# 256K x 36/512K x 18 Synchronous Flow-Thru SRAM with NoBLTM Architecture 

## Features

- Zero Bus Latency, no dead cycles between write and read cycles
- Fast access times: 2.5 ns, 3.0 ns , and 3.5 ns
- Fast clock speed: 133, 117, and 100 MHz
- Fast OE access time: 6.5, 7.0, and 7.5ns
- Internally synchronized registered outputs eliminate the need to control OE
- $3.3 \mathrm{~V}-5 \%$ and $+5 \%$ power supply
- 3.3 V or 2.5 V I/O supply
- Single WEN (READ/WRITE) control pin
- Positive clock-edge triggered, address, data, and control signal registers for fully pipelined applications
- Interleaved or linear four-word burst capability
- Individual byte write ( $\overline{\mathrm{BWa}}-\overline{\mathrm{BWd}}$ ) control (may be tied LOW)
- CEN pin to enable clock and suspend operations
- Three chip enables for simple depth expansion
- Automatic Power-down feature available using ZZ mode or CE deselect.
- JTAG boundary scan (except CY7C1357A)
- Low-profile 119-bump, 14-mm $\times 22-\mathrm{mm}$ BGA (Ball Grid Array) for CY7C1355A, and 100-pin TQFP packages for both devices

## Functional Description

The CY7C1355A and CY7C1357A SRAMs are designed to eliminate dead cycles when transitions from READ to WRITE or vice versa. These SRAMs are optimized for 100 percent bus utilization and achieves Zero Bus Latency (ZBL). They integrate $262,144 \times 36$ and 524,288 $\times 18$ SRAM cells, respectively, with advanced synchronous peripheral circuitry and a 2-bit counter for internal burst operation. These employ high-speed, low power CMOS designs using advanced triple-layer polysilicon, double-layer metal technology. Each memory cell consists of Six transistors.

All synchronous inputs are gated by registers controlled by a positive-edge-triggered Clock Input (CLK). The synchronous inputs include all addresses, all data inputs, depth-expansion Chip Enables ( $\overline{\mathrm{CE}}, \mathrm{CE}_{2}$, and $\mathrm{CE}_{3}$ ), Cycle Start Input ( $\left.\mathrm{ADV} / \overline{\mathrm{LD}}\right)$, Clock Enable ( $\overline{\mathrm{CEN}}$ ), Byte Write Enables ( $\overline{\mathrm{BWa}}, \overline{\mathrm{BWb}}, \overline{\mathrm{BWc}}$, and BWd), and read-write control (WEN). BWc and BWd apply to CY7C1355A only.
Address and control signals are applied to the SRAM during one clock cycle, and one cycle later, its associated data occurs, either read or write.
A Clock Enable ( $\overline{\mathrm{CEN}}$ ) pin allows operation of the CY7C1355A/CY7C1357A to be suspended as long as necessary. All synchronous inputs are ignored when ( $\overline{\mathrm{CEN}}$ ) is HIGH and the internal device registers will hold their previous values.
There are three Chip Enable pins ( $\overline{\mathrm{CE}}, \mathrm{CE}_{2}, \overline{\mathrm{CE}}_{3}$ ) that allow the user to deselect the device when desired. If any one of these three are not active when ADV/ $\overline{\mathrm{LD}}$ is LOW, no new memory operation can be initiated and any burst cycle in progress is stopped. However, any pending data transfers (read or write) will be completed. The data bus will be in high-impedance state one cycle after chip is deselected or a write cycle is initiated.
The CY7C1355A and CY7C1357A have an on-chip 2-bit burst counter. In the burst mode, the CY7C1355A and CY7C1357A provide four cycles of data for a single address presented to the SRAM. The order of the burst sequence is defined by the MODE input pin. The MODE pin selects between linear and interleaved burst sequence. The ADV/LD signal is used to load a new external address (ADV/LD $=$ LOW) or increment the internal burst counter (ADV/LD $=\mathrm{HIGH}$ )
Output Enable ( $\overline{\mathrm{OE}})$, Sleep Enable (ZZ) and burst sequence select (MODE) are the asynchronous signals. OE can be used to disable the outputs at any given time. ZZ may be tied to LOW if it is not used.

Four pins are used to implement JTAG test capabilities. The JTAG circuitry is used to serially shift data to and from the device. JTAG inputs use LVTTL/LVCMOS levels to shift data during this testing mode of operation.

## Pin Descriptions (CY7C1355A)

| $\begin{aligned} & 256 \mathrm{~K} \times 36 \\ & \text { TQFP Pins } \end{aligned}$ | $\begin{aligned} & 256 \mathrm{~K} \times 36 \\ & \text { PBGA Pins } \end{aligned}$ | Name | Type | Description |
| :---: | :---: | :---: | :---: | :---: |
| $\begin{gathered} \hline 37, \\ 36, \\ 32,33,34,35, \\ 44,45,46,47, \\ 48,49,50,81, \\ 82,83,99,100 \end{gathered}$ | 4 P 4 N 2A, 3A, 5A, 6A, 3B, 5B, 2C, 3C, 5C, 6C, 4G, 2R, $6 R, 3 T, 4 T, 5 T$ | A0, <br> A1, <br> A | Input- <br> Synchronous | Synchronous Address Inputs: The address register is triggered by a combination of the rising edge of CLK, ADV/LD LOW, CEN LOW and true chip enables. A0 and A1 are the two least significant bits of the address field and set the internal burst counter if burst cycle is initiated. |
| $\begin{aligned} & 93, \\ & 94, \\ & 95, \\ & 96 \end{aligned}$ | $\begin{aligned} & \text { 5L } \\ & \text { 5G } \\ & \text { 3G } \\ & \text { 3L } \end{aligned}$ | $\overline{B W a}$, BWb, BWc, BWd | InputSynchronous | Synchronous Byte Write Enables: Each nine-bit byte has its own active LOW byte write enable. On load write cycles (when WEN and ADV/LD are sampled LOW), the appropriate byte write signal ( $\overline{\mathrm{BWx}}$ ) must be valid. The byte write signal must also be valid on each cycle of a burst write. Byte write signals are ignored when WEN is sampled HIGH. The appropriate byte(s) of data are written into the device one cycle later. BWa controls DQa pins; BWb controls DQb pins; BWc controls DQc pins; BWd controls DQd pins. BWx can all be tied LOW if always doing a write to the entire 36-bit word. |
| 87 | 4M | $\overline{\mathrm{CEN}}$ | InputSynchronous | Synchronous Clock Enable Input: When $\overline{\mathrm{CEN}}$ is sampled HIGH, all other synchronous inputs, including clock are ignored and outputs remain unchanged. The effect of CEN sampled HIGH on the device outputs is as if the LOW-to-HIGH clock transition did not occur. For normal operation, CEN must be sampled LOW at rising edge of clock. |
| 88 | 4H | $\overline{\text { WEN }}$ | InputSynchronous | Read Write: $\overline{\text { WEN }}$ signal is a synchronous input that identifies whether the current loaded cycle and the subsequent burst cycles initiated by ADV/LD is a Read or Write operation. The data bus activity for the current cycle takes place one clock cycle later. |
| 89 | 4K | CLK | InputClock | Clock: This is the clock input to CY7C1355A. Except for $\overline{\mathrm{OE}}, \mathrm{ZZ}$, and MODE, all timing references for the device are made with respect to the rising edge of CLK. |
| 98, 92 | 4E, 6B | $\overline{\overline{\mathrm{CE}}_{1}},$ | InputSynchronous | Synchronous Active LOW Chip Enable: $\overline{\mathrm{CE}}_{1}$ and $\overline{\mathrm{CE}}_{3}$ are used with $\mathrm{CE}_{2}$ to enable the CY7C1355A. $\overline{\mathrm{CE}}_{1}$ or $\overline{\mathrm{CE}}_{3}$ sampled HIGH or $\mathrm{CE}_{2}$ sampled LOW, along with ADV/LD LOW at the rising edge of clock, initiates a deselect cycle. The data bus will be High-Z one clock cycle after chip deselect is initiated. |
| 97 | 2B | $\mathrm{CE}_{2}$ | InputSynchronous | Synchronous Active High Chip Enable: $\mathrm{CE}_{2}$ is used with $\overline{\mathrm{CE}}_{1}$ and $\mathrm{CE}_{3}$ to enable the chip. $\mathrm{CE}_{2}$ has inverted polarity but otherwise is identical to $\overline{\mathrm{CE}}_{1}$ and $\overline{\mathrm{CE}}_{3}$. |
| 86 | 4F | $\overline{\mathrm{OE}}$ | Input Asynchronous | Asynchronous Output Enable: $\overline{\mathrm{OE}}$ must be LOW to read data. When $\overline{O E}$ is HIGH, the I/O pins are in high-impedance state. $\overline{O E}$ does not need to be actively controlled for read and write cycles. In normal operation, $\overline{\mathrm{OE}}$ can be tied LOW. |
| 85 | 4B | $\overline{\mathrm{ADV} /}$ | InputSynchronous | Advance/Load: ADV/ $\overline{\mathrm{LD}}$ is a synchronous input that is used to load the internal registers with new address and control signals when it is sampled LOW at the rising edge of clock with the chip is selected. When ADV/LD is sampled HIGH, then the internal burst counter is advanced for any burst that was in progress. The external addresses and $\bar{W} E N$ are ignored when ADV/LD is sampled HIGH. |
| 31 | 3R | MODE | Input- <br> Static | Burst Mode: When MODE is HIGH or NC, the interleaved burst sequence is selected. When MODE is LOW, the linear burst sequence is selected. MODE is a static DC input. |
| 64 | 7T | ZZ | InputAsynchronous | Sleep Enable: This active HIGH input puts the device in low power consumption standby mode. For normal operation, this input has to be either LOW or NC. |

## IEEE 1149.1 Serial Boundary Scan (JTAG)

## Overview

This device (except for CY7C1357A) incorporates a serial boundary scan access port (TAP). This port is designed to operate in a manner consistent with IEEE Standard 1149.1-1990 (commonly referred to as JTAG), but does not implement all of the functions required for IEEE 1149.1 compliance. Certain functions have been modified or eliminated because their implementation places extra delays in the critical speed path of the device. Nevertheless, the device supports the standard TAP controller architecture (the TAP controller is the state machine that controls the TAPs operation) and can be expected to function in a manner that does not conflict with the operation of devices with IEEE Standard 1149.1-compliant TAPs. The TAP operates using LVTTL/ LVCMOS logic level signaling.

## Notes:

6. This assumes that $\overline{\mathrm{CEN}}, \overline{\mathrm{CE}}, \mathrm{CE}_{2}$, and $\overline{\mathrm{CE}}_{2}$ are all True.
7. All addresses, control and data-in are only required to meet set-up and hold time with respect to the rising edge of clock. Data out is valid after a clock-to-data delay from the rising edge of clock.
8. DQc and DQd apply to $256 \mathrm{~K} \times 36$ device only.
9. L means logic LOW. H means logic HIGH. X means "Don't Care." High-Z means High Impedance. $\overline{\mathrm{BWx}}=\mathrm{L}$ means $[\overline{\mathrm{BWa}} * \overline{\mathrm{BWb}} * \overline{\mathrm{BWc}} \star \overline{\mathrm{BWd}}]$ equals LOW . $\overline{\mathrm{BWx}}$ $\equiv \mathrm{H}$ means $\left[\overline{\mathrm{BWa}}{ }^{*} \overline{\mathrm{BWD}}{ }^{*} \overline{\mathrm{BW}} \mathrm{B}^{*} \overline{\mathrm{BWd}]}\right.$ equals HIGH . $\overline{\mathrm{BWc}}$ and $\overline{\mathrm{BWd}}$ apply to $256 \mathrm{~K} \times 36$ device only.
10. $\overline{\overline{C E}}=H$ means $\overline{C E}$ and $\overline{C E}_{2}$ are LOW along with $\mathrm{CE}_{2}$ being HIGH. $\overline{C E}=L$ means $\overline{C E}$ or $C E_{2}$ is $\operatorname{HIGH}$ or $C E_{2}$ is $L O W$. $\overline{C E}=X$ means $\overline{C E}, \overline{C E}{ }_{2}$, and $C E_{2}$ are "Don't Care."
11. BWa enables WRITE to byte "a" (DQa pins). $\overline{B W b}$ enables WRITE to byte "b" (DQb pins). $\bar{B} W c$ enables WRITE to byte "c" (DQc pins). $\overline{\text { BWd }}$ enables WRITE to byte "d" (DQd pins). DQc, DQd, BWc, and BWd apply to $256 \mathrm{~K} \times 36$ device only.
12. The device is not in Sleep Mode, i.e., the $Z Z$ pin is LOW.
13. During Sleep Mode, the ZZ pin is HIGH and all the address pins and control pins are "Don't Care." The Sleep Mode can only be entered one cycle after the WRITE cycle, otherwise the WRITE cycle may not be completed
14. All inputs, except $\overline{O E}, \mathrm{ZZ}$, and MODE pins, must meet set-up time and hold time specification against the clock (CLK) LOW-to-HIGH transition edge.
15. OE may be tied to LOW for all the operation. This device automatically turns off the output driver during WRITE cycle.
16. Device outputs are ensured to be in High-Z during device power-up.
17. This device contains a two-bit burst counter. The address counter is incremented for all Continue Burst cycles. Address wraps to the initial address every fourth burst cycle.
18. Continue Burst cycles, whether READ or WRITE, use the same control signals. The type of cycle performed, READ or WRITE, depends upon the WEN control signal at the BEGIN BURST cycle. A Continue Deselect cycle can only be entered if a Deselect cycle is executed first.
19. Dummy Read and Abort WRITE cycles can be entered to set up subsequent READ or WRITE cycles or to increment the burst counter
20. When an Ignore Clock Edge cycle enters, the output data ( $Q$ ) will remain the same if the previous cycle is READ cycle or remain High- $Z$ if the previous cycle is WRITE or Deselect cycle.

## TMS—Test Mode Select (INPUT)

The TMS input is sampled on the rising edge of TCK. This is the command input for the TAP controller state machine. It is allowable to leave this pin unconnected if the TAP is not used. The pin is pulled up internally, resulting in a logic HIGH level.

## TDI—Test Data In (INPUT)

The TDI input is sampled on the rising edge of TCK. This is the input side of the serial registers placed between TDI and TDO. The register placed between TDI and TDO is determined by the state of the TAP controller state machine and the instruction that is currently loaded in the TAP instruction register (refer toFigure 1). It is allowable to leave this pin unconnected if it is not used in an application. The pin is pulled up internally, resulting in a logic HIGH level. TDI is connected to the most significant bit (MSB) of any register. (See Figure 2.)

## TDO—Test Data Out (OUTPUT)

The TDO output pin is used to serially clock data-out from the registers. The output that is active depending on the state of the TAP state machine (refer to Figure 1). Output changes in response to the falling edge of TCK. This is the output side of the serial registers placed between TDI and TDO. TDO is connected to the least significant bit (LSB) of any register. (See Figure 2.)

## Performing a TAP Reset

The TAP circuitry does not have a reset pin (TRST, which is optional in the IEEE 1149.1 specification). A RESET can be performed for the TAP controller by forcing TMS HIGH ( $\mathrm{V}_{\mathrm{CC}}$ ) for five rising edges of TCK and pre-loads the instruction register with the IDCODE command. This type of reset does not affect the operation of the system logic. The reset affects test logic only.
At power-up, the TAP is reset internally to ensure that TDO is in a High-Z state.

## Test Access Port Registers

## Overview

The various TAP registers are selected (one at a time) via the sequences of ones and zeros input to the TMS pin as the TCK is strobed. Each of the TAPs registers are serial shift registers that capture serial input data on the rising edge of TCK and push serial data out on subsequent falling edge of TCK. When a register is selected, it is connected between the TDI and TDO pins.

## Instruction Register

The instruction register holds the instructions that are executed by the TAP controller when it is moved into the run test/idle or the various data register states. The instructions are three bits long. The register can be loaded when it is placed between the TDI and TDO pins. The parallel outputs of the instruction register are automatically preloaded with the IDCODE instruction upon power-up or whenever the controller is placed in the test-logic reset state. When the TAP controller is in the Capture-IR state, the two least significant bits of the serial instruction register are loaded with a binary "01" pattern to allow for fault isolation of the board-level serial test data path.

## Bypass Register

The bypass register is a single-bit register that can be placed between TDI and TDO. It allows serial test data to be passed through the device TAP to another device in the scan chain with minimum delay. The bypass register is set LOW ( $\mathrm{V}_{\mathrm{SS}}$ ) when the BYPASS instruction is executed.

## Boundary Scan Register

The Boundary scan register is connected to all the input and bidirectional I/O pins (not counting the TAP pins) on the device. This also includes a number of NC pins that are reserved for future needs. There are a total of 70 bits for $\times 36$ device and 51 bits for $x 18$ device. The boundary scan register, under the control of the TAP controller, is loaded with the contents of the device I/O ring when the controller is in Capture-DR state and then is placed between the TDI and TDO pins when the controller is moved to Shift-DR state. The EXTEST, SAMPLE/PRELOAD and SAMPLE-Z instructions can be used to capture the contents of the I/O ring.
The Boundary Scan Order table describes the order in which the bits are connected. The first column defines the bit's position in the boundary scan register. The MSB of the register is connected to TDI, and LSB is connected to TDO. The second column is the signal name and the third column is the bump number. The third column is the TQFP pin number and the fourth column is the BGA bump number.

## Identification (ID) Register

The ID Register is a 32-bit register that is loaded with a device and vendor specific 32-bit code when the controller is put in Capture-DR state with the IDCODE command loaded in the instruction register. The register is then placed between the TDI and TDO pins when the controller is moved into Shift-DR state. Bit 0 in the register is the LSB and the first to reach TDO when shifting begins. The code is loaded from a 32-bit on-chip ROM. It describes various attributes of the device as described in the Identification Register Definitions table.

## TAP Controller Instruction Set

## Overview

There are two classes of instructions defined in the IEEE Standard 1149.1-1990; the standard (public) instructions and device specific (private) instructions. Some public instructions are mandatory for IEEE 1149.1 compliance. Optional public instructions must be implemented in prescribed ways.
Although the TAP controller in this device follows the IEEE 1149.1 conventions, it is not IEEE 1149.1 compliant because some of the mandatory instructions are not fully implemented. The TAP on this device may be used to monitor all input and I/O pads, but can not be used to load address, data, or control signals into the device or to preload the I/O buffers. In other words, the device will not perform IEEE 1149.1 EXTEST, INTEST, or the preload portion of the SAMPLE/PRELOAD command.
When the TAP controller is placed in Capture-IR state, the two least significant bits of the instruction register are loaded with 01 . When the controller is moved to the Shift-IR state the instruction is serially loaded through the TDI input (while the previous contents are shifted out at TDO). For all instructions, the TAP executes newly loaded instructions only when the
controller is moved to Update-IR state. The TAP instruction sets for this device are listed in the following tables.

## EXTEST

EXTEST is an IEEE 1149.1 mandatory public instruction. It is to be executed whenever the instruction register is loaded with all Os. EXTEST is not implemented in this device.
The TAP controller does recognize an all-0 instruction. When an EXTEST instruction is loaded into the instruction register, the device responds as if a SAMPLE/PRELOAD instruction has been loaded. There is one difference between two instructions. Unlike SAMPLE/PRELOAD instruction, EXTEST places the device outputs in a High-Z state.

## IDCODE

The IDCODE instruction causes a vendor-specific, 32-bit code to be loaded into the ID register when the controller is in Capture-DR mode and places the ID register between the TDI and TDO pins in Shift-DR mode. The IDCODE instruction is the default instruction loaded in the instruction upon power-up and at any time the TAP controller is placed in the test-logic reset state.

## SAMPLE-Z

If the High- Z instruction is loaded in the instruction register, all output pins are forced to a High-Z state and the boundary scan register is connected between TDI and TDO pins when the TAP controller is in a Shift-DR state.

## SAMPLE/PRELOAD

SAMPLE/PRELOAD is an IEEE 1149.1 mandatory instruction. The PRELOAD portion of the command is not implemented in
this device, so the device TAP controller is not fully IEEE 1149.1-compliant.

When the SAMPLE/PRELOAD instruction is loaded in the instruction register and the TAP controller is in the Capture-DR state, a snap shot of the data in the device's input and I/O buffers is loaded into the boundary scan register. Because the device system clock(s) are independent from the TAP Clock (TCK), it is possible for the TAP to attempt to capture the input and I/O ring contents while the buffers are in transition (i.e., in a metastable state). Although allowing the TAP to sample metastable inputs will not harm the device, repeatable results can not be expected. To guarantee that the boundary scan register will capture the correct value of a signal, the device input signals must be stabilized long enough to meet the TAP controller's capture set up plus hold time ( $\mathrm{t}_{\mathrm{CS}}$ plus $\mathrm{t}_{\mathrm{CH}}$ ). The device clock input(s) need not be paused for any other TAP operation except capturing the input and $\mathrm{I} / \mathrm{O}$ ring contents into the boundary scan register.
Moving the controller to Shift-DR state then places the boundary scan register between the TDI and TDO pins. Because the PRELOAD portion of the command is not implemented in this device, moving the controller to the Update-DR state with the SAMPLE/PRELOAD instruction loaded in the instruction register has the same effect as the Pause-DR command.

## BYPASS

When the BYPASS instruction is loaded in the instruction register and the TAP controller is in the Shift-DR state, the bypass register is placed between TDI and TDO. This allows the board level scan path to be shortened to facilitate testing of other devices in the scan path.

## Notes:

28. Overshoot: $\mathrm{V}_{\mathrm{IH}} \leq+6.0 \mathrm{~V}$ for $\mathrm{t} \leq \mathrm{t}_{\mathrm{KC}} / 2$

Undershoot: $\mathrm{V}_{\text {IL }} \leq-2.0 \mathrm{~V}$ for $\mathrm{t} \leq \mathrm{t}_{\mathrm{KC}} / 2$.
29. MODE pin has an internal pull-up and $Z Z$ pin has an internal pull-down. These two pins exhibit an input leakage current of $\pm 50 \mu \mathrm{~A}$.
30. $I_{c c}$ is given with no output current. I ${ }_{c c}$ increases with greater output loading and faster cycle times.
31. "Device Deselected" means the device is in Power-Down mode as defined in the truth table. "Device Selected" means the device is active.
32. Typical values are measured at $3.3 \mathrm{~V}, 25^{\circ} \mathrm{C}$, and 20 ns cycle time.
33. At $f=f_{\text {MAX }}$, inputs are cycling at the maximum frequency of read cycles of $1 / t_{C Y C} ; f=0$ means no input lines are changing.

## Notes:

34. $T_{A}$ is the case temperature.
35. Test conditions as specified with the output loading as shown in part (a) of AC Test Loads unless otherwise noted.
36. Output loading is specified with $\mathrm{C}_{\mathrm{L}}=5 \mathrm{pF}$ as in part (a) of AC Test Loads.
37. At any given temperature and voltage condition, $\mathrm{t}_{\mathrm{KOHZ}}$ is less than $\mathrm{t}_{\mathrm{KOLZ}}$ and $\mathrm{t}_{\mathrm{OEHZ}}$ is less than $\mathrm{t}_{\mathrm{OELZ}}$.
38. This is a synchronous device. All synchronous inputs must meet specified setup and hold time, except for "don't care" as defined in the truth table.

CY7C1357A
CY7C1355A

## Switching Waveforms

Read Timing ${ }^{[39,40,41,42,43]}$

## Notes:

39. $Q\left(A_{1}\right)$ represents the first output from the external address $A_{1}$. $Q\left(A_{2}\right)$ represents the first output from the external address $A_{2}$; $Q\left(A_{2}+1\right)$ represents the next output data in the burst sequence of the base address $A_{2}$, etc. where address bits SA0 and SA1 are advancing for the four word burst in the sequence defined by the state of the MODE input.
40. $\overline{\mathrm{CE}}_{2}$ timing transitions are identical to the $\overline{\mathrm{CE}}$ signal. For example, when $\overline{\mathrm{CE}}$ is LOW on this waveform, $\overline{\mathrm{CE}}_{2}$ is LOW. $\mathrm{CE}_{2}$ timing transitions are identical but inverted to the CE signal. For example, when CE is LOW on this waveform, $\mathrm{CE}_{2}$ is HIGH.
41. Burst ends when new address and control are loaded into the SRAM by sampling ADV/DD LOW.
42. WEN is "Don't Care" when the SRAM is bursting (ADV/LD sampled HIGH). The nature of the burst access (Read or Write) is fixed by the state of the WEN signal when new address and control are loaded into the SRAM.
43. BWc and BWd apply to $256 \mathrm{~K} \times 36$ device only.

CY7C1357A
CY7C1355A
Switching Waveforms (continued)
Write Timing ${ }^{[40, ~ 41, ~ 42, ~ 43, ~ 44, ~ 45] ~}$

Notes:
44. $D\left(A_{1}\right)$ represents the first input to the external address $A 1 . D\left(A_{2}\right)$ represents the first input to the external address $A_{2}$; $D\left(A_{2}+1\right)$ represents the next input data in the burst sequence of the base address $A_{2}$, etc. where address bits SA0 and SA1 are advancing for the four word burst in the sequence defined by the state of the MODE input.
45. Individual Byte Write signals ( $\overline{\mathrm{BWx}}$ ) must be valid on all write and burst-write cycles. A write cycle is initiated when $\overline{W E N}$ signal is sampled LOW when ADV/LD is sampled LOW. The byte write information comes in one cycle before the actual data is presented to the SRAM.

## Switching Waveforms (continued)

Read/Write Timing ${ }^{[40,43,45,46]}$

Note:
46. $Q\left(A_{1}\right)$ represents the first output from the external address $A_{1}$. $D\left(A_{2}\right)$ represents the input data to the SRAM corresponding to address $A_{2}$.

CY7C1357A
CY7C1355A
Switching Waveforms (continued)
$\overline{\text { CEN }}$ Timing ${ }^{[40, ~ 43, ~ 45, ~ 46, ~ 47] ~}$

Note:
47. CEN when sampled HIGH on the rising edge of clock will block that L-H transition of the clock from propagating into the SRAM. The part will behave as if the L-H clock transition did not occur. All internal register in the SRAM will retain their previous state.

## Switching Waveforms (continued)

$\overline{\text { CE Timing }}{ }^{[40,43,45,48,49]}$

## Notes:

48. $Q\left(A_{1}\right)$ represents the first output from the external address $A_{1} . D\left(A_{3}\right)$ represents the input data to the SRAM corresponding to address $A_{3}$, etc.
49. When either one of the Chip enables ( $\overline{\mathrm{CE}}, \mathrm{CE}_{2}$ or $\overline{\mathrm{CE}}_{2}$ ) is sampled inactive at the rising clock edge, a chip deselect cycle is initiated. The data-bus High-Z one cycle after the initiation of the deselect cycle. This allows for any pending data transfers (reads or writes) to be completed.

## Switching Waveforms (continued)

## ZZ Mode Timing ${ }^{[50,51]}$

Note:
50. Device must be deselected when entering ZZ mode. See Cycle Descriptions Table for all possible signal conditions to deselect the device. 51. I/Os are in three-state when exiting ZZ sleep mode.
