.6 Interrupts

The COP does not generate CPU interrupt requests.

15.7 Monitor Mode

The COP is disabled in monitor mode when $V_{DD} + V_{HI}$ is present on the \overline{IRQ} pin or on the \overline{RST} pin.

15.8 Wait Mode

The WAIT instruction puts the MCU in low power-consumption standby mode.

The COP continues to operate during wait mode.

15.9 Stop Mode

Stop mode turns off the COP prescaler clock. Service the COP immediately before entering or after exiting stop mode to ensure a full COP timeout period after entering or exiting stop mode.

15.10 COP Module During Break Mode

The COP is disabled during a break interrupt when $V_{DD} + V_{HI}$ is present on the \overline{RST} pin.

16.8	IRQ Module During Break Mode	302
16.9	IRQ Status and Control Register	303

16.2 Introduction

This section describes the external interrupt module, which supports external interrupt functions.

16.3 Features

Features of the IRQ module include:

- A dedicated external interrupt pin, $\overline{\text{IRQ}}$
- Hysteresis buffers

16.4 Functional Description

A logic 0 applied to any of the external interrupt pins can latch a CPU interrupt request. **Figure 16-1** shows the structure of the IRQ module.

Interrupt signals on the $\overline{\text{IRQ}}$ pin are latched into the IRQ latch. An interrupt latch remains set until one of the following actions occurs:

- Vector fetch — A vector fetch automatically generates an interrupt acknowledge signal that clears the latch that caused the vector fetch.
- Software clear — Software can clear an interrupt latch by writing to the appropriate acknowledge bit in the interrupt status and control register (ISCR). Writing a logic 1 to the ACK1 bit clears the IRQ latch.
- Reset — A reset automatically clears both interrupt latches.

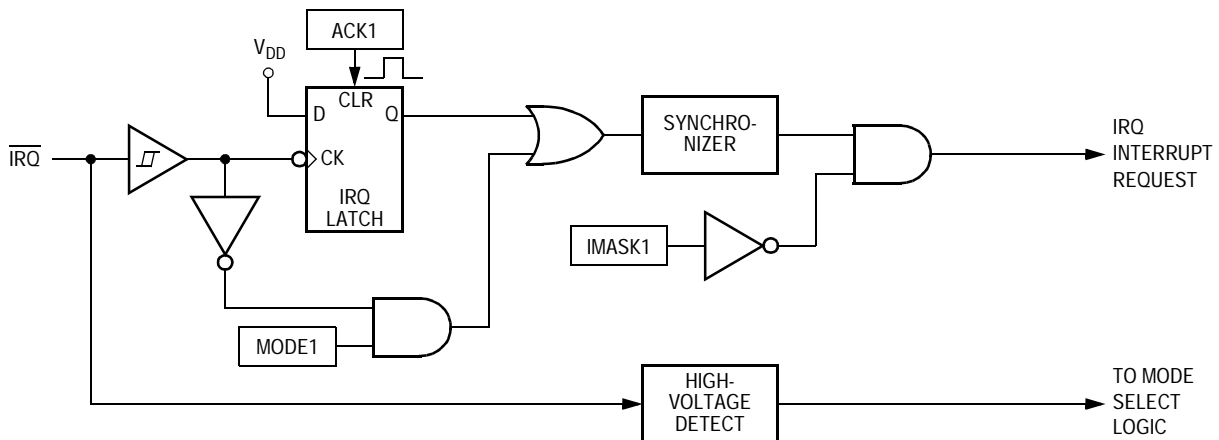

Figure 16-1. IRQ Module Block Diagram

Addr.	Register Name		Bit 7	6	5	4	3	2	1	Bit 0

		Write:	R	R	R	R		ACK1		
		Reset:	0	0	0	0	0	0	0	0

R = Reserved

Figure 16-2. IRQ I/O Register Summary

The external interrupt pins are falling-edge-triggered and are software-configurable to be both falling-edge and low-level-triggered. The MODE1 bit in the ISCR controls the triggering sensitivity of the $\overline{\text{IRQ}}$ pin.

When the interrupt pin is edge-triggered only, the interrupt latch remains set until a vector fetch, software clear, or reset occurs.

When the interrupt pin is both falling-edge and low-level-triggered, the interrupt latch remains set until both of these occur:

- Vector fetch, software clear, or reset
- Return of the interrupt pin to logic 1

The vector fetch or software clear can occur before or after the interrupt pin returns to logic 1. As long as the pin is low, the interrupt request remains pending.

When set, the IMASK1 bit in the ISCR mask all external interrupt requests. A latched interrupt request is not presented to the interrupt priority logic unless the IMASK bit is clear.

NOTE: *The interrupt mask (I) in the condition code register (CCR) masks all interrupt requests, including external interrupt requests. See [Figure 16-3](#).*

External Interrupt (IRQ)

Figure 16-3. IRQ Interrupt Flowchart

16.5 $\overline{\text{IRQ}}$ Pin

A logic 0 on the $\overline{\text{IRQ}}$ pin can latch an interrupt request into the IRQ latch. A vector fetch, software clear, or reset clears the IRQ latch.

If the MODE1 bit is set, the $\overline{\text{IRQ}}$ pin is both falling-edge-sensitive and low-level-sensitive. With MODE1 set, both of these actions must occur to clear the IRQ latch:

- Vector fetch, software clear, or reset — A vector fetch generates an interrupt acknowledge signal to clear the latch. Software can generate the interrupt acknowledge signal by writing a logic 1 to the ACK1 bit in the interrupt status and control register (ISCR). The ACK1 bit is useful in applications that poll the $\overline{\text{IRQ}}$ pin and require software to clear the IRQ latch. Writing to the ACK1 bit can also prevent spurious interrupts due to noise. Setting ACK1 does not affect subsequent transitions on the $\overline{\text{IRQ}}$ pin. A falling edge that occurs after writing to the ACK1 bit latches another interrupt request. If the IRQ mask bit, IMASK1, is clear, the CPU loads the program counter with the vector address at locations \$FFFA and \$FFFB.
- Return of the $\overline{\text{IRQ}}$ pin to logic 1 — As long as the $\overline{\text{IRQ}}$ pin is at logic 0, the IRQ latch remains set.

The vector fetch or software clear and the return of the $\overline{\text{IRQ}}$ pin to logic 1 can occur in any order. The interrupt request remains pending as long as the $\overline{\text{IRQ}}$ pin is at logic 0.

If the MODE1 bit is clear, the $\overline{\text{IRQ}}$ pin is falling-edge-sensitive only. With MODE1 clear, a vector fetch or software clear immediately clears the IRQ latch.

Use the branch if $\overline{\text{IRQ}}$ pin high (BIH) or branch if $\overline{\text{IRQ}}$ pin low (BIL) instruction to read the logic level on the $\overline{\text{IRQ}}$ pin.

NOTE: *When using the level-sensitive interrupt trigger, avoid false interrupts by masking interrupt requests in the interrupt routine.*

16.6 IRQ Module During Wait Mode

The IRQ module remains active in wait mode. Clearing the IMASK1 bit in the IRQ status and control register (ISCR) enables IRQ central processor unit (CPU) interrupt requests to bring the microcontroller unit (MCU) out of wait mode.

16.7 IRQ Module During Stop Mode

The IRQ module remains active in stop mode. Clearing the IMASK1 bit in the IRQ status and control register (ISCR) enables IRQ CPU interrupt requests to bring the MCU out of stop mode.

16.8 IRQ Module During Break Mode

The system integration (SIM) module controls whether the IRQ interrupt latch can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear the latches during the break state. See [7.7.5 SIM Break Flag Control Register](#).

To allow software to clear the IRQ latch during a break interrupt, write a logic 1 to the BCFE bit. If a latch is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect the latches during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), writing to the ACK1 bit in the IRQ status and control register during the break state has no effect on the IRQ latches. See [16.9 IRQ Status and Control Register](#).

16.9 IRQ Status and Control Register

The IRQ status and control register (ISCR) has these functions:

- Clears the IRQ interrupt latch
- Masks IRQ interrupt requests
- Controls triggering sensitivity of the $\overline{\text{IRQ}}$ interrupt pin

Ad-
dress: \$003F

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	IRQF	0	IMASK1	MODE1
Write:	R	R	R	R		ACK1		
Reset:	0	0	0	0	0	0	0	0

R = Reserved

Figure 16-4. IRQ Status and Control Register (ISCR)

ACK1 — IRQ Interrupt Request Acknowledge Bit

Writing a logic 1 to this write-only bit clears the IRQ latch. ACK1 always reads as logic 0. Reset clears ACK1.

IMASK1 — IRQ Interrupt Mask Bit

Writing a logic 1 to this read/write bit disables IRQ interrupt requests. Reset clears IMASK1.

- 1 = IRQ interrupt requests disabled
- 0 = IRQ interrupt requests enabled

MODE1 — IRQ Edge/Level Select Bit

This read/write bit controls the triggering sensitivity of the $\overline{\text{IRQ}}$ pin. Reset clears MODE1.

- 1 = $\overline{\text{IRQ}}$ interrupt requests on falling edges and low levels
- 0 = $\overline{\text{IRQ}}$ interrupt requests on falling edges only

IRQF — IRQ Flag

This read-only bit acts as a status flag, indicating an IRQ event occurred.

- 1 = External IRQ event occurred.
- 0 = External IRQ event did not occur.

17.2 Introduction

This section describes the low-voltage inhibit (LVI) module, which monitors the voltage on the V_{DD} pin and can force a reset when the V_{DD} voltage falls to the LVI trip voltage.

17.3 Features

Features of the LVI module include:

- Programmable LVI reset
- Programmable power consumption
- Digital filtering of V_{DD} pin level
- Selectable LVI trip voltage

17.4 Functional Description

Figure 17-1 shows the structure of the LVI module. The LVI is enabled out of reset. The LVI module contains a bandgap reference circuit and comparator.

The LVI power bit, LVIPWR, enables the LVI to monitor V_{DD} voltage. The LVI reset bit, LVIRST, enables the LVI module to generate a reset when V_{DD} falls below a voltage, $V_{LV\text{RX}}$, and remains at or below that level for nine or more consecutive CGMXCLK.

- $V_{LV\text{RX}}$ and $V_{LV\text{HX}}$ are determined by the TRPSEL bit in the LVI status and control register (LVISCR). See **Figure 17-2**.
- LVIPWR and LVIRST are in the configuration (CONFIG) register. See **5.4 CONFIG Bits**.

Once an LVI reset occurs, the MCU remains in reset until V_{DD} rises above a voltage, $V_{LV\text{RX}} + V_{LV\text{HX}}$. V_{DD} must be above $V_{LV\text{RX}} + V_{LV\text{HX}}$ for only one central processor unit (CPU) cycle to bring the microcontroller unit (MCU) out of reset. See **7.4.2.5 Low-Voltage Inhibit (LVI) Reset**. The output of the comparator controls the state of the LVIOOUT flag in the LVISCR.

NOTE: An LVI reset also drives the \overline{RST} pin low to provide low-voltage protection to external peripheral devices.

		Reset:	0	0	0	0	0	0	0	0

R = Reserved

Figure 17-2. LVI I/O Register Summary

17.4.1 Polled LVI Operation

In applications that can operate at V_{DD} levels below V_{LVRX} , software can monitor V_{DD} by polling the LVIOUT bit. In the configuration register, the LVIPWR bit must be at logic 1 to enable the LVI module, and the LVIRST bit must be at logic 0 to disable LVI resets. TRPSEL in the LVISCR selects V_{LVRX} . See [5.4 CONFIG Bits](#).

17.4.2 Forced Reset Operation

In applications that require V_{DD} to remain above V_{LVRX} , enabling LVI resets allows the LVI module to reset the MCU when V_{DD} falls to the V_{LVRX} level and remains at or below that level for nine or more consecutive CPU cycles. In the CONFIG register, the LVIPWR and LVIRST bits must be at logic 1 to enable the LVI module and to enable LVI resets. TRPSEL in the LVISCR selects V_{LVRX} .

17.4.3 False Reset Protection

The V_{DD} pin level is digitally filtered to reduce false resets due to power supply noise. In order for the LVI module to reset the MCU, V_{DD} must remain at or below V_{LVRX} for nine or more consecutive CPU cycles. V_{DD} must be above $V_{LVRX} + V_{LVHX}$ for only one CPU cycle to bring the MCU out of reset. TRPSEL in the LVISCR selects $V_{LVRX} + V_{LVHX}$.

Low-Voltage Inhibit (LVI)

17.4.4 LVI Trip Selection

The TRPSEL bit allows the user to choose between 5 percent and 10 percent tolerance when monitoring the supply voltage. The 10 percent option is enabled out of reset. Writing a logic 1 to TRPSEL will enable the 5 percent option.

NOTE: The MCU is guaranteed to operate at a minimum supply voltage. The trip point (V_{LVR1} or V_{LVR2}) may be lower than this.

17.5 LVI Status and Control Register

The LVI status register flags V_{DD} voltages below the V_{LVRX} level.

Ad- dress:	\$FE0F

R									

Figure 17-3. LVI Status and Control Register (LVISCR)

LVIOU — LVI Output Bit

This read-only flag becomes set when the V_{DD} voltage falls below the V_{LVRX} voltage for 32 to 40 CGMXCLK cycles. See [Table 17-1](#). Reset clears the LVIOU bit.

Table 17-1. LVIOU Bit Indication

V_{DD}		LVIOU
At level:	For number of CGMXCLK cycles:	
$V_{DD} > V_{LVRX} + V_{LVHX}$	Any	0
$V_{DD} < V_{LVRX}$	< 32 CGMXCLK CYCLES	0
$V_{DD} < V_{LVRX}$	Between 32 and 40 CGMXCLK cycles	0 or 1
$V_{DD} < V_{LVRX}$	> 40 CGMXCLK cycles	1

Table 17-1. LVIOUT Bit Indication

V_{DD}		LVIOUT
At level:	For number of CGMXCLK cycles:	
$V_{LVRX} < V_{DD} < V_{LVRX} + V_{LVHX}$	Any	Previous value

TRPSEL — LVI Trip Select Bit

This bit selects the LVI trip point. Reset clears this bit.

1 = 5 percent tolerance. The trip point and recovery point are determined by V_{LVR1} and V_{LVH1} respectively.

0 = 10 percent tolerance. The trip point and recovery point are determined by V_{LVR2} and V_{LVH2} respectively.

NOTE: *If LVIPWR and LVIRST are at logic 1, note that when changing the tolerance, LVI reset will be generated if the supply voltage is below the trip point.*

17.6 LVI Interrupts

The LVI module does not generate interrupt requests.

17.7 Wait Mode

The WAIT instruction puts the microcontroller unit (MCU) in low power-consumption standby mode.

With the LVIPWR bit in the configuration register programmed to logic 1, the LVI module is active after a WAIT instruction.

With the LVIRST bit in the configuration register programmed to logic 1, the LVI module can generate a reset and bring the MCU out of wait mode.

17.8 Stop Mode

The STOP instruction puts the MCU in low power-consumption standby mode.

Low-Voltage Inhibit (LVI)

With the LVIPWR bit in the configuration register programmed to logic 1, the LVI module is active after a STOP instruction.

With the LVIRST bit in the configuration register programmed to logic 1, the LVI module can generate a reset and bring the MCU out of stop mode.

18.2 Introduction

This section describes the 10-bit analog-to-digital converter (ADC).

For further information regarding analog-to-digital converters on Motorola microcontrollers, please consult the HC08 ADC Reference Manual, ADCRM/AD.

18.3 Features

Features of the ADC module include:

- Four to seven channels with multiplexed input
- Linear successive approximation
- 10-bit resolution, 8-bit accuracy
- Single or continuous conversion
- Conversion complete flag or conversion complete interrupt
- Selectable ADC clock
- Left or right justified result.
- Left justified sign data mode
- High impedance buffered ADC input

18.4 Functional Description

Depending on the package option, up to seven ADC channels are available for sampling external sources at pins PTA6/ATD6:PT00/ATD0. To achieve the best possible accuracy, these pins are implemented as input-only pins when the analog-to-digital (A/D) feature is enabled. An analog multiplexer allows the single ADC to select one of the seven ADC channels as ADC voltage IN (ADCVIN). ADCVIN is converted by the successive approximation algorithm. When the conversion is completed, the ADC places the result in the ADC data register (ADRH and ADRL) and sets a flag or generates an interrupt. See [Figure 18-1](#).

18.4.2 Voltage Conversion

When the input voltage to the ADC equals V_{REFH} , the ADC converts the signal to \$3FF (full scale). If the input voltage equals V_{SS} , the ADC converts it to \$000. Input voltages between V_{REFH} and V_{REFL} are straight-line linear conversions. All other input voltages will result in \$3FF if greater than V_{REFH} and \$000 if less than V_{SS} .

NOTE: *Input voltage should not exceed the analog supply voltages.*

18.4.3 Conversion Time

Conversion starts after a write to the ADC status and control register (ADSCR). A conversion is between 16 and 17 ADC clock cycles, therefore:

$$\text{Conversion time} = \frac{16 \text{ to } 17 \text{ ADC cycles}}{\text{ADC frequency}}$$

$$\text{Number of bus cycles} = \text{conversion time} \times \text{bus frequency}$$

The ADC conversion time is determined by the clock source chosen and the divide ratio selected. The clock source is either the bus clock or CGMXCLK and is selectable by ADICLK located in the ADC clock register. For example, if CGMXCLK is 4 MHz and is selected as the ADC input clock source, the ADC input clock /4 prescale is selected:

$$\text{Conversion time} = \frac{16 \text{ to } 17 \text{ ADC cycles}}{4 \text{ MHz}/4} = 16 \text{ to } 17 \mu\text{s}$$

NOTE: *The ADC frequency must be between f_{ADIC} minimum and f_{ADIC} maximum to meet A/D specifications.*

Since an ADC cycle may be comprised of several bus cycles (four in the prior example) and the start of a conversion is initiated by a bus cycle write to the ADSCR, from zero to four additional bus cycles may occur before the start of the initial ADC cycle. This results in a fractional ADC cycle and is represented as the 17th cycle.

18.4.4 Continuous Conversion

In the continuous conversion mode, the ADC data registers (ADRH and ADRL) will be filled with new data after each conversion. Data from the previous conversion will be overwritten whether that data has been read or not. Conversions will continue until the ADCO bit is cleared. The COCO bit is set after the first conversion and will stay set for the next several conversions until the next write of the ADC status and control register or the next read of the ADC data register.

18.4.5 Result Justification

The conversion result may be formatted in four different ways:

1. Left justified
2. Right justified
3. Left justified sign data mode
4. 8-bit truncation mode

All four of these modes are controlled using MODE0 and MODE1 bits located in the ADC clock register (ADCLK).

Left justification will place the eight most significant bits (MSB) in the corresponding ADC data register high, ADRH. This may be useful if the result is to be treated as an 8-bit result where the two least significant bits (LSB), located in the ADC data register low, ADRL, can be ignored. However, ADRL must be read after ADRH or else the interlocking will prevent all new conversions from being stored.

Right justification will place only the two MSBs in the corresponding ADC data register high, ADRH, and the eight LSBs in ADC data register low, ADRL. This mode of operation is typically used when a 10-bit unsigned result is desired.

Left justified sign data mode is similar to left justified mode with one exception. The MSB of the 10-bit result, AD9 located in ADRH, is complemented. This mode of operation is useful when a result, represented as a signed magnitude from mid-scale, is needed.

Finally, 8-bit truncation mode will place the eight MSBs in ADC data register low, ADRL. The two LSBs are dropped. This mode of operation

Analog-to-Digital Converter (ADC)

is used when compatibility with 8-bit ADC designs are required. No interlocking between ADRH and ADRL is present.

NOTE: Quantization error is affected when only the most significant eight bits are used as a result. See [Figure 18-2](#).

Figure 18-2. 8-Bit Truncation Mode Error

18.4.6 Monotonicity

The conversion process is monotonic and has no missing codes.

18.5 Interrupts

When the AIEN bit is set, the ADC module is capable of generating a CPU interrupt after each ADC conversion. A CPU interrupt is generated if the COCO bit is at logic 0. The COCO bit is not used as a conversion complete flag when interrupts are enabled.

18.6 Wait Mode

The WAIT instruction can put the MCU in low power-consumption standby mode.

The ADC continues normal operation during wait mode. Any enabled CPU interrupt request from the ADC can bring the MCU out of wait mode. If the ADC is not required to bring the MCU out of wait mode, power down the ADC by setting ADCH[4:0] in the ADC status and control register before executing the WAIT instruction.

18.7 Stop Mode

The STOP instruction can put the MCU in low power-consumption standby mode.

The ADC module becomes inactive after the execution of a STOP instruction. Any pending conversion is aborted. ADC conversions resume when the MCU exits stop mode after an external interrupt. Allow one conversion cycle to stabilize the analog circuitry after exiting stop mode.

18.8 I/O Signals

The ADC module has seven input signals that are shared with port A.

18.8.1 ADC Voltage Reference Pin (V_{REFH})

V_{REFH} is the power supply for setting the reference voltage. Connect the V_{REFH} pin to the same voltage potential as V_{DDA} . There will be a finite current associated with V_{REFH} .

NOTE: *Route V_{REFH} carefully for maximum noise immunity and place bypass capacitors as close as possible to the package.*

18.8.2 ADC Voltage In (ADVIN)

ADVIN is the input voltage signal from one of the seven ADC channels to the ADC module.

18.8.3 ADC External Connection

18.8.3.1 V_{REFH}

Both ac and dc current are drawn through V_{REFH} . The ac current is in the form of current spikes required to supply charge to the capacitor array at each successive approximation step. The dc current flows through the internal resistor string. The best external component to meet both these current demands is a capacitor in the 0.01 μF to 1 μF range with good high-frequency characteristics. This capacitor is connected between V_{REFH} and V_{SS} and must be placed as close as possible to the package pins. Resistance in the path is not recommended because the dc current will cause a voltage drop which could result in conversion errors.

18.8.3.2 ANx

Empirical data shows that capacitors from the analog inputs to V_{RL} improve ADC performance. 0.01 μF and 0.1 μF capacitors with good high-frequency characteristics are sufficient. These capacitors must be placed as close as possible to the package pins.

18.8.3.3 *Grounding*

In cases where separate power supplies are used for analog and digital power, the ground connection between these supplies should be at the V_{SS} pin. This should be the only ground connection between these supplies if possible. The V_{SS} pin makes a good single-point ground location.

18.9 I/O Registers

These I/O registers control and monitor operation of the ADC:

- ADC status and control register (ADSCR)
- ADC data registers (ADRH and ARDL)
- ADC control register (ADCR)
- ADC clock register (ADCLK)

18.9.1 ADC Status and Control Register

These paragraphs describe the function of the ADC status and control register (ADSCR). Writing ADSCR aborts the current conversion and initiates a new conversion.

Ad- dress:	\$0040							
	Bit 7	6	5	4	3	2	1	Bit 0
Read:	COCO	AIEN	ADCO	ADCH4	ADCH3	ADCH2	ADCH1	ADCH0
Write:								
Reset:	0	0	0	1	1	1	1	1

Figure 18-3. ADC Status and Control Register (ADSCR)

COCO — Conversions Complete Bit

When AIEN bit is a logic 0, the COCO is a read-only bit which is set each time a conversion is completed except in the continuous conversion mode where it is set after the first conversion. This bit is cleared whenever the ADC status and control register is written or whenever the ADC data register is read.

If AIEN bit is a logic 1, the COCO is a read/write bit which selects the CPU to service the ADC interrupt request. Reset clears this bit.

1 = Conversion completed (AIEN = 0) interrupt (AIEN = 1)

0 = Conversion not completed (AIEN = 0)/CPU interrupt (AIEN = 1)

AIEN — ADC Interrupt Enable Bit

When this bit is set, an interrupt is generated at the end of an ADC conversion. The interrupt signal is cleared when the data register is read or the status/control register is written. Reset clears the AIEN bit.

1 = ADC interrupt enabled

0 = ADC interrupt disabled

ADCO — ADC Continuous Conversion Bit

When set, the ADC will convert samples continuously and update the ADR register at the end of each conversion. Only one conversion is allowed when this bit is cleared. Reset clears the ADCO bit.

1 = Continuous ADC conversion

0 = One ADC conversion

ADCH[4:0] — ADC Channel Select Bits

ADCH4, ADCH3, ADCH2, ADCH1, and ADCH0 form a 5-bit field which is used to select one of the ADC channels detailed in [Table 18-1](#). Take care to prevent switching noise from corrupting the analog signal when simultaneously using a port pin as both an analog and digital input.

The ADC subsystem is turned off when the channel select bits are all set to 1. This feature allows for reduced power consumption for the MCU when the ADC is not used.

NOTE: *Recovery from the disabled state requires one conversion cycle to stabilize.*

The voltage levels supplied from internal reference nodes as specified in [Table 18-1](#) are used to verify the operation of the ADC converter both in production test and for user applications.

Table 18-1. Mux Channel Select

* If any unused channels are selected, the resulting ADC conversion will be unknown.

** Used for factory testing.

Analog-to-Digital Converter (ADC)

18.9.2 ADC Data Register High

In left justified mode, this 8-bit result register holds the eight MSBs of the 10-bit result. This register is updated each time an ADC single channel conversion completes. Reading ADRH latches the contents of ADRL until ADRL is read. Until ADRL is read, all subsequent ADC results will be lost.

**Figure 18-4. ADC Data Register High (ADRH)
Left Justified Mode**

In right justified mode, this 8-bit result register holds the two MSBs of the 10-bit result. All other bits read as 0. This register is updated each time a single channel ADC conversion completes. Reading ADRH latches the contents of ADRL until ADRL is read. Until ADRL is read, all subsequent ADC results will be lost.

**Figure 18-5. ADC Data Register High (ADRH)
Right Justified Mode**

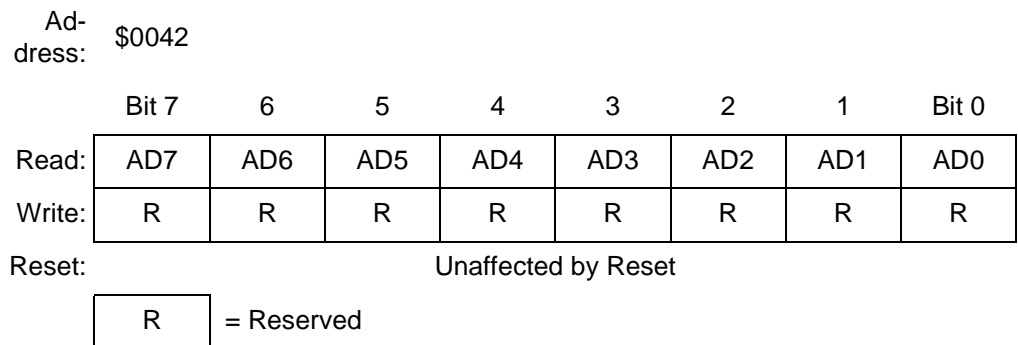

18.9.3 ADC Data Register Low

In left justified mode, this 8-bit result register holds the two LSBs of the 10-bit result. All other bits read as 0. This register is updated each time a single channel ADC conversion completes. Reading ADRH latches the contents of ADRL until ADRL is read. Until ADRL is read all subsequent ADC results will be lost.

**Figure 18-6. ADC Data Register Low (ADRL)
Left Justified Mode**

In right justified mode, this 8-bit result register holds the eight LSBs of the 10-bit result. This register is updated each time an ADC conversion completes. Reading ADRH latches the contents of ADRL until ADRL is read. Until ADRL is read all subsequent ADC results will be lost.

**Figure 18-7. ADC Data Register Low (ADRL)
Right Justified Mode**

Analog-to-Digital Converter (ADC)

In 8-bit mode, this 8-bit result register holds the eight MSBs of the 10-bit result. This register is updated each time an ADC conversion completes. In 8-bit mode, this register contains no interlocking with ADRH.

Ad-
dress: \$0042

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	AD9	AD8	AD7	AD6	AD5	AD4	AD3	AD2
Write:	R	R	R	R	R	R	R	R

Reset: Unaffected by Reset

R = Reserved

**Figure 18-8. ADC Data Register Low (ADRL)
8-Bit Mode**

18.9.4 ADC Clock Register

This register selects the clock frequency for the ADC, selecting between modes of operation.

Ad-
dress: \$0043

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	ADIV2	ADIV1	ADIV0	ADICLK	MODE1	MODE0	0	0
Write:							0	R

Reset: 0 0 0 0 0 1 0 0

R = Reserved

Figure 18-9. ADC Clock Register (ADCLK)

ADIV2:ADIV0 — ADC Clock Prescaler Bits

ADIV2, ADIV1, and ADIV0 form a 3-bit field which selects the divide ratio used by the ADC to generate the internal ADC clock. [Table 18-2](#) shows the available clock configurations. The ADC clock should be set to between 500 kHz and 1 MHz.

Table 18-2. ADC Clock Divide Ratio

ADIV2	ADIV1	ADIV0	ADC Clock Rate
0	0	0	ADC input clock /1
0	0	1	ADC input clock /2
0	1	0	ADC input clock /4
0	1	1	ADC input clock /8
1	X	X	ADC input clock /16

X = don't care

ADICLK — ADC Input Clock Select Bit

ADICLK selects either bus clock or CGMXCLK as the input clock source to generate the internal ADC clock. Reset selects CGMXCLK as the ADC clock source.

If the external clock (CGMXCLK) is equal or greater than 1 MHz, CGMXCLK can be used as the clock source for the ADC. If CGMXCLK is less than 1 MHz, use the PLL-generated bus clock as the clock source. As long as the internal ADC clock is at f_{ADIC} , correct operation can be guaranteed.

1 = Internal bus clock

0 = External clock, CGMXCLK

$$f_{ADIC} = \frac{\text{CGMXCLK or bus frequency}}{\text{ADIV}[2:0]}$$

MODE1:MODE0 — Modes of Result Justification Bits

MODE1:MODE0 selects among four modes of operation. The manner in which the ADC conversion results will be placed in the ADC data registers is controlled by these modes of operation. Reset returns right-justified mode.

00 = 8-bit truncation mode

01 = Right justified mode

10 = Left justified mode

11 = Left justified sign data mode

Section 19. Power-On Reset (POR)

19.1 Contents

19.2 Introduction	327
19.3 Functional Description	327

19.2 Introduction

This section describes the power-on reset (POR) module.

19.3 Functional Description

The POR module provides a known, stable signal to the MCU at power-on. This signal tracks V_{DD} until the MCU generates a feedback signal to indicate that it is properly initialized. At this time, the POR drives its output low. The POR is not a brown-out detector, low-voltage detector, or glitch detector. V_{DD} at the POR must go completely to 0 to reset the MCU. To detect power-loss conditions, use a low-voltage inhibit module (LVI) or other suitable circuit.

20.2 Introduction

This section describes the break (BRK) module. The break module can generate a break interrupt that stops normal program flow at a defined address to enter a background program.

20.3 Features

Features of the break module include:

- Accessible input/output (I/O) registers during the break interrupt
- Central processor unit (CPU) generated break interrupts
- Software-generated break interrupts
- Computer operating properly (COP) disabling during break interrupts

20.4 Functional Description

When the internal address bus matches the value written in the break address registers, the break module issues a breakpoint signal to the CPU. The CPU then loads the instruction register with a software interrupt instruction (SWI) after completion of the current CPU instruction. The program counter vectors to \$FFFC and \$FFFD (\$FEFC and \$FEFD in monitor mode).

These events can cause a break interrupt to occur:

- A CPU-generated address (the address in the program counter) matches the contents of the break address registers.
- Software writes a logic 1 to the BRKA bit in the break status and control register.

When a CPU-generated address matches the contents of the break address registers, the break interrupt begins after the CPU completes its current instruction. A return-from-interrupt instruction (RTI) in the break routine ends the break interrupt and returns the microcontroller unit (MCU) to normal operation. [Figure 20-1](#) shows the structure of the break module.

20.4.1 Flag Protection During Break Interrupts

The BCFE bit in the system integration module (SIM) break flag control register (SBFCR) enables software to clear status bits during the break state.

Figure 20-1. Break Module Block Diagram

Figure 20-2. I/O Register Summary

Break (BRK)

Figure 20-2. I/O Register Summary

20.4.2 CPU During Break Interrupts

The CPU starts a break interrupt by:

- Loading the instruction register with the SWI instruction
- Loading the program counter with \$FFFC and \$FFFD (\$FEFC and \$FEFD in monitor mode)

The break interrupt begins after completion of the CPU instruction in progress. If the break address register match occurs on the last cycle of a CPU instruction, the break interrupt begins immediately.

20.4.3 TIM During Break Interrupts

A break interrupt stops the timer counters.

20.4.4 COP During Break Interrupts

The COP is disabled during a break interrupt when V_{TST} is present on the RST pin.

20.5 Low-Power Modes

The WAIT and STOP instructions put the MCU in low power-consumption standby modes.

20.5.1 Wait Mode

If enabled, the break module is active in wait mode. In the break routine, the user can subtract one from the return address on the stack if SBSW is set. Clear the BW bit by writing logic 0 to it.

20.5.2 Stop Mode

A break interrupt causes exit from stop mode and sets the SBSW bit in the break status register.

20.6 Break Module Registers

These registers control and monitor operation of the break module:

- Break status and control register (BRKSCR)
- Break address register high (BRKH)
- Break address register low (BRKL)
- SIM break status register (SBSR)
- SIM break flag control register (SBFCR)

20.6.1 Break Status and Control Register

The break status and control register (BRKSCR) contains break module enable and status bits.

Figure 20-3. Break Status and Control Register (BRKSCR)

Break (BRK)

Read:	BRKE	BRKA	0	0	0	0	0	0
Write:								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 20-3. Break Status and Control Register (BRKSCR)

BRKE — Break Enable Bit

This read/write bit enables breaks on break address register matches. Clear BRKE by writing a logic 0 to bit 7. Reset clears the BRKE bit.

- 1 = Breaks enabled on 16-bit address match
- 0 = Breaks disabled on 16-bit address match

BRKA — Break Active Bit

This read/write status and control bit is set when a break address match occurs. Writing a logic 1 to BRKA generates a break interrupt. Clear BRKA by writing a logic 0 to it before exiting the break routine. Reset clears the BRKA bit.

- 1 = When read, break address match
- 0 = When read, no break address match

20.6.2 Break Address Registers

The break address registers (BRKH and BRKL) contain the high and low bytes of the desired breakpoint address. Reset clears the break address registers.

Address: \$FE0C

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	Bit 15	14	13	12	11	10	9	Bit 8
Write:								
Reset:	0	0	0	0	0	0	0	0

Figure 20-4. Break Address Register High (BRKH)

Figure 20-5. Break Address Register Low (BRKL)

20.6.3 SIM Break Status Register

The SIM break status register (SBSR) contains a flag to indicate that a break caused an exit from wait mode. The flag is useful in applications requiring a return to wait mode after exiting from a break interrupt.

Ad-
dress: \$FE00

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	1	0	0	BW	0
Write:	R	R	R	R	R	R	Note	R
Reset:	0	0	0	1	0	0	0	0

Note: Writing a logic 0 clears BW.

R

 = Reserved

Figure 20-6. SIM Break Status Register (SBSR)

BW — Break Wait Bit

This read/write bit is set when a break interrupt causes an exit from wait mode. Clear BW by writing a logic 0 to it. Reset clears BW.

1 = Break interrupt during wait mode

0 = No break interrupt during wait mode

BW can be read within the break interrupt routine. The user can modify the return address on the stack by subtracting 1 from it. The example code shown in [Figure 20-7](#) works if the H register was stacked in the break interrupt routine. Execute this code at the end of the break interrupt routine.

```

HIBYTE EQU 5
LOBYTE EQU 6

; If not BW, do RTI
BRCLR BW,BSR, RETURN ; See if wait mode or stop
; mode was exited by break.
TST LOBYTE,SP ; If RETURNLO is not 0,
BNE DOLO ; then just decrement low byte.
DEC HIBYTE,SP ; Else deal with high byte also.
DOLO DEC LOBYTE,SP ; Point to WAIT/STOP opcode.
RETURN PULH ; Restore H register.
RTI

```

Figure 20-7. Example Code

20.6.4 SIM Break Flag Control Register

The SIM break flag control register (SBFCR) contains a bit that enables software to clear status bits while the MCU is in a break state.

Figure 20-8. SIM Break Flag Control Register (SBFCR)

BCFE — Break Clear Flag Enable Bit

This read/write bit enables software to clear status bits by accessing status registers while the MCU is in a break state. To clear status bits during the break state, the BCFE bit must be set.

1 = Status bits clearable during break

0 = Status bits not clearable during break

Break (BRK)

21.2 Introduction

This section contains electrical and timing specifications. These values are design targets and have not yet been fully characterized.

21.3 Absolute Maximum Ratings

Maximum ratings are the extreme limits to which the MCU can be exposed without permanently damaging it.

NOTE: *This device is not guaranteed to operate properly at the maximum ratings. Refer to [21.6 DC Electrical Characteristics](#) for guaranteed operating conditions.*

Characteristic ⁽¹⁾	Symbol	Value	Unit
Supply voltage	V_{DD}	-0.3 to +6.0	V
Input voltage	V_{In}	$V_{SS} - 0.3$ to $V_{DD} + 0.3$	V
Input high voltage	V_{HI}	$V_{DD} + 4$	V
Maximum current per pin excluding V_{DD} and V_{SS}	I	± 25	mA
Storage temperature	t_{STG}	-55 to +150	°C
Maximum current out of V_{SS}	I_{MVSS}	100	mA
Maximum current Into V_{DD}	I_{MVDD}	100	mA

1. Voltages are referenced to V_{SS} .

NOTE: *This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. For proper operation, it is recommended that V_{In} and V_{Out} be constrained to the range $V_{SS} \leq (V_{In} \text{ or } V_{Out}) \leq V_{DD}$. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (for example, either V_{SS} or V_{DD}).*

21.4 Functional Operating Range

Characteristic	Symbol	Value	Unit
Operating temperature range ⁽¹⁾ MC68HC908MR8CP MC68HC908MR8CFA MC68HC908MR8CDW MC68HC908MR8VFA MC68HC908MR8VP MC68HC908MR8VDW MC68HC908MR8MFA MC68HC908MR8MP MC68HC908MR8MDW	T_A	–40 to +85 –40 to +85 –40 to +85 –40 to +105 –40 to +105 –40 to +105 –40 to +105 –40 to +125 –40 to +125 –40 to +125	°C
Operating voltage range	V_{DD}	5.0 ± 10%	V

1. Contact a Motorola representative for temperature availability.

C = Extended temperature range (–40 to +85°C)

V = Industrial temperature range (–40 to +105°C)

M = Automotive temperature range (–40 to +125°C)

21.5 Thermal Characteristics

Characteristic	Symbol	Value	Unit
Thermal resistance 32-pin LQFP 28-pin PDIP 28-pin SOIC	θ_{JA}	68.9 ⁽¹⁾ — —	°C/W
I/O pin power dissipation	$P_{I/O}$	User determined	W
Power dissipation ⁽²⁾	P_D	$P_D = (I_{DD} \times V_{DD})$ $+ P_{I/O} = K/(T_J + 273^\circ\text{C})$	W
Constant ⁽³⁾	K	$P_D \times (T_A + 273^\circ\text{C})$ $+ P_D^2 \times \theta_{JA}$	W/°C
Average junction temperature	T_J	$T_A + (P_D \times \theta_{JA})$	°C
Maximum junction temperature	T_{JM}	125	°C

1. 32-pin LQFP resistance measured at 200 ft/min.

2. Power dissipation is a function of temperature.

3. K is a constant unique to the device. K can be determined for a known T_A and measured P_D . With this value of K, P_D and T_J can be determined for any value of T_A .

21.6 DC Electrical Characteristics

Characteristic ⁽¹⁾	Symbol	Min	Typ ⁽²⁾	Max	Unit
Output high voltage $I_{Load} = -2.0$ mA for all I/O pins except: Port A bits 0 and 1 Port B bits 5 and 6 $I_{Load} = -7.0$ mA for: Port A bits 0 and 1 and port B bits 5–6, a maximum of four 15-mA outputs may be active at any time	V_{OH}	$V_{DD} - 0.8$ $V_{DD} - 1.0$	—	—	V
Output low voltage $I_{Load} = 1.6$ mA for all I/O pins except: Port A bits 0 and 1 Port B bits 5 and 6 $I_{Load} = 15$ mA for: Port A bits 0 and 1 and Port B bits 5–6, a maximum of four 15-mA outputs may be active at any time	V_{OL}	— —	— —	0.4 1.5	V
Input high voltage All ports, IRQs, RESET, OSC1	V_{IH}	$0.7 \times V_{DD}$	—	V_{DD}	V
Input low voltage All ports, IRQs, RESET, OSC1	V_{IL}	V_{SS}	—	$0.3 \times V_{DD}$	V
V_{DD} supply current Run ⁽³⁾ Wait ⁽⁴⁾ Stop ⁽⁵⁾ Up to 85°C Above 85°C 25°C with LVI enabled Quiescent ⁽⁵⁾	I_{DD}	— — — — — —	— — — — — —	40 12 5 15 350 100	mA mA μ A μ A μ A μ A

Low-voltage recover rising	V_{LVRR1}	—	4.5	4.75	V

Electrical Specifications

Characteristic ⁽¹⁾	Symbol	Min	Typ ⁽²⁾	Max	Unit
— Continued					
Low-voltage inhibit falling	V_{LVRF2}	3.8	4.1	—	V
Low-voltage reset/recover hysteresis	V_{LVH2}	50	100	—	mV
Low-voltage recover rising	V_{LVRR2}	—	4.2	4.6	V
POR re-arm voltage ⁽⁶⁾	V_{POR}	0	—	100	mV
POR rise time ramp rate ⁽⁷⁾	R_{POR}	0.035	—	—	V/ms

1. $V_{DD} = 5.0 \text{ Vdc} \pm 10\%$, $V_{SS} = 0 \text{ Vdc}$, $T_A = T_L$ to T_H , unless otherwise noted
2. Typical values reflect average measurements at midpoint of voltage range, 25°C only.
3. Run (operating) I_{DD} measured using external square wave clock source ($f_{OSC} = 8.2 \text{ MHz}$); all inputs 0.2 V from rail; no dc loads; less than 100 pF on all outputs; $C_L = 20 \text{ pF}$ on OSC2; all ports configured as inputs; OSC2 capacitance linearly affects run I_{DD} ; measured with all modules enabled
4. Wait I_{DD} measured using external square wave clock source ($f_{OSC} = 8.2 \text{ MHz}$); all inputs 0.2 V from rail; no dc loads; less than 100 pF on all outputs; $C_L = 20 \text{ pF}$ on OSC2; all ports configured as inputs; OSC2 capacitance linearly affects wait I_{DD} ; measured with PLL and LVI enabled
5. Quiescent I_{DD} measured with PLL and LVI disengaged; OCS1 grounded; no port pins sourcing current. It is measured through combination of V_{DD} and V_{DDA} .
6. Maximum is highest guaranteed voltage for POR.
7. Maximum is the highest possible voltage for POR. If minimum V_{DD} is not reached before the internal POR reset is released, RST must be driven low externally until minimum V_{DD} is reached.

21.7 Memory Characteristics

Characteristic	Symbol	Min	Typ	Max	Unit
RAM data retention voltage	V_{RDR}	1.3	—	—	V
FLASH program bus clock frequency	—	1	—	—	MHz
FLASH read bus clock frequency	$f_{Read}^{(1)}$	32k	—	8.4M	Hz
FLASH page erase time	$t_{Erase}^{(2)}$	1	—	—	ms
FLASH mass erase time	$t_{MErase}^{(3)}$	4	—	—	ms
FLASH PGM/ERASE to HVEN set up time	t_{nvs}	10	—	—	μs
FLASH high-voltage hold time	t_{nvh}	5	—	—	μs
FLASH high-voltage hold time (mass erase)	t_{nvhl}	100	—	—	μs
FLASH program hold time	t_{pgs}	5	—	—	μs
FLASH program time	t_{PROG}	30	—	40	μs
FLASH return to read time	$t_{rcv}^{(4)}$	1	—	—	μs
FLASH cumulative program HV period	$t_{HV}^{(5)}$	—	—	4	ms
FLASH row erase endurance ⁽⁶⁾	—	10k	100k ⁽⁷⁾	—	Cycles
FLASH row program endurance ⁽⁸⁾	—	10k	100k ⁽⁷⁾	—	Cycles
FLASH data retention time ⁽⁹⁾	—	10	100 ⁽¹⁰⁾	—	Years

Notes:

- f_{Read} is defined as the frequency range for which the FLASH memory can be read.
- If the page erase time is longer than t_{Erase} (Min), there is no erase-disturb, but it reduces the endurance of the FLASH memory.
- If the mass erase time is longer than t_{MErase} (Min), there is no erase-disturb, but it reduces the endurance of the FLASH memory.
- t_{rcv} is defined as the time it needs before the FLASH can be read after turning off the high voltage charge pump, by clearing HVEN to logic 0.
- t_{HV} is defined as the cumulative high voltage programming time to the same row before next erase.
 t_{HV} must satisfy this condition: $t_{nvs} + t_{nvh} + t_{pgs} + (t_{PROG} \times 64) \leq t_{HV} \text{ max.}$
- The minimum row endurance value specifies each row of the FLASH memory is guaranteed to work for at least this many erase / program cycles.
- FLASH endurance is a function of the temperature at which erasure occurs. Typical endurance degrades when the temperature while erasing is less than 25°C.
- The minimum row endurance value specifies each row of the FLASH memory is guaranteed to work for at least this many erase / program cycles.
- The FLASH is guaranteed to retain data over the entire operating temperature range for at least the minimum time specified.
- Motorola performs reliability testing for data retention. These tests are based on samples tested at elevated temperatures. Due to the higher activation energy of the elevated test temperature, calculated life tests correspond to more than 100 years of operation/storage at 55°C

21.8 Control Timing

Characteristic ⁽¹⁾	Symbol	Min	Max	Unit
Frequency of operation ⁽²⁾ Crystal option External clock option ⁽³⁾	f_{OSC}	1 dc ⁽⁴⁾	8 32.8	MHz
Internal operating frequency	f_{OP}	—	8.2	MHz
\overline{RESET} input pulse width low ⁽⁵⁾	t_{IRL}	50	—	ns

1. $V_{DD} = 5.0 \text{ Vdc} \pm 10\%$; $V_{SS} = 0 \text{ Vdc}$; timing shown with respect to 20% V_{DD} and 70% V_{DD} , unless otherwise noted

2. See [21.8 Control Timing](#) for more information.

3. No more than 10 percent duty cycle deviation from 50 percent.

4. Some modules may require a minimum frequency greater than dc for proper operation; see appropriate table for this information.

5. Minimum pulse width reset is guaranteed to be recognized. It is possible for a smaller pulse width to cause reset.

21.9 Timer Interface Module Characteristics

Characteristic	Symbol	Min	Max	Unit
Input capture pulse width	t_{TIH} t_{TIL}	125	—	ns
Input clock pulse width	t_{TCH} t_{TCL}	$(1/f_{OP}) + 5$	—	ns

21.10 Clock Generation Module Component Specifications

Characteristic	Symbol	Min	Typ	Max	Notes
Crystal load capacitance	C_L	—	—	—	Consult crystal manufacturing data
Crystal fixed capacitance	C_1	—	$2 * C_L$	—	Consult crystal manufacturing data
Crystal tuning capacitance	C_2	—	$2 * C_L$	—	Consult crystal manufacturing data
Feedback bias resistor	R_B	—	22 M Ω	—	
Series resistor	R_S	0	330 k Ω	1 M Ω	Not required
Filter capacitor	C_F	—	$C_{FACT} * (V_{DDA}/f_{XCLK})$	—	—
Bypass capacitor	C_{BYP}	—	0.1 μ F	—	C_{BYP} must provide low ac impedance from $f = f_{XCLK}/100$ to $100 * f_{VCLK}$, so series resistance must be considered.

21.11 CGM Operating Conditions

Characteristic	Symbol	Min	Typ	Max
Crystal reference frequency	f_{XCLK}	1 MHz	—	8 MHz
Range nominal multiplier	f_{NOM}	—	4.9152 MHz	—
VCO center-of-range frequency	f_{VRS}	4.9152 MHz	—	32.8 MHz
VCO frequency multiplier	N	1	—	15
VCO center of range multiplier	L	1	—	15
VCO operating frequency	f_{VCLK}	f_{VRSMIN}	—	f_{VRSMAX}

21.12 CGM Acquisition/Lock Time Specifications

Description	Symbol	Min	Typ	Max	Notes
Filter capacitor multiply factor	C_{FACT}	—	0.0154	—	F/sV
Acquisition mode time factor	K_{ACQ}	—	0.1135	—	V
Tracking mode time factor	K_{TRK}	—	0.0174	—	V
Manual mode time to stable	t_{ACQ}	—	$(8 * V_{DDA}) / (f_{XCLK} * K_{ACQ})$	—	If C_F chosen correctly
Manual stable to lock time	t_{AL}	—	$(4 * V_{DDA}) / (f_{XCLK} * K_{TRK})$	—	If C_F chosen correctly
Manual acquisition time	t_{Lock}	—	$t_{ACQ} + t_{AL}$	—	—
Tracking mode entry frequency tolerance	Δ_{TRK}	0	—	$\pm 3.6\%$	—
Acquisition mode entry frequency tolerance	Δ_{ACQ}	$\pm 6.3\%$	—	$\pm 7.2\%$	—
Lock entry frequency tolerance	Δ_{Lock}	0	—	$\pm 0.9\%$	—
Lock exit frequency tolerance	Δ_{UNL}	$\pm 0.9\%$	—	$\pm 1.8\%$	—
Reference cycles per acquisition mode measurement	n_{ACQ}	—	32	—	—
Reference cycles per tracking mode measurement	n_{TRK}	—	128	—	—
Automatic mode time to stable	t_{ACQ}	n_{ACQ} / f_{XCLK}	$(8 * V_{DDA}) / (f_{XCLK} * K_{ACQ})$	—	If C_F chosen correctly
Automatic stable to lock time	t_{AL}	n_{TRK} / f_{XCLK}	$(4 * V_{DDA}) / (f_{XCLK} * K_{TRK})$	—	If C_F chosen correctly
Automatic lock time	t_{Lock}	—	$t_{ACQ} + t_{AL}$	—	—
PLL jitter (deviation of average bus frequency over 2 ms)	f_J	0	—	$\pm (f_{CRYS})$ * (0.025 %) * (N/4)	N = VCO freq. mult. (GBNT)

21.13 Analog-to-Digital Converter (ADC) Characteristics

Characteristic	Symbol	Min	Typ	Max	Unit	Notes
A/D reference voltage	V_{REFH}	4.5	—	5.5	V	—
Input voltages	V_{ADIN}	0	—	V_{REFH}	V	$V_{ADIN} \leq V_{REFH}$
Resolution	B_{AD}	10	—	10	Bits	—
Absolute accuracy	A_{AD}	—	—	4	Counts	Includes quantization
ADC internal clock	f_{ADIC}	500 k	—	1 M	Hz	$t_{AIC} = 1/f_{ADIC}$
Conversion range	R_{AD}	V_{SSA}	—	V_{REFH}	V	—
Power-up time	t_{ADPU}	16	—		t_{AIC} cycles	—
Conversion time	t_{ADC}	16	—	17	t_{AIC} cycles	—
Sample time	t_{ADS}	5	—	—	t_{AIC} cycles	—
Monotonicity	M_{AD}	Guaranteed				
Zero input reading	Z_{ADI}	000	—	003	Hex	$V_{ADIN} = V_{SSA}$
Full-scale reading	F_{ADI}	3FD	—	3FF	Hex	$V_{ADIN} = V_{REFH}$
Input capacitance	C_{ADI}	—	—	30	pF	Not characterized
Absolute accuracy (8-bit truncation mode)	A_{AD}	—	—	± 1	Counts	Includes quantization
Quantization error (8-bit truncation mode)	—	—	—	$+7/8$ $-1/8$	LSB	—

Section 22. Mechanical Specifications

22.1 Contents

22.2	Introduction	351
22.3	32-Pin LQFP (Case #873A)	352
22.4	28-Pin PDIP (Case #710)	353
22.5	28-Pin SOIC (Case #751F)	353

22.2 Introduction

The MC68HC908MR8 is available in these packages:

- 32-pin low-profile quad flat pack (LQFP)
- 28-pin dual in-line package (PDIP)
- 28-pin small outline package (SOIC)

The package information contained in this section is the latest available at the time of this publication. To make sure that you have the latest package specifications, contact one of the following:

- Local Motorola Sales Office
- World Wide Web at <http://www.motorola.com/semiconductors/>

Follow World Wide Web on-line instructions to retrieve the current mechanical specifications.

Mechanical Specifications

22.3 32-Pin LQFP (Case #873A)

- NOTES:
1. DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
 2. CONTROLLING DIMENSION: MILLIMETER.
 3. DATUM PLANE -AB- IS LOCATED AT BOTTOM OF LEAD AND IS COINCIDENT WITH THE LEAD WHERE THE LEAD EXITS THE PLASTIC BODY AT THE BOTTOM OF THE PARTING LINE.
 4. DATUMS -T-, -U-, AND -Z- TO BE DETERMINED AT DATUM PLANE -AB-.
 5. DIMENSIONS S AND V TO BE DETERMINED AT SEATING PLANE -AC-.
 6. DIMENSIONS A AND B DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.250 (0.010) PER SIDE. DIMENSIONS A AND B DO INCLUDE MOLD MISMATCH AND ARE DETERMINED AT DATUM PLANE -AB-.
 7. DIMENSION D DOES NOT INCLUDE DAMBAR PROTRUSION. DAMBAR PROTRUSION SHALL NOT CAUSE THE D DIMENSION TO EXCEED 0.520 (0.020).
 8. MINIMUM SOLDER PLATE THICKNESS SHALL BE 0.0076 (0.0003).
 9. EXACT SHAPE OF EACH CORNER MAY VARY FROM DEPICTION.

DIM	MILLIMETERS		INCHES	
	MIN	MAX	MIN	MAX
A	7.000 BSC		0.276 BSC	
A1	3.500 BSC		0.138 BSC	
B	7.000 BSC		0.276 BSC	
B1	3.500 BSC		0.138 BSC	
C	1.400	1.600	0.055	0.063
D	0.300	0.450	0.012	0.018
E	1.350	1.450	0.053	0.057

23.2 Introduction

This section contains instructions for ordering the MC68HC908MR8.

23.3 MC Order Numbers

Table 23-1. MC Order Numbers

MC Order Number ⁽¹⁾	Operating Temperature Range (°C)
MC68HC908MR8CFA	- 40 to + 85
MC68HC908MR8CP	- 40 to + 85
MC68HC908MR8CDW	- 40 to + 85
MC68HC908MR8VFA	- 40 to + 105
MC68HC908MR8VP	- 40 to + 105
MC68HC908MR8VDW	- 40 to + 105
MC68HC908MR8MFA	- 40 to + 125
MC68HC908MR8MP	- 40 to + 125
MC68HC908MR8MDW	- 40 to + 125

- 1. FA = quad flat pack
- P = plastic dual in line package
- DW = Small outline integrated circuit (SOIC) package

Introduction

This section contains the revision history for the MC68HC908MR8 advance information data book.

Changes from Rev 3.0 published in April 2002 to Rev 4.0 published in July 2002

Section	Page (in Rev 0.4)	Description of change
Electrical Specifications	343	V_{OL} max updated for $I_{Load} = 15$ mA Stop I_{DD} limits updated for different temperature specs

Revision History

Glossary

A — See accumulator (A).

accumulator (A) — An 8-bit general-purpose register in the CPU08. The CPU08 uses the accumulator to hold operands and results of arithmetic and logic operations.

acquisition mode — A mode of PLL operation during startup before the PLL locks on a frequency. Also see tracking mode.

address bus — The set of wires that the CPU or DMA uses to read and write memory locations.

addressing mode — The way that the CPU determines the operand address for an instruction. The M68HC08 CPU has 16 addressing modes.

ALU — See arithmetic logic unit (ALU).

arithmetic logic unit (ALU) — The portion of the CPU that contains the logic circuitry to perform arithmetic, logic, and manipulation operations on operands.

asynchronous — Refers to logic circuits and operations that are not synchronized by a common reference signal

baud rate — The total number of bits transmitted per unit of time.

BCD — See binary-coded decimal (BCD)

binary — Relating to the base 2 number system

binary number system — The base 2 number system, having two digits, 0 and 1. Binary arithmetic is convenient in digital circuit design because digital circuits have two permissible voltage levels, low and high. The binary digits 0 and 1 can be interpreted to correspond to the two digital voltage levels.

binary-coded decimal (BCD) — A notation that uses 4-bit binary numbers to represent the 10 decimal digits and that retains the same positional structure of a decimal number. For example,

$$234 \text{ (decimal)} = 0010 \ 0011 \ 0100 \text{ (BCD)}$$

bit — A binary digit. A bit has a value of either logic 0 or logic 1.

branch instruction — An instruction that causes the CPU to continue processing at a memory location other than the next sequential address.

break module — A module in the M68HC08 Family. The break module allows software to halt program execution at a programmable point to enter a background routine.

breakpoint — A number written into the break address registers of the break module. When a number appears on the internal address bus that is the same as the number in the break address registers, the CPU executes the software interrupt instruction (SWI).

break interrupt — A software interrupt caused by the appearance on the internal address bus of the same value that is written in the break address registers.

bus — A set of wires that transfers logic signals.

bus clocks — There are two bus clocks, IT12 and IT23. These clocks are generated by the CGM and distributed throughout the MCU by the SIM. The frequency of the bus clocks, or operating frequency, is f_{OP} . While the frequency of these two clocks is the same, the phase is different.

byte — A set of eight bits.

C — The carry/borrow bit in the condition code register. The CPU08 sets the carry/borrow bit when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some logical operations and data manipulation instructions also clear or set the carry/borrow bit (as in bit test and branch instructions and shifts and rotates).

CCR — See condition code register.

central processor unit (CPU) — The primary functioning unit of any computer system. The CPU controls the execution of instructions.

CGM — See clock generator module (CGM).

clear — To change a bit from logic 1 to logic 0; the opposite of set.

clock — A square wave signal used to synchronize events in a computer.

clock generator module (CGM) — A module in the M68HC08 Family. The CGM generates a base clock signal from which the system clocks are derived. The CGM may include a crystal oscillator circuit and/or phase-locked loop (PLL) circuit.

comparator — A device that compares the magnitude of two inputs. A digital comparator defines the equality or relative differences between two binary numbers.

computer operating properly module (COP) — A counter module in the M68HC08 Family that resets the MCU if allowed to overflow.

condition code register (CCR) — An 8-bit register in the CPU08 that contains the interrupt mask bit and five bits that indicate the results of the instruction just executed.

control bit — One bit of a register manipulated by software to control the operation of the module.

control unit — One of two major units of the CPU. The control unit contains logic functions that synchronize the machine and direct various operations. The control unit decodes instructions and generates the internal control signals that perform the requested operations. The outputs of the control unit drive the execution unit, which contains the arithmetic logic unit (ALU), CPU registers, and bus interface.

COP — See computer operating properly module (COP).

counter clock — The input clock to the TIM counter. This clock is an output of the prescaler sub-module. The frequency of the counter clock is f_{TCNT} , and the period is t_{TCNT} .

CPU — See central processor unit (CPU).

CPU08 — The central processor unit of the M68HC08 Family.

CPU cycles — A CPU clock cycle is one period of the internal bus-rate clock, f_{OP} , normally derived by dividing a crystal oscillator source by two or more so the high and low times will be equal. The length of time required to execute an instruction is measured in CPU clock cycles.

CPU registers — Memory locations that are wired directly into the CPU logic instead of being part of the addressable memory map. The CPU always has direct access to the information in these registers. The CPU registers in an M68HC08 are:

- A, 8-bit accumulator
- H:X, 16-bit index register
- SP, 16-bit stack pointer
- PC, 16-bit program counter
- CCR, condition code register containing the V, H, I, N, Z, and C bits

CSIC — customer-specified integrated circuit

cycle time — The period of the operating frequency: $t_{CYC} = 1/fOP$.

decimal number system — Base 10 numbering system that uses the digits zero through nine.

direct memory access module (DMA) — A M68HC08 Family module that can perform data transfers between any two CPU-addressable locations without CPU intervention. For transmitting or receiving blocks of data to or from peripherals, DMA transfers are faster and more code-efficient than CPU interrupts.

DMA — See direct memory access module (DMA).

DMA service request — A signal from a peripheral to the DMA module that enables the DMA module to transfer data.

duty cycle — A ratio of the amount of time the signal is on versus the time it is off. Duty cycle is usually represented by a percentage.

EEPROM — Electrically erasable, programmable, read-only memory. A non-volatile type of memory that can be electrically reprogrammed.

EPROM — Erasable, programmable, read-only memory. A non-volatile type of memory that can be erased by exposure to an ultraviolet light source and then reprogrammed.

exception — An event such as an interrupt or a reset that stops the sequential execution of the instructions in the main program.

external interrupt module (IRQ) — A module in the M68HC08 Family with both dedicated external interrupt pins and port pins that can be enabled as interrupt pins.

fetch — To copy data from a memory location into the accumulator.

firmware — Instructions and data programmed into non-volatile memory.

free-running counter — A device that counts from zero to a predetermined number, then rolls over to zero and begins counting again.

full-duplex transmission — Communication on a channel in which data can be sent and received simultaneously.

H — The upper byte of the 16-bit index register (H:X) in the CPU08.

H — The half-carry bit in the condition code register of the CPU08. This bit indicates a carry from the low-order four bits of the accumulator value to the high-order four bits. The half-carry bit is required for binary-coded decimal arithmetic operations. The decimal adjust accumulator (DAA) instruction uses the state of the H and C bits to determine the appropriate correction factor.

hexadecimal — Base 16 numbering system that uses the digits 0 through 9 and the letters A through F.

high byte — The most significant eight bits of a word.

illegal address — An address not within the memory map.

illegal opcode — A non-existent opcode.

I — The interrupt mask bit in the condition code register of the CPU08. When I is set, all interrupts are disabled.

index register (H:X) — A 16-bit register in the CPU08. The upper byte of H:X is called H. The lower byte is called X. In the indexed addressing modes, the CPU uses the contents of H:X to determine the effective address of the operand. H:X can also serve as a temporary data storage location.

input/output (I/O) — Input/output interfaces between a computer system and the external world. A CPU reads an input to sense the level of an external signal and writes to an output to change the level on an external signal.

instructions — Operations that a CPU can perform. Instructions are expressed by programmers as assembly language mnemonics. A CPU interprets an opcode and its associated operand(s) and instruction.

interrupt — A temporary break in the sequential execution of a program to respond to signals from peripheral devices by executing a subroutine.

interrupt request — A signal from a peripheral to the CPU intended to cause the CPU to execute a subroutine.

I/O — See input/output (I/O).

IRQ — See external interrupt module (IRQ).

jitter — Short-term signal instability.

latch — A circuit that retains the voltage level (logic 1 or logic 0) written to it for as long as power is applied to the circuit.

latency — The time lag between instruction completion and data movement.

least significant bit (LSB) — The rightmost digit of a binary number.

logic 1 — A voltage level approximately equal to the input power voltage (V_{DD}).

logic 0 — A voltage level approximately equal to the ground voltage (V_{SS}).

low byte — The least significant eight bits of a word.

low voltage inhibit module (LVI) — A module in the M68HC08 Family that monitors power supply voltage.

LVI — See low-voltage inhibit module (LVI).

M68HC08 — A Motorola family of 8-bit MCUs.

mark/space — The logic 1/logic 0 convention used in formatting data in serial communication.

mask — 1. A logic circuit that forces a bit or group of bits to a desired state. 2. A photomask used in integrated circuit fabrication to transfer an image onto silicon.

mask option — An optional microcontroller feature that the customer chooses to enable or disable.

MCU — Microcontroller unit. See microcontroller.

memory location — Each M68HC08 memory location holds one byte of data and has a unique address. To store information in a memory location, the CPU places the address of the location on the address bus, the data information on the data bus, and asserts the write signal. To read information from a memory location, the CPU places the address of the location on the address bus and asserts the read signal. In response to the read signal, the selected memory location places its data onto the data bus.

memory map — A pictorial representation of all memory locations in a computer system.

microcontroller — Microcontroller unit (MCU). A complete computer system, including a CPU, memory, a clock oscillator, and input/output (I/O) on a single integrated circuit.

modulo counter — A counter that can be programmed to count to any number from zero to its maximum possible modulus.

monitor ROM — A section of ROM that can execute commands from a host computer for testing purposes.

most significant bit (MSB) — The leftmost digit of a binary number.

multiplexer — A device that can select one of a number of inputs and pass the logic level of that input on to the output.

N — The negative bit in the condition code register of the CPU08. The CPU sets the negative bit when an arithmetic operation, logical operation, or data manipulation produces a negative result.

nibble — A set of four bits (half of a byte).

object code — The output from an assembler or compiler that is itself executable machine code or is suitable for processing to produce executable machine code.

opcode — A binary code that instructs the CPU to perform an operation.

open-drain — An output that has no pullup transistor. An external pullup device can be connected to the power supply to provide the logic 1 output voltage.

operand — Data on which an operation is performed. Usually, a statement consists of an operator and an operand. For example, the operator may be an add instruction, and the operand may be the quantity to be added.

oscillator — A circuit that produces a constant frequency square wave that is used by the computer as a timing and sequencing reference.

overflow — A quantity that is too large to be contained in one byte or one word.

page zero — The first 256 bytes of memory (addresses \$0000–\$00FF).

parity — An error-checking scheme that counts the number of logic 1s in each byte transmitted. In a system that uses odd parity, every byte is expected to have an odd number of logic 1s. In an even parity system, every byte should have an even number of logic 1s. In the transmitter, a parity generator appends an extra bit to each byte to make the number of logic 1s odd for odd parity or even for even parity. A parity checker in the receiver counts the number of logic 1s in each byte. The parity checker generates an error signal if it finds a byte with an incorrect number of logic 1s.

PC — See program counter (PC).

peripheral — A circuit not under direct CPU control.

phase-locked loop (PLL) — An oscillator circuit in which the frequency of the oscillator is synchronized to a reference signal.

PLL — See phase-locked loop (PLL).

pointer — Pointer register. An index register is sometimes called a pointer register because its contents are used in the calculation of the address of an operand and, therefore, points to the operand.

polarity — The two opposite logic levels, logic 1 and logic 0, which correspond to two different voltage levels, V_{DD} and V_{SS} .

polling — Periodically reading a status bit to monitor the condition of a peripheral device.

port — A set of wires for communicating with off-chip devices.

prescaler — A circuit that generates an output signal related to the input signal by a fractional scale factor such as 1/2, 1/8, 1/10, etc.

program — A set of computer instructions that causes a computer to perform a desired operation or operations.

program counter (PC) — A 16-bit register in the CPU08. The PC register holds the address of the next instruction or operand that the CPU will use.

pull — An instruction that copies into the accumulator the contents of a stack RAM location. The stack RAM address is in the stack pointer.

pullup — A transistor in the output of a logic gate that connects the output to the logic 1 voltage of the power supply.

pulse-width — The amount of time a signal is on as opposed to being in its off state.

pulse-width modulation (PWM) — Controlled variation (modulation) of the pulse width of a signal with a constant frequency.

push — An instruction that copies the contents of the accumulator to the stack RAM. The stack RAM address is in the stack pointer.

PWM period — The time required for one complete cycle of a PWM waveform.

PMC — Pulse width modulated motor control module

RAM — Random access memory. All RAM locations can be read or written by the CPU. The contents of a RAM memory location remain valid until the CPU writes a different value or until power is turned off.

RC circuit — A circuit consisting of capacitors and resistors having a defined time constant.

read — To copy the contents of a memory location to the accumulator.

register — A circuit that stores a group of bits.

reserved memory location — A memory location that is used only in special factory test modes. Writing to a reserved location has no effect. Reading a reserved location returns an unpredictable value.

reset — To force a device to a known condition.

ROM — Read-only memory. A type of memory that can be read but cannot be changed (written). The contents of ROM must be specified before manufacturing the MCU.

SCI — See serial communication interface module (SCI).

serial — Pertaining to sequential transmission over a single line.

serial communication interface module (SCI) — A module in the M68HC08 Family that supports asynchronous communication.

serial peripheral interface module (SPI) — A module in the M68HC08 Family that supports synchronous communication.

set — To change a bit from logic 0 to logic 1; opposite of clear.

shift register — A chain of circuits that can retain the logic levels (logic 1 or logic 0) written to them and that can shift the logic levels to the right or left through adjacent circuits in the chain.

signed — A binary number notation that accommodates both positive and negative numbers. The most significant bit is used to indicate whether the number is positive or negative, normally logic 0 for positive and logic 1 for negative. The other seven bits indicate the magnitude of the number.

SIM — See system integration module (SIM).

software — Instructions and data that control the operation of a microcontroller.

software interrupt (SWI) — An instruction that causes an interrupt and its associated vector fetch.

SPI — See serial peripheral interface module (SPI).

stack — A portion of RAM reserved for storage of CPU register contents and subroutine return addresses.

stack pointer (SP) — A 16-bit register in the CPU08 containing the address of the next available storage location on the stack.

start bit — A bit that signals the beginning of an asynchronous serial transmission.

status bit — A register bit that indicates the condition of a device.

stop bit — A bit that signals the end of an asynchronous serial transmission.

subroutine — A sequence of instructions to be used more than once in the course of a program. The last instruction in a subroutine is a return from subroutine (RTS) instruction. At each place in the main program where the subroutine instructions are needed, a jump or branch to subroutine (JSR or BSR) instruction is used to call the subroutine. The CPU leaves the flow of the main program to execute the instructions in the subroutine. When the RTS instruction is executed, the CPU returns to the main program where it left off.

synchronous — Refers to logic circuits and operations that are synchronized by a common reference signal.

system integration module (SIM) — One of a number of modules that handle a variety of control functions in the modular M68HC08 Family. The SIM controls mode of operation, resets and interrupts, and system clock distribution.

TIM — See timer interface module (TIM).

timer interface module (TIM) — A module used to relate events in a system to a point in time.

timer — A module used to relate events in a system to a point in time.

toggle — To change the state of an output from a logic 0 to a logic 1 or from a logic 1 to a logic 0.

tracking mode — Mode of low-jitter PLL operation during which the PLL is locked on a frequency. Also see acquisition mode.

two's complement — A means of performing binary subtraction using addition techniques. The most significant bit of a two's complement number indicates the sign of the number (1 indicates negative). The two's complement negative of a number is obtained by inverting each bit in the number and then adding 1 to the result.

unbuffered — Utilizes only one register for data; new data overwrites current data.

unimplemented memory location — A memory location that is not used. Writing to an unimplemented location has no effect. Reading an unimplemented location returns an unpredictable value. Executing an opcode at an unimplemented location causes an illegal address reset.

V — The overflow bit in the condition code register of the CPU08. The CPU08 sets the V bit when a two's complement overflow occurs. The signed branch instructions BGT, BGE, BLE, and BLT use the overflow bit.

variable — A value that changes during the course of program execution.

VCO — See voltage-controlled oscillator.

vector — A memory location that contains the address of the beginning of a subroutine written to service an interrupt or reset.

voltage-controlled oscillator (VCO) — A circuit that produces an oscillating output signal of a frequency that is controlled by a dc voltage applied to a control input.

waveform — A graphical representation in which the amplitude of a wave is plotted against time.

wired-OR — Connection of circuit outputs so that if any output is high, the connection point is high.

word — A set of two bytes (16 bits).

write — The transfer of a byte of data from the CPU to a memory location.

X — The lower byte of the index register (H:X) in the CPU08.

Z — The zero bit in the condition code register of the CPU08. The CPU08 sets the zero bit when an arithmetic operation, logical operation, or data manipulation produces a result of \$00.

HOW TO REACH US:

USA/EUROPE/LOCATIONS NOT LISTED:

Motorola Literature Distribution;
P.O. Box 5405, Denver, Colorado 80217
1-303-675-2140 or 1-800-441-2447

JAPAN:

Motorola Japan Ltd.; SPS, Technical Information Center,
3-20-1, Minami-Azabu Minato-ku, Tokyo 106-8573 Japan
81-3-3440-3569

ASIA/PACIFIC:

Motorola Semiconductors H.K. Ltd.;
Silicon Harbour Centre, 2 Dai King Street,
Tai Po Industrial Estate, Tai Po, N.T., Hong Kong
852-26668334

TECHNICAL INFORMATION CENTER:

1-800-521-6274
