

DESCRIPTION

The A7108 is a high efficiency monolithic synchronous buck regulator using a constant frequency, current mode architecture. The device is available in an adjustable version. Supply current with no load is 300uA and drops to <1uA in shutdown. The 2.5V to 6.5V input voltage range makes the A7108 ideally suited for single Li-lon, two to four AA battery-powered applications. 100% duty cycle provides low dropout operation, extending battery life in portable systems. PWM pulse skipping mode operation provides very low output ripple voltage for noise applications. Switching frequency is internally set at 1.5MHz, allowing the use of small surface mount inductors and capacitors. The internal synchronous switch increases efficiency and eliminates the need for an external Schottky diode. Low output voltages are easily supported with the 0.6V feedback reference voltage.

The A7108 is available in SOT-25 package.

ORDERING INFORMATION

Package Type	Part Number		
COT 25	E5	A7108E5R-ADJ	
SOT-25		A7108E5VR-ADJ	
	ADJ: Adjustable Output Voltage		
Note	V: Halogen fr	: Halogen free Package	
	R: Tape & Reel		
AiT provides all RoHS products			
Suffix " V " means Halogen free Package			

FEATURES

- High Efficiency: Up to 96%
- 1.5MHz Constant Switching Frequency
- 800mA Output Current at V_{IN}=3V
- Integrated Main switch and synchronous rectifier. No Schottky Diode Required
- 2.5V to 6.5V Input Voltage Range
- Output Voltage as Low as 0.6V
- 100% Duty Cycle in Dropout
- Quiescent Current: 300µA(input < 4.2V)
- Slope Compensated Current Mode Control for Excellent Line and Load Transient Response
- Short Circuit Protection
- <1uA Shutdown Current
- Soft start
- Available in SOT-25 Package

APPLICATION

- Cellular and Smart Phones
- Microprocessors and DSP Core Supplies
- Wireless and DSL Modems
- PDAs
- MP3 / MP4 /PMP Player
- Digital Still and Video Cameras
- Portable Instruments

PIN DESCRIPTION

Top View

Pin#	Symbol	Function
	RUN	Regulator Enable control input. Drive RUN above 1.5V to turn on the part. Drive
1		RUN below 0.6V to turn it off. In shutdown, all functions are disabled drawing
		<1µA supply current. Do not leave RUN floating.
2	GND	Ground
0	CIM	Power Switch Output. It is the Switch note connection to Inductor. This pin
3 SW		connects to the drains of the internal P-CH and N-CH MOSFET switches.
4	V _{IN}	Supply Input Pin. Must be closely decoupled to GND, Pin 2, with a 2.2µF or
4		greater ceramic capacitor.
5	V _{FB}	V _{FB} (A7108): Feedback Input Pin. Connect FB to the center point of the external
		resistor divider. The feedback threshold voltage is 0.6V.

ABSOLUTE MAXIMUM RATINGS

Input Supply Voltage	-0.3V~ +7V
RUN, V _{FB} Voltages	-0.3V~V _{IN} +0.3V
SW Voltages	-0.3V~ V _{IN} +0.3V
P-Channel Switch Source Current (DC)	1000mA
N-Channel Switch Sink Current (DC)	1000mA
Peak SW Sink and Source Current	1.4A
Package Thermal Resistance NOTE1	
θ_{JA}	220°C/W
θ _{JC}	110°C/W
Operating Temperature Range	-40°C~+85°C
Junction Temperature NOTE2	+125°C
Storage Temperature Range	-65°C~+150°C
Lead Temperature (Soldering, 10s)	+260°C

Stress beyond above listed "Absolute Maximum Ratings" may lead permanent damage to the device. These are stress ratings only and operations of the device at these or any other conditions beyond those indicated in the operational sections of the specifications are not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

NOTE1: Thermal Resistance is specified with approximately 1 square of 1 oz copper.

NOTE2: T_J is calculated from the ambient temperature T_A and power dissipation PD according to the following formula:

A7108: $T_J = T_A + (P_D)x(220^{\circ}C/W)$

ELECTRICAL CHARACTERISTICS NOTE3

 V_{IN} = V_{RUN} = 3.6V, T_A =25 $^{\circ}$ C, unless otherwise noted

DETAILED INFORMATION

Operation

A7108 is a monolithic switching mode Step-Down DC-DC converter. It utilizes internal MOSFETs to achieve high efficiency and can generate very low output voltage by using internal reference at 0.6V. It operates at a fixed switching frequency, and uses the slope compensated current mode architecture.

Current Mode PWM Control

Slope compensated current mode PWM control provides stable switching and cycle-by-cycle current limit for excellent load and line responses and protection of the internal main switch (P-Ch MOSFET) and synchronous rectifier (N-CH MOSFET). During normal operation, the internal P-Ch MOSFET is turned on for a certain time to ramp the inductor current at each rising edge of the internal oscillator, and switched off when the peak inductor current is above the error voltage. The current comparator, Icomp, limits the peak inductor current. When the main switch is off, the synchronous rectifier will be turned on immediately and stay on until either the inductor current starts to reverse, as indicated by the current reversal comparator, Izero, or the beginning of the next clock cycle. The OVDET comparator controls output transient overshoots by turning the main switch off and keeping it off until the fault is no longer present.

Idle Mode Operation

At very light loads, the A7108 automatically enters pulse skipping Mode. In the pulse skipping Mode, the inductor current may reach zero or reverse on each pulse. The PWM control loop will automatically skip pulses to maintain output regulation. The bottom MOSFET is turned off by the current reversal comparator, I_{ZERO}, and the switch voltage will ring. This is discontinuous mode operation, and is normal behavior for the switching regulator.

Dropout Operation

When the input voltage decreases toward the value of the output voltage, the A7108 allows the main switch to remain on for more than one switching cycle and increases the duty cycle NOTE4 until it reaches 100%. The output voltage then is the input voltage minus the voltage drop across the main switch and the inductor. At low input supply voltage, the R_{DS(ON)} of the P-Channel MOSFET increases, and the efficiency of the converter decreases. Caution must be exercised to ensure the heat dissipated not to exceed the maximum junction temperature of the IC.

NOTE 4: The duty cycle D of a step-down converter is defined as:

$$D = T_{ON} \times f_{OSC} \times 100\% \approx \frac{V_{OUT}}{V_{IN}} \times 100\%$$

Where Ton is the main switch on time and fosc is the oscillator frequency (1.5MHz).

Maximum Load Current

The A7108 will operate with input supply voltage as low as 2.5V, however, the maximum load current decreases at lower input due to large IR drop on the main switch and synchronous rectifier. The slope compensation signal reduces the peak inductor current as a function of the duty cycle to prevent sub-harmonic oscillations at duty cycles greater than 50%. Conversely the current limit increases as the duty cycle decreases.

Layout Guidance

When laying out the PCB board, the following suggestions should be taken to ensure proper operation of the A7108. These items are also illustrated graphically in Figure 2.

- 1. The power traces, including the GND trace, the SW trace and the V_{IN} trace should be kept short, direct and wide.
- 2. The V_{FB} pin should be connected directly to the feedback resistor. The resistive divider R1/R2 must be connected between the (+) plate of Cout and ground.
- 3. Connect the (+) plate of C1 to the V_{IN} pin as closely as possible. This capacitor provides the AC current to internal power MOSFET.
- 4. Keep the switching node, SW, away from the sensitive V_{FB} node.
- 5. Keep the (-) plates of C1 and C3 as close as possible.

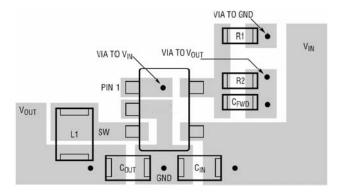

Figure 2. A7108-ADJ output Suggested Layout

Setting the Output Voltage

Figure 1 above shows the basic application circuit with A7108 adjustable output version. The external resistor sets the output voltage according to the following equation:

$$V_{OUT} = 0.6V \times \left(1 + \frac{R2}{R1}\right)$$

R1= $200k\Omega$ for all outputs; R2= $200k\Omega$ for $V_{OUT}=1.2V$,

R2=300k Ω for Vout=1.5V, R2=400k Ω for Vout=1.8V, and R2=633.3k Ω for Vout=2.5V.

Inductor Selection

For most designs, the A7108 operates with inductors of 1μ H to 4.7μ H. Low inductance values are physically smaller but require faster switching, which results in some efficiency loss. The inductor value can be derived from the following equation:

$$L = \frac{V_{out} \times \left(V_{IN} - V_{out}\right)}{V_{IN} \times \Delta I_L \times f_{osc}}$$

Where ΔI_L is inductor Ripple Current. Large value inductors lower ripple current and small value inductors result in high ripple currents. Choose inductor ripple current approximately 35% of the maximum load current 800mA, or ΔI_L =280mA.

For output voltages above 2.0V, when light-load efficiency is important, the minimum recommended inductor is $2.2\mu H$. For optimum voltage-positioning load transients, choose an inductor with DC series resistance in the $50m\Omega$ to $150m\Omega$ range. For higher efficiency at heavy loads (above 200mA), or minimal load regulation (but some transient overshoot), the resistance should be kept below $100m\Omega$. The DC current rating of the inductor should be at least equal to the maximum load current plus half the ripple current to prevent core saturation (800mA+140mA). Table 1 lists some typical surface mount inductors that meet target applications for the A7108.

Table 1Typical Surface Mount Inductors

Input Capacitor Selection

The input capacitor reduces the surge current drawn from the input and switching noise from the device. The input capacitor impedance at the switching frequency shall be less than input source impedance to prevent high frequency switching current passing to the input. A low ESR input capacitor sized for maximum RMS current must be used. Ceramic capacitors with X5R or X7R dielectrics are highly recommended because of their low ESR and small temperature coefficients. A 4.7µF ceramic capacitor for most applications is sufficient.

Output Capacitor Selection

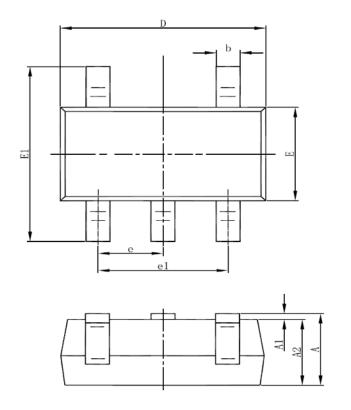

The output capacitor is required to keep the output voltage ripple small and to ensure regulation loop stability. The output capacitor must have low impedance at the switching frequency. Ceramic capacitors with X5R or X7R dielectrics are recommended due to their low ESR and high ripple current. The output ripple V_{OUT} is determined by:

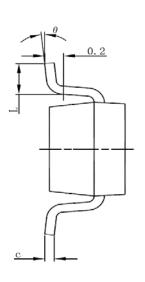

$$\Delta V_{OUT} \leq \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times f_{OSC} \times L} \times \left(ESR + \frac{1}{8 \times f_{osc} \times C3}\right)$$
